2. Enter **y** in `Data Module` if this terminal is to be connected to a data terminal via a 6400 data module. If you enter **y**, you must complete the `Data Module` form. Default is **n**.
  3. Accept the default of **y** in `Mute Button Enabled?` if this terminal should have the mute button available. Enter **n** if you want to disable the mute button.
  4. Enter **y** in `Expansion Module` (for 6416D+ and 6424D+ terminals only) if a XM24 expansion module is attached to the terminal. If you enter **y**, an optional page of the form appears to allow you to administer the `Expansion Module` buttons. Default is **n**.

**Screen 6-26. 6400 Display Station form (Page 5 of X)**

■ **SOFTKEY BUTTON ASSIGNMENTS**

The 6408D, 6408D+, 6416D+, and 6424D+ terminals support 12 display softkeys. These are the default softkeys that the system administrators:

|       |        |       |       |
|-------|--------|-------|-------|
| Dir   | Drop   | HFAns | Timer |
| PCall | AutCB  | Prog  | Pause |
| LWC   | RingOf | BtnVu | Admin |

You can assign features to these softkeys, making them “virtual” buttons. When you assign a feature to a softkey, the system automatically downloads the appropriate information to the terminal for operating the feature.

You may also customize the softkey displays for English, French, Italian, or Spanish. These are displayed in the Display Languages field on page 1 of the Station form. To customize the labels, use the Language Translation form, set Display Languages to **user-defined**, and type the command **change display-messages softkey-labels**. You may enter a five-character label for each of the softkeys.

## **7302H, 7303H, and 7305H MERLIN voice terminals**

---

Administer 7302H voice terminals (5-Button) with the 7303S Station form.

Administer 7303H voice terminals (10-Button) with the 7305S Station form. Only the first 12 feature function buttons apply. Of these 12 buttons, 8 have two lamps and 4 have no lamps. However, the system treats the 8 double-lamp buttons as though they have a single (green) lamp. Administer the 4 buttons (with no lamps) with features that do not require status indications.

Administer 7305H voice terminals (34-Button) with the 7305S Station form. The system treats the terminal's 24 feature function buttons (two lamps each) as single (green) lamp function buttons.

## 7303S, 7305S, and 7309H voice terminals

---

### Form instructions

---

To administer a 7303S, 7305S, 7309S voice terminal, complete the standard as well as the following unique Station form fields.

Figure 6-19. 7309H voice terminal

## **7313H, 7314H, 7315H, 7316H, and 7317H voice terminals**

The following feature differences and restrictions exist for hybrid voice terminals in the system:

- Hybrid voice terminals equipped with displays cannot be used as ACD agents.
- The following feature buttons do not operate on Hybrid terminals: STOP, PAUSE, RECALL, MESSAGE, HFAL, and HFAL/MIC. The replacement for Hands Free Automatic Answer on Intercom (HFAL) is Internal Automatic Answer (IAA).
- When administering IAA on a 731xH series voice terminal, you should assign a feature button with a lamp so the lamp status of IAA can be observed.

**NOTE:**

When placing a call to pager equipment, do not immediately hang up when finished dialing until receipt of confirmation. Failure to wait for confirmation may result in an incomplete signal being sent to the pager resulting in an incomplete call message.

### **Form instructions**

To administer a 7313H (BIS-10), 7314H (BIS-22), 7315H (BIS-22D), 7316H (BIS-34), or 7317H (BIS-34D) voice terminal, complete the standard as well as the following unique Station form fields.

### **Page 1 of the form**

### ■ BUTTON ASSIGNMENTS

The feature buttons that you can assign to the 7313H, 7314H, 7315H, 7316H, and 7317H voice terminals are listed below. The first three button assignments may only be call appearance. The abrdg-appr, brdg-appr and call-appr buttons can only be assigned to button numbers 1 through 10 on this page of the form. Button assignments 1 through 10 correspond to the first and second columns of buttons on the voice terminal.

#### ■ FEATURE BUTTON ASSIGNMENTS

The features and functions that you can assign to the 7314H, 7315H, 7316H, and 7317H on Page 3 of the form are the same as those listed for BUTTON ASSIGNMENTS above. For the 7314H and 7315H, only buttons 1 through 12 display and correspond to the third column of buttons on the voice terminal. For the 7316H and 7317H, buttons 1 through 24 correspond to the third and fourth columns of buttons.

Screen 6-45. 7404D Station form (Page 3 of X)

- **Headset** — For a 7401D or 7404D, enter n, these terminals cannot have a headset. For a 7403D, enter y if the terminal is to have a headset. Default is n.

- **BUTTON ASSIGNMENTS**

The feature buttons that you can assign to the 7401D, 7401+, 7403D, 7404D, 7410D, or 7410+ voice terminals are listed below. For 7401D and 7401+, only buttons 1 through 9 display. Buttons 1 and 2 are assigned as call-appr. Buttons 3 through 9 are used to assign features to dial pad keys 1 through 7. For 7403D, 7404D, 7410D, and 7410+ voice terminals, the 3 three buttons default as call appearance buttons.

Screen 6-61. 7407D and 7407+ Voice-terminal form (Page 4 of X)

■ **FEATURE BUTTON ASSIGNMENTS**

The features and functions that you can assign to the 7406D, 7406+, 7407D, or 7407+ voice terminal administrable buttons are the same as those listed for BUTTON ASSIGNMENTS above.

For 7406D and 7406+ voice terminals, only buttons 1 through 4 have status lamps. It is recommended that feature button assignments requiring status lamp indications not be administered to buttons 5 through 18. Feature buttons 2 and 3 do not work, even if administered, for set versions. Buttons 5 through 11 are dual function buttons. An associated Shift button on the voice terminal is used to enable either buttons 5 through 11 or enable associated buttons 12 through 18.

For 7407D and 7407+ voice terminals, only buttons 1 and 2 have status lamps. It is recommended that feature button assignments requiring status lamp indications not be administered to buttons 3 through 24.

■ **BUTTON ASSIGNMENTS**

The feature buttons that you can assign are the same as those listed for BUTTON ASSIGNMENTS above. This form is used to assign features to the 24 administrable buttons on the 7434D or 7444D voice terminal (may include call appearance and bridged call appearance buttons). If you want to assign feature buttons to the optional Coverage Module, assign them on the Coverage Module page of the form.

Screen 6-68. 7434D Coverage Module form (Page Y of X)

This page displays only if Coverage Module is **y**. The features buttons that you can assign are the same as those listed for BUTTON ASSIGNMENTS above except that you cannot assign display-type buttons. A minimum of 2 or a maximum of 10 call appearance buttons can be administered. When 2 call appearance buttons are administered, the maximum number of Bridged Appearance buttons that can be administered is 52 with a Coverage Module or 32 without a Coverage Module.

## 7505D, 7506D, 7507D, 8503D, 8510T, and 8520T ISDN-BRI voice terminals

### Form instructions

To administer a 7505D, 7506D, 7507D, 8503D, 8510T, or 8520T ISDN-BRI voice terminal, complete the standard as well as the following unique Station form fields.

### Page 1 of the form

Page 1 of X

Screen 6-73. 7505D, 7506D, 7507D, 8510T, and 8520T Station form (Page 3 of X)

## Implementation note

For a 7505D or 7506D voice terminal, button 7 can be administered as a call appearance button if an Asynchronous Data Module (ADM) is not attached to the station. When an ADM is attached, button 7 acts as a DATA button whether or not the data module has been administered. If the ADM has been administered, button 7 is set to DATA and access to the field is restricted. If the station is aliased as a 7505D or 7506D via Enhanced Terminal Administration, button 7 can be administered as a call appearance button whether or not an ADM is assigned. There is no Data button on 7507D, 8510T, and 8520T voice terminals.

Screen 6-78. 8520T Station form (Page 4 of X)

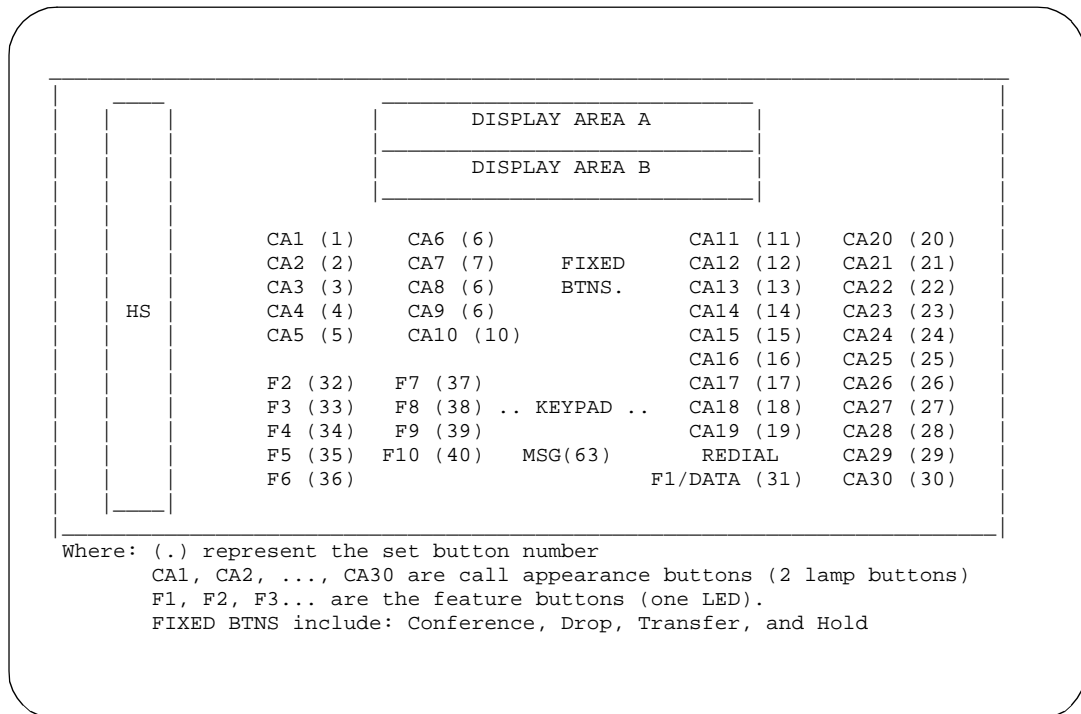

Screen 6-80. 7505D and 7506D voice-terminal feature button layout

**Notes:**

1. Buttons F4 through F6 are accessed by shifting buttons F1 through F3. Button F7 is accessed by shifting the fixed REDIAL button.
2. CA7/DATA button can be administered as a call appearance button. However, CA7 button should not be administered when ADM is attached to the terminal. When the ADM is attached, the button acts as a DATA button, regardless of administration. For 7505D and 7506D terminals, if ADM is administered, the CA7 button is set to DATA and the field is restricted. If a terminal is aliased as a 7505D or 7506D voice terminal via ETA, button CA7 is always administrable as a call appearance button, whether or not the data module is administered.

**Screen 6-81. 7507D Voice-terminal Feature button Layout**

**Notes:**

1. F1/DATA button can be administered as a feature button. However, F1 should not be administered if ADM is attached to the terminal. If the ADM is attached, F1 acts as a DATA button regardless of administration. For 7507D terminal, if ADM is administered, F1 is set to DATA and the field is restricted. If a terminal is aliased as 7507D via ETA, F1 button is always administrable as a feature button whether or not the data module is administered.
2. The 7507D terminal supports 31 buttons with two LEDs; however, the software only supports administration of 30 of these as call appearance buttons (buttons CA1-CA30). The system maximum of 10 call appearance buttons still applies. The CA1-CA30 buttons that are not used as call appearance buttons may be administered as bridged appearance buttons.

Figure 6-40. 8520T station set layout

**NOTE:**

The 8520T terminal supports 20 call appearances. The system maximum of 10 call appearance buttons still applies. The (1)–(20) buttons that are not used as call appearance buttons can be administered as bridged appearance buttons.

## CALLMASTER II and III voice terminals

---

The CALLMASTER II and CALLMASTER III voice terminals provide internal nonvolatile memory and native support. Native support means the switch stores a predefined terminal type and automatically downloads the terminal type information to the terminal.

These enhancements provide several benefits. First, the internal nonvolatile memory of the terminal stores information even if the terminal loses power. Second, native support removes from the customer or service technician the burden of having to alias the terminals, that is — manually map call appearance and feature buttons onto some other supported terminal type. Also, the nonvolatile memory can support transmission changes for applications in various countries.

The 603-type CALLMASTER voice terminal is available in three models: 603A1, 603D1, and 603E1. The only difference among these three is the ability of the 603D1 to tape recording equipment and of the 603E1 to operate on either the standard 4-wire DCP circuit pack or on a 2-wire circuit pack (16-port, A-law/Mu-law selectable).

### NOTE:

The 603s must have their handset unplugged to receive the downloaded parameters.

You can check `Download Status` on the Status Station screen to verify that the system successfully completes each download. You do not need to download the information to the terminals, as the switch does it automatically after the initialization period during the first periodic maintenance cycle.

## Form instructions

---

To administer a 603 CALLMASTER voice terminal, complete the standard as well as the following unique Station form fields.

### NOTE:

If you have one or more 603-type CALLMASTER voice terminals, you must also have a Lucent technician complete the Terminal Parameters form (see [“Terminal Parameters form” on page 6-9](#)). Only Lucent technicians can complete this form.

■ **FEATURE BUTTON ASSIGNMENTS**

The features and functions that you can assign to the terminal's administrable buttons are the same as those for BUTTON ASSIGNMENTS above.

Feature button 6 is preassigned as mute and button 18 is preassigned as release (they are not administrable). Feature button 12 is already labeled on the terminal as a login button, but you must still administer it as a login button.

## CALLMASTER VI voice terminal

The CALLMASTER VI (606) terminal is a miniature, 8-button, 2-headset jack, digital voice terminal that is controlled by the user's personal computer (PC) through an RS-232 serial-port connection.

### Form instructions

To administer a CALLMASTER VI voice terminal, complete the standard as well as the following unique Station form fields.

#### ⇒ NOTE:

If you have one or more 606-type CALLMASTER voice terminals, you must also have a Lucent technician complete the [“Terminal Parameters form”](#) (see [6-9](#)). Only Lucent technicians can complete this form.

## Personal Computer

The personal computer (PC) must be an IBM-compatible PC that can be used with a 7400D series voice terminal to form a workstation arrangement.

### Form instructions

To administer a personal computer with a 7400D series terminal, complete the standard as well as the following unique Station form fields.

### Page 1 of the form

Page 1 of X

## Constellation voice/data terminals

The Constellation voice/ data terminal is a workstation that provides an integrated environment for applications using digital communications protocol (DCP) signaling. It operates in conjunction with a voice terminal.

The Constellation terminal provides enhanced capability for a telemarketing environment. It interacts with the switch and a host computer to provide agents with information about the calling and called party. The terminal interprets information about a call, passes the information to a host computer, and receives information from the host. Information sent by the host appears on the terminal monitor.

### Form instructions

To administer a Constellation voice/data terminal, complete the standard as well as the following unique Station form fields.

#### ⇒ NOTE:

The fields that display depend on what you enter in the *Set* field, because each terminal requires different administration. The form included in this section displays when you set the *Set* field to 7401D. Please refer to the individual terminal forms to determine which fields display for each *Set* type.

## Page 3 of the 8403B form

### ■ FEATURE BUTTON ASSIGNMENTS

On the form for the 8403B voice terminal, these fields correspond to the 12 feature buttons accessed from the 8403B voice terminal by first pressing the feature button and then pressing a number on the dial pad. You cannot administer these buttons as a bridged appearance (brdg-appr or abrdg-appr).

## 8405D, 8405D+, 8410D, and 8434D voice terminals

### Form instructions

To administer a 8405D, 8405+, 8410D, or 8434D voice terminal, complete the standard as well as the following unique Station form fields. For information about adjusting the system-level parameters and audio levels for the 8400-series voice terminals, see [“Terminal Parameters form” on page 6-9](#).

■ **SOFTKEY BUTTON ASSIGNMENTS**

The 8405D, 8405D+, and 8410D voice terminals support 12 display softkeys and the 8434D voice terminal supports 15 softkeys. You can assign features to these softkeys, making them “virtual” buttons. When you assign a feature to a softkey, the system automatically downloads to the terminal the appropriate information for operating the feature.

You may also customize the softkey displays, for English, French, Italian, or Spanish. To customize the labels, use the Language Translation form by issuing the command “change display-messages softkey-labels”. You may enter a five-character label for each of the softkeys.

Pages 6 or 7 of the 8434D form (EXPANSION MODULE) appear only if Expansion Module is set to **y**. Use these pages to administer buttons on the ZE801A Expansion Module if one is attached to the 8434D terminal. Fields 1–9 on the form correspond to the 18 dual-LED feature buttons on the Expansion Module; buttons 10–12 correspond to the 6 single-LED feature buttons. You can assign to these buttons any of the features or functions that you can assign to the feature buttons on the 8434D terminal from the previous list.

## 8411B and 8411D voice terminals

### Form instructions

To administer a 8411B or 8411D voice terminal, complete the standard as well as the following unique Station form fields. For information about adjusting the system-level parameters and audio levels for the 8411-series voice terminals, see [“Terminal Parameters form” on page 6-9](#).

Screen 6-123. 8411B and 8411D Station form (Page 1 of X)

- **Type** — Enter **8411B** or **8411D** as appropriate.
- **Data Option** — If you are using the administered analog adjunct, enter analog and complete the Analog Adjunct form. If you are using a 7400B or 8400B data module, enter data-module and complete the Data Module form.

When an endpoint changes its terminal from a non-8411 terminal to a 8411B/D terminal, the options in the station forms remain the same except for the Data Option, Data Module and PassageWay.

- **PassageWay** — Enter **y** if you are using PassageWay.

**CAUTION:**

*Do not enable PassageWay unless the user of the PC at this extension has a valid licensed copy of PassageWay Direct Connection to DEFINITY ECS running on the PC.*

#### ■ SOFTKEY BUTTON ASSIGNMENTS

The 8411B and 8411D voice terminals support 12 display softkeys. You can assign features to these softkeys, making them “virtual” buttons. When you assign a feature to a softkey, the system automatically downloads to the terminal the appropriate information for operating the feature.

#### NOTE:

On the 8411, do not administer buttons 9 and 10 if you set Data Option to **analog** and set PassageWay to **yes**.

## World Class Basic Rate Interface terminal

---

World Class Basic Rate Interface (WCBRI) terminal provides an international BRI platform that offers multiple protocol options to meet specific country and application requirements.

WCBRI supports the following country protocols:

- Bellcore National ISDN-1 protocol in the United States (TR268)
- Australia (AUSTEL TS013 and Telecom Australia TPH 1962)
- Japan (NTT BRI)
- Singapore (FETEX 150 TIF 218)
- ETSI NET 3 protocol (ETS 300 102) for use in most of Europe

WCBRI supports multipoint (up to 2 devices per port) for Bellcore National ISDN-1 Country Protocol.

DEFINITY ECS does not support the following for WCBRI terminals:

- Transfer, hold, drop, or conference
- Administrable feature buttons
- Multiple call appearances and features requiring multiple call appearances

DEFINITY ECS does not control the display information or ring type at a WCBRI terminal.

When DEFINITY ECS delivers a call to a WCBRI station the called number IE in the SETUP message contains the dialed principal's extension. The extension can be different from the WCBRI station extension if the call is a hunt group call, TEG call, a redirected call from coverage, or a call routed by call vectoring.

WCBRI should not be designated as coverage points for many different principals.

### Form instructions

---

To administer a World Class BRI terminal, complete the standard as well as the following unique Station form fields.

Some WCBRI endpoints must be programmed with their assigned extension before they will accept an incoming call. Furthermore, many WCBRI endpoints can be programmed with multiple directory numbers, one of which must be their assigned extension. In this case, the WCBRI endpoint will accept calls delivered

to the endpoint with any of the programmed numbers. See also [“Multiple Subscriber Number \(MSN\) - Limited”](#) on page 6-214.

### Interactions

The unique capabilities of WCBRI terminals impact the way many DEFINITY ECS features work, as shown in the following table.

**Table 6-8. World Class BRI feature interactions**

| <b>Feature</b>   | <b>Support without limits</b> | <b>Support with limits</b> | <b>No support</b> | <b>Comments below</b> |
|--|-------------------------------|----------------------------|-------------------|-----------------------|
| A-law/mu-law companding selection                          |                               | x                          |                   | x                     |

- A-law/mu-law companding selection

Companding selections for the WCBRI stations must be compatible with the switch companding on the System-Parameters Customer-Options form.

- Abbreviated/delayed ringing  
You cannot select Alternate-ring values of no-ring, abbreviated-ring, and delayed-ring. You can enable automatic A/D transition for calls to a WCBRI station. This allows another user, bridged to a WCBRI station, to use the feature.
- Abbreviated Dialing  
Feature buttons are not supported. Use FAC codes.
- Adjunct controlled splits  
Extra phone functions such as hold or transfer are unavailable to an agent in an adjunct-controlled split.
- Adjunct routing  
An adjunct provides priority ringing to a call routed by the adjunct. A WCBRI station or country protocol may not fully support priority ringing.
- Administered repetitive call-waiting tone interval  
Call-waiting tones are not available on WCBRI stations.
- Administrable conference/intrusion tones  
Conference and intrusion tones are heard at the WCBRI terminal. You cannot administer a verify button on the terminal.
- Administrable wait answer supervision timer  
A call made from or to a WCBRI station rings for the allotted time. If the feature is active, the caller hears intercept tone and the call stops ringing at the terminal.
- Administration without Hardware  
You can administer WCBRI stations without port information.
- Agent after-hour call work button  
Because WCBRI stations do not support feature buttons, use FACs.
- Agent login/logout  
Agents use a FAC to log in or log out. If an agent receives a call while on-hook (to enter an FAC), the agent can miss the call. The agent may be unable to hear dial tone (in order to enter the FAC) after going on-hook if the split is continuously busy with calls.
- Agent-home (using CONVERSANT VIS)  
WCBRI stations are not suitable for home-agent stations because of feature limitations.
- Agent position, Agent work modes  
Because WCBRI stations do not support feature buttons, an agent uses a FAC to establish or change work modes.

- Agent with multiple splits

The WCBRI station can accept calls delivered with each logged-in split extension.

- ASAI

WCBRI stations are not suitable as ASAI agent-voice terminals because WCBRI stations do not have administrable buttons, lamp control, and display control. Use the stations for ASAI with these limitations:

- WCBRI stations do not support the message-waiting lamp, but audible-message waiting indication is available.
- The system considers the WCBRI station as a single-line analog station with no display, no special-alerting pattern, and no system control of off-hook/on-hook status.

WCBRI stations can answer switch-classified calls that ASAI uses for outgoing call management. WCBRI stations do impose some limitations for user-classified calls. For example, when an ASAI adjunct initiates a user-classified call and the originator is on-hook, the system selects an originator's call appearance and forces it off-hook. WCBRI stations do not support this processing. Instead, the system treats a WCBRI terminal as an analog terminal and waits 5 seconds for the WCBRI-originating station to go off-hook. If the originating station is off-hook with a dial tone, the system completes dialing to the destination.

- Assist

An agent at a WCBRI station can use only a FAC to request supervisor assistance. Since an active call is the reason for needing assistance, Assist is not available to WCBRI users. A WCBRI station does not provide the agent with a hold button.

- Attendant call-coverage point

A WCBRI station can use an attendant as a coverage point. Because a WCBRI terminal is treated by the system as an analog terminal, it cannot have a simulated bridged appearance.

- AUDIX

WCBRI stations can call AUDIX for messages and can use AUDIX as a coverage point. Although WCBRI stations do not support message lamps, they do support audible message waiting. Because WCBRI stations do not support Conference, they also do not support Call Conference into AUDIX.

- Automatic answering with zip tone

Automatic answering with zip tone is dependent upon the selected call appearance, which is not supported for WCBRI stations.

- Automatic Call Distribution

WCBRI stations do not support release or drop buttons for ACD call disconnecting. Agents can drop a call by going on-hook. If the WCBRI station has a drop button that sends either a DISCONNECT or RELEASE COMPLETE message during an active call, then the call is dropped.

WCBRI stations do not support either stroke counts or call work codes. Administer these features via feature buttons. WCBRI stations do not support feature buttons.

ACD calls delivered to a WCBRI station send the hunt-group extension, not the station extension, as the called number in the SETUP message. For the WCBRI station to accept such calls, it must either:

- Not check the delivered called number
- Administer with additional directory numbers (hunt-group extensions) that can be delivered in SETUP messages as called numbers

The system allows one active call per hunt-group extension. You can avoid this limitation by using Call Vectoring to route two calls to a single data-module extension.

- Automatic circuit assurance (includes referrals)

Use a WCBRI station as a remote-referral destination for ACA calls. Use speech-synthesis boards to voice the ACA to the user. If the WCBRI station is an A-law terminal, use a British or Italian speech-synthesis board; if Mu-law, use a North American speech-synthesis board.

- Bridged Call Appearance (single-line, multiappearance)

WCBRI stations support bridging features in only one direction. Administer a WCBRI station as a bridged appearance on a multiappearance station. WCBRI stations cannot support bridged appearances for other extensions.

- Call Coverage-consult

WCBRI stations do not support feature buttons, therefore WCBRI stations support Call Coverage-consult when the WCBRI terminal is the covered user, but not when it is the covering user.

- Call Coverage-cover for PCOL calls

Call Coverage-cover for PCOL calls is supported for WCBRI when the WCBRI terminal is used as a covering user.

- Call Coverage-caller response interval

WCBRI stations do not support feature buttons. The only thing a user can do during the interval is hang up.

- Call Coverage-send all calls

Activate via the FAC.

- Call Forwarding All Calls

A WCBRI user can activate Call Forwarding All Calls by using a FAC, but there is no visual indication that the feature is active. When a call is forwarded, the system applies a burst ring to the forwarding terminal.

The system does not send a signal IE in the INFO message to a WCBRI terminal administered for country protocols 2 (Australia), etsi, or 6 (Singapore).

- Call Forward-Busy and Don't Answer

A WCBRI user can access Call Forward-Busy and Don't Answer with a FAC.

- Call Park

A user cannot park a call from a WCBRI terminal. A WCBRI user can pick up a parked call using a FAC.

- Call Pickup

A WCBRI terminal can be part of a pickup group and can answer calls directed to other members of the group by using a FAC.

- Caller response interval

WCBRI stations do not support feature buttons. The only thing a user can do during the interval is hang up.

- Call Vectoring-distinctive alerting (ringing)

The switch controls a WCBRI ringer via a signal IE. The country protocol assigned to a WCBRI station impacts signal IE. Specifically, the signal IE is not permitted for country protocol 2 (Australia) or etsi, and station ringing is controlled solely by the WCBRI station. In addition, the signal IE is supported only in a SETUP message for country protocol 6. (Singapore)

For all other situations, the ringer response to the different signal IE values depends upon station characteristics and local station options that modify station ringing.

- Calling number display

The system sends a calling number IE message to a WCBRI terminal or, if the call is an incoming PRI-trunk call, the system tandems the received calling-number IE to the terminal. Some WCBRI terminals cannot display the information.

- Calling number display (SID/ANI/Extn ID)

The system delivers the calling party number IE received in a PRI setup message to a WCBRI station. The station can display the number.

- Consult

WCBRI stations support Consult for the covered user, but not for the covering user.

- Data Call Setup-dialing

Basic-terminal dialing is supported for WCBRI terminals. The WCBRI terminal controls the digits sent to the system.
- Data Call Setup-alphanumeric

Data Call Setup-alphanumeric is supported for WCBRI terminals that provide alphanumeric characters in keypad IEs during call setup.
- Data Call Setup-default

Data Call Setup-default is supported if the terminal sends either a sending complete IE (0xa1) or a called-party number IE with no digits specified in the SETUP message or subsequent information message.
- DCS Attendant Call Coverage Point

A WCBRI station can use an attendant as a coverage point. Because a WCBRI terminal is treated by the system as an analog terminal, it cannot have a simulated bridged appearance.
- DCS Automatic Circuit Assurance

Use a WCBRI station as a remote-referral destination for ACA calls. You must use speech-synthesis boards to voice the ACA to the user. If the WCBRI station is an A-law terminal, use a British or Italian speech-synthesis board; if Mu-law, use a North American speech-synthesis board.
- DCS Automatic Callback

A WCBRI terminal cannot activate DCS Automatic Callback. A user cannot key the FAC and the extension to activate DCS Automatic Callback because the switch allows this procedure for held calls. Call hold is not available to WCBRI users.

A remote-caller can activate DCS Automatic Callback for a WCBRI terminal when the terminal is busy or does not answer. When the terminal is on-hook, the system alerts the caller. When the caller is off-hook, the system generates a new call and alerts the WCBRI terminal.
- DCS Distinctive Alerting (Ringing)

The switch controls a WCBRI ringer via a signal IE. The country protocol assigned to a WCBRI station impacts signal IE. Specifically, signal IE is not permitted for country protocol 2 (Australia) or etsi, and station ringing is controlled solely by the WCBRI station. In addition, the signal IE is supported in a SETUP message for country protocol 6. (Singapore)

For all other situations, the ringer response to different signal IE values depends upon station characteristics and local station options that modify station ringing.

- DCS Leave Word Calling

It is possible to leave a DCS Leave Word Calling message for a WCBRI terminal user. The user can retrieve the message using the voice-retrieval message FAC.

A WCBRI terminal can leave a message for a user on a different DCS node by dialing the LWC send a message FAC and the remote extension.

- Dialed number identification service

WCBRI stations do not support DNIS. Calls delivered to WCBRI stations have the dialed-principal's extension as the called-party number.

- Direct Agent Calling - via adjunct

The special-alert pattern (ring ping) used to deliver direct agent calls may not be supported in all WCBRI stations or country protocols.

- Direct department calling distribution.

Calls delivered to WCBRI stations have the DDC-group extension as the called-party number.

- Distinctive Alerting (Ringing)

The switch controls a WCBRI ringer via a signal IE. The country protocol assigned to a WCBRI station impacts signal IE. Specifically, signal IE is not permitted for country protocol 2 (Australia) or etsi, and station ringing is controlled solely by the WCBRI station. In addition, the signal IE is supported in a SETUP message for country protocol 6. (Singapore)

For all other situations, the ringer response to different signal IE values depends upon station characteristics and local station options that modify station ringing.

- DNIS display

WCBRI stations do not support DNIS Display. WCBRI stations can display information in the called-party number IE, but this information is different from called-number information received over PRI.

- Drop

The switch provides limited support for Drop on WCBRI stations. If a WCBRI station has a Drop button that sends a DISCONNECT or RELEASE COMPLETE message to DEFINITY 5.4 during an active call, the call drops. Do not use the Drop button on the WCBRI station to selectively drop the last party added to a conference call.

- Hospitality-Automatic Wakeup

Hospitality-Automatic Wakeup is supported with the TN725B speech-synthesis board and by using voice prompting and the automatic wakeup FAC. The display is under the control of the WCBRI terminal.

- Hospitality-controlled restriction

Hospitality-controlled restriction allows an operator on the Property Management System to change a room's restrictions. WCBRI does not interact with this function.

A WCBRI terminal cannot be a front-desk station and cannot be used to change restrictions from the front desk.
- Hospitality-Do Not Disturb

Hospitality-Do Not Disturb is supported by voice prompting and the Do Not Disturb FAC.
- Hospitality-Message Waiting Notification

WCBRI terminals do not have buttons and cannot notify other extensions. A WCBRI terminal can be notified of waiting messages by setting the audible message waiting field on the Station form to yes.
- ISDN-QSIG call diversion

A WCBRI user can activate ISDN-QSIG call diversion by using a FAC, but there is no visual indication that the feature is active. When a call is forwarded, the system applies a burst ring to the forwarding terminal.

The system does not send a signal IE in the INFO message to a WCBRI terminal administered for country protocols 2 (Australia), etsi, or 6 (Singapore).

Display updates of QSIG call diversion are not supported for WCBRI terminals.
- Loudspeaker Paging Access w/answerback

A WCBRI user can activate this feature via an FAC.
- Loudspeaker Paging Access Deluxe w/answerback

A WCBRI user can activate this feature via an FAC.
- Malicious Call Trace

A WCBRI user can activate this feature for another station from a WCBRI station by entering a FAC. When the WCBRI user hangs up, the trunk is not released.
- Multiple Subscriber Number (MSN) - Limited

The ISDN standard MSN feature lets you assign multiple extensions to a single BRI endpoint. The DEFINITY ECS MSN feature works with BRI endpoints that allow the Channel ID IE to be encoded as "preferred." The endpoint must be administered as the far end of an NT-side ISDN-BRI trunk group. Also, the customer must use the Uniform Dial Plan (UDP) feature to assign the desired extensions to the "node" at the far end of the trunk group.

- Music-on-Hold-Access held calls

WCBRI stations cannot place a call on hold. If a WCBRI station is placed on hold by another station, the WCBRI user hears the music provided by Music-on-Hold-Access held calls.
- Music-on-Hold conference/terminal calls

WCBRI stations cannot initiate a conference. If a WCBRI station is placed on hold for conference by another station, the WCBRI user hears the music provided by Music-on-Hold conference/terminal calls.
- Music-on-Hold Access transferred trunk calls

WCBRI stations cannot place a call on hold for transfer. If a WCBRI station is placed on hold for transfer by another station, the WCBRI user hears the music provided by Music-on-Hold-Access transferred-trunk calls.
- Night Service (Night Station Service)

WCBRI stations can serve as night stations, but can handle only one call at a time.
- Night Service (Trunk Answer from any Station)

A WCBRI station can answer a TAAS call by dialing the FAC.
- Night Service (Trunk Group)

Because WCBRI stations do not support feature buttons, do not assign a WCBRI station the feature button required to activate Night Service-Trunk Group. A WCBRI station can serve as a night-service destination once this feature is activated by another station.
- Personalized Ringing

Personalized Ringing is controlled by the WCBRI terminal.
- Priority Calling

WCBRI station users can access Priority Calling with the FAC.
- Privacy-Manual Exclusion

WCBRI stations lack the feature buttons necessary to access Privacy-Manual Exclusion. A WCBRI station can bridge to another multiappearance station that has the necessary feature button. When the WCBRI station is bridged onto a call where another station activates exclusion, the WCBRI station is removed from the call. If exclusion is activated before the WCBRI station attempts to bridge onto the call, the call is blocked.
- Ringback Queuing

Ringback Queuing is blocked for multiappearance stations. WCBRI stations are considered multiappearance by the software.

- **Service Observing**

WCBRI cannot support Service Observing because it uses feature buttons. Another station can use Service Observing to observe an active call at a WCBRI station.
- **Split Supervisor**

WCBRI stations are not suitable to be split supervisors because the stations have limited functions — for example, no displays and the inability to activate Service Observing.
- **Terminal Translation Initialization**

Terminal Translation Initialization is supported for terminals that provide SPID initialization, including Nation ISDN BRI terminals, but not other WCBRI terminals.
- **Third-Party Call Control**

Third-party selective hold and third-party merge are not supported if the third-party controlled call is on a WCBRI station. Third-party selective drop is supported.
- **Third-Party Domain (station)**

The system treats a WCBRI station as an analog station. It waits 5 seconds for the station to go off-hook before delivering a call to the station or originating a call for a station.
- **Third-Party Domain (station/split)**

The system treats a WCBRI station as an analog station. It waits 5 seconds for the station to go off-hook before delivering a call to the station or originating a call.
- **VDN Return Destination**

Always administer 1-step clearing to yes. If you administer 1-step clearing to no, a call does not terminate again at the WCBRI terminal when the user drops from the call. If 1-step clearing is set to yes, the call terminates again at the WCBRI terminal.

## **PC Interface Administration**

## EIA Interface

---

EIA Interface provides an alternative to digital terminal data modules and modular processor data modules within the system for interconnection between EIA 232-compatible digital terminal equipment and the system. The EIA Interface consists of a data-line circuit-pack port and an asynchronous data unit (ADU).

### Administration Commands

---

Use the following commands to access the EIA Interface.

#### Required forms

---

| Form                      | Field  | Page                  |
|---------------------------|--|-----------------------|
| Station (multiappearance) | ■ Feature Button Assignments<br>— data-ext (Ext:___) | <a href="#">6-28</a>  |
| Data Module (all forms)   | ■ All  | <a href="#">7-115</a> |

### Detailed description

---

EIA Interface supports speeds of LOW, 300, 1200, 2400, 9600, and 19200 bps.

A data-line port differs from a data module when functions (options) are set in the system rather than at the hardware. Users do not have access to the data-line port, but can access all data-module-related functions. Users can examine and change such items as speed and parity via a menu-driven selection mode at the DTE. You can use the management terminal to examine and change functions.

Use a data-line port in conjunction with an ADU to connect the system to:

- Administrative terminals
- The outside world via an integrated modem pool card or external modem pool resource
- A PMS interface
- Asynchronous data terminals
- Journal printers

Available ADUs are the Z3A1, Z3A2, and Z3A4.

Connect the DCE to a data-line port using a null modem.

## **Considerations**

---

- There is no limit to the number of data-line circuit packs the system can support, subject to slot availability and the system limit of digital-data endpoints.
- The system does not provide flow-control signaling.

## **Interactions**

---

- **Data Terminal Dialing**  
Grant Data Terminal (Keyboard) Dialing permission before you use keyboard dialing.

## PC Interface

---

The personal computer (PC) Interface consists of the PC/PBX Connection, the PC/PBX platforms, and PC/ISDN Platform product family. These products are used with DEFINITY ECS to provide users of IBM-compatible PCs fully-integrated voice and data workstation capabilities. (PC/PBX Connection is a voice and data call-management application.)

### Administration Commands

---

Use the following commands to access the PC Interface.

#### Required forms

---

| Form                        | Field | Page                  |
|-----------------------------|-------|-----------------------|
| Station (personal computer) | ■ All | <a href="#">6-153</a> |

---

### Detailed description

---

Two groups of different configurations are available for PC Interface: group 1 uses Digital Communications Protocol (DCP) and group 2 uses the ISDN-BRI (Basic Rate Interface) protocol.

The group 1 configurations consist of DCP configurations that use a PC/PBX Interface card (formerly DCP expansion card) in the PC to link to the switch. Group 1 (shown in [Figure 6-1](#)) uses the following connections:

- The PC Interface card plugs into an expansion slot on the PC. The card has 2 standard 8-pin modular jacks (line and phone).
- The digital phone plugs into the phone jack on the PC Interface card.
- The line jack on the card provides a digital port connection to DEFINITY ECS.
- The distance between the PC Interface card and the PBX should be no more than 1524m for 24-gauge wire or 1219m for 26-gauge wire.

dcppcgp2 PDH 061296

### Figure Notes

- |  |   |
|--|---|
| 1. IBM-compatible PC with DCP Interface card | 4. DCP voice terminal   |
| 2. IBM-compatible PC with DCP Interface card | 5. DEFINITY ECS (TN754B, TN2181, or TN2224 digital-line circuit pack) |
| 3. DCP                                       | 6. Host   |

Figure 6-1. DCP PC interface configuration (Group 1)

The group 2 configurations link to the switch using a PC/ISDN Interface card installed in the PC. This group can include a stand-alone PC terminal, or up to four voice terminals, handsets, or headsets. Group 2 (shown in [Figure 6-2](#)) uses PC/ISDN Interface cards (up to four cards) which plug into expansion slots on the PC. These cards each provide 2 standard 8-pin modular-jack connections for both line connections (to the switch) and phone connections. A standard 4-pin modular jack is also available for use with a handset or headset.

isdnbri PDH 061296

**Figure Notes**

- |   |                     |
|---|---------------------|
| 1. ISDN voice terminal  | 7. DEFINITY ECS     |
| 2. PC with application  | 8. PRI trunks       |
| 3. Handset or Headset   | 9. BRI stations     |
| 4. BRI Interface card   | 10. Interworking    |
| 5. 2B + D   | 11. DMI             |
| 6. TN556 (ISDN-BRI Line, 4-wire S/T-NT, interface circuit pack) | 12. Switch features |

**Figure 6-2. ISDN—BRI PC interface configuration (Group 2)**

PC Interface users have multiple appearances (depending on the software application used) for their assigned extension. Designate one or more of these appearances for use with data calls. With the ISDN-BRI version, you can use up to 4 separate PC/ISDN Interface cards on the same PC. Assign each card a separate extension, and assign each extension one or more appearances. The availability of specific features depends on the COS of the extension and the COS for the switch. Modem Pooling is provided to ensure general availability of off-net data-calling services.

## Security

---

There are two areas where unauthorized use may occur with this feature: unauthorized local use and remote access.

### SECURITY ALERT:

*Unauthorized local use involves unauthorized users who attempt to make calls from a PC. The PC software has a security setting so users can place the PC in Security Mode when it is unattended. You can also assign Automatic Security so that the administration program on the PC is always active and runs in Security Mode. This mode is password-protected.*

### SECURITY ALERT:

*Remote access involves remote access to the PC over a data extension. Remote users can delete or copy PC files with this feature. You can password-protect this feature. Consult the BCS Product Security Handbook for additional steps to secure your system and to find out about obtaining information regularly about security developments.*

## Considerations

---

- Use the Function Key Module of the 7405D with PC Interface.
- BRI terminals normally are initializing terminals and require you to assign an SPID. The PC/ISDN Platform (Group 2), in a stand-alone configuration, is a noninitializing BRI terminal and does not require you to assign a SPID.
  - Set a locally-defined terminal type with General Terminal Administration
  - Define the terminal type as a noninitializing terminal that does not support Management Information Messages (MIM).
  - Assign the PC/ISDN Platform with an associated (initializing) ISDN-BRI voice terminal (such as an ISDN 7505) using a SPID.
  - Assign the station (using a locally-defined terminal type) to take full advantage of the capabilities of the PC Interface. This terminal type is also noninitializing with no support of MIMs.
- Do not use voice terminals with data modules with the PC Interface. (You can still use 3270 Data Modules if you also use 3270 emulation). If you attach a DCP data module or ISDN data module to a voice terminal that is connected to a PC Interface card, the data module is bypassed (not used). All the interface functions are performed by the interface card even if a data module is present.
- The 7404D voice terminal with messaging cartridge cannot be used with PC Interface. However, the 7404D with PC cartridge can be used, but only with Group 1 configurations.

## Interactions

---

- Data Communications Access

PC Interface uses a digital interface and is not directly compatible with Data Communications Access, which uses an analog interface. Apply Modem Pooling conversion if you use these features together.
- Data Protection

Assign Data Protection—Permanent for use with PC Interface for data communications.
- Host Computer Access

Both PC Interface and Host Computer Access use digital interfaces. These features are compatible and Modem Pooling conversion is unnecessary.
- ISDN-BRI

Each card can have its own separate voice terminal or voice-calling device. A voice terminal does not require special application software on the PC. However, a handset or headset alone requires special application software.
- Modem Pooling

Use Modem Pooling if you use PC Interface to place calls to, or receive calls from, off-premises stations over analog trunks.

# **Data Module Administration**

## Data Modules — general

---

A Data Module is a connection device between a basic-rate interface (BRI) or digital-communications protocol (DCP) interface of the switch and data-terminal equipment (DTE) or data-communications equipment (DCE).

The following types of data modules can be used with the system:

- Announcement data module
- Data line data module
- Processor/trunk data module (P/TDM)
- Netcon data module (R5vs and R5si and later configurations only)
- Processor interface data module (R5vs and R5si and later configurations only)
- System port data module (R5r and later configurations only)
- X.25 data module (R5r and later configurations only)
- 7500 data module
- World Class BRI data module

### Administration Commands

---

You assign each data module to your system by administering a Data Module form. Each Data Module form requires you to specify the type of data module in the `TYPE` field; this is how you distinguish between the many different types of data modules. Use the following commands to access the appropriate Data Module form.

**Table 6-1. Administration commands**

| Action    | Object      | Qualifier <sup>1</sup>                                   |
|-----------|-------------|--|
| add       | data-module | xxxx (extension or 'next')                               |
| change    | data-module | xxxx (extension number)                                  |
| display   | data-module | xxxx (extension number) [print or schedule]              |
| duplicate | data-module | xxxx (extension number to be duplicated)                 |
| list      | data-module | (starting ext number) xxxx ('count') [print or schedule] |
| remove    | data-module | xxxx (extension number)                                  |

---

1. Brackets [ ] indicate the qualifier is optional.

---

**⇒ NOTE:**

The 51X series Business Communications Terminals (BCTs) are not administered on the Data Module form. The 510 BCT (equivalent to a 7405D with a display and built-in DTDM), 515 BCT (equivalent to a 7403D integrated with 7405D display module function, data terminal and built-in DTDM), and the 7505D, 7506D, and 7507D have a DCP interface but have built-in data module functionality. Both are administered through the Station form.

**⇒ NOTE:**

To administer a data module with a 7400D-series voice terminal, refer to the 7400D voice terminal information provided earlier in this book.

## Detailed description of data modules

---

TTI allows data modules without hardware translation to merge with an appropriate data module connected to an unadministered port. The unadministered port is given TTI default translation sufficient to allow a terminal connected to the data module (connected to the port) to request a TTI merge with the extension of a data module administered without hardware translation.

**⇒ NOTE:**

TTI is not useful for Announcement and X.25 hardware.

Administration Without Hardware Translation supports PDM, TDM, Data-Line, Announcement, and X.25 data modules.

**⇒ NOTE:**

The 513 BCT has an EIA interface rather than a DCP interface (no built in data module, attachable telephone, or telephone features). The 513 BCT is not administered; only the data module to which the 513 BCT is connected is administered.

### 7400A/7400B+7400B+ Data Module

Use the 7400A data module instead of an MTDM when you support combined Modem Pooling. The 7400A data module supports asynchronous operation at speeds up to 19200-bps, and provides a DCP interface to the switch and an EIA 232C interface to the associated modem. The 7400A operates in stand-alone mode as a data module.

7400B+ and 8400B+ data modules support asynchronous-data communications and operate in stand-alone mode for data-only service or in linked mode, which provides simultaneous voice and data service. The 7400B+ and 8400B+ provide voice and data communications to 7400D series voice terminals and 602A1 CALLMASTER voice terminals that have a connection to a data terminal or personal computer. The data modules integrate data and voice into the DCP protocol required to interface with the switch via a port on a digital-line circuit

pack. Use the 7400B+ or 8400B+ instead of an MPDM when you need asynchronous operation at speeds up to 19.2-kbps to provide a DCP interface to the switch for data terminals and printers. The 7400B+ and 8400B+ do not support synchronous operation and keyboard dialing.

## **7400D**

This data module supports synchronous operation with AUDIX, CMS, and DCS. It provides synchronous data transmissions at speeds of 19.2-Kbps full duplex.

## **7400C High Speed Link**

The 7400C high-speed link (HSL) is a data-service unit that allows access to DCP data services. It provides synchronous data transmission at speeds of 56- and 64-Kbps and provides a link to high-speed data networks. Used for Group 4 fax applications that include electronic mail and messaging, and electronic storage of printed documents and graphics. Use the 7400C for video teleconferencing and LAN interconnect applications.

## **7500 Data Modules**

The 7500 Data Module connects data-terminal equipment (DTE) or data-communications equipment (DCE) to the ISDN network. The 7500 Data Module supports EIA 232C and V.35 interfaces and RS-366 automatic-calling unit interface (for the EIA 232C interface only).

The 7500 has no voice functions. Configure in the following ways:

- Asynchronous DCE  
300, 1200, 2400, 4800, 9600, 19200-bps
- Synchronous DCE  
1200, 2400, 4800, 9600, 19200, 56000, 64000-bps
- Asynchronous DTE (used for modem pooling)  
up to 19200-bps

The 7500 Data Module is stand-alone or in a multiple-mount housing.

## Asynchronous Data Module

 **NOTE:**

The alias station command cannot be used to alias data modules.

Use the Asynchronous Data Module (ADM) with asynchronous DTEs as a data stand for the 7500 Series of ISDN-BRI voice terminals, thus providing connection to the ISDN network. The ADM provides integrated voice and data on the same voice terminal and supports data rates of 300, 1200, 2400, 4800, 9600, and 19200-bps. This module also supports the Hayes command set, providing compatibility with PC communications packages.

## Data module form field description

The following section provides descriptions of standard fields on Data Module forms. Some of the fields are used for specific data module types; others are used for all data modules. Unique fields and fields requiring special consideration are listed with the appropriate data module descriptions later in this book.

The standard fields are organized alphabetically for easy access.

- **ABBREVIATED DIALING List1** — Enter **p** (personal), **s** (system), **g** (group), or **e** (enhanced). If you enter **p** or **g**, you also must enter a personal list number or a group number, respectively. Entry in this field supports Data Hot Line. This field can be left blank.
- **BCC** — (Bearer Capability Class) Displays when `ISDN-PRI` or `ISDN-BRI Trunks` is enabled on the System-Parameters Customer-Options form. It is a display-only field. The value in the field corresponds to the speed setting of the data module. A BCC of "1" relates to 56-kbps, BCC values of 2, 3, and 4 relate to 64 kbps. This field may be compared with the BCC value in an associated routing pattern when attempted calls utilizing the data module fail to complete. The BCC values must be the same.

See "Generalized Route Selection" in this book for a detailed description of Bearer Capability Classes (BCC) and their ability to provide specialized routing for various types of voice and data calls. The BCC value is used to determine compatibility when non-ISDN-PRI facilities are connected to ISDN facilities (ISDN-PRI Interworking).

- **Board** — Enter the five character announcement board number that identifies the physical board to which the announcement module is connected. If you are using Administration Without Hardware, enter **X** in this field to indicate that there is no hardware associated with this port assignment. Default is blank.

The five character announcement board number is comprised of:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)  |
|            |                | 01 through 03 (R5si and later configurations) |
|            |                | 01 (R5vs and later configurations)            |
| 3          | Carrier        | A through E                                   |
| 4-5        | Slot Number    | 01 through 20                                 |

- **COR** — Enter a Class of Restriction (COR) number (**0** through **95**) to select the desired restriction; default is **1**.

- **COS** — Enter the desired Class of Service (COS) number (**0** through **15**) to select allowed features; default is **1**.
- **Data Extension** — Enter the extension assigned to the data module. A data extension can be a 1- to 5-digit number and must agree with the Dial Plan.
- **Default Dialing Abbreviated Dialing Dial Code** — Only displays when the Special Dialing Option is set to default. Enter a list number (**0** through **999**) associated with the AD list. When the user goes off-hook and enters a carriage return following the DIAL prompt, the system dials the AD number. The data call originator can also perform data-terminal dialing by specifying a dial string that may or may not contain alphanumeric names. Default is blank.
- **Ext and Name** — Make no entry. This is the extension number and name of the user (previously administered) with associated Data Extension buttons who shares the module.
- **HOT LINE DESTINATION — Abbreviated Dialing Dial Code** — Displays only when `Special Dialing Option` is **hot-line**. Enter a list number (associated with the AD List) from **0** to **999**. When the user goes off-hook on a Data Hot Line call, the system dials the AD number. Entry in this field supports Data Hot Line.
- **ITC (Information Transfer Capability)** — Only displays when `Comm Type` is **56k-data** or **64k-data**. Enter **restricted** (default) or **unrestricted** to indicate the type of transmission facilities to be used for ISDN calls originated from this endpoint. The field does not display for voice-only or BRI stations.
  - If you set ITC to **restricted**, either restricted or unrestricted transmission facilities are used to complete the call. A restricted facility is a transmission facility that enforces 1's density digital transmission (that is, a sequence of 8 digital zeros are converted to a sequence of 7 zeros and a digital 1).
  - If you set ITC to **unrestricted**, only unrestricted transmission facilities are used to complete the call. An unrestricted facility is a transmission facility that does not enforce 1's density digital transmission (that is, digital information is sent exactly as is).
- **MM Complex Voice Ext:** (display only) — This field contains the number of the associated voice terminal in the multimedia complex. This field only displays after you set `Multimedia` to **y**. This field is left blank until you enter the data module extension in MM Complex Data Ext on the Station form. Once you complete the field on the station form, these two extensions are associated as two parts of a one-number complex, which is the extension of the voice terminal. Valid values conform to your dial plan.
- **Multimedia** — Enter **y** to make this data module part of a multimedia complex. This field only appears if **MM** on the System-Parameters Customer Options form is **y**.

- **Name** — Enter the name of the user associated with the data module. The name is optional and can be blank.
- **Port** — Enter 7 characters to specify a port location to which the data module is connected as follows:

| Characters | Meaning        | Value  |
|------------|----------------|--|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)<br>01 through 03 (R5si and later configurations)<br>01 (R5vs) |
| 3          | Carrier        | A through E  |
| 4-5        | Slot Number    | 01 through 20  |
| 6-7        | Circuit Number | 01 through 04 (x.25 circuit pack)<br>01 through 32 (R5si and later configurations)                         |

 **NOTE:**

You can enter X in the `Port` field to indicate that there is no hardware associated with the port assignment (Administration Without Hardware). These stations are referred to as “phantom stations.” If this data module is designated as a secondary data module (Secondary data module set to y) X cannot be entered into this field. The Port of a primary data module cannot be changed to X if a secondary data module is administered.

- **SPECIAL DIALING OPTION** — Enter **hot-line**, **default**, or leave blank for regular (normal) keyboard dialing. This field identifies the type of dialing for calls when this data module originates calls.
- **TN** — Enter the Tenant Partition number. Default is 1.

## Announcement Data Module

The TN750 Announcement circuit pack has a built-in data module that is administered using the Announcement Data Module form. This data module (in conjunction with an administered Netcon Data Module in R5vs and R5si and later configurations) allows the system to save the recorded announcements file from the TN750 announcement circuit pack to the system tape/disk/memory card (depending on system configuration) and restore from the system tape/disk/memory card to the announcement circuit pack. Only one TN750A or TN750B board can be automatically restored during a system reload. TN750C is not automatically restored during a system reload.

The TN750C board contains flash memory which provides internal backup of announcements on the boards. Thus, the TN750C board does not need the Save and Restore processes still available for the TN750 and TN750B boards. However, you can use the Save and Restore processes to copy announcements between TN750B/C boards.

### NOTE:

Announcements are not saved when a save translations command is executed. Execute the save announcements command to save announcements. This operation does not save announcements on external announcement units connected to AUX or Analog line circuit packs.

## Form instructions

To administer an Announcement Data Module, complete the standard as well as the following unique Data Module form fields.

- **Type** — Enter “announcement”.

```
add data-module next                                Page 1 of 1
                                                    DATA MODULE

## Data Line Data Module

---

The Data Line Data Module (DLDM) form assigns ports on the TN726 Data Line circuit pack (DLC) that allows EIA 232C devices to connect to the system. The DLC, with a companion Asynchronous Data Unit (ADU), provides a less expensive data interface to the system than data modules such as Digital Terminal Data Modules (DTDMs), Modular Processor Data Modules (MPDMs), Modular Trunk Data Modules (MTDMs), or other asynchronous DCP data modules.

The DLC supports asynchronous transmissions at speeds of Low and 300, 1200, 2400, 4800, 9600, and 19200 bps over 2-pair (full-duplex) lines. These lines can have different lengths, depending on the transmission speed and wire gauge.

The DLC has 8 ports. The connection from the port to the EIA device is *direct*, meaning that no multiplexing is involved. A single port of the DLC is equivalent in functionality to a data module and a digital line port. The DLC appears as a data module to the Digital Terminal Equipment (DTE) and as a digital line port to the switch.

The DLC connects the following EIA 232C equipment to the system:

- Printers
- Non-Intelligent Data Terminals
- Intelligent Terminals, Personal Computers (PCs)
- Host Computers
- Information Systems Network (ISN), RS-232C Local Area Networks (LANs), or other data switches.

### Form instructions

---

To administer a Data Line Data Module, complete the standard as well as the following unique Data Module form fields.

6 Data Module Administration  
Data Line Data Module

Screen 6-4. Data Line Data Module form (Page 2 of 2) — if KYBD Dialing set to n)

- **Type** — Enter “**data-line**”.
- **Connected To** — Enter **dte** (Data Terminal Equipment) or **isn** (Information Systems Network). This field shows to what the ADU (Asynchronous Data Unit) is connected. Default is **dte**.

Page 2 of the form

See “DLC Option Settings” following these instructions for additional information when assigning entries for the remaining fields on the form.

- **KYBD Dialing** — Enter **y** to allow keyboard dialing. This enables the data endpoint to receive and transmit text during call origination or termination. If you enter **y**, Low must be set to **n**.

This option must be enabled to allow data endpoints to originate calls via the EIA 232C interface and obtain ASCII feedback text. When enabled, the user gets the dial prompt. This option normally is enabled for “originate/receive” DTE that has a need to set up data calls. If this option is disabled, originations cannot be done at the DTE and text feedback does not occur at the DTE during call setup/take down. Data call answering is still allowed but without text feedback.

 **NOTE:**

ADU-type hunt groups connecting the system to terminal servers on a host computer should have these hunt group extensions assigned as “no” keyboard dialing.

- **Configuration** — Displays when KYBD Dialing is enabled. Enter **y** to allow the viewing and changing of options from the DTE.

This option normally is enabled for “originate/receive” DTE such as non-intelligent terminals and disabled for intelligent devices such as computers. Keyboard dialing must be enabled with this option.

- **Busy Out** — Enter **y** to place the DLC port in a busied-out state once the DTE control lead to the DLC is dropped. This option should be enabled for DTEs that are members of a hunt group and to allow “busy out” when DTE turns power off so that calls do not terminate on that DTE.
- **SPEEDS** — Enter **y** to select operating speeds as follows:
  - **Low** — Enter **y** to instruct the DLC to operate at a low speed from 0 to 1800 bits per second (bps). Enter **n** if **y** is entered in the `Keyboard Dialing` field.
  - **300, 1200, 2400, 4800, 9600, or 19200** — Enter **y** beside the desired operating speed. Enter **n** if the speed is not desired. The DLC can be any one of these speeds. The speed is matched for the duration of the call, from call setup to call takedown.

When multiple speeds are selected (select three or more, do not select just two speeds) and autoadjust is disabled, the DTE's speed must be the highest selected speed. This is required because all feedback text is delivered to the DTE at the highest selected speed.
  - **Autoadjust** — Displays when `KYBD Dialing` is enabled. Enter **y** which tells the DLC port to automatically adjust to the operating speed and parity of the DTE it is connected to. Enter **n** if this option is not desired. Autoadjust can be selected with any of the speeds selected in the previous step. Autoadjust allows the DLC port to determine the speed and parity of the DTE and then match itself to this speed. Autoadjust only applies to calls originated by the user through Keyboard Dialing.
- **Permit Mismatch** — Enter **y** to instruct the DLC to operate at the highest selected speed, which is a higher rate than the far-end data module. Enter **n** if this option is not desired.

This option allows the EIA interface to operate at a rate different than that agreed to in the data module handshake. (The data module handshake is always the highest compatible rate as determined by the reported speed option of each data module.) Permit Mismatch eliminates the need to change the DTE/DLC speed every time a call is placed to/from an endpoint operating at a different speed. When this option is enabled, the DLC reports the highest optioned speed and all the lower speeds (or the previously selected autoadjust speed) during the handshake process.

 **CAUTION:**

*Caution must be used when using this option to send information from a DTE/DCE that is transmitting data at higher rates than that of the far end. Sustained usage of this type transmission results in loss of data. Whenever this option is enabled, the DTE must match the highest speed selected for the associated DLC port.*

This option is intended to be used by a DTE device operating locally at a higher baud rate than that of its far-end connection but transmitting relatively low amounts of data (for example, a user typing at a terminal). Also, this option may be selected whether or not Keyboard Dialing is selected.

**NOTE:**

The Low speed setting is not reported as an available speed when `Permit Mismatch` is enabled.

- **Dial Echoing** — Displays when `KYBD Dialing` is enabled. Enter **y** to echo characters back to the DTE. Dial echoing should be disabled when keyboard dialing is done by an intelligent device.
- **Disconnect Sequence** — Displays when `KYBD Dialing` is enabled. Enter **long-break** or **two-breaks** to select the sequence for a disconnect. A long-break is greater than 2 seconds and two-breaks is within 1 second.
- **Answer Text** — Displays when `KYBD Dialing` is enabled. Enter **y** to allow text messages to be delivered to the DTE when a call is being answered. Enter **n** if this option is not desired.

This option enables text feedback that is normally delivered to the DTE when a call is answered or disconnected. The Answer Text option applies to DLC-generated text as well as text received from the system. If this option is disabled, the system still generates the text, but the DLC prevents it from being sent to the device.

This applies to the following messages:

- INCOMING CALL
- ANSWERED
- DISCONNECTED
- DISCONNECTED OTHER END

This option is usually disabled when the answering DTE is a computer or an intelligent device.

- **Parity** — Displays when `KYBD Dialing` is enabled. Enter **even**, **odd**, **mark**, or **space** to select the desired type of parity. The DLC generates the parities (even, odd, mark, and space) when call setup text is sent to the DTE. The DLC does not check the parity when receiving dialing characters. Parity has nothing to do with the far end; it is used by the DLC to terminal communications during call setup.
- **Connected Indication** — Displays when `KYBD Dialing` is enabled. Enter **y** to give text feedback to the DTE when a connection has been established. This option generates a "CONNECTED" message to the DTE when the connection has been established. If `KYBD Dialing` is not selected, the connected indication is provided by the DLC activating its EIA 232C control lead.

## DLC Option Settings

The following provides additional information on the option settings for DLCs when used with the following types of devices:

- Printers
- Non-intelligent terminals
- Data terminals and personal computers
- Host computers
- Information Systems Network (ISN)

### Printers

A DLC port, attached to a printer, usually terminates a data call. Therefore, in this connection, the printer is the endpoint device. The originating device may be attached to a DCP mode 2 data module (such as the MPDM) or the DLC. A Z3A ADU extends the range of the EIA 232C connection.

When a receive-only printer (or any printer that does not generate the Transmit Data and DTR leads) is used, the ADU must be powered from a small plug-mounted transformer (2012D, or equivalent) connected to pins 7 and 8 of the modular jack. (See *ADU User Manual* for details.)

An ADU cannot be used if the printer has hardware flow control using the Clear To Send (CTS) lead. An ADU can be used, however, if the printer is using software flow control.

A printer connected to a DLC is usually assigned as a line. [Table 6-2](#) lists the option settings for printer connections.

**Table 6-2. DLDM form settings for printer connection**

| Field on form   | Option                                      | Comments   |
|-----------------|---|--|
| Speed           | Highest speed at which the Printer operates | Subject to distance limitations; Autoadjust not used |
| KYBD Dialing    | no  |  |
| Busy Out        | yes   | If printer is member of Hunt Group                   |
| Permit Mismatch | yes   | No, if printer is low speed                          |
| Parity          | -   | Don't care   |
| Dial Echoing    | -   | Don't care   |

*Continued on next page*

**Table 6-2. DLDM form settings for printer connection — Continued**

| Field on form        | Option | Comments   |
|----------------------|--------|------------|
| Disconnect Sequence  | -      | Don't care |
| Answer Text          | -      | Don't care |
| Connected Indication | -      | Don't care |
| Configuration        | no     |            |

### Non-intelligent terminals

A non-intelligent terminal connected to the DLC usually is assigned as a line. [Table 6-3](#) lists the option settings for non-intelligent terminals.

**Table 6-3. DLDM form settings for connection to non-intelligent terminals**

| Field On form        | Option   | Comments   |
|----------------------|--|--|
| Speed                | All speeds at which the terminal can operate; autoadjust | Subject to distance limitations; Autoadjust when Keyboard Dialing is "y" and the Terminal can generate an ASCII "return" |
| KYBD Dialing         | yes  |  |
| Busy Out             | no   | Yes, if terminal is member of a hunt group   |
| Permit Mismatch      | yes  | -  |
| Parity               | Same as DTE  |  |
| Dial Echoing         | yes  | Only if KYBD Dialing is yes  |
| Disconnect Sequence  | 2 <BREAK>s   | Depends on terminal  |
| Answer Text          | yes  |  |
| Connected Indication | -  | Don't care   |
| Configuration        | yes  |  |

## Data terminals and personal computers

An intelligent data terminal or a personal computer (PC) attached to a DLC can either originate or terminate a data call. A single ADU at the site of the originating device extends the distance signals can travel to the switch (the model ADU depends on the terminal connector). An analog telephone can be attached to this arrangement whenever an ADU uses the standard building wiring. [Table 6-4](#) lists the option settings used for data terminal and personal computer connections.

**Table 6-4. DLDM form settings for connection to data terminal or personal computer**

| Field on form        | Option  | Comments  |
|----------------------|---|---|
| Speed                | All speeds at which the Data Terminal or PC can operate | Subject to distance limitations; Autoadjust not used                  |
| KYBD Dialing         | yes   |   |
| Busy Out             | no  | Yes, if device is accessed through a hunt group                       |
| Permit Mismatch      | yes   | No, if device does not support XON/XOFF flow control                  |
| Parity               | Same as DTE   |   |
| Dial Echoing         | no  | These devices can dial in the ASCII stream without human intervention |
| Disconnect Sequence  | Long <BREAK>  | -   |
| Answer Text          | no  | These devices may not want to see any text                            |
| Connected Indication | -   | Don't care  |
| Configuration        | yes   |   |

## Host computers

A host computer may originate and terminate a data call. For this application, the number of DLCs required depends on the number of ports needed. An MADU can be used (instead of eight ADUs) to complete the connection. [Table 6-5](#) lists option settings for a port that has a terminating connection to a host computer. [Table 6-5](#) shows the option settings for a port that has an originating connection from a host computer.

**NOTE:**

If `Keyboard Dialing` is disabled, the rest of the option settings are irrelevant.

**Table 6-5. DLDM form settings for terminating connection to host computer**

| Field on form        | Option                                       | Comments   |
|----------------------|--|--|
| Speed                | All speeds at which the computer can operate | Subject to distance limitations; Autoadjust not used |
| KYBD Dialing         | no   |  |
| Busy Out             | -  | Don't care   |
| Permit Mismatch      | -  | Don't care   |
| Parity               | -  | Don't care   |
| Dial Echoing         | -  | Don't care   |
| Disconnect Sequence  | -  | Don't care   |
| Answer Text          | -  | Don't care   |
| Connected Indication | -  | Don't care   |
| Configuration        | -  | Don't care   |

## **Processor/Trunk Data Module**

---

These forms assign Modular Processor Data Modules (MPDMs) and Modular Trunk Data Modules (MTDMs). One form is required for assigning MPDMs (700D), 7400B, 7400D or 8400B Data Module, and another form for MTDMs (700B, 700C, 700E, 7400A). One form must be completed for each MPDM, 7400B, 7400D, 8400B or MTDM.

The MPDM or 7400B Data Module provides a Data Communications Equipment (DCE) interface for connection to equipment such as data terminals, CDR output devices, on-premises administration terminal, Message Server, Property Management System (PMS), AUDIX, and host computers. It also provides a Digital Communications Protocol (DCP) interface to the digital switch. (DCE is the equipment on the network side of a communications link that provides all the functions required to make the binary serial data from the source or transmitter compatible with the communications channel.)

The MTDM provides an Electronic Industries Association (EIA) Data Terminal Equipment (DTE) interface for connection to off-premises private line trunk facilities or a switched telecommunications network and a DCP interface for connection to the digital switch. (DTE is the equipment comprising the endpoints in a connection over a data circuit. For example, in a connection between a data terminal and a host computer, the terminal, the host, and their associated modems or data modules make up the DTE.) The MTDM or 7400A Data Module can also serve as part of a conversion resource for Combined Modem Pooling.

### Screen 6-5. MPDM/MTDM Data Module form (Page 1 of 1)

To administer a MPDM or MTDM, complete the standard as well as the following unique Data Module form fields.

- **Type** — Enter **pdm** (default) when assigning a DCE interface or **tdm** when assigning a DTE interface.
- **Connected To** — Only displays when **Type** is **pdm**. Enter **dte** if the data module is connected to Data Terminal Equipment (DTE) or enter **isn** if connected to an Information Systems Network (ISN).
- **Remote Loop-Around Test** — Enter **y** if the data module supports a loop-back test at the EIA interface. In general, Lucent Technologies equipment supports this test but it is not required by Level 2 Digital Communications Protocol.
- **Secondary data module** — Only displays when **Type** is **pdm**. Enter **y** if this PDM is the secondary data module used for Dual I-channel AUDIX networking. Enter **n** if this is the primary PDM, or if this data module is not used for AUDIX networking. The primary data module must be administered before the secondary data module may be added. If **Port** is **X**, **Secondary data module** cannot be **y**.

## Netcon Data Module

Netcon data modules are the Processor Data Modules (PDMs) that are integrated into the system's network control ports that provide asynchronous circuit switched interfaces to the maintenance and administration terminals, Hospitality journal printers, and CDR digital output. They are characterized by their special locations, that is, special port identifications.

**⇒ NOTE:**

The Netcon data module is only applicable to R5vs and R5si and later configurations. For R5r and later configurations, see "[System Port Data Module](#)" on page 6-248.

Screen 6-6. Netcon Data Module form (Page 1 of 1)

To administer a Netcon Data Module, complete the standard as well as the following unique Data Module form fields.

- **Type** — Enter **netcon**.
- **Physical Channel** — Enter a netcon data channel number from **01** through **04**.
- **Maintenance Extension** — Enter the extension number required to perform maintenance functions on the standby netcon physical channel in a duplicated system. The standby remote loop around tests fails if this field is not administered.

## Processor Interface Data Module

---

The Processor Interface data modules are the Processor Data Modules (PDMs) that are integrated into the system's synchronous/asynchronous Processor Interface circuit pack ports.

 **NOTE:**

The Processor Interface data module is applicable only to R5vs and R5si and later configurations.

They are used to provide the following interfaces:

- 3B/Call Management System (maximum of one)
- 3B/Message Server (maximum of one)
- Distributed Communications System (maximum of eight)
- AUDIX (maximum of one)
- ISDN-PRI (maximum of eight)

 **NOTE:**

Not all maximums can be achieved at the same time

Connections for these interfaces are achieved via a digital line port and MPDM combination, and/or in the case of DCS or ISDN-PRI, via a DS1 interface. One direct EIA connection is available (labeled as Processor Interface on the back of the Control Cabinet) for simplex operation. When used, the physical channel assignment (see below) must be "01". Use of the EIA connection eliminates the need for one digital line port/MPDM combination.

## Form instructions

---

Page 1 of 1

DATA MODULE

Data Extension:  
Type: procr-infc      COS: 1      Maintenance Extension: \_\_\_\_\_

| 1:  |      |

### Screen 6-7. Processor Interface Data Module form (Page 1 of 1)

To administer a Processor Interface Data Module, complete the standard as well as the following unique Data Module form fields.

- **Type** — Enter **procr-infc**.
- **Maintenance Extension** — Enter the extension number required to perform maintenance functions on the standby physical channel in a duplicated system. The standby remote loop around tests fail if this field is not administered.
- **Physical Channel** — Enter the 2-digit circuit number of the Processor Interface port. A multi-carrier cabinet system supports the use of two Processor Interface circuit packs, the first circuit pack (mounted in Control Carrier A) supports physical channels or links 01 through 04; the second (mounted in Control Carrier A) supports physical channels or links 05 through 08. A single-carrier cabinet system supports one Processor Interface circuit pack and physical channels or links 01 through 04 only. The Physical Channel number is referred to on associated system forms as the Interface Link number.

## System Port Data Module

```

```

Screen 6-8. System Port Data Module form (Page 1 of 4)

To administer a System Port Data Module, complete the standard as well as the following unique Data Module form fields.

- **Type** — Enter **system-port**.
- **PDATA Port** — Used to relate the physical PDATA port to which the mode 3 portion of the system port is connected. Enter a seven alphanumeric-digit port location to which the data module is connected where the first two characters identify the cabinet number (**01** to **22**); the third character identifies the carrier (**A** through **E**); the fourth and fifth characters identify the slot number in the carrier (**01** to **20**); the last two characters identify the circuit number (**01** to **12**). This entry must be assigned to a port on a PDATA Line Board.

## X.25 Data Module

These forms assign BX.25 Data Modules in R5r and later configurations for communications to Adjuncts and other nodes in a DCS network. Each one of these data modules must correspond to an entry in the Interface Link form.

### Form instructions

To administer a X.25 Data Module, complete the standard as well as the following unique Data Module form fields.

### Page 1 of the form

| Permanent Virtual Circuit? y |              | Highest PVC Logical Channel: 64 |
| Switched Virtual Circuit? n  |              |                                 |

Screen 6-9. X.25 Data Module form (Page 1 of 2)

- **Type** — Enter **x.25**.
- **Endpoint Type** — Must be assigned as **adjunct**. An endpoint type is a type of packet switched data endpoint that uses X.25 call control procedures. The X.25 Endpoint connects to external ports on the PGATE board and to the TDM bus via a DS1 trunk. Ports connected to the adjunct endpoint can be either DTEs or DCEs. The type of endpoint (DTE or DCE) is administrable on the “data-mod” form.
- **DTE/DCE** — Specifies how the above endpoint type acts (DTE or DCE). Default is dte.
- **Baud Rate** — The maximum raw data transmission speed (**300, 1200, 2400, 4800, 9600, or 19200**; may also be **switched** if Cable Type on the PGATE form is **none**). Default is blank.
- **Error Logging** — To record X.25 protocol errors in the hardware error log, enter **y**. See the *DEFINITY Enterprise Communications Server Maintenance manual* for more information about error logs.

- **Remote Loop-Around Test** — To allow remote loop-around tests on this port, enter **y**. An **n** aborts a request for this test. See the *DEFINITY Enterprise Communications Server Maintenance manual* for more information about remote loop-around tests.
- **Permanent Virtual Circuit** — Indicates that the logical channels for PVC are allowed for this port; default is **y** (cannot be changed).
- **Switched Virtual Circuit** — Indicates that the Switched Virtual Circuit is not allowed for this port; default is **n** (cannot be changed).
- **Highest PVC Logical Channel** — Indicates that 1 to 64 Logical Channels are allowed on this port. Default is **64** (cannot be changed).

    Number of Outstanding Frames (w): 4
        Retry Attempt Counter (N2): 2
            Frame Size (N1): 135
Retransmission (T1) Timer (1/10 seconds): 10
    Idle (T4) Timer (1/10 seconds): 30
LAYER 3 PARAMETERS
    Number of Outstanding Packets: 2
    Restart (T20) Timer (seconds): 8
    Reset (T22) Timer (seconds): 10
    
```

Screen 6-10. Adjunct Data Module form (Page 2 of 2)

- **Number of Outstanding Frames (w)** — Specifies layer 2 window size (**1** to **7** frames). If the value is **2**, up to 2 frames can be sent without confirmation. Default is **4**.
- **Retry Attempt Counter (N2)** — Specifies the number of times (**0** to **7**) to send one frame when this frame is not confirmed for a period of time. Default is **2**.
- **Frame Size (N1)** — Specifies the number of bytes (**135** or **263**) in a frame. Default is **135**. If the value is **135**, there can be up to 1080 bits within a frame. This value is suitable for all adjuncts and for DCS.
- **Retransmission (T1) Timer (1/10 seconds)** — The T1 timer is started at the beginning or the end of the transmission of a frame. At the end of this timer (**0** to **250**), retransmission of a frame is initiated according to the procedures for link set-up and disconnection or information transfer. Default is **10**.

- **Idle (T4) Timer (1/10 seconds)** — The T4 timer is a system parameter that represents the time a DTE allows without frames being exchanged on the data link (0 to 250). Default is 30.
- **Number of Outstanding Packets** — Specifies the number of packets (2 to 7) that can be sent without confirmation. Default is 2.
- **Restart (T20) Timer (seconds)** — The T20 timer is a DTE time-limit (0 to 500) started when DTE issues a restart indication and terminated when the restart request is received or confirmed. Default is 8.
- **Reset (T22) Timer (seconds)** — The T22 timer is a DTE time-limit (0 to 500) started when DTE issues a reset indication and terminated when the reset request is received or confirmed. Default is 10.

## 7500 Data Module

The 7500 data module supports automatic TEI, B-channel, maintenance and management messaging, and SPID initialization capabilities. BRI endpoints, both voice and/or data, are assigned to either the TN556 ISDN-BRI circuit pack or the TN2198 ISDN-BRI circuit pack. Each can support up to 12 ports. Since BRI provides multipoint capability, more than one ISDN endpoint (voice or data) can be administered on one port. For BRI, multipoint administration allows for terminals having SPID initialization capabilities, and can only be allowed if no endpoint administered on the same port is a fixed tie endpoint and no station on the same port has B-channel data capability. Currently, multipoint is restricted to 2 endpoints per port.

### Form instructions

To administer a 7500 Data Module, complete the standard as well as the following unique Data Module form fields.

### Page 1 of the form

Page 1 of 2

CIRCUIT SWITCHED DATA ATTRIBUTES (used for modem pooling)  
 Default Duplex: full Default Mode: async Default Speed: 1200\_

DATA MODULE CAPABILITIES  
 Default ITC: restricted Default Data Application? M2\_A

### Screen 6-11. 7500 Data Module form (Page 1 of 2)

- **Type** — Enter **7500**.
- **CIRCUIT SWITCHED DATA ATTRIBUTES**

**NOTE:**

These fields represent defaults needed for modem pooling conversion resource insertion when the endpoint does not support data query capability. These fields have no significance for data

modules providing data query [all Lucent Technologies-supported ISDN-BRI data modules (7500 and ADM)]. For Lucent Technologies ISDN-BRI data modules, use the default settings.

- **Default Duplex** — Used to identify the duplex mode. Valid entries are **full** (default) or **half**.
- **Default Mode** — Used to identify the data mode. Valid entries are **sync** (synchronous) or **async** (asynchronous). Default is **async**.
- **Default Speed** — Used to identify the data rate. Valid entries are **1200** (default), **2400**, **4800**, and **19200**. When default mode is **sync**, valid entries also include speeds of **56000** and **64000**.

■ **DATA MODULE CAPABILITIES**

- **Origination Default Data Applications** — Used to identify mode to be used for originating data calls when the mode is not specified with the calling parameters. This mode is also used for terminating trunk calls that do not have bearer capability specified or administered connections. Possible mode values are M0 (mode 0), M1 (mode 1), M2 (mode 2), and M3/2 (mode 3/2 adaptable), or blank. Valid entries are **M0**, **M1**, **M2\_A** (default), **M2\_S**, or **M3/2**.

Page 2 of 2

DATA MODULE

BRI LINK/MAINTENANCE PARAMETERS

|                |               |               |                 |
|----------------|---------------|---------------|-----------------|
| XID? y         | Fixed TEI? n  | TEI: ____     |                 |
| MIM Support? y | Endpt Init? y | SPID: 300____ | MIM Mtce/Mgt? y |

Screen 6-12. 7500 Data Module form (Page 2 of 2)

- **XID** — Used to identify layer 2 XID testing capability. Default is **y**.
- **Fixed TEI** — Used to indicate whether or not the endpoint has Fixed Terminal Equipment Identifier (TEI) capability. TEI identifies a unique access point within a service. For Fixed TEI stations, the TEI must be administered. Terminals with automatic TEI capability, the associated TEI is assigned by the system. Default is **n**.
- **TEI** — Only displays if **Fixed TEI** is **y**. Enter a 1- to 2-digit number in the range of **0** through **63**.
- **MIM Support** — (Management Information Message Support) Used to support two types of capabilities: MIM endpoint initialization capability (SPID support), and other Maintenance/Management capability. Default is **y**.

- **Endpt Init** — Only displays if `MIM Support` is **y**. Used to indicate the terminal's endpoint initialization capability. Endpoint initialization is a procedure, required for multipoint operation, by which User Service Order Profile (USOP) is associated with an endpoint on the ISDN-BRI. This association is made via the Service Profile Identifier (SPID), administered into the system and entered into the ISDN-BRI terminal. For a ISDN-BRI terminal to become operational in a multipoint configuration, both the administered SPID and the SPID programmed into the ISDN-BRI terminal must be the same. This means that the SPID of the new or re-used terminals must be programmed to match the administered SPID value. Default is **y**.
- **SPID** — Only displays if `Endpt Init` is **y**. The Service Profile Identifier (SPID) is a variable parameter of up to ten digits. The SPID must be different for all terminals on the ISDN-BRI and from the Service SPID. The SPID should always be assigned, if the SPID is not assigned for the first ISDN-BRI on a port, any other ISDN-BRI assignment to that port is blocked. Valid entries are numeric strings in the range of **0** through **9999999999**. Default is the station's extension number.
- **MIM Mtce/Mgt** — Only displays if `MIM Support` is **y** (default). Used to indicate if the terminal supports MIM Maintenance and Management capabilities, other than endpoint initialization

## World Class BRI Data Module

### Form instructions

To administer a World Class BRI Data Module, complete the standard as well as the following unique Data Module form fields.

### Page 1 of the form

```

                                                                 Page 1 of 2
                                DATA MODULE

Data Extension:
  Type: 7wcbri_____

DATA MODULE CAPABILITIES
Default ITC: restricted           Default Data Application: M2_A
```

### Screen 6-13. World Class BRI Data Module form (Page 1 of 2)

- **Type** — Enter **wcbri**.
- **CIRCUIT SWITCHED DATA ATTRIBUTES**

#### NOTE:

These fields represent defaults needed for modem pooling conversion resource insertion when the endpoint does not support data query capability (typically a DMI Mode2 BRI endpoint). These fields have no significance for data modules providing data query. For World Class ISDN-BRI data modules, the default settings should be used.

- **Default Duplex** — Used to identify the duplex mode. Valid entries are **full** (default) or **half**.

- **Default Mode** — Used to identify the data mode. Valid entries are **sync** (synchronous) or **async** (asynchronous). Default is **async**.
- **Default Speed** — Used to identify the data rate. Valid entries are **1200** (default), **2400**, **4800**, and **19200**. When default mode is **sync**, valid entries also include speeds of **56000** and **64000**.
- **DATA MODULE CAPABILITIES** — These fields are used when a BRI endpoint is the originator of an administered connection.
  - **Default ITC** — Should be set to **unrestricted** for a WCBRI endpoint used as an administered connection.
  - **Origination Default Data Applications** — Used to identify the mode to be used for originating data calls when the mode is not specified with the calling parameters. This mode is also used for terminating trunk calls that do not have bearer capability specified or administered connections. Possible mode values are M0 (mode 0), M1 (mode 1), and M3/2 (mode 3/2 adaptable,) or blank. Valid entries are **M0**, **M2\_2**, **M2\_S**, or **M3/2**. Default is **M2\_A**. This field should be **M0** (DMI Mode 0) for a WCBRI endpoint used as an administered connection.

DATA MODULE

BRI LINK/MAINTENANCE PARAMETERS

|                         |               |              |                |
|-------------------------|---------------|--------------|----------------|
|                         | XID? n        | Fixed TEI? n | TEI: ____      |
| Country Protocol: 1____ | Endpt Init? y | SPID: _____  | Endpt ID: ____ |

Screen 6-14. World Class Data Module form (Page 2 of 2)

- **XID** — Used to identify layer 2 XID testing capability. Default is **n**.
- **Fixed TEI** — Used to indicate whether or not the endpoint has Fixed Terminal Identification (TEI) capability. TEI is used to identify a unique access point within a service. For Fixed TEI stations, the TEI must be administered. For terminals with automatic TEI capability, the associated TEI is assigned by the system. Default is **n**.
- **TEI** — Only displays if **Fixed TEI** is **y**. Enter a number in the range of **0** through **63**.

- **Country Protocol** — Enter the protocol that corresponds to your supported initialization and codesets. The Country Protocol must match any previously-administered endpoint on the same port. The following table lists the valid protocol entries. Default is 1 (US Bellcore).

| Country/Area                           | Protocol |
|--|----------|
| Australia                              | 2        |
| ETSI (Europe)                          | etsi     |
| Japan                                  | 3        |
| Singapore                              | 6        |
| United States (Bellcore National ISDN) | 1        |

- **Endpt Init** — Displays only if `MIM Support` is **y** and indicates the terminal's endpoint initialization capability. Enter **y** (default) if the terminal supports Bellcore ISDN-1 terminal initialization procedures or enter **n** for all other country protocols.

Endpoint initialization is a procedure, required for multipoint operation, by which User Service Order Profile (USOP) is associated with an endpoint on the ISDN-BRI. This association is made via the SPID, administered into the system, and entered into the ISDN-BRI terminal. For an ISDN-BRI terminal to be operational in a multipoint configuration, both the administered SPID and the SPID programmed into the ISDN-BRI terminal must be the same. Therefore, the SPID of new or reused terminals must be programmed to match the administered SPID value.

- **SPID** — (Service Profile Identifier) This field displays only if `Endpt Init` is **y**. Enter a variable length parameter (up to 10 digits). SPID is a numeric string, which means that the value of 00 is different from 000. The SPID must be different for all terminals on the BRI and from the Service SPID. The SPID should always be assigned. If the SPID is not assigned for the first BRI on a port, any other BRI assignments to that port are blocked. Valid entries are numeric strings in the range of **0** through **9999999999**. Default is the station extension.

 **NOTE:**

If using Administration Without Hardware for an ISDN-BRI extension (Port set to X) and Terminal Translation Initialization (TTI) is intended to be used to assign the port, then the SPID number must equal the station number.

- **Endpt ID** — This field displays only if `Endpt Init` is **y**. Enter a 2-digit number (**00–62**). Each Endpt ID field must have a unique value for each endpoint on the same port.

This field provides for multipoint configuration conformance to the Bellcore Terminal Initialization procedures. In these procedures, a multipoint configuration requires that the last 2 digits of the Service Profile Identifier (SPID) be between 00 and 63 and be binary unique for each endpoint. This field, combined with the SPID, gives the effective SPID administered into the terminal. Bellcore ISDN-1 requires that the SPID programmed into the endpoint contain at least 9 digits. (For example, if `SPID` is **1234**, and `Endpt ID` is set to **01**, then the SPID administered on the terminal is 000123401. The three leading zeros are necessary to create a 9-digit SPID.)

# Trunk Group Administration

---

## Automatic Transmission Measurement System

---

Automatic Transmission Measurement System (ATMS) measures transmission performance for voice and data trunk facilities. Performance is evaluated against user-defined threshold values.

The measurement report contains data on trunk signal loss, noise, signaling return loss, and echo return loss.

### How to administer ATMS

---

A Lucent Technologies administrator must enable ATMS on the System-Parameters Customer-Options form before you can administer ATMS.

#### Required forms

| Form                     | Field                           | Page                  |

| Hunt Group               | ■ All (optional)                | <a href="#">5-158</a> |
| Trunk Groups             | ■ All (ATMS Thresholds)         | <a href="#">7-115</a> |

### Detailed description

---

You can initiate ATMS to perform either demand testing or scheduled testing. Use the system administration terminal to perform demand testing. Use the ATMS Trunk Test Schedule form to set the testing schedule.

Trunk-test results are stored in a database. These measurements reflect the state of the trunk at the time of its last test. If trunks are tested on a regular basis, trunk measurements should not be more than 3 weeks old.

The entire set of measurements for all test cases is usually polled by an adjunct for historical reporting and printing.

Measurements can be output to a G3-MT printer, a system printer, or a G3-MA. If output is to a G3-MA, data is collected by a personal computer for offline analysis. Approximately 10 measurements are listed per page on a G3-MT screen; about 50 measurements are listed per page on a printer.

When a trunk fails a test twice and the administered busyout limit is not exceeded, then this trunk is busied out. You can administer the busyout limit at 25, 50, 75, or 100 percent, including trunks busied out for any reason. For example, if the limit is 25 percent and 30 percent of the trunks are busied out because of hardware problems, then a failing trunk is not busied out.

When a decision to busyout a trunk is made, the trunk is not rechecked when other events cause the number of busied-out trunks to change. This means that ATMS could take 25 percent of the trunks out of service, and a later hardware failure could take an additional 25 percent out of service. If the ATMS busyout limit is 25 percent, it is not rechecked and the trunks remain out of service.

Setting limits incorrectly can cause trunks to be busied out unnecessarily. Resetting limits does not immediately affect the busied-out state of a trunk. You can put the trunk back into service immediately by either changing the limits and running a demand test or using the release command on the entire trunk group.

## Terminating test lines

A terminating test line (TTL) is an extension over a DID or tie trunk that users call into to generate a random set of far-end measurements about the facility used to make the call. The originating switch compares the far-end measurements to the near-end measurements to determine the quality of the facility (per customer-set thresholds).

ATMS allows the following measurements for TTLs:

- Two-way transmission loss at 404 Hz, 1004 Hz, and 2804 Hz
- Near-end and far-end C-message and C-notched noise
- Near-end and far-end signaling and echo return loss
- Central office 100-type TTLs
- One-way transmission loss at 1004 Hz
- Near-end C-message noise
- Near-end signaling and echo return loss
- Central office 102-type TTLs
- One-way transmission loss at 1004 Hz
- Central office 105-type TTLs
- Two-way transmission loss at 404 Hz, 1004 Hz, and 2804 Hz
- Near-end and far-end C-message and C-notched noise
- Near-end and far-end signaling and echo return loss

## Test schedules

With R5r and later configurations, you can assign up to 30 test schedules. Each schedule consists of up to 60 trunk group/member fields. This allows you to create up to 1,800 different trunk group/member combinations for testing. With R5si and later configurations, you can assign up to 5 test schedules. Each schedule consists of up to 10 trunk group/member fields, allowing you to create up to 50 different trunk/group member combinations for testing. Administering this feature is a two-step process:

1. Define test times for each schedule
2. Assign trunks to the test times

After you define the test schedules, the system automatically makes the connections and takes the measurements at the specified time and day without any additional user intervention. Schedules ready to run are queued and run in a round-robin (FIFO) manner. Scheduled tests run until all trunk groups/members in the schedule have been tested or until the scheduled test duration is exceeded.

Test schedules assigned the same run time are selected to run based on the schedule number (smaller schedule numbers first).

### NOTE:

If schedules are assigned at the same time, it is unlikely that all scheduled tests will complete during the allotted time if other schedules are vying for the same resources.

## Determining schedule times

Trunk test schedules should run during trunk idle times (when resource consumption is low). The trunk idle times will be the time frames available for testing each node connected to the switch.

Once the idle times are determined, the next step is to compute the time required for testing the trunks between each node. Time requirements between each node are based on the quantity of trunks between nodes and the time needed to test each trunk to that node. Only outgoing trunks from the originating system need to be considered. Currently, there is no way to test incoming-only trunks in the near-end mode.

The characteristics of a trunk along with the test objectives are used to determine the total test time per trunk. The trunk characteristics might determine the type of test to run:

- Digital Facilities

For digital facilities that go between switching systems without needing digital channel banks, a supervision-only test is recommended to detect an initial tone from a TTL. For digital facilities that go between an analog CO switch and a digital PBX switch via a channel bank, all tests might be considered.

- 2-Wire Facilities

For 2-wire facilities such as local CO trunks, only loss and noise measurements are recommended since echo is usually not controlled on these facilities.

- 4-Wire Facilities

For 4-wire facilities such as interlocation tie trunks between different locations, all measurements are appropriate. For 4-wire facilities such as intralocation tie trunks (only wire conductors between switches), loss measurements may not be meaningful because of the short distances.

Test objectives might determine the per trunk test time, such as:

- How often you want to test various trunk groups. For example, you may want to test network trunks daily, but test non-network trunks only weekly. You may want to test more frequently immediately after installation and less frequently thereafter.
- You may want to test daily to all TTLs with free access and weekly to those with cost access.

After these objectives and characteristics have been considered, the test time for a trunk group is figured using the following formula:

$$TT = q [dt + nt + ttt]$$

Where:

- TT = the Trunk group test time in seconds
- q = the Number of trunks in the trunk group
- dt = the Dial time in seconds
  - For Touch Tone: 0.1 times (# of dialed digits)
  - For Rotary: 0.7 times (# of dialed digits) + 0.1 times (sum of dialed digits, with 0 equal to 10)
- nt = the Network time (always 2 seconds)
- ttt = the Transmission test time (see [Table 7-1](#))

**Table 7-1. Transmission Test Lines**

| <b>Test Type</b>                    | <b>Time (sec)</b> |
|-------------------------------------|-------------------|
| All Tests                           |                   |
| 56A (old)                           | 35                |
| 100                                 | 20                |
| 102                                 | 2                 |
| 105 (ZLC12,SN261)                   | 65                |
| 56A (new)                           | 65                |
| All Tests Except Return Loss        |                   |
| 56A (old)                           | 30                |
| 100                                 | 10                |
| LC/SN                               | 30                |
| 105 or new 56A                      | 50                |
| All Tests Except Self               |                   |
| 56A (old)                           | 20                |
| 105 (ZLC12,SN261)                   | 35                |
| 56A (new)                           | 35                |
| All Tests Except Self & Return Loss |                   |
| 56A (old)                           | 15                |
| 105 or new 56A                      | 25                |
| Supervision Tests                   |                   |
| All types                           | 2                 |

## ATMS test schedule example

Assume that the variables have the following values as an example for figuring the total test time for a trunk group:

$q = 100$

$dt = 0.7$  seconds (7 digits \* 0.1 seconds/digit)

$nt = 2$  seconds

$ttt = 65$  seconds (105 test type)

The total Originating Test Line (OTL) time required for this trunk group is 6,770 seconds.

Each trunk groups test time is assigned to an idle hour slot. The sum total of all test times assigned to a particular node should not exceed the idle time available for testing that node.

If the total test time exceeds the trunk idle hours, the following options are available:

- Additional TTLs can be added on the far-end nodes.
- The trunk group members can be split across schedules which test portions of a trunk group on alternate weeks.

### NOTE:

When setting up test times, the analog port in the TN771C cannot serve as an OTL and TTL at the same time.

## Managing OTL/TTL resources

Trunk group testing can occur concurrently when multiple boards exists. The number of available OTL resources determines the number of tests that can occur concurrently. Some internal limits have been set to control the number of concurrent tests. For background scheduling, the limit is four concurrent tests and the foreground demand test is limited to the number of maintenance users that can be operating simultaneously, which is currently set to three. Altogether, seven concurrent tests can run at the same time. If the number of OTL resources are less than the number of schedules being tested, the schedules are queued and tested sequentially.

OTLs are assigned to test schedule entries (a test entry is an individual trunk within a trunk group member/range field). Whenever an OTL is requested for test assignments, it is dedicated to the first available untested schedule entry on the test queue. An OTL remains dedicated to a schedule until all test entries in the schedule have been tested. When the last test entry in the schedule has been

tested, the OTL is assigned to the next untested schedule entry. A throttle parameter is provided which limits the number of OTLs that can be assigned per schedule.

When multiple OTL boards exist and the test schedule entries terminate at the same location, there must be a one-to-one correspondence between every OTL and TTL. When multiple OTLs terminate at the same TTL, the contention for the TTL will cause some tests to abort due to the far-end TTL being busy. One way to avoid this condition is to make sure that the number of far-end TTL resources equals the number of near-end OTLs used for testing. If this is not possible, limit the number of OTLs tested within each schedule with the OTL Throttle field to prevent entries within the same test schedule from originating multiple tests to a far-end system that can only support a single TTL resource. (This does not prevent entries from different schedules for competing for the same TTL resource.) In general, find the group within the schedule that has the fewest TTLs at the far end, and set the OTL Throttle field to this value.

**⇒ NOTE:**

If the OTL Throttle value is greater than the actual number of system OTLs, a test may be aborted due to the unavailability of an OTL resource.

If the OTL Throttle value for a schedule is 4, the next queued schedule cannot be run until all the entries from the current schedule are complete. This is because OTL resources are assigned to test schedule entries and not to test schedules. The use of the OTL throttle parameter can limit the number of entries being tested within the same test schedule and can, therefore, allow trunk group entries from different schedules to be tested concurrently.

### OTL throttle value example

To illustrate the use of the OTL throttle value, assume that the tests take the same amount of time to run and are administered as follows:

| Schedule # | Test time | OTL throttle | Trunk group | Members in trunk group |
|------------|-----------|--------------|-------------|------------------------|
| 1          | 1 am      | 4            | 10          | 4                      |
|            |           |              | 11          | 2                      |
| 2          | 1 am      | 1            | 12          | 1                      |
| 3          | 1 am      | 4            | 13          | 4                      |

All schedules are set to run at the same time. When the schedules are started, Schedule 1 is assigned 4 OTLs and Schedules 2 and 3 are put into a queue waiting for an OTL assignment. For the first round of tests the OTLs are assigned as follows:

| <b>OTL #</b> | <b>Assigned to schedule #</b> | <b>Trunk group/member assignment</b> |
|--------------|-------------------------------|--------------------------------------|
| 1            | 1                             | 10/1                                 |
| 2            | 1                             | 10/2                                 |
| 3            | 1                             | 10/3                                 |
| 4            | 1                             | 10/4                                 |

For the second round of tests the OTLs are assigned as follows:

| <b>OTL #</b> | <b>Assigned to schedule #</b> | <b>Trunk group/member assignment</b> |
|--------------|-------------------------------|--------------------------------------|
| 1            | 1                             | 11/1                                 |
| 2            | 1                             | 11/2                                 |
| 3            | 2                             | 12/1                                 |
| 4            | 3                             | 13/1                                 |

For the third round of tests the OTLs are assigned as follows:

| <b>OTL #</b> | <b>Assigned to schedule #</b> | <b>Trunk group/member assignment</b> |
|--------------|-------------------------------|--------------------------------------|
| 1            | 3                             | 13/2                                 |
| 2            | 3                             | 13/3                                 |
| 3            | 3                             | 13/4                                 |
| 4            |                               |                                      |

After this round of tests, all schedules have been tested and the OTLs are put back into an inactive state waiting for the next test schedule to start.

## **Considerations**

---

- At least one TN771C circuit pack is required because of the Local Area Network (LAN) bus maintenance which the board performs. The number of TN771C circuit packs administrable on the switch is limited by the number of EPNs and PPNs in a switch network. Each PPN contains one TN771C and each EPN may contain one TN771C. Each TN771C circuit pack supports testing of one analog trunk at a time. The number of OTL and TTL circuit packs required in a System depends on:
  1. The frequency that the customer requires their trunks to be tested
  2. The number of trunks
  3. The number of TTL devices on far-end switches that are available to test against
  4. The time per day that can be used for testing
- The number of concurrent tests that can be run is limited by the number of OTLs available and is also dependent on the type of test command, demand or scheduled. Demand test are limited to three concurrent tests, while scheduled tests are limited to four concurrent tests (such as 4 active OTLs). If more than four tests are needed simultaneously, the requests are queued and run on a round-robin basis. The number of TTLs that can be administered is limited by the number of available ports.

## **Interactions**

---

Interacts with the trunk threshold values defined on the Trunk Group form. The marginal values defined on that form are used to highlight measurements on the G3-MT report that are out of tolerance. The unacceptable values are used to identify (by blinking) the trunk members on the G3-MT report that are unusable. You can quickly identify out-of-tolerance or unusable trunks.

## DS1 Trunk Service

---

Digital Signal Level 1 (DS1) trunk service is bit-oriented signaling (BOS) that multiplexes 24 channels into a single 1.544-Mbps stream. DS1 can be used for voice or voice-grade data and for data-transmission protocols.

E1 trunk service is BOS that multiplexes 32 channels into a single 2.048-Mbps stream. Both T1 and E1 provide a digital interface for trunk groups.

### How to administer DS1 trunk service

---

#### Required forms

---

| Form                 | Field | Page                  |
|----------------------|-------|-----------------------|
| DS1 Circuit Pack     | ■ All | <a href="#">7-79</a>  |
| Trunk Group          | ■ All | <a href="#">7-115</a> |
| Access               |       | <a href="#">7-150</a> |
| APLT                 |       | <a href="#">7-168</a> |
| CO                   |       | <a href="#">7-168</a> |
| DID                  |       | <a href="#">7-178</a> |
| DIOD                 |       | <a href="#">7-183</a> |
| DMI-BOS              |       | <a href="#">7-188</a> |
| FX                   |       | <a href="#">7-193</a> |
| ISDN-PRI             |       | <a href="#">7-219</a> |
| RLT                  |       | <a href="#">7-252</a> |
| Tandem               |       | <a href="#">7-257</a> |
| Tie                  |       | <a href="#">7-262</a> |
| WATS                 |       | <a href="#">7-268</a> |
| Synchronization Plan | ■ All | <a href="#">7-112</a> |

**NOTE:**

Assign the DS1 circuit pack before you administer the members of the associated trunk groups.

**CAUTION:**

*If enhanced DS1 administration is not enabled, you cannot not make changes to the DS1 Circuit Pack form before you remove related member translations of all trunks from the trunk group.*

For information about how to administer DS1 with enhanced administration, see [“Enhanced DS1 administration” on page 7-14.](#)

## **Detailed description of DS1**

---

DS1 trunk service provides a digital interface for the following trunks.

- Voice-grade DS1 tie trunks
- Alternate voice/data (AVD) DS1 tie trunks
- Robbed-bit AVD (RBAVD) DS1 tie trunks
- Digital Multiplexed Interface (DMI) tie trunks
- ISDN-PRI trunks
- Central Office (CO) trunks
- Foreign Exchange (FX) trunks
- Remote-access trunks
- WATS trunks
- Direct Inward Dialing (DID) trunks
- Main/Satellite tie trunks
- Tie trunks that link Common-Control Switching Arrangement (CCSA) or Enhanced Private Switched Communications Service (EPSCS) networks
- Release-link trunks for Centralized Attendant Service (CAS)
- Access trunks
- Off-premises stations (also known as station-side DS1)
- Access endpoints (Release 5si and later configurations)

DS1 functions in public and private networks:

- Electronic tandem networks (ETN) or tandem tie-trunk networks (TTTN)
- Direct access to local exchange carriers

## DS1 operational and signaling parameters

[Table 7-2](#) provides the recommended combination of parameters for each DS1 interface.

**Table 7-2. DS1 Operational and signaling parameters**

| DS1 Circuit Packs            | # Trunk Members       | Bit Rate Mbps      | Companding              | Signaling Mode        | Trunk Type <sup>1</sup>       |                       |            |
|------------------------------|-----------------------|--------------------|-------------------------|-----------------------|-------------------------------|-----------------------|------------|
| TN722                        | 1-23                  | 1.544              | mulaw                   | common-chan           | Tie, DMI-BOS, CO <sup>2</sup> |                       |            |

|                              | 1-30                  |                    |                         | 2.048                 | alaw/mulaw                    | CAS                   | CO/DID/Tie |

*Continued on next page*

1. CO is any of the following trunk types: CO, FX, WATS.  
Tie is any of the following trunk types: access, tie, tandem, RLT, APLT.

2. Common-channel DS1 circuit packs used in CO trunk groups must have a trunk type of auto.
  3. Integrated CSU functionality is available only with the TN767D and TN464E or later-suffix DS1 circuit packs. Enhanced ICSU functionality only is available with the TN767E and TN464F or later-suffix DS1 circuit packs.
  4. Mixed-mode signaling is allowed. This means that if the signaling mode is isdn-ext or isdn-pri, a port from that circuit pack may be used in any trunk group that allows robbed-bit signaling.
  5. The TN464B's companding is based upon the system companding that you administer.
  6. ISDN-PRI calls are not guaranteed to work for the TN464B if the system's companding is set to mu-law.
- 

## Enhanced DS1 administration

---

You can change some of the fields on the DS1 Circuit Pack form without removing the related translations of all trunks from the trunk group if on the System-Parameters Customer-Options form DS1 MSP is enabled and you are assigned the associated login permissions. The following enhanced DS1 administration login permissions must be assigned on the Command Permission Categories form:

- Maintain Enhanced DS1 must be **y**.
- Maintain Trunks must be **y**.
- Maintain Switch Circuit Packs must be **y**.

If you busy out the DS1 circuit pack, you can change the following fields: `CRC`, `Connect`, `Country Protocol`, `Framing Mode`, `Interface`, `Interconnect`, `Line Coding`, and `Protocol Version`. After changing these fields, you may also have to change and resubmit associated forms.

## DS1 field implementation guidelines

The `ITC` (Information Transfer Capability) field appears on the route-pattern (Pattern Number) form, Trunk Group form, and Access Endpoint form. The `Line Coding` and the `Bit Rate` appear on the DS1 Circuit Pack form. Set the fields as shown below.

### ITC and corresponding Line Coding for bit rate 1.544-Mbps

---

| ITC field    | Line Coding field |
|--------------|-------------------|
| restricted   | ami-zcs           |
| unrestricted | b8zs              |

---

### ITC and corresponding Line Coding for bit rate 2.048-Mbps

| ITC field    | Line Coding field |
|--------------|-------------------|
| restricted   | ami-basic         |
| unrestricted | hdb3              |

The `Interconnect` field appears on the DS1 Circuit Pack form. The `Group Type` field appears on the Trunk Group form. Set the fields as shown below.

### Interconnect and corresponding Group Type entries

| Interconnect field | Group Type field                       |
|--------------------|--|
| co                 | co, did, diod, fx, or wats             |
| pbx                | access, aplt, isdn-pri, tandem, or tie |

## DS1 form implementation guidelines

For enhanced DS1 administration, field settings on the DS1 Circuit Pack form must be consistent with those on other forms. Therefore, if you change values on the DS1 form, you must change related values on the other forms and resubmit them.

### DS1 fields and corresponding forms (for ISDN)

| DS1 Circuit Pack field | Affected forms    | Page                  |

|                        | ■ Trunk Group     | <a href="#">7-115</a> |

## Expanded technical information

### Signaling modes

Common-channel signaling (CCS) is an industry-standard technique in which any one of a group of channels carries the signals for the other channels. Lucent Technologies uses the 24th channel of a group for signaling. This signaling technique differs from 24-channel signaling. When the system is configured for Facility-Associated Signaling, 24-channel signaling uses the 24th channel in a DS1 facility to carry signals; this technique is also called clear channel, out-of-band, or alternate voice data (AVD) signaling.

Channel Associated Signaling (CAS) is similar to common-channel signaling, and is used only when the Bit Rate is 2.048 (the trunk is used with a CEPT1 (E1) interface). Signaling is carried on the 16th channel.

Robbed-bit signaling is a per-channel signaling technique for transmitting signaling bits on each channel in a DS1 facility. The least-significant bit in every 6th transmitted information frame is robbed and replaced by a signaling bit. This technique is also called in-band signaling.

ISDN-PRI signaling requires use of the TN767 or TN464 (C or later) DS1 interface circuit pack. Signaling is carried on the 24th channel for a 1.544 Mbps connection and the 16th channel for a 2.048 Mbps connection.

ISDN-ext signaling also requires use of the TN767 or TN464 (C or later) DS1 interface circuit pack. This choice enables the TN767 or TN464 to use ISDN signaling. Neither the 24th channel for TN767 nor the 16th channel for TN464 can be used as a D-channel. When the system is configured for Non-Facility-Associated Signaling, all channels on a DS1 facility may be used for voice or data. The system may be configured for Facility-Associated Signaling and Non-Facility-Associated Signaling at the same time.

### ISDN signaling requirements

For ISDN capabilities with the R5si and later configurations, the Processor Interface (PI) or Packet Control (PACCON) board is required. For ISDN capabilities with the R5r and later configurations, the Packet Interface (PKTINT) board is required. These boards terminate layer 2 (LAPD) of the PRI protocol.

## Public network signaling administration

**Table 7-3. DEFINITY ECS Public Network Access connections (ISDN-PRI Layer 3)**

## Digital Multiplexed Interface

---

Digital Multiplexed Interface (DMI) supports two signaling techniques: bit-oriented signaling and message-oriented signaling for direct connection to host computers.

### How to administer DMI

---

#### Required forms

---

| Form                 | Field | Page                  |
|----------------------|-------|-----------------------|
| DS1 Circuit Pack     | All   | <a href="#">7-79</a>  |
| Trunk Group          |       |                       |
| DMI-BOS              | All   | <a href="#">7-188</a> |
| ISDN-PRI             | All   | <a href="#">7-219</a> |
| Synchronization Plan | All   | <a href="#">7-112</a> |

### Detailed description

---

Use message-oriented signaling with ISDN-PRI. You cannot use ISDN-PRI for bit-oriented signaling.

DMI provides 23 64-kbps data channels, plus one 64-kbps channel for common-channel signaling. Within the data channel, DMI provides control-information exchange and data formats supporting data transport at all standard data rates. Use each data channel in one of the following transfer modes:

- Mode 0 — 64-kbps channel (raw, unformatted)
- Mode 1 — 56-kbps channel
- Mode 2 — 0 — 19.2-kbps synchronous/asynchronous
- Mode 3 — multiple virtual channels (up to 64k)

 **NOTE:**

TN767, TN464C, and later revisions of the DS1 circuit packs provide a DSX1 interface.

Access DMI trunks the same way as you access tie trunks. DMI trunks connect to host computers; Tie trunks connect to another switch. Each trunk functions like a PDM because the DMI protocol is identical to the DCP protocol used by the data modules.

## **Interactions**

---

- **Data Restriction**

DMI trunks cannot be data restricted.

- **Modem Pooling**

Data calls dialed from a local analog data endpoint to a DMI trunk contain the data-origination access code to obtain a conversion resource. Data calls on DMI trunks to local analog data endpoints obtain conversion resources.

## Enhanced ICSU

---

The Integrated Channel Service Unit (ICSU) is the combination of a 120A CSU module and a TN464E, TN767D, or later suffix DS1 circuit pack.

### NOTE:

The term 120A refers to the 120A1 and later suffix CSU modules. The TN767 and the TN464C and later revisions of the DS1 circuit packs provide a DSX1 interface.

The DS1 circuit pack automatically initializes and tests the 120A CSU module, and detects on-line alarms. The 120A CSU module, in combination with the DS1 circuit pack, provides the essential functions that have historically been provided by external CSUs. For more information about the ICSU, see *DEFINITY Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 Integrated CSU Module Installation and Operation*.

The Enhanced ICSU functionality provides for the administration and maintenance of the ICSU by local and remote personnel. It also provides for additional performance measurements of a DS1 facility and for new loopback tests. Enhanced ICSU is only available for use in the US with 1.544 Mbps DS1 service. It requires a 120A CSU module with the TN767E, TN464F or later suffix DS1 board.

### NOTE:

A CSU module is not required for the Enhanced ICSU functionality for performance measurements or the on-demand long-duration loopback tests.

## How to administer Enhanced Integrated Channel Service Unit

---

The ICSU can be administered for connection to any DS1 trunk service.

The Enhanced ICSU is administered on the DS1 Circuit Pack form by entering the add ds1 or change ds1 command. On this form, when *Near-End CSU Type* is identified as **integrated**, additional CSU module administration options become available.

**Required forms**

| <b>Form</b>      | <b>Field</b>                     | <b>Page</b>          |
|------------------|----------------------------------|----------------------|
| DS1 Circuit Pack | ■ Near-End CSU Type              | <a href="#">7-79</a> |
|                  | ■ Transmit LBO                   |                      |
|                  | ■ Receive ALBO                   |                      |
|                  | ■ Upon DTE LOS                   |                      |
|                  | ■ Supply CPE Loopback Jack Power |                      |

**Detailed description**

**Testing**

The following testing and performance measurement functions can be performed with Enhanced ICSU.

- On-demand short-duration loopback testing of the DS1 board and CSU module, including board loopback, equipment loopback, and repeater loopback tests
- On-demand long-duration loopback testing of building wiring to the CPE loopback jack
- On-demand long-duration loopback testing to the far-end CSU
- On-demand long-duration 1-way span testing to and from remote test equipment or another DEFINITY ECS
- The ability to inject bit errors in long-duration loopback test patterns

The enhanced feature allows users to view long-duration loopback/span test results during testing on the DS1 Link Performance Measurements Summary report. The summary report provides loopback/span test information about the type of test being run, the pattern being sent, whether the DS1 board is synchronized to the looped test pattern, the bit-error count, and the test duration. It also provides performance information, described in the next section. See *DEFINITY Enterprise Communications Server System Monitoring and Reporting* for more detailed information including a sample summary report.

At any time during testing, Loopback/Span Test Bit-Error Count and Test Duration and `ESF Error Events` on the summary report can be cleared. Also, at any time during testing, the loopback test can be terminated.

## Performance measurements

The following performance measurements are added to the DS-1 Link Performance Measurements Summary report. An **N/A** in any of these fields indicates that enhanced functionality is not activated.

- Controlled slip seconds (CSS)
- Loss of frame count (LOFC)
- The Failed Seconds (FS) field is replaced by Unavailable/Failed Seconds (UAS/FS)
- ESF error events

The following performance measurements are added to the DS1 Link Performance Measurements Detailed Log report. An **N/A** in any of these fields indicates that enhanced functionality is not activated.

- Controlled slip seconds (CSS)
- Loss of frame count (LOFC)
- The Failed Seconds (FS) field is replaced by “Unavailable/Failed Seconds (UAS/FS)”

Performance measurement reports can be created for local, carrier-local, and remote facilities.

- Local reports display user measurements.  
These measurements are the user copies of the local (near-end) performance measurements and can be cleared by the user. They cannot be cleared by the carrier.
- Carrier-local reports display network measurements.  
These measurements are the carrier copies of the local (near-end) performance measurements. They can only be cleared by the carrier.
- Remote reports display remote CSU measurements.  
These measurements are available from the CSU at the far-end of the link. They can be cleared from the near-end of the link.

See *DEFINITY Enterprise Communications Server System Monitoring and Reporting* for additional information.

## **Considerations**

---

- The DS1 circuit pack must be taken out of service with the busyout board command before loopback/span tests can be run on-demand.
- Only one loopback/span test can be active at any one time on a DS1 facility.
- If the DS1 circuit pack is currently functioning as part of a network requested loopback test, loopback/span testing is denied.
- If the DS1 span is being used as the clock reference for the switch, a different reference must be selected before the DS1 span is looped.

## **Interactions**

---

None.

## ISDN Trunks— General

---

The Integrated Services Digital Network (ISDN) provides a message-oriented signaling method that allows information to be sent along with a call. ISDN gives you access to a variety of public and private network services and facilities. The ISDN standard consists of layers 1, 2, and 3 of the Open System Interconnect (OSI) model. DEFINITY ECS can be connected to an ISDN using standard frame formats: Basic Rate Interface (BRI) and the Primary Rate Interface (PRI).

An ISDN provides end-to-end digital connectivity and uses a high-speed interface which provides service-independent access to switched services. Through internationally accepted standard interfaces, an ISDN provides circuit or packet-switched connectivity within a network and can link to other ISDN supported interfaces to provide national and international digital connectivity.

ISDN supports the following:

- Call-by-Call Service Selection (CBC)
- Distributed Communications System (DCS) connectivity (Only ISDN-PRI supports DCS+ and DCS with Rerouting)
- Electronic Tandem Network (ETN) connectivity
- Facility Associated Signaling (FAS) and Non-Facility Associated Signaling (NFAS) (Only ISDN-PRI supports this)
- Generalized Route Selection (GRS)
- Call Identification Display — Calling Party Number (CPN) and Billing Number (BN)
- Administered Connections and Access Endpoints
- Interworking (a mixture of ISDN and non-ISDN trunking and stations)
- Wideband Switching (H0, H11, H12, and NxDS0) (Only ISDN-PRI supports this)
- QSIG Multivendor Connectivity
- Lookahead Inteflow
- Lookahead Routing
- Usage Allocation

The following forms (listed in [Trunk Group Administration Forms](#) on page [7-71](#)) are used in implementing ISDN:

- Access Endpoints
- ISDN-BRI and ISDN-PRI Trunk Groups
  - Supplementary Service Protocol (supports public network connection)
  - Calling Number (supports CPN)

- Incoming Call Handling Treatment Table (supports digit manipulation, CPN or BN requests, and night service destinations)
- CBC Trunk Group Usage Allocation form (supports Call-by-Call Service Selection Usage Allocation Plans)
- CBC Trunk Group Allocation Plan Assignment Schedule (supports Call-by-Call Service Selection Usage Allocation Plans)
- Wideband Support Options (supports Wideband Switching)
- ISDN Numbering — Private
- ISDN Numbering — Public or Unknown
- ISDN TSC Gateway Channel Assignment
- Network-Facilities (supports usage allocation used in Call-by-Call Service Selection)
- Signaling Group (group of B-channels for which a given D-channel or D-channel pair carries signaling information)

## How to administer ISDN

---

See [“ISDN-BRI trunk group” on page 7-198](#) or [“ISDN-PRI trunk group” on page 7-219](#) for instructions on how to administer ISDN. See the following features for information on how to administer each feature.

| Feature  | Page                  |
|--|-----------------------|
| Administered Connections                       | <a href="#">4-13</a>  |
| Call-by-Call Service Selection                 | <a href="#">7-42</a>  |
| Distributed Communications System              | <a href="#">12-11</a> |
| Facility and Non-Facility Associated Signaling | <a href="#">7-49</a>  |
| Generalized Route Selection                    | <a href="#">8-33</a>  |
| Lookahead Interflow                            | <a href="#">9-98</a>  |
| Lookahead Routing                              | <a href="#">8-45</a>  |
| QSIG Call Diversion                            | <a href="#">12-82</a> |
| QSIG Call Transfer                             | <a href="#">12-84</a> |
| QSIG Name Identification                       | <a href="#">12-86</a> |
| QSIG Path Replacement                          | <a href="#">12-90</a> |
| Wideband Switching                             | <a href="#">7-56</a>  |

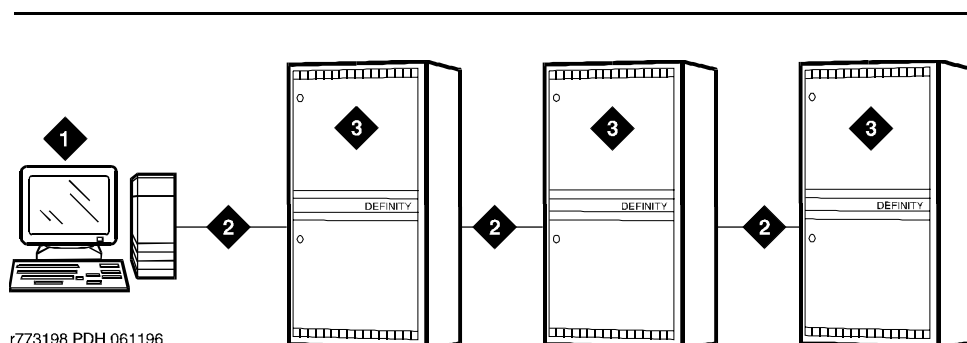

## Detailed description

In ISDN-PRI, the transmission standard for layer 1 (the physical layer) is either DS1 T1 or E1. The DS1 T1 (used in North America and Japan) is a digital-transmission standard that carries traffic at the rate of 1.544 Mbps, and the E1 (used in Europe) carries traffic at a rate of 2.048 Mbps. The “D” (data) channel multiplexes signaling messages for the “B” (bearer) channels carrying voice or data. In a T1, when a D-channel is present, it occupies Channel 24. In an E1, when a D-channel is present, it occupies channel 16.

DEFINITY ECS offers several administrable protocols, each of which provides a different set of services that ISDN allows. See “DS1 Trunk Service” for more information. These protocols are discussed in detail later in this section. The following combination of services, including but not limited to Basic Call, Basic Supplementary Services, Supplementary Services with Rerouting, Display, and QSIG Networking are supported on the ISDN-PRI interface. The services available with global ISDN are country dependent.

With ISDN, DEFINITY ECS interfaces with a wide range of other products including switches, network switches, and host computers. These products include earlier DEFINITY communications systems, public network switches (for example, 4ESS, 5ESS, and Northern Telecom DMS250), and other products that adhere to the ISDN signaling protocol.

As an example of how ISDN is used in private- and public-network configurations, see [Figure 7-1](#) and [Figure 7-2](#). As seen, ISDN can be used to connect a switch to a public-switched network, a switch to a host computer, or a switch to another switch.

**AT&T Switched Network Protocol**

DEFINITY ECS supports the AT&T Switched Network Protocol described in the TR41449 (for 4ESS to common carrier) and TR41459 (for 5ESS to CO) ISDN protocol standards as defined by AT&T. This protocol is used when the DS1 circuit pack is administered for Country Code 1, Protocol Version a. The AT&T Switched Network provides you with the following services.

**Access to AT&T Switched Network Services**

ISDN provides access to AT&T Switched Network Services. See *Service Type* on the ISDN Trunk Group form for a table that outlines these switched-network services. An ISDN trunk group may be dedicated to a particular feature. Alternately, an ISDN call-by-call trunk group may provide access to several features. For a description of the services accessible via ISDN (either via dedicated or call-by-call trunk groups), see [“Call-by-Call Service Selection” on page 7-42.](#)

## Call Identification Display

ISDN Call Identification Display provides a transparent name and number display for all display-equipped voice terminals within an ISDN network. The feature is transparent in that the same information can be provided at all ISDN facilities. Voice terminals using this feature should be digital voice terminals with a 40-character alphanumeric display. The Merlin hybrid sets with 32-character displays (7315H and 7317H) also support this feature.

ISDN Call Identification Display is provided in addition to the normal Voice Terminal Display and Attendant Display features when the network supports end-to-end ISDN connectivity. When both ISDN and DCS display information are received, the switch can display either the DCS or ISDN call identification information. If only ISDN display information is received, information displays in ISDN format. See [“Expanded technical information” on page 7-34](#) for more detail on CPN and BN.

The display fields that may be used for ISDN are: Name, Number, Miscellaneous Call Identification, and Reason for Call Redirection. The display information varies, depending on the type of call, how the call is handled (for example, whether it is redirected or not), and the information is available on the call. The display information for basic calls (those with just a caller and called party) and for redirected calls is provided in [“Expanded technical information” on page 7-34](#).

## CPN/BN to Host Call Identification

The CPN/BN to Host Call Identification enables CPN and BN information to be passed from the switch to the ISDN Gateway, so that the ISDN Gateway can forward the information to a host for data-screen delivery to agents in an ACD split.

By delivering call-identification information such as CPN/BN and switch information such as the answering-agent's extension to an adjunct network (ISDN Gateway), the adjunct automatically delivers data screens to agents for new call arrivals and call transfers.

[Figure 7-3](#) shows a simplified diagram of a CPN- and BN-to-host arrangement. The ISDN Gateway is a UNIX or MSDOS computer connected to the switch on one side and to a host computer on the other side. The connection to the switch is over a synchronous interface with BX.25 protocol.

## Private network services

In addition to providing access to switched-public networks, ISDN provides private-network services by connecting DEFINITY ECS in an Electronic Tandem Network (ETN), Distributed Communications System (DCS), or QSIG Network. This gives you more efficient private networks that support new integrated voice and data services. ETN, DCS, and QSIG networking services are provided as follows.

### ETN services

DEFINITY ECS that function as tandem nodes in an ETN can be interconnected using DS1 trunking facilities with ISDN. All signaling between the tandem switches is done with ISDN D-channel and normal ISDN protocol. The ISDN can also be used to connect ETN tandem and main switches. In this case, the main switch collects all of the address digits from local users as well as users at other satellite and tributary switches, and originates a call over ISDN to the tandem switch.

Automatic Alternate Routing (AAR) and Automatic Route Selection (ARS) are used with ISDN and DS1 trunking facilities to access ETN facilities. AAR and ARS are used to collect the dialing information for the call that is originated from the main switch.

### **DCS services**

ISDN-PRI facilities can be used in a DCS arrangement whenever tie trunks are used to connect the DCS nodes. Most DCS features are not affected by ISDN-PRI. However, there is a minor impact on a few of the DCS features, as far as the functions that the local and remote switches perform.

### **QSIG services**

QSIG networking provides compliance to the International Organization for Standardization (ISO) ISDN private-networking specifications. The QSIG Networking platform is supported over the ISDN Basic Call setup protocol. DEFINITY ECS supports QSIG Supplementary Services. For more information, see [“QSIG” on page 12-77](#).

### **Wideband Switching (ISDN-PRI only)**

Wideband Switching provides support for services that require large bandwidth, such as high-speed video conferencing. Wideband also supports multiple channel calls end-to-end. These services have traditionally been handled by dedicated facilities. With Wideband Switching, dedicated facilities are no longer a requirement for these large bandwidth services.

### **Call-by-Call Service Selection**

Call-by-Call Service Selection allows the same ISDN trunk group to carry calls to a variety of services or facilities. Embodied in this feature is the ability to allocate usage. It provides significant flexibility for creating user-defined incoming and outgoing services and is used on any ISDN trunk group.

### **Access to Software Defined Data Network**

With ISDN, the SDDN service may be accessed. SDDN provides virtual private-line connectivity via the switched public network. The services provided by SDDN include voice, data, and video applications. SDDN services complement the ISDN voice services.

### **Access to Switched Digital International**

Switched Digital International (SDI) provides 64 kbps of unrestricted connectivity to international locations via the AT&T Switched Network. It is also the backbone for the AT&T International ISDN network. SDI complements the ACCUNET digital service already available to United States locations. This service can be accessed using Call-by-Call Service Selection. SDI provides economical high-speed data transfer to international locations.

## National ISDN-2 Services

DEFINITY ECS supports National ISDN-2 (NI-2), which offers many of the same services as the AT&T Switched Network protocol. The NI-2 protocol is used when the DS1 circuit pack is administered for Country Code 1, Protocol Version b.

NI-2 provides users with the following services:

- Calling Line Identification
- Non-Facility Associated Signaling (ISDN-PRI only)
- D-Channel Backup (ISDN-PRI only)
- Wideband Switching (ISDN-PRI only)
- Call-by-Call Service Selection

### Calling Line Identification

Calling Line Identification for NI-2 is essentially Calling Party Number (CPN) identification, as previously described.

### Non-Facility Associated Signaling (ISDN-PRI only)

Non-Facility Associated Signaling (NFAS) allows an ISDN-PRI T1 or E1 Interface D-channel (signaling channel) to convey signaling information for B-channels (voice and data) on ISDN-PRI T1 or E1 facilities other than the one containing the D-channel. See [“Facility and Non-Facility Associated Signaling” on page 7-49](#) for more information.

### D-Channel Backup (ISDN-PRI only)

D-Channel Backup is provided to improve reliability in the event of a signaling-link failure. See [“Facility and Non-Facility Associated Signaling” on page 7-49](#) for more information.

### Wideband Switching (ISDN-PRI only)

Wideband Switching for NI-2 is essentially the same as that of the AT&T Switched Network ISDN-PRI protocol.

### Call-by-Call Service Selection

Call-by-Call Service Selection for NI-2 is essentially the same as that for the AT&T Switched Network ISDN-PRI protocol.

## ISDN interworking

ISDN interworking is a call that uses a combination of both ISDN trunking and station facilities and non-ISDN trunking and station facilities. A non-ISDN trunking facility is any trunk facility supported by the system that does not use the ITU-T recommended Q.931 message set for signaling. Non-ISDN trunking facilities include facilities such as analog trunks, AVD DS1 trunks, and DS1 trunks with bit-oriented signaling (robbed-bit or common channel).

DEFINITY ECS supports the conversion of ISDN signaling to non-ISDN in-band signaling and the conversion of non-ISDN in-band signaling to ISDN signaling for interworking purposes.

A mixture of ISDN and non-ISDN signaling is required in order to provide end-to-end signaling when using different types of trunk or station facilities on a call. See [Figure 7-4](#) for an example of interworking. In this example, a call for someone at Switch B comes into Switch A. Interworking allows the ISDN signaling of the call to be converted at Switch A to non-ISDN in-band signaling before the call forwards to Switch B. Even though the call comes into Switch A on an ISDN trunk, Switch A can send the call to Switch B over a non-ISDN trunk by converting the signaling information.

**Figure Notes**

- |                                  |                   |
|----------------------------------|-------------------|
| 1. Call from network to Switch B | 4. Non-ISDN trunk |
| 2. ISDN trunk                    | 5. Switch B       |
| 3. Switch A                      |                   |

**Figure 7-4. Interworking example**

The system provides accurate CDR billing information on calls that are not interworked. Accuracy of CDR billing information on interworked calls is equivalent to the accuracy provided by the public network.

DEFINITY ECS supports sending a non-ISDN trunk name as the connected name. Therefore, a non-ISDN trunk name can be sent as the connected name even when a call starts out as an ISDN call but is interworked over non-ISDN trunks.

## Expanded technical information

### ISDN-related hardware

ISDN-PRI is supported by the TN767 circuit pack (for assignment of a T1 signaling link and up to 24 ISDN-PRI trunk group members), or the TN464C or later circuit pack (for assignment of a T1 or E1 signaling link and up to 24 or 31 ISDN-PRI trunk group members, respectively). The TN2185 ISDN Trunk-side BRI circuit pack supports the ISDN-BRI trunk group.

- For R6si and later configurations, the D-channel is switched through either the TN765 Processor Interface (PI) circuit pack or the TN778 Packet Control (PACCON) circuit pack.
- For R6r and later configurations, the D-channel is switched through the TN1655 Packet Interface (PKTINT) circuit pack.

#### NOTE:

The TN767 cannot be used to carry the D-channel if either the TN778 (PACCON) or TN1655 (PKTINT) circuit pack is used to switch the D-channel; however, the TN767, in these circumstances, can be used for NFAS interfaces carrying only B-channels.

ISDN-BRI is supported by the TN2185 Trunk-side BRI circuit pack (for implementing the user side on the BRI interface) and the TN556B (or TN556C) and TN2198 ISDN BRI Line circuit packs.

- For R6si and R6vs and later configurations, the D-channel switches through the TN7778 Packet Control circuit pack.
- For R6r and later configurations, the D-channel switches through the TN1655 Packet Interface circuit pack.

A TN780 or TN2182 Tone Clock circuit pack provides synchronization for the ISDN-BRI Trunk circuit pack.

### Call Identification Display

Two types of identification numbers are provided with ISDN. These identification numbers may be used in the various types of displays used with ISDN. The two types of identification numbers are as follows:

- Calling Party Number (CPN): A 0–15 digit DDD number associated with a specific station. When a system user makes a call that uses ISDN, that user's CPN is provided by the system for ISDN. ISDN public-unknown numbering or ISDN private numbering forms are administered to create a 0–15 digit CPN from a local station number.
- Billing Number (BN): The calling party's billing number, which is provided to an inter-exchange network via Equal Access or Centralized Automatic Message Accounting (CAMA). This number is stored at either a local or network switch. If a customer is connected directly to the AT&T Switched

Network, the BN is the customer's billing number stored in that network. If the CPN is not provided on an incoming ISDN call, the network uses the BN for the station identification number.

The following types of display information are provided with ISDN.

- Calling Party's Number

The calling party's number appears on the called party's display. This number is provided only if the outgoing ISDN trunk group is administered to send the CPN, and if ISDN public-unknown numbering or ISDN private numbering forms are administered to create a CPN. On calls incoming to a system, the network may provide either the CPN or BN as the calling party's number. Extensions and 12-digit international numbers display without dashes. Dashes are only used for 7-digit and 10-digit numbers when `North American Area Code` is enabled on the Dial Plan form.

- Calling Party's Name

The calling party's name appears on the called party's display. On calls generated from a DEFINITY ECS, the calling party's name is provided if the ISDN trunk group is administered to send the name to the network. On calls incoming to a DEFINITY ECS, the (public or private) network may provide the calling party's name. If the calling party's name is not available, the called party's display shows "CALL FROM" instead, followed by the calling party's number (if available).

- Connected Party's Number

The connected party's number appears on the calling party's display. On calls generated from a DEFINITY ECS, the called party's number appears on the calling party's display as the calling party dials the number. If the (public or private) ISDN network provides the connected party's number, the calling party's display is updated to show the connected party's number. The format of the connected party's number is the same as that of the calling party's number described previously on calls incoming to a DEFINITY ECS. The 0–15 digit number of the party who answers the call is provided to the ISDN network only if the incoming ISDN trunk group is administered to send connected number to the network and ISDN public-unknown numbering or ISDN private numbering forms are administered to create a CPN.

 **NOTE:**

The connected party may be the party actually called, in the event the call is transferred before the connected party answers the call.

- Connected Party's Name

The connected party's name appears on the calling party's display. On calls generated from a DEFINITY ECS, the (public or private) ISDN network may provide the connected party's name to the DEFINITY ECS,

when the call is answered. If the connected party's name is not available, the calling party's display shows *ANSWERED BY*, followed by the connected party's number (if available).

On calls incoming to a DEFINITY ECS, the connected party's name is provided if the incoming ISDN trunk group is administered to send the name to the network.

## ISDN basic call

A basic ISDN call has both a caller and a called party, and the called party answers the call. When the caller goes off-hook, a= appears on the display. The digits then appear as they are dialed. These digits may be overwritten by the trunk group name if *Outgoing Display* of the Trunk Group Administration form is *y*. Once the called party (or a user with a bridged appearance for the called party) answers the call, the displays for the caller and called parties are described below.

- If *both the name and number information are available*, the displays are as follows. The *MISCID* (Miscellaneous Identification) field may be blank if that information is not available.

- Caller Display

- a= CALLED NAME CALLED NUMBER MISCID

- Called Party Display

- a= CALLER NAME CALLER NUMBER MISCID

- If *only the name information is available*, the displays are as follows:

- Caller Display

- a= CALLED NAME MISCID

- Called Party Display

- a= CALLER NAME MISCID

- If *only the number information is available*, the displays are as follows:

- Caller Display

- a= ANSWERED BY CALLED NUMBER MISCID

- Called Party Display

- a= CALL FROM CALLER NUMBER MISCID

- If *neither the name nor the number information is available*, the displays are as follows:
  - Caller Display (shows one of the following, depending on administration)
    - a= DIALED NUMBER                      MISCID
    - a= TRUNK NAME                          MISCID
  - Called Party Display
    - a= TRUNK NAME                          MISCID

## Redirected ISDN call

This is a call that has been redirected from the called party's extension by a feature such as Call Coverage, Call Forwarding All Calls, Bridged Call Appearance, or Call Pickup. Once the call is connected, the displays for the calling, called, and connected parties are as follows.

- Calling Party Display

a= CONNECTED NAME    CONNECTED NUM    MISCID

- Called Party Display

The following information appears on the display if the called party bridges onto the redirected call after it has been answered. In this situation, the connected party's display (given later) shows the same information. The calling party's display is also updated if the calling and called parties are on the same switch.

a= CONFERENCE 2

- Connected Party Display

The connected party is who answers the redirected call. The "R" indicates the reason for redirection.

a= CALLING ID    to    CALLED ID            R

The CALLING ID and the CALLED ID may be the name or the number, depending on what has been received from the far end.

## Interactions

---

- Attendant Display

The information provided by ISDN Call Identification Display is in addition to the display features already provided.

When an ISDN call is redirected to the attendant, and both name and number display information is available, the name displays on the console for the caller and called party identification. When a call is transferred or conferenced, DEFINITY ECS can redisplay DCS and ISDN caller/called/connected party information.

- Bridged Call Appearance

ISDN Call Identification Display information is provided at both the primary extension and the extension with the bridged call appearance. Both displays show the same called-party information, whether the call is made from the primary extension or the bridged call appearance. On a call to a primary extension, the caller's display shows the identification of the called primary extension, even if the call is answered by the bridged call appearance.

- Call Forwarding

When an ISDN call is forwarded, no ISDN Call Identification Display information is shown on the display of the forwarding extension.

The forwarded-to extension's display shows information on the caller, called party (if the forwarded-to station is on the same switch), and the reason for redirection.

- Call Pickup

When an ISDN call is answered via Call Pickup, the caller's display identifies the answering party, the called party's display identifies the caller, and the answering party's display identifies both the caller and called parties.

- Caller Information Forwarding

With CINFO you can use a vector *collect digits* step to retrieve caller entered digits (ced) and customer database-provided digits (cdpd) supplied by the network in an incoming call's ISDN SET UP message. ISDN is required if the CINFO comes from the network.

- Conference — Attendant

A conference call is identified as a call with "n" number of conferees. This display information generates locally and does not change the display on another switch. If the conference call eventually drops back to a two-party call, the original display information is restored.

- Conference — Terminal

A conference call is identified as a call with “n” number of conferees. This display information generates locally and does not change the display on another switch. If the conference call eventually drops back to a two-party call, the original display information is restored. However, when two DCS and/or ISDN calls (or any possible combination of each) are conferenced and revert to a two-party call, the trunk group of the remaining call displays.

- DCS

If both DCS and ISDN features are provided over the same facility with a DEFINITY ECS, DCS displays generally override ISDN displays. However, with DEFINITY ECS, the ISDN connected name and number can override the DCS called name and number if `Display Connected Name/Number for ISDN DCS Calls` is `y` on the Feature-Related System Parameters form

When two DCS and/or ISDN calls (or any possible combination of each) are conferenced and revert to a two-party call, the trunk group of the remaining call displays.

- Facility Restriction Level and Traveling Class Mark

The TCM used to pass on the originating facility’s FRL is sent by ISDN facilities in the SETUP message only if the trunk services type is tandem.

- Hold

When an ISDN call is placed on Hold, the display of the party who activates Hold goes blank, and then identifies the new caller or connected party, if there is one. The held party’s display remains unchanged. When the held party is reconnected to the holding party, the holding party’s display is updated to indicate the current status of the call.

- Hunting

On ISDN calls to a hunt group extension, the caller’s display identifies either the hunt group name or the group member who answers the call, depending on hunt group administration.

- Information Indicator Digits (II-digits)

With II-digits you can make vector-routing decisions based on the type of the originating line. II-digits are provided for an incoming call by ISDN-PRI. It is a generally available ISDN AT&T Network service.

- LookAhead Interflow

LookAhead Interflow requires ISDN connectivity end-to-end over a private network.

- Look Ahead Routing

Look Ahead Routing allows you to continue to try to reroute an outgoing ISDN call when initial attempts fail because you receive certain cause values which indicate a congestion situation. You can indicate the next route-pattern preference or indicate that the current route pattern should be attempted again.
- Malicious Call Trace

ISDN calling number identification is sent when MCT notification is activated on an ISDN trunk.
- Multiple Subscriber Number (MSN) - Limited

The ISDN standard MSN feature lets you assign multiple extensions to a single BRI endpoint. A side effect of supporting the NT interface is the MSN feature works with BRI endpoints allowing the Channel ID IE to be encoded as “preferred.” The endpoint must be administered as the far end of an NT-side ISDN-BRI trunk group. Also, you must use the Uniform Dial Plan (UDP) feature to assign the desired extensions to the “node” at the far end of the trunk group.
- Overlap Sending

You can administer overlap sending on AAR and ARS calls routed over ISDN trunk groups. This allows you to send and receive digits one digit at a time instead of enbloc. (With enbloc, digits are not sent until the entire group of digits is received).
- Terminating Extension Group

On ISDN calls to a TEG, the caller’s display identifies either the group or the group member who answers the call, depending on administration.
- Transfer

When a call is transferred across an ISDN trunk, the display of the party who transfers the call goes blank. The transferred party’s display does not change. The display of the transferred-to party identifies the party transferred.

When an ISDN call is transferred to a party on the same switch as the party who transfers the call, the information on the display of the party who transfers the call shows on the transferred-to party’s display.

When QSIG Call Transfer is enabled for a non-DCS ISDN call, the transferred-to party’s name and number displays for the party that was not transferred.
- Voice Terminal

The information provided by ISDN Call Identification Display is in addition to the display features already provided.

When an ISDN call is redirected to a voice terminal, and both name and number display information are available, the name displays on the terminal for the calling and called party identification. When a call is

transferred or conferenced, DEFINITY ECS can redisplay DCS and ISDN calling/called/connected party information. However, when two DCS and/or ISDN calls (or any possible combination of each) are conferenced and revert to a two-party call, the trunk group of the remaining call displays.

## Call-by-Call Service Selection

Call-by-Call Service Selection enables a single ISDN trunk group to carry calls to a variety of services. It does not require that each trunk group be dedicated to a specific service. It allows you to set up various voice and data services and features for a particular call.

### How to administer Call-by-Call Service Selection

You administer Call-by-Call Service Selection on a per trunk group basis.

### Detailed description

Call-by-Call Service Selection uses the same route patterns and route preferences that are used by Automatic Alternate Routing (AAR), Automatic Route Selection (ARS), and Generalize Route Selection (GRS). The service or facility used on an outgoing Call-by-Call Service Selection call is determined by information assigned in the AAR/ARS/GRS route patterns.

You can allow a variety of services to use a single trunk group. The system obtains trunking efficiency by distributing traffic over all the available trunks. Then you can assign services that are used on incoming and outgoing Call-by-Call Service Selection calls.

Using Country Protocol 1, you integrate services and features such as MEGACOM, ACCUNET, and INWATS onto a single transmission facility (ISDN-PRI trunk group) with flexible assignment of trunks to each service or feature. Calls such as an incoming 800 Service call that requires through-switching as an Outgoing WATS call can be routed via the same facility. See the ISDN-PRI trunk group form on page [“ISDN-PRI trunk group” on page 7-219](#) for a listing of available services.

**NOTE:**

When the DEFINITY ECS is connected to 5ESS, all of the services supported under the Lucent Technologies and NI-2 country options are available.

A Call-by-Call Service Selection example is shown in [Figure 7-5](#).

## ISDN messages and information elements for Usage Allocation

Understanding the technical details of ISDN messages and information elements may help you implement ISDN.

Call-by-Call Service Selection allows the system to specify one of the preceding service types on a call-by-call basis. You can specify service types by classifying incoming calls to an ISDN Call-By-Call trunk group using the called-party's number.

You can also specify service types with a SETUP message that indicates the intent of the originating system to initiate a call using the specified service or facility. The SETUP message may contain units called information elements (IE) that specify call-related information. The IE used with Call-by-Call Service Selection are:

- Network-Specific Facility (NSF) — Indicates which facilities or services are to be used to complete the call (typically not used outside the US and Canada).

The system also checks all incoming ISDN trunk calls for the presence of an NSF IE. If an NSF IE is present, the system makes sure that the requested service is compatible with the trunk administration before it accepts a call.

For an outgoing call on a Call-By-Call trunk group, the NSF IE is constructed using the Service/Feature specified on the routing-pattern preference selected for the call.

If the Service/Feature specified does not have an associated NSF, an NSF IE is not sent. For example, SETUP messages for incoming and outgoing calls classified only by a called-party number do not contain an NSF IE.

- Transit Network Selection — Indicates which interexchange carrier is to be used on an inter-LATA call.

If a call requires both the Service/Feature and the interexchange carrier to be specified, the interexchange carrier information is sent in the NSF IE rather than the Transit Network Selection IE.

## Usage Allocation Plans

Optional Usage Allocation Plans (UAP) may be assigned to provide more control over a Call-by-Call Service Selection trunk group. You can allocate a minimum and maximum number of channels for incoming and outgoing called numbers, privileged users, and voice and data calls.

A UAP allows the customer to set the following options:

- Maximum number of trunks that each service can use at any given time. The sum for all services may exceed the total number of trunk-group members. For example, for a 15-member trunk group, you could administer a maximum of seven MEGACOM service calls, six MEGACOM

800 service calls, and eight SDN calls. This ensures that all trunk-group members are not dominated by a specific service, yet allows for fluctuations in demand.

- Minimum number of trunks that always must be available for each service. The sum for all services may not exceed the total number of trunk-group members. For example, for a 10-member trunk group that provides access to MEGACOM service, MEGACOM 800 service, and SDN, the minimum number of trunks to be used for each of these services cannot add up to more than 10.

When these UAP limits are exceeded, the system rejects the call, even if a trunk is available. On outgoing calls, the calling party receives a reorder tone unless other preferences are available.

You can assign either fixed or scheduled UAP for each Call-by-Call Service Selection trunk group.

- With a fixed UAP, one plan applies at all times.
- With a scheduled UAP, different plans can be administered to apply at different times of day and days of week. As many as 6 activation times and associated plans can be assigned for each day of the week.

You can have anything from a simple fixed UAP to a very flexible UAP with many scheduling options. You can even start out with no UAP and build one as the need arises.

## Incoming Call-Handling Treatment

Call-by-Call Service Selection provides special Incoming Call-Handling Treatment for ISDN trunk groups. An incoming call on an ISDN trunk is handled according to a treatment table administered for the trunk group. Depending on the platform you use, the table allows for a different number of combinations of call treatments.

The treatment for an incoming call is selected based on the first 3 columns in the ICHT table on the ISDN Trunk Group form. When the attributes of an incoming call match these specifications, the call is treated according to the corresponding following 4 columns. If an incoming call matches more than one set of specifications, the most restrictive case applies. [Table 7-4](#) lists the possible cases from most restrictive to least restrictive.

**Table 7-4. Call-by-Call Service Selection specifications**

|                   | Service / Feature | Called Len    | Called Number                             |
|-------------------|-------------------|---------------|---|
| Most restrictive  | Specified         | Specified     | x leading digits specified                |
|                   | Specified         | Specified     | y leading digits specified, where $y < x$ |
|                   | Specified         | Specified     | not specified                             |
|                   | Specified         | Not specified | not specified                             |
|                   | “other”           | Specified     | x leading digits specified                |
|                   | “other”           | Specified     | y leading digits specified, where $y < x$ |
|                   | “other”           | Specified     | Not specified                             |
| Least restrictive | “other”           | Not specified | Not specified                             |

## Considerations

Call-by-Call Service Selection provides the following benefits:

- Cost reduction — Since many services share the same trunks, the total number of trunks can be reduced.
- Improved service — Features and services are less likely to be blocked.
- Simplified Networking — Network engineering is simplified because analysis of trunking needs can be done based on total traffic instead of on a per-service basis.
- Timely response to changes — With UAPs, the network does not have to be consulted.
- Measurement of Call-by-Call Service Selection calls

## Interactions

- Automatic Alternate Routing and Automatic Route Selection  
 Call-by-Call Service Selection uses the same routing tables and routing preferences that are used by AAR and ARS.

- Call Detail Recording

On successful call attempts using ISDN Call-By-Call trunk groups, CDR records the NSF specified by the call's NSF IE. CDR refers to this information as the ISDN Network Service (INS). The value passed to CDR is the 3-digit equivalent of NSF IE. NSF information for Facility Type 2 calls (used with ISDN-Pri Call-by-Call trunk groups) also is recorded if the NSF is available in the incoming SETUP message.

If an outgoing Call-by-Call Service Selection call uses an interexchange carrier other than the presubscribed common carrier, CDR records the 3-digit or 4-digit Interexchange Carrier Code (IXC). CDR may not record the IXC properly if the dialed-code format differs from the US IXC formats.

When a Call-by-Call Service Selection call is rejected because of a UAP, CDR records the cause as an ineffective call attempt. The NSF recording takes place also for the user-defined Facility Type 2. However, the NSF recording takes place only if the NSF is available in the incoming SETUP message.

- Generalized Route Selection

Call-by-Call Service Selection uses the same routing tables and routing preferences used by GRS.

- Multiquest Flexible Billing

Do not use a Service/Facility with `Facility Type` set to **2** or **3**. NSF processing is not performed for Facility Type 2. An NSF is not included in the outgoing SETUP message for Facility Type 3.

- Time-of-Day Routing

Any Time-of-Day Routing administration that affects routing preference also affects Call-by-Call Service Selection. Use Time-of-Day Routing to vary the IXC based on the time of day and day of week.

- Traffic Measurements

The system provides traffic measurements for each individual service administered for a ISDN Call-by-Call Service Selection trunk group.

## Facility and Non-Facility Associated Signaling

---

Facility Associated Signaling (FAS) allows an ISDN-PRI T1/E1 interface D-channel to carry signaling information for the 23 bearer (B) channels on its associated span.

Non-Facility Associated Signaling (NFAS) allows an ISDN-PRI T1/E1 interface D-channel to carry signaling information for the 23 bearer (B) channels on its associated spans. With NFAS, one D-channel can carry signaling for up to 300 B-channels.

### How to administer FAS and NFAS.

---

#### Required forms

| Form                 | Field               | Page                  |

| ISDN-PRI Trunk Group | ■ Port<br>■ Sig Grp | <a href="#">7-219</a> |
| DS1 Circuit Pack     | ■ Signaling Mode    | <a href="#">7-79</a>  |

### Detailed description

---

A D-channel can carry signaling information for numerous B-channels located on different DS1/E1 circuit packs.

#### NOTE:

NFAS is only valid for DS1/E1 Country Protocol 1.

### D-Channel Backup with NFAS

When NFAS is used, a backup D-channel can be administered to improve reliability. The system switches to the backup D-channel if a signaling link failure occurs on the primary D-channel span.

One D-channel is administered as the Primary D-channel and another D-channel is administered as the Secondary D-channel. These assignments ensure that both D-channels are in the same state at the same time and neither can be used to carry B-channel traffic at any time. The Primary D-channel is given precedence over the Secondary D-channel.

When D-Channel Backup is activated, all calls that have been answered are preserved. However, some call-related information may be lost. Calls that are not answered when D-channels are switched also may lose call-related information.

Figure 7-6 shows a possible configuration involving 3 ISDN-PRIs between a DEFINITY ECS and another DEFINITY ECS or the public network. With DS1 (24 channel) interfaces, 2 of the ISDN-PRIs contain a D-channel and 23 B-channels, while the other ISDN-PRI contains 24 B-channels. One of the D-channels is the Primary D-channel, and the other is the Secondary D-channel. Together, this pair of D-channels signals for all 70 (23+24+23) of the B-channels that are part of the 3 PRIs.

Since the D-channels are signaling for more than one DS1/E1 facility, D-Channel Backup requires the use of NFAS. At any given time, one of the two D-channels is carrying Layer 3 signaling messages, while the other D-channel is active at layer 2, but in a standby mode only. Any layer 3 messages received over the standby D-channel are ignored. Since only one of the D-channels can be active at a time, load sharing between the two D-channels is not possible. The two D-channels can provide signaling for only a predefined set of B-channels and cannot dynamically backup other D-channels on other interfaces.

**Figure Notes**

- 1. DEFINITY ECS
- 2. Secondary D-Channel
- 3. Primary D-Channel
- 4. ISDN-PRI controlled by D-Channel
- 5. Network Far-End Switch DEFINITY ECS

Figure 7-6. Example D-Channel Backup with 3 ISDN-PRIs

## D-Channel Backup activation

- D-Channel Failure

If the signaling link fails on the active D-channel (D1) or the hardware carrying D1 fails, the system sends a message over the standby D-channel (D2). D2 then becomes the active D-channel and carries all subsequent signaling messages. When the signaling link or hardware on D1 recovers from the failure, D1 becomes the standby D-channel.

- System Technician Commands

If a system technician commands that a D-channel switchover take place, the first action taken by the system is to tear down the signaling link on D1. After this is completed, a message is sent on D2 to request that D2 become the active D-channel. D2 then becomes the active D-channel and the switchover is complete.

## Guidelines for administering FAS and NFAS

Coordinate the following when implementing FAS and NFAS:

- Decide which DS1/E1 facilities will use FAS.
- Decide which of the remaining DS1/E1 facilities carries D-channel signaling information on the 16th (E1) or 24th (DS1) channel. For those channels that have a D-Channel Backup, D-channel pairs must be allocated.
- Define Signaling Groups. A Signaling Group is a group of B-channels for which a given D-channel (or D-channel pair) carries the signaling information. Each Signaling Group must be designated as either a FAS or NFAS Signaling Group.
  - A FAS Signaling Group must contain all the ISDN B-Channels on the DS1/E1 interface associated with the group's D-channel, and cannot contain B-channels from any other DS1/E1 circuit pack. For 24-channel DS1 boards, some of the DS1 ports may use in-band (robbed-bit) signaling and be members in a tie trunk group rather than an ISDN trunk group. These tie trunks cannot be members of a Signaling Group.
  - There is no restriction on which DS1/E1 ports can belong to an NFAS Signaling Group. Normally, an NFAS Signaling Group consists of one or two D-channels and several complete DS1/E1 interfaces.

If a Signaling Group contains only a subset of a DS1/E1's B-channels (ports 1–12, for example), it is considered an NFAS Signaling Group, not a FAS Signaling Group. The remaining B-channels on the DS1/E1 are then assigned as members of another NFAS Signaling Group.

- An Interface ID must be assigned to each DS1/E1 facility in an NFAS Signaling Group. For example, if the B-channels in a Signaling Group span 3 DS1/E1 facilities, a unique Interface ID must be assigned to each of the 3 DS1/E1 facilities. This designation is required to uniquely identify the same B-channel (port) number on each of the DS1/E1 facilities in the Signaling Group. Therefore, this interface must be agreed upon by both sides of the interface and administered prior to initialization.
- Primary and Secondary D-Channel Backup must be agreed upon by both sides of the interface and administered prior to initialization. If the IDs do not match, the signaling group will come up but calls will fail.

The following forms show the DS1 interface configuration for NFAS. When implementing FAS and NFAS, the DS1 form must be submitted first, followed by the Interface Link and associated forms, followed by the ISDN-PRI trunk group, Signaling Group, and Trunk Group Members forms.

The Interface Link and associated forms may be administered at any time after the DS1 forms have been administered, with the following restrictions:

- A D-channel cannot be assigned on a Signaling Group form unless the associated link is disabled.
- A trunk member cannot be assigned unless its associated Signaling Group has been administered.

The `Signaling Mode` must be specified for each DS1 circuit pack. Because this circuit pack has `Signaling Mode` set to `isdn-ext`, all trunks on this circuit pack are signaled using either inband robbed-bit signaling, or by a D-channel on another DS1 circuit pack.

                                 Trunk Group for Channel Selection: \_\_\_\_\_

Screen 7-4. Signaling Group form (Group 3) — Facility Associated Signaling

Note that in [Screen 7-2](#), [Screen 7-3](#) and [Screen 7-4](#):

- Signaling Group 1 B-channels on DS1 circuit packs (boards) B0 and B1 are signaled by D-channel pair B1524 (see Primary D-channel field) and B1624 (see Secondary D-channel field).
- Signaling Group 2 B-channels on board B1 are signaled by D-channel B1824.
- Board B0 has no D-channel. The B-channels on board B0 can be signaled by either D-channel pair B1524/B1624 (Signaling Group 1) or D-channel B1824 (Signaling Group 2).
- The DS1 interface on board B19 (Signaling Group 3) is a Facility Associated Signaling case. Note that Secondary D-channel and Trunk Board/Interface ID are not displayed when Associated Signaling is y.

The following 2 communications-interface forms must be completed for the ISDN-PRI interface on R5vs/si and later configurations if the D-channel is switched through the TN765 Processor Interface (PI) circuit pack:

- Interface Links form — Used to create an association between the D-channel on a DSI circuit pack and the port on a TN765 Processor Interface circuit pack used for this link.
- Processor Channels form — Used to assign processor channels to the link administered on the Interface Links form.

Finally, trunk ports are added to the ISDN-PRI trunk group and to Signaling Groups.

**Screen 7-5. ISDN-PRI Trunk Group form — Trunk Members with Required Signaling Group**

The Sig Grp column on the above trunk group form is completed as follows:

- If a DS1 interface appears in one and only one Signaling Group, then Sig Grp may be left blank because the system automatically populates the field with the correct Signaling Group.
- If a DS1 circuit pack appears in more than one Signaling Group, then the Signaling Group numbers must be entered in the appropriate fields before submitting the form.

## **Interactions**

---

Non-Facility Associated Signaling is not supported with ISDN-BRI trunks.

## Wideband Switching

---

Wideband Switching provides the ability to dedicate 2 or more ISDN-PRI B-channels or DS0 endpoints for applications that require large bandwidth. It provides high-speed end-to-end connectivity between endpoints where dedicated facilities are not economic or appropriate.

### How to administer Wideband Switching

---

#### Required forms

---

| Form                                 | Field | Page                  |
|--------------------------------------|-------|-----------------------|

### Detailed description

---

ISDN-PRI divides a T1 or E1 trunk into 24 (31 for E1) information channels and one signaling channel for standard narrowband communication. Certain applications, like video conferencing, require greater bandwidth. You can combine several narrowband channels into one wideband channel to accommodate the extra bandwidth requirement. DEFINITY ECS serves as a gateway to many types of high-bandwidth traffic. In addition, DS1 converters (TN1654) are used for wideband switching at remote locations.

Wideband Switching supports:

- High-speed video conferencing
- WAN disaster recovery
- Scheduled batch processing (for example, nightly file transfers)
- LAN interconnections and imaging
- Other applications involving high-speed data transmission, video transmission, or high bandwidth

[Table 7-5](#) provides information on Wideband Switching channel types.

**Table 7-5. Wideband switching channel types**

| Channel Type | Number of Channels | Data Rate     |
|--------------|--------------------|---------------|
| H0           | 6                  | 384 Kbps      |
| H11          | 24                 | 1536 Kbps     |
| H12          | 30                 | 1920 Kbps     |
| NXDS0 (T1)   | 2-24               | 128–1536 Kbps |
| NXDS0 (E1)   | 2-31               | 128–1984 Kbps |

## Channel allocation

Perform wideband-channel allocation using one of three allocation algorithms: fixed, flexible, or floating.

- Fixed allocation — Provides contiguous-channel aggregation. The starting channel is constrained to a predetermined starting point. (Used only for H0, H11, and H12 calls.)
- Flexible allocation — Allows a wideband call to occupy noncontiguous positions within a single T1 or E1 facility.
- Floating allocation — Enforces contiguous-channel aggregation. The starting channel is not constrained to a predetermined starting point.

## Typical uses

A typical video application uses an ISDN-PRI interface to DS0 1 through 6 of the line-side facility. See to [Figure 7-7](#).

| 5. Line-side ISDN-PRI    | 12. DS0 24 D-channel      |
| 6. DEFINITY ECS          | 13. DS0 7-23 narrow bands |
| 7. ISDN trunk            | 14. DS0 1-6 wideband      |

**Figure 7-7. Wideband Switching Video Application**

**Endpoint applications**

An endpoint application is the origination or destination point of a wideband call. Endpoint applications can be any number of data applications based on the customer's particular needs.

**ISDN-PRI terminal adapters**

ISDN-PRI terminal adapters translate standard ISDN signaling into a form that can be used by the endpoint application and vice versa. The terminal adapter also must adhere to the PRI-endpoint boundaries as administered on the DEFINITY ECS switch when handling both incoming (to the endpoint) applications and outgoing calls.

The terminal adapter passes calls to and receives calls from the line-side ISDN-SETUP messages indicating the data rate and specific B-channels (DS0) to be used and communicates all other call status information via standard ISDN messages. See the *DEFINITY Line-Side ISDN Primary Rate Interface Technical Reference* for more information.

### **Line-side (T1 or E1) ISDN-PRI facility**

A line-side ISDN-PRI (T1 or E1) facility is comprised of a group DS0s (24 for a T1 facility and 32 for an E1 facility). In this context, these DS0s are also called channels. There are 23 B-channels and a single D-channel for a T1 facility and 30 B-channels and a single D-channel for an E1 facility. Data flows bi-directionally across the facility between the switch and the ISDN-PRI terminal adapter.

### **PRI-endpoints**

A PRI-endpoint (PE) is a combination of DS0 B-channels on a line-side T1 or E1 ISDN-PRI facility that has been assigned an extension.

A PRI-endpoint can support calls of lower bandwidth. In other words, a PE having a width 6 (six DS0s) can handle a call of one channel (64 Kbps) up to and including six channels (384 Kbps). Also, a PE can support calls on non-adjacent channels. For example, an endpoint application connected to a PE defined as using B-channels 1 through 6 of an ISDN-PRI facility could originate a call using B-channels 1, 3, and 5 successfully. If the PE has been administered to use flexible channel allocation, the algorithm for offering a call to the PE starts from the first DS0 administered to the PE. Since only one active call is permitted on a PE, contiguous B-channels are always selected unless one or more B-channels are not in service.

A PE remains in service unless all of its B-channels are out of service. In other words, if B-channel 1 is out of service and the PE is five B-channels wide, a wideband call of up to four B-channels in width could still be handled by the PE. A PE can only be active on a single call at any given time, that is, it is either considered idle, active (busy), or out of service.

One facility can support multiple separate and distinct PRI-endpoints (several extensions) within a single facility. Non-overlapping contiguous sets of DS0s (B-channels) are associated with each PE.

### **Universal digital signal level 1 board**

The UDS1 board is the interface for line-side and network facilities carrying wideband calls. The board is a TN464C or later circuit pack.

## **Non-signaling configuration**

Wideband can also support configurations using non-signaling (non-ISDN-PRI) line-side T1 or E1 facilities. The endpoint applications are the same as those defined for configurations with signaling.

## Data service unit/channel service unit

This unit simply passes the call to the endpoint application. Unlike terminal adapters, the DSU/CSU does not have a signaling capability.

### NOTE:

No DSU/CSU is needed if the endpoint application has a fractional T1 interface.

## Line-side (T1 or E1) facility

This facility, like the ISDN-PRI facility, is composed of a group of DS0s (24 for a T1 facility and 31 for an E1 facility). Line-side facilities are controlled solely from the switch. Through the access-endpoint command, a specific DS0 or group of DS0s is assigned an extension. This individual DS0 or group, along with the extension, is known as a wideband access endpoint (WAE).

## Wideband access endpoint

WAEs have no signaling interface to the switch. These endpoints simply transmit and receive wideband data when the connection is active.

### NOTE:

The switch can determine if the connection is active, but this does not necessarily mean that data is actually coming across the connection.

A WAE is treated as a single endpoint and can support only one call. If all DS0s comprising a wideband access endpoint are in service, then the wideband access endpoint is considered in service. Otherwise, the wideband access endpoint is considered out of service. If an in-service wideband access endpoint has no active calls on its DS0s, it is considered idle. Otherwise, the wideband access endpoint is considered busy.

Multiple WAEs are separate and distinct within the facility and endpoint applications must be administered to send and receive the correct data rate over the correct DS0s. An incoming call at the incorrect data rate is blocked.

## Guidelines and examples

---

This section examines wideband and its components in relation to the following specific customer usage scenarios:

- High-speed video conferencing
- Data backup connection
- Scheduled batch processing
- Primary data connectivity
- Networking

## High-speed video conferencing

All data rates are multiples of 64 Kbps; from 128 Kbps to 1,536 Kbps (T1) and 1,984 Kbps (E1) are supported. Key customer data rates are listed in [Table 7-5](#).

## Data backup connection

Using wideband for data transmission backup provides customers with alternate transmission paths for critical data in the event of primary transmission path failure.

### Scheduled batch processing

Scheduled batch processing applications are used for periodic database updates (for example, retail inventory) or distributions (for example, airline fare schedules). These updates are primarily done after business hours and are often referred to as nightly file transfers. Wideband meets the high bandwidth requirements at low cost for scheduled batch processing. In addition, wideband allows the dedicated-access bandwidth for busy-hour switch traffic to be used for these applications after business hours; no additional bandwidth costs are incurred.

The non-ISDN backup data connection is also appropriate for scheduled batch processing applications. Administered Connections are used to schedule daily or weekly sessions originating from this application.

### Primary data connectivity

Permanent data connections (those always active during business hours), such as interconnections between LANs, are well suited for DEFINITY ECS when ISDN-PRI endpoints are used. The ISDN end-to-end monitoring and the endpoint's ability to react to failures provide for critical data availability needs. With ISDN, endpoints can detect network failures and initiate backup connections through the switch; ISDN endpoints can also establish additional calls when extra bandwidth is needed.

Any failures not automatically restored by DEFINITY ECS are signaled to the endpoint application, which can initiate backup data connections over the same PRI endpoint. DEFINITY ECS routes the backup data connections over alternate facilities if necessary.

## Networking

All of the wideband networking is over ISDN-PRI facilities but may connect to a variety of networks, other domestic interexchange carriers' services, private line, RBOC services, and services in other countries.

## ISDN-PRI trunk groups and channel allocation

---

Only ISDN-PRI trunks support wideband calls to the network. Wideband's bandwidth requirements have necessitated modification of the algorithms by which trunks look for clear channels. The following section describes the search methods and their relationship to the available wideband data services.

### Facility lists

A wideband call accessing the network must reside on a single ISDN-PRI facility. Trunks within a trunk group must be organized based on the facility on which they reside. This is accomplished by compiling a facility list as trunks are administered to a trunk group; if a trunk is added to a trunk group from a facility not already on that trunk group's list, that facility is added to the list in an order based on the facility's signaling group number and interface identifier. In other words, the facility list is compiled in an ascending order based first on signaling group number and second on the interface identifier assigned to the facility within the signaling group. For example, if three facilities having signaling group/interface identifier combinations of 1/1, 1/2, and 2/1 were associated with a trunk group, then a call offered to that trunk group would search those facilities in the order as they were just listed. Also note that since trunks within a given facility can span several trunk groups, a single facility can be associated with several different trunk groups.

Given this facility list concept, the algorithms have the ability to search for trunks, by facility, in an attempt to satisfy the bandwidth requirements of a given wideband call. If one facility does not have enough available bandwidth to support a given call, or it is not used for a given call due to the constraints presented in the following section, then the algorithm searches the next facility in the trunk group for the required bandwidth (if there is more than one facility in the trunk group).

In addition to searching for channels based on facilities and required bandwidth, Port Network (PN) preferential trunk routing is also employed. This PN routing applies within each algorithm at a higher priority than the constraints put on the algorithm by the parameters listed later in this section. In short, all facilities that reside on the same PN as the originating endpoint are searched in an attempt to satisfy the bandwidth of a given call, prior to searching any facilities on another PN.

### Direction of trunk/hunting within facilities

The algorithms have the ability to select trunks from low B-channel to high B-channel or from high B-channel to low B-channel with an ISDN facility. This is a per ISDN trunk group option, but infers the direction of search within all ISDN facilities (or portions of those facilities) administered within that trunk group. This is necessary so the selection of trunks are not prone to as much glare as they otherwise would be if trunks were chosen in the same direction by both user and

network sides of the ISDN interface. Note that in previous DEFINITY ECS releases, the order in which trunks were selected, whether through linear or circular hunting, would always be with respect to the order in which trunks were administered within the trunk group. Now, with the support of wideband services, all trunks within an ISDN trunk group optioned for wideband are ordered based on this new "direction of trunk/hunt with facilities" parameter, and without regard to the order in which trunks are administered within the trunk group. If an ISDN trunk group is not optioned for wideband, then a cyclical trunk hunt based on the administration of trunks within the trunk group is still available.

## H11

When a trunk group is administered to support H11, the algorithm to satisfy a call requiring 1,536 Kbps of bandwidth uses a fixed allocation scheme. That is, the algorithm searches for an available facility using the following facility-specific channel definitions.

- T1: H11 can only be carried on a facility without a D-channel being signaled in an NFAS arrangement (B-channels 1-24 are used).
- E1: Although the 1,536-kbps bandwidth could be satisfied using a number of fixed starting points (for example, 1, 2, 3, etc.) the only fixed starting point being supported is 1. Hence, B-channels 1–15 and 17–25 are always used to carry an H11 call on an E1 facility.

If the algorithm cannot find an available facility within the trunk group that meets these constraints, then the call is blocked from using this trunk group. In this case, the call may be routed to a different trunk group preference via Generalized Route Selection (GRS), at which time, based on the wideband options administered on that trunk group, the call would be subject to another hunt algorithm (that is, either the same H11 algorithm or perhaps an N x DS0 algorithm described in a later paragraph).

This same hunt algorithm, when offered any other call (other than a 1,920-kbps call) attempts to preserve idle facilities by selecting trunk(s) in a partially contaminated facility if one exists. If the bandwidth required by this call cannot be satisfied by any partially contaminated facility, then the call is placed on available trunk(s) within an idle facility, thus contaminating the facility. Again, facilities are selected via the trunk group's facility list and with PN preference, and trunk(s) within a facility are selected based on the direction of channel search administered. Note that on a T1 facility, a D-channel is not considered a busy trunk and results in a facility with a D-channel always being partially contaminated. On an E1 facility, however, a D-channel is not considered a busy trunk because H11 and H12 calls may still be placed on that facility; an E1 facility with a D-channel and idle B-channels is considered an idle facility.

## H12

Since H12 is 1,920 Kbps which is comprised of 30 B-channels, a 1,920-kbps call can only be carried on an E1 facility. As with H11, the hunt algorithm uses a fixed allocation scheme with channel 1 being the fixed starting point. Hence, an H12 call always is carried on B-channels 1 to 15 and 17 to 31 on an E1 facility (as illustrated in the following table). When offered any other call (other than a 1,536-kbps call), the algorithm behaves as it does when H11 is optioned.

| Facility | ISDN Interface | DS0s Comprising Each Channel |             |
|----------|----------------|------------------------------|-------------|
|          |                | H11                          | H12         |
| T1       | 23B + D        | -                            | -           |
| T1       | 24B (NFAS)     | 1-24                         | -           |
| E1       | 30B + D        | 1-15, 17-25                  | 1-15, 17-31 |
| E1       | 31B (NFAS)     | 1-15, 17-25                  | 1-15, 17-31 |

## H0

When a trunk group is administered to support H0, the algorithm to satisfy a call requiring 384 Kbps of bandwidth also uses a fixed allocation scheme. Unlike the H11 fixed scheme which only supports a single fixed starting point, the H0 fixed scheme supports four (T1) or five (E1) fixed starting points. The H0 algorithm searches for an available quadrant within a facility based on the direction of trunk or hunt administered. If the algorithm cannot find an available quadrant within any facility allocated to this trunk group, then the call is blocked from using this trunk group. Again, based on GRS administration, the call may route to a different trunk group preference and be subject to another algorithm based on the wideband options administered.

This same trunk or hunt algorithm, when offered any narrowband or N x DS0 call, attempts to preserve idle quadrants by choosing a trunk(s) in a partially contaminated quadrant if one exists. If a partially contaminated quadrant capable of carrying the call does not exist, then the call is placed on available trunk(s) within an idle quadrant, thus contaminating the quadrant. Again, facilities are selected via the trunk group's facility list and with PN preference, and a trunk(s) within a facility is selected based on the direction administered. Note that a D-channel is considered a busy trunk and results in the top most quadrant of a T1, B-channels 19 to 24, always being partially contaminated. This is *not true* for NFAS.

If this H0 optioned trunk group is also administered to support H11, H12, or N x DS0, then this algorithm also attempts to preserve idle facilities. In other words, when offered a narrowband, H0, or N x DS0 call, the algorithm searches partially-contaminated facilities before it searches to idle facilities.

## N x DS0

For the N x DS0 multi-rate service, a trunk group parameter determines whether a floating or a flexible trunk allocation scheme is to be used. The algorithm to satisfy an N x DS0 call is either floating or flexible.

- Floating (Contiguous) — In the floating scheme, an N x DS0 call is placed on a contiguous group of B-channels large enough to satisfy the requested bandwidth without any constraint being put on the starting channel (that is, no fixed starting point trunk).
- Flexible — In the flexible scheme, an N x DS0 call is placed on any set of B-channels as long as the requested bandwidth is satisfied. There is absolutely no constraint such as contiguity of B-channels or fixed starting points. Of course, as with all wideband calls, all the B-channels comprising the wideband call must reside on the same ISDN facility.

Regardless of the allocation scheme employed, the N x DS0 algorithm, like the H11 and H12 algorithms, attempts to preserve idle facilities when offered B, H0, and N x DS0 calls. This is important so that N x DS0 calls, for large values of N, have a better chance of being satisfied by a given trunk group. However, if one of these calls cannot be satisfied by a partially-contaminated facility and an idle facility exists, a trunk on that idle facility is selected, thus contaminating that facility.

There are additional factors to note regarding specific values of N and the N x DS0 service:

- N = 1 — this is considered a narrowband call and is treated as any other voice or narrowband-data (B-channel) call.
- N = 6 — if a trunk group is optioned for both H0 and N x DS0 service, a 384-kbps call offered to that trunk group is treated as an H0 call and the H0 constraints apply. If the H0 constraints cannot be met, then the call is blocked.
- N = 24 — if a trunk group is optioned for both H11 and N x DS0 service, a 384-kbps call offered to that trunk group is treated as an H0 call and the H0 constraints apply. If the H0 constraints cannot be met, then the call is blocked.
- N = 24 — if a trunk group is optioned for both H11 and N x DS0 service, a 1,536-kbps call offered to that trunk group is treated as an H11 call and the H11 trunk allocation constraints apply.
- N = 30 — if a trunk group is optioned for both H12 and N x DS0 service, a 1,920-kbps call offered to that trunk group is treated as an H12 call and the H12 trunk allocation constraints apply.

## Glare and blocking

---

### Glare prevention

Glare occurs when both sides of an ISDN interface select the same B-channel for call initiation. For example, a user side of an interface selects the B-channel for an outgoing call and, before the switch receives and processes the SETUP message, the switch selects the same B-channel for call origination. Since wideband uses more channels, the chances of glare are greater. Glare conditions can be limited with proper channel administration but may never be eliminated and some calls might still be dropped.

Some glare situations might not be resolvable. In one case, the network and the user side may send SETUP messages simultaneously or nearly simultaneously. Another glare scenario can occur in the brief window after the SETUP message has been sent but before the first response is received from the switch at the other side of the interface. If an incoming SETUP arrive during this window, the incoming SETUP message is allowed to proceed and the outgoing call is dropped. Various glare situations and their resolution are described in [Table 7-6](#).

DEFINITY ECS does not negotiate channels for wideband calls.

**Table 7-6. Handling Glare**

| GLARE RESOLUTION   |                    |   |  |
|--------------------|--------------------|---|--|
| Outgoing Call Type | Incoming Call Type | Switch-Supporting User Protocol   | Switch-Supporting Network Protocol   |
| B-channel          | B-channel          | No negotiation<br>Incoming call (from network) wins   | Negotiation is attempted<br>Incoming call (from user) dropped if negotiation is unsuccessful   |
|                    |                    | Outgoing call (to network) retried on another trunk   | Outgoing call (to user) stays up   |
| B-channel(s)       | Wide               | No negotiation  | No negotiation   |
|                    |                    | Incoming call (from network) dropped  | Incoming call (from user) dropped  |
|                    |                    | Outgoing calls (to network) stay up but likely are dropped by network because channels are in use, although there is a possibility some switches might negotiate these calls. | Outgoing calls (to user) stay up and possibly stay up if other side lets the network call win. |

*Continued on next page*

Table 7-6. Handling Glare — *Continued*

| GLARE RESOLUTION   |                    |  |  |
|--------------------|--------------------|--|--|
| Outgoing Call Type | Incoming Call Type | Switch-Supporting User Protocol  | Switch-Supporting Network Protocol   |
| Wide               | B-channel(s)       | No negotiation   | Negotiation is attempted   |
|                    |                    | Incoming call (from network) wins  | Incoming call (from user) dropped if negotiation is unsuccessful   |
|                    |                    | Outgoing call (to network) retried on another trunk  | Outgoing call (to user) stays up   |
| Wide               | Wide               | No negotiation   | No negotiation   |
|                    |                    | Incoming call (from network) dropped   | Incoming call (from user) dropped  |
|                    |                    | Outgoing call (to network) stays up but likely are dropped by network because channels are in use. | Outgoing call (to user) stays up and may not be dropped by other side because other side, if it is not a DEFINITY ECS, may let the network call win. |

To reduce glare probability, the network needs to be administered so both sides of the interface select channels from opposite ends of facilities. For example, on a 23B+D trunk group, the user side could be administered to select B-channels starting at channel 23 while the network side would be administered to start selecting at channel 1. Using the same example, if channel 22 is active but channel 23 is idle, the user side should select channel 23 for re-use. This is known as linear trunk hunt and is the hunt option used by DEFINITY ECS for wideband.

### Blocking prevention

Blocking occurs when insufficient B-channels required to make a call are available. Narrowband calls require only one channel so blocking is less likely than with wideband calls which require multiple B-channels. Blocking also occurs for wideband calls when bandwidth is not available in the appropriate format (that is, fixed, floating, or flexible).

DEFINITY ECS selects trunks for both wideband and narrowband calls to maximize availability of idle fixed channels for H0, H11, and H12 calls and idle floating channels for N x DS0 calls that require a contiguous bandwidth. The strategy for preserving idle channels to minimize blocking depends on the channel type.

| Channel Type   | Blocking Minimization Strategy             |
|----------------|--|
| H0             | Preserve idle quadrants                    |
| H11            | Preserve idle facilities                   |
| H12            | Preserve idle facilities                   |
| Flexible NxDS0 | Preserve idle facilities                   |
| Floating NxDS0 | Preserve idle facilities as first priority |

## Considerations

---

- Glare arises when both sides of an ISDN-PRI interface simultaneously select the same B-channel for call initiation. Because Wideband Switching uses multiple B-channels, the possibility of glare is greater than it is with other calls.
- To reduce glare, administer the system so that each side of the ISDN-PRI interface selects channels from opposite ends of the interface.
- For wideband switching with non-ISDN-PRI equipment, you can use an ISDN-PRI terminal adapter.
- For example, if the user side is provisioned to start at the high side (DS0 23) and DS0 22 is idle but DS0 23 is active, reselect DS0 22 for the next call. This is known as linear trunk hunting. Only the direction of hunt is administrable.
- Blocking occurs when not enough bandwidth is available for a call.
- To reduce blocking, the switch selects trunks to maximize availability of idle fixed channels for H0, H11, and H12 calls and idle floating channels for NxDS0 calls. The strategy depends on the channel type. The chances for blocking are reduced if you use a flexible algorithm, assuming it is supported on the other end.

## Interactions

---

- Administered Connections  
Provides call initiation for WAEs. All Administered Connections that originate from WAEs use the entire bandwidth administered for WAE. The destination of an Administered Connection can be a PRI endpoint.
- Automatic Circuit Assurance  
Treats wideband calls as single-trunk calls so that a single ACA-referral call is made if an ACA-referral call is required. The call is on the lowest B-channel associated with the wideband call.

- Call Coverage

A wideband endpoint extension cannot be administered as a coverage point in a call-coverage path.
- Call Detail Recording

When CDR is active for the trunk group, all wideband calls generate CDR records. The feature flag indicates a data call and CDR records contain bandwidth and Bearer Capability Class (BCC).
- Call Forwarding

You must block Call Forwarding through Class of Service.
- Call Management System and Basic Call Management System

Wideband calls can be carried over trunks that are measured by CMS and BCMS. Wideband endpoints are not measured by CMS and BCMS.
- Call Vectoring

PRI endpoints use a vector-directory number when dialing. For example, PRI endpoint 1001 dials VDN 500. VDN 500 points to Vector 1. Vector 1 can point to other PRI endpoints such as route-to 1002, or route-to 1003, or busy.

Call Vectoring is used by certain applications. When an incoming wideband call hunts for an available wideband endpoint, the call can route to a VDN, that sends the call to the first available PRI endpoint.
- Class of Restriction

COR identifies caller and called-party privileges for PRI endpoints. Administer the COR so that account codes are not required. Forced entry of account codes is turned off for wideband endpoints.
- Class of Service

COS determines the class of features that a wideband endpoint can activate.
- Facility and Non-Facility Associated Signaling

FAS and NFAS with or without D-Channel Backup requires administration via signaling groups for trunk-side wideband interfaces.
- Facility Busy Indication

You can administer a busy-indicator button for a wideband-endpoint extension, but the button does not accurately track endpoint status.
- Facility Test Calls

Use Facility Test Calls to perform loop-back testing of the wideband call facility.
- Fiber Link Administration

Use Fiber Link Administration for adding remote locations.

- Generalized Route Selection

GRS supports wideband BCC to identify wideband calls. GRS searches a route pattern for a preference that has wideband BCC. Route preferences that support wideband BCC also support other BCCs to allow different call types to share the same trunk group.

- Subnet Trunking

Accomplish Subnet Trunking via GRS and routing pattern administration.

- Wideband Switching

Not supported with ISDN-BRI trunks.

## **Trunk Group Administration Forms**

This section contains the following Trunk Group Administration forms.

- Access Endpoint
- ATMS Trunk Test Schedule
- DS1 Circuit Pack
- Digit Absorption
- ISDN Numbering — Private
- ISDN Numbering — Public/Unknown
- ISDN TSC Gateway Channel Assignments
- Network-Facilities
- PRI Endpoint
- Signaling Group
- Synchronization Plan
- Trunk Groups — General
- Access trunk group
- APLT trunk group
- CAMA - E911 trunk group
- CO trunk group
- CPE trunk group
- DID trunk group
- DIOD trunk group
- DMI-BOS trunk group
- FX trunk group
- ISDN-BRI trunk group
- ISDN-PRI trunk group
- PCOL trunk group
- RLT trunk group
- Tandem trunk group
- Tie trunk group
- WATS trunk group

## Access Endpoint

---

This form administers Access Endpoints and Wideband Access endpoints.

### ⇒ NOTE:

You can administer Wideband Access Endpoints only if Wideband Switching is enabled on the System-Parameters Customer-Options form.

An Access Endpoint is a nonsignaling trunk that neither responds to signaling nor generates signaling. Access Endpoints eliminate the need to dedicate an entire trunk group for the access of a single trunk by providing the capability to assign an extension number to a single trunk. An Access Endpoint can be specified as the Originator or Destination endpoint of an administered connection.

A Wideband Access Endpoint (WAE) is an endpoint application connected to line-side non-ISDN T1 or E1 facilities and, like Access Endpoints, have no signaling interface with the system. For information on endpoint applications connected to line-side ISDN-PRI facilities, see [“PRI Endpoint” on page 7-102](#).

The WAE is defined by a starting port (DS0) and a width specifying the number of adjacent nonsignaling DS0s (positioned within a DS1 facility) that make up the endpoint. This width may be between 2 and 31 adjacent DS0s.

### ⇒ NOTE:

Access Endpoints and Wideband Access Endpoints consume the same resources that trunks use. Thus, the sum of Access Endpoints and trunks cannot exceed the maximum number of trunks available in your system configuration.

## Administration commands

---

Use the following commands to administer the Access Endpoint form

| Action    | Object          | Qualifier <sup>1</sup>                        |
|-----------|-----------------|---|
| add       | access-endpoint | xxxx (ext. or 'next')                         |
| change    | access-endpoint | xxxx (ext. or 'next')                         |
| display   | access-endpoint | xxxx (ext. or 'next') ['print' or 'schedule'] |
| duplicate | access-endpoint | xxxx (ext. or 'next')                         |
| remove    | access-endpoint | xxxx (ext. or 'next')                         |
| list      | access-endpoint | xxxx ['count' 1-MAX] ['print' or 'schedule']  |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

## Form instructions

```

add access-endpoint next                                Page 1 of 1
                                ACCESS ENDPOINT
                                Extension: 30001      (Starting) Port:
Communication Type: voice-grade-data                   Name: 27 character name ext 30001
                                COR: 1                  COS: 1
                                TN: 1                   ITC: restricted
    
```

### Screen 7-1. Access Endpoint form

- **Extension** — Display-only field. Shows the extension number as specified in the command line, or shows the next available extension number if "next" was entered on the command line. This is the extension number assigned to the nonsignaling trunk and used to access the trunk endpoint.
- **(Starting) Port** — Enter seven characters.

The entry breaks down as follows:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)<br>01 through 03 (R5si and later configurations)<br>01 (R5vs and later configurations) |
| 3          | Carrier        | A through E   |
| 4-5        | Slot Number    | 01 through 20   |
| 6-7        | Circuit Number | 01 through 04 (Analog TIE trunks)<br>01 through 31 (DS1 Interface ports)  |

#### NOTE:

For Wideband Access Endpoints, analog tie trunks cannot be used and the TN464C (or greater) DS1 circuit pack must be used.

The DS1 circuit number corresponds to the channel that will carry the data traffic. Channels 1 through 31 (TN464 only) or channels 1 through 24 (TN722, TN767, or TN464) may be used when the DS1 Signaling Type is

"robbed-bit" or "isdn-ext". For Common Channel or ISDN-PRI signaling, channel use is limited to channels 1 through 30 (TN464 only) or channels 1 through 23 (TN464 or TN767). A channel can be administered as an access endpoint regardless of the DS1 signaling type.

- **Communication Type** — For an analog tie trunk access endpoint, enter **voice-grade-data**. For a DS1 access endpoint, enter either **56k-data**, **64k-data**, or **voice-grade-data** (default) as appropriate (**64k-data** is not allowed for robbed-bit trunks). For a Wideband access endpoint, enter **wideband**.
- **Name** — Enter up to 27 alphanumeric characters to identify the endpoint. Default is blank.
- **Width** — Only displays if `Communication Type` is **wideband**. Enter the number of adjacent DS0 ports (**2 to 31**), beginning with the specified Starting Port, that make up the WAE. A width of **6** (default) defines a 384 Kbps WAE. This field cannot be blank.
- **COR** — Enter the appropriate class of restriction (COR) number from **0–95**. The COR is administered so that only an administered connection (AC) endpoint can be connected to another AC endpoint. Default is **1**.
- **COS** — Enter the appropriate COS number from **0–15**. The COS is administered (see COS form instructions) so that the use of the Call Forwarding All Calls feature for access endpoints is prohibited. Default is **1**.
- **TN** — Enter the Tenant Partition number. Default is **1**.
- **ITC** — (Information Transfer Capability) Displays when `Communication Type` is **56k-data**, **64k-data**, or **Wideband**. Valid entries are **restricted** (default) or **unrestricted**. This field is used to determine the type of transmission facilities to be used for ISDN calls originating from this endpoint.

When **unrestricted**, only unrestricted transmission facilities (b8zs) will be used to complete the call. An unrestricted facility is a transmission facility that does not enforce 1's density digital transmission (that is, digital information is sent exactly as is).

When **restricted**, either restricted (zcs-ami) or unrestricted transmission facilities is used to complete the call. A restricted facility is a transmission facility that enforces 1's density digital transmission (that is, a sequence of eight digital zeros is converted to a sequence of seven zeros and a digital one) via zcs coding on DS1 circuit pack.

**NOTE:**

For Wideband Access Endpoints, enter **unrestricted**.

When adding an access endpoint with the ITC administered as **unrestricted**, its associated port has to be a channel of a DS1 circuit pack with `Zero Code Suppression` administered as **B8ZS**. If the port is not a

channel of a DS1 circuit pack with its Zero Code Suppression administered as B8ZS, the end validation fails and the form submission is rejected. The cursor is moved to ITC with the following error message:

```
An unrestricted access endpoint can only be from B8ZS  
DS1 circuit pack
```

When adding an access endpoint with the ITC administered as restricted, its associated port can be a channel from a DS1 circuit pack with Zero Code Suppression administered as ZCS or B8ZS.

For an existing access endpoint, ITC can only be changed from restricted to unrestricted if its associated port is a channel of a DS1 circuit pack with its Zero Code Suppression field administered as B8ZS. If the port is not a channel of a DS1 circuit pack with its Zero Code Suppression field administered as B8ZS, the end validation fails and the form submission is rejected. The cursor is moved to ITC with the following error message:

```
An unrestricted access endpoint can use only B8ZS DS1  
circuit pack
```

Without this end validation, a user could administer an access endpoint as unrestricted when in fact it is restricted, that is its associated port is a member of a DS1 circuit pack that uses ZCS data transmission.

## ATMS Trunk Test Schedule

---

Automatic Transmission Measurement System (ATMS) provides advanced maintenance procedures for monitoring system trunk facilities. This system performs transmission tests on system trunks to determine if trunks are performing satisfactorily. These tests can be initiated in two different manners: demand and/or scheduled. The *demand* test command can be entered by the system user directly from the System Administration Terminal (SAT) to initiate a test immediately. The *schedule* test command schedules tests, via a schedule form, to automatically initiate tests at a predetermined time.

### Administration Commands

---

Use the following commands to access the ATMS Trunk Test Schedule form.

| Action  | Object        | Qualifier <sup>1</sup>     |
|---------|---------------|----------------------------|
| add     | test-schedule | ['schedule_number'] [next] |
| change  | test-schedule | ['schedule_number']        |
| display | test-schedule | ['schedule_number']        |
| list    | test-schedule |                            |
| remove  | test-schedule | ['schedule_number']        |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.

| —   | —   | —   | —   | —   | —   | —   | —   | —   | —   | —   | —   | —   | —   | —   |

Screen 7-2. ATMS Trunk Test Schedule Form (Page 1 of 1)

Make assignments as required for the following fields on the form.

- **Schedule** — Display-only field shows the current schedule number.
- **Schedule Time** — Enter the hour and minute that test are to begin in 24-hour time conventions. A time of "00:00" represents midnight. This time must be greater than the current time.
- **Schedule Date** — Enter the month (1 to 12), day (1 to 31), and year on which testing will begin; default is the system date. This date must be equal to or greater than the current date.
- **Schedule Test Days (SU:, MO:, TU:, WE:, TH:, FR:, SA:)** — Enter a y next to the days of the week on which this schedule will run.
- **Interval** — Enter the length of this schedule in weeks. If this field is 0 (default), the schedule runs on the specified days only once.
- **OTL Throttle** — Enter the number of concurrent tests run within a schedule. This guarantees that all trunk members within a schedule are tested serially or if multiple trunk members are tested from the same schedule.
- **Test Type** — Enter one of the following types of test to be performed on the trunk group/members in this schedule:
  - full
    - (Default) Runs the most comprehensive test and collects all associated measurements for each TTL type.

— **supv**

Performs a supervision test and will only confirm the presence of the test set at the far end. No measurements will be taken for this test.

— **no-st**

Runs the "full" test, but skips any self-test sequences. This saves about 20 seconds on the type 105 test and will not have any effect on type 100 or 102 tests.

— **no-rl**

Runs the "full" test, but skips any return loss sequences. This saves about 20 seconds on the type 105 test and will not have any effect on type 100 or 102 tests.

— **no-st/rl**

Runs the "full" test, but skips all self-test and return loss sequences. This saves about 40 seconds on the type 105 test and will not have any effect on type 100 or 102 tests.

- **Duration** — Enter the maximum number of hours (**1 to 24**) a schedule can remain active. Schedules continue to run until all trunk group/members for that particular schedule are tested or until the schedule duration is reached. If the duration is reached before all trunk groups/members can be tested, the schedule will stop.
- **Trk Grp** — Enter the trunk group numbers to be tested when this schedule runs. There is no limit to the number of times that a trunk group can appear on any particular schedule, or to the number of different schedules in which a trunk group can appear. Default is blank.
- **Bgn Mbr** — Enter the beginning member number of the trunk group to be tested; default is **1**.
- **End Mbr** — Enter the ending member number of the trunk group to be tested. This value must be greater than or equal to the value of the beginning member field.

## Implementation Note

The number of fields displayed will vary depending on system configuration. The form shown above is for R5r and later configurations.

## DS1 Circuit Pack form

See the *DEFINITY ECS System Description Pocket Reference* for information on the maximum number of DS1 circuit packs that you can administer.

### Administration commands

Use the following commands to administer the DS1 circuit pack form

| Action  | Object                   | Qualifier <sup>1</sup> |
|---------|--------------------------|------------------------|
| add     | ds1                      | [P]Css <sup>2</sup>    |
| change  | ds1                      | [P]Css(board)          |
| display | ds1                      | [P]Css                 |
| list    | measurements ds1 summary | location               |
| list    | measurements ds1 log     | location               |
| remove  | ds1                      | [P]Css                 |

1. Brackets [ ] indicate the qualifier is optional.
2. [P] — representing port network number, C — representing carrier (A-F), and ss — representing slot number.

Screen 7-6. DS1 Circuit Pack form for Croatia and South Africa (page 1 of 1)

- **Location** — This is a 7-character display-only field when the form is accessed using an administration command such as **add** or **change**.

The entry breaks down as follows:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)<br>01 through 03 (R5si and later configurations)<br>01 (R5vs and later configurations) |
| 3          | Carrier        | A through E   |
| 4-5        | Slot Number    | 01 through 20   |

The location also should be identified for record purposes on the Port Assignment Record and the Circuit Pack Administration form.

- **Name** — Enter the name of the DS1 link (limit 15-characters). Typically, this is the destination of the link.
- **Bit Rate** — Enter **1.544** for the 24-channel DS1 rate. Enter **2.048** for the 32-channel E1 rate (TN464 only). Integrated CSU requires that you enter the Bit Rate of **1.544**.

 NOTE:

Once an **add ds1** operation is complete (that is, the DS1 form has been submitted) `Bit Rate` can not be changed. To change `Bit Rate`, execute a **remove ds1** command followed by an **add ds1** command, then reenter the DS1 form.

 NOTE:

The TN464C (and later release) and TN767D (and later release) circuit packs must have an option switch or plug on the circuit board set to match the `Bit Rate` selection.

- **Line Coding** — Enter **b8zs** (bipolar eight zero substitution), **ami-basic** (alternate mark inversion basic), **ami-zcs** (alternate mark inversion with zero code suppression), or **hdb3** (high density bipolar 3). The line coding method must match the method used on the other end of the link. Or, it must be converted by an intervening CSU. If line coding does not match, voice calls will work, but a single data call will bring down the DS1. The line coding entry indicates which line coding format should be used to ensure that the data meets T1 or E1 carrier requirements. When the DS1 circuit pack is used for ISDN, the ISDN D-channel data is inverted when **ami-basic** or **ami-zcs** is entered and not inverted when **b8zs** or **hdb3** is entered.

**Hdb3** or **ami-basic** is allowed when `Bit Rate` is **2.048**. **B8zs**, **ami-basic** or **ami-zcs** is allowed when `Bit Rate` is **1.544**.

Zero code suppression (`zcs`) is a technique for ensuring adequate ones density. It checks for all zeros in an 8-bit time slot. If all zeros exist, bit 2 is changed from a 0 to a 1. When `zcs` is invoked on an all zeros octet; data is lost permanently.

 CAUTION:

*If you make a change in this field, you must busyout the DS1 circuit pack. You must also change the following forms: Route-Pattern, Access Endpoint, PRI Endpoint, Signaling-Group, and Trunk-Group.*

 NOTE:

ZCS line coding is not recommended for digital-data applications.

- **Line Compensation** — Enter a number from **1** to **5** as follows:
  - For 22-gauge ABAM cable terminated on a DSX-1 cross-connect:

| Compensation | Length (feet) | Length (m) |
|--------------|---------------|------------|
| 1 (default)  | 000–133       | 000–40.5   |
| 2            | 133–266       | 40.5–81.0  |
| 3            | 266–399       | 81.0–122   |
| 4            | 399–533       | 122–163    |
| 5            | 533–655       | 163–200    |

- For 22-gauge ABAM cable directly connecting to DS1 interfaces:

| Compensation | Length (feet) | Length (m) |
|--------------|---------------|------------|
| 1 (default)  | 0000–0266     | 000–081    |
| 2            | 0266–0532     | 081–162    |
| 3            | 0532–0798     | 162–243    |
| 4            | 0798–1066     | 243–325    |
| 5            | 1066–1310     | 325–400    |

- **Framing Mode** — Enter **d4** or **esf** (default). This mode must match the method used on the other end of the link. D4 is a framing format of 12 frames for analog representation on T1 carriers using DS1 signals.
 

To get enhanced performance measurements, the framing mode must be **esf** on the DS1 Circuit Pack form. When **esf** is entered for a TN464F or TN767E or later suffix DS1 circuit pack, a second page of the DS1 Circuit Pack form becomes available to administer ESF Data Link options.
- **Signaling Mode** — Enter **CAS** (Channel Associated Signaling), **robbed-bit**, **isdn-pri**, **isdn-ext**, or **common-chan** (default). This mode must match the method used on the other end of the link.
- **Connect** — Only displays when *Signaling Mode* is **isdn-pri**. Specify what is on the far end of the PBX to control Layer 3 protocol properly. If **pbx** is entered, *Interface* displays. When **line-side** is entered, this implies that the switch is acting as the network side of the isdn-pri interface. This is used to support the Roll About Video capability. Valid entries are **network** (system default), **host**, **line-side**, and **pbx**.
- **Interface** — Only displays when *Connect* is **pbx**. Valid entries are **network**, **peer-master**, **peer-slave**, or **user** (system default). Specify whether the PBX corresponds to the network or user side of the interface, which is needed for the ISDN-PRI Layer 2 protocol, and is also used at

Layer 3 to handle glare conditions. If you are connecting to a network, your side should be **user**. If you are connecting to a host, your side should be **network**.

 **NOTE:**

When the far end is a DEFINITY ECS, the `Interface` field on one end of the connection must be `user` and the other end must be translated as `network`.

For PRI private network protocol layer 2 operations, two other values are possible: **peer-master** and **peer-slave**. Entering either of these values causes two additional fields to appear: `Peer Protocol` and `Side`.

- **Interconnect** — Enter **pbx** or **CO**. If **pbx** is selected, the trunk operates as a tie trunk. If **CO** is selected, the trunk operates as a CO or DID trunk.
- **Country Protocol** — Enter a country code or **etsi** to indicate the type of Primary Rate Interface (PRI) protocol that you want to use on this line. Your choice is determined by the country where the trunk terminates. For more information on country protocols, see [Table 7-3](#) on [7-17](#).
- **Interworking Message** — Appears if `Signaling Mode` is **isdn-pri**. Enter **PROGress** (default) or **ALERTing** to indicate whether a PROGress message or ALERTing message should be sent when interworking a call.
- **Peer Protocol** — Displays if `Interface` is **peer-master** or **peer-slave**. This allows you to administer the peer level protocol that will operate in the private network. The value **Q-SIG** is necessary for implementing QSIG Network Basic Call.

 **NOTE:**

To enter **Q-SIG**, you must have `QSIG Optional Features Basic Call Setup` enabled on the System-Related Customer-Options form.

- **Side** — Appears if `Interface` is **peer-master** or **peer-slave**. This value is used for call collision (glare) resolution at layer 3. The default value of the field changes depending upon which value `Peer Protocol` contains. The default **a** is paired with **peer-master**, and the default **b** is paired with **peer-slave**. The reason for these defaults is that logically, side a is the master at layer 3, in that side a wins the contested trunk in call collision situations. However, it is critical that this administration correctly pairs with the far-end administration. If the far-end is administered as the b side, this field should be set to a regardless of whether layer 2 designation is peer-master or peer-slave, and vice versa.
- **Interface Companding** — Enter **alaw** or **mulaw**. This field displays only if the circuit pack is a TN464C or later.
- **CRC** — Enter **y** to indicate that a cyclic redundancy check is to be performed on transmissions that the board receives.

- **Protocol Version** — Appears under the following conditions:
  - `Country` on the trunk group form is **1** (USA), **10** (UK), **12** (France), **13** (Germany), or **etsi**.

**NOTE:**

Use protocol version `c` only when the country protocol is 1 (USA).

- `Signaling Mode` is **isdn-pri**
- `Connect` is **pbx** or **network**
- `Interface` is **user** or **network**

**WARNING:**

*The AT&T Switched Network Protocol does not support restricted displays of connected numbers. Therefore, if you administer the 1a country-protocol/protocol-version combination on the DS1 form, you cannot administer Send Connected Number to r (restricted) on the ISDN-PRI Trunk Group form, as this causes display problems.*

- **Idle Code** — Enter the 8-digit string to be sent out on idle DS0 channels. The string to be entered must be compatible with the protocol of the country where the trunk terminates.
- **DMI-BOS** — Only displays when `Signaling Mode` is **common-chan**. Enter **y** (default) to activate the Digital Multiplexed Interface Bit Oriented Signaling (DMI BOS) mode.

DMI/BOS is a 24th channel signaling scheme using a DS1 facility that uses 23 message channels and 1 signaling channel (24th). DMI/BOS has greater capacity than the 24th-channel Robbed-Bit Signaling scheme. Entering **n** indicates that the DS1 provides the Lucent Technologies proprietary format; **y** indicates that the DS1/DMI interface provides the DMI format.
- **DCP/ANALOG Bearer Capability** — Displays when `Signaling Mode` is **isdn-pri**. It is used to determine bearer capability encoding. Enter **3.1kHz** (default) or **speech**.
- **MMI Cabling Board** — Enter the slot location (cabinet, carrier, slot) of the multimedia interface circuit pack that is connected to the Expansion Services Module (ESM). This field appears only if MMCH is enabled on the System-Parameters Customer-Options form.
- **MMI Interface** — A display only field that appears only if MMCH is enabled and there is a value in the MMI Cabling Board field.

- **Received Digital Metering Pulse Minimum (ms)** — Only displays when Signal Mode is **CAS** (Channel Associated Signaling), Country Protocol is **21** or **7**, and Interconnect is **co** or **tie**. This field is administerable from **20 ms** to **1000 ms** in increments of 10ms. Visible only for countries that use periodic pulse metering (PPM) as defined in [Table 7-7](#). The default is a value which depends on Country Protocol's entry. The entry for this field must be less than Received Digital Metering Pulse Maximum. [Table 7-7](#) shows the default values for this field.
- **Received Digital Metering Pulse Maximum (ms)** — Only displays when Signal Mode is **CAS** (Channel Associated Signaling), Country Protocol is **21** or **7**, and Interconnect is **co** or **tie**. This field is administerable from **20 ms** to **1000 ms** in increments of 10ms. Visible only for countries that use periodic pulse metering (PPM) as defined in [Table 7-7](#). The default is a value which depends on Country Protocol's entry. The entry for this field must be higher than Received Digital Metering Pulse Maximum. [Table 7-7](#) shows the default values for this field.
- **Received Digital Metering Pulse Value** — (Country Code 21 only) Only displays when Signal Mode is **CAS** (Channel Associated Signaling), Country Protocol is **21** or **7**, and Interconnect is **co** or **tie**. Valid entries are **0** and **1**. It defaults to a value which depends on the Country Protocol field's entry. [Table 7-7](#) shows the default values for this field.

 **NOTE:**

If Country Protocol has a value whose corresponding row in [Table 7-7](#) has only entries of "NA", then the Incoming Digital PPM fields will be blank when Country Protocol is set to that country code.

**Table 7-7. Incoming Digital PPM Signaling Default (per Country Protocol code)**

| Code | Country     | PPM Min (ms) | PPM Max (ms) | PPM Value |
|------|-------------|--------------|--------------|-----------|
| 0    | null        | NA           | NA           | NA        |
| 1    | U.S.        | NA           | NA           | NA        |
| 2    | Australia   | 80           | 180          | 0         |
| 3    | Japan       | NA           | NA           | NA        |
| 4    | Italy       | 120          | 150          | 1         |
| 5    | Netherlands | 90           | 160          | 0         |
| 6    | Singapore   | NA           | NA           | NA        |

*Continued on next page*

Table 7-7. Incoming Digital PPM Signaling Default (per Country Protocol code) — *Continued*

| Code | Country        | PPM Min (ms) | PPM Max (ms) | PPM Value |
|------|----------------|--------------|--------------|-----------|
| 7    | Mexico         | 20           | 180          | 1         |
| 8    | Belgium        | 20           | 180          | 1         |
| 9    | Saudia Arabia  | NA           | NA           | NA        |
| 10   | UK             | NA           | NA           | NA        |
| 11   | Spain          | 50           | 220          | 0         |
| 12   | France         | NA           | NA           | NA        |
| 13   | Germany        | NA           | NA           | NA        |
| 14   | Czech Republic | 40           | 340          | 1         |
| 15   | Russia CIS     | NA           | NA           | NA        |
| 16   | Argentina      | 10           | 180          | 1         |
| 17   | Greece         | 100          | 180          | 1         |
| 18   | China          | NA           | NA           | NA        |
| 19   | Hong Kong      | NA           | NA           | NA        |
| 20   | Thailand       | 20           | 180          | 1         |
| 21   | Macedonia      | 120          | 150          | 1         |
| 22   | Poland         | 100          | 150          | 0         |
| 23   | Brazil         | NA           | NA           | NA        |

- **Slip Detection** — Enter **y** to enable the slip-rate status of this circuit pack to be used by maintenance software to determine whether an excessive frame slip rate exists. Enter **n** (default) when DMI is used or when testing is not required.

**NOTE:**

Those DS1 facilities that are used to provide the primary and secondary synchronization references should be administered for slip detection **y**. Typically, those other DS1/T1 spans that are used for data applications and which are used as a synchronization service should also be administered for slip detection. This excludes all T1-spans connecting channel banks, unless the channel bank is externally timed. Normally, those DS1/T1 spans that are used exclusively for voice and that are not designed as the primary or secondary synchronization source, should be administered for slip detection **n**.

The digital switch maintains a slip count record for each DS1 interface. The slip count is used to determine if the T1-span is experiencing errors and, if so, the severity of the errors (type alarm). Option **y** enables switching between the primary, secondary, or internal high-accuracy clock.

 **NOTE:**

If as many as 50 percent of those spans that are administered for slip detection are experiencing slips (with respect to the primary), then a decision is made to switch to the secondary.

- **Near-end CSU Type** — Appears only when the DS1 circuit pack is a TN767E or TN464F or later suffix model, `Bit Rate` is **1.544** and `Country Protocol` is **1** (U.S.). Enter **other** or **integrated**.
  - The value **other** indicates that no CSU is attached to the DS1 facility, or that the CSU is an external unit. No options are available for administering the CSU.
  - The value **integrated** indicates that a 120A CSU module is attached to the DS1 board. This integrated CSU (ICSU) can accept software administrable option downlinks and perform the enhanced ICSU functionality if the following conditions are met. The correct suffix of DS1 circuit pack (TN767E or TN464F or later) must be administered via a circuit pack form or must be installed in the PBX. When you enter a value of **integrated**, a second page of the DS1 Circuit Pack form is available to administer CSU module options.

**Alarm When PRI Endpoint Detached** — Displays only when `Connect` is **line-side**. Enter **y** if the UDS1 circuit pack is connected to Roll About Video equipment. (Normally if the video equipment is disconnected, off-board alarms are raised to indicate the loss of connectivity from the system). Valid entries are **y** (default), and **n**.

If you enter **n** in this field, when the UDS1 circuit pack detects a loss of signal, it assumes that the equipment is disconnected and no alarms are raised.

## Page 2 of the form

```
DS1 CIRCUIT PACK

ESF DATA LINK OPTIONS

Network Management Protocol: tabs
Send ANSI-T1.403 One-Second Performance Reports? n
Far-end CSU Address: b

INTEGRATED CSU OPTIONS

Transmit LBO: 0db
Receive ALBO: -26db
Upon DTE LOS: loopback

CPE LOOPBACK JACK OPTIONS

Supply CPE Loopback Jack Power? n
```

### Screen 7-7. DS1 Circuit Pack form (page 2 of 2)

Page 2 of the form appears only when: the version is V3 or greater; the DS1 circuit pack is TN767E, TN464F, or later release; and Framing Mode is **esf** or Near-end CSU Type is **integrated**.

#### ⇒ NOTE:

The following three fields appear only if Framing Mode is **esf**.

- **Network Management Protocol** — Enter **tabs** (default).
- **Send ANSI-T1.403 One-Second Performance Reports** — Appears only when the Network Management Protocol is **tabs**. Enter **y** or **n** (default).
- **Far-end CSU Address** — Appears only when the Network Management Protocol is **tabs**. This field administers the transmit direction address used for the **ESF data link** command. Enter **a** or **b** (default).

#### ⇒ NOTE:

The following four fields appear only if Near-end CSU Type is integrated:

- **Transmit LBO** — (Transmit Line Build-Out) The amount of fixed loss inserted in the transmit direction. Enter **0db** (default), **-7.5db**, **-15db**, or **-22.5db**.
- **Receive ALBO** — (Receive Automatic Line Build-Out) The gain is inserted automatically in the receive direction to compensate for line losses. Enter **26db** (default) or **36db**.

- **Upon DTE LOS** — Identifies how the signal should be handled if the signal is lost (LOS) from the DTE (DS1 circuit pack) towards the network. Enter **loopback** (default) for returning the network signal to the network, or enter **ais** to send an unframed all-ones signal to the network (the AIS or Blue Alarm).
- **Supply CPE Loopback Jack Power** — Enter **y** if the DS1 board should supply power to the CPE Loopback Jack equipment during loopback testing. Otherwise, enter **n** (default).

### Implementation note

The fields that appear on a particular screen vary depending upon the type of circuit pack being administered, the speed, signaling mode, and so on.

## Digit Absorption

---

This form implements up to 5 digit absorption lists. The form may be required for each CO and FX trunk group connected to a step-by-step CO. Each outgoing digit string from the switch to the step-by-step CO is treated per entries in the "Absorption Treatment Assignment" section of the form.

### Administration commands

---

Use the following commands to administer the Digit Absorption form

| Action  | Object           | Qualifier <sup>1</sup>  |
|---------|------------------|-------------------------|
| change  | digit-absorption | 0-4                     |
| display | digit-absorption | 0-4 [print or schedule] |

- 
1. Brackets [ ] indicate the qualifier is optional.

### Form instructions

---

 **NOTE:**

If `Expected Digits` on the Trunk Group form is blank, you cannot administer Digit Absorption.

Pages 1–8 of the form

Page 1 of 1

DIGIT ABSORPTION

List Number:     

ABSORPTION TREATMENT INFORMATION (All selections must be from same group)

|           | Choice | Meaning   |
|-----------|--------|---|
| Group I.  | A      | Digit not absorbed.   |
|           | B      | Digit absorbed repeatedly.  |
|           | C      | Digit absorbed once with no further absorption.   |
| Group II. | A      | Digit not absorbed.   |
|           | D      | Digit absorbed only if it is the first digit.   |
|           | E      | Digit absorbed only if it is the second digit and the first digit was already absorbed. |
|           | F      | Digit asorbed only if it is the first or second digit.                                  |

ABSORPTION TREATMENT ASSIGNMENT (select treatment (A-F) for each digit below)

|      |      |      |      |      |
|------|------|------|------|------|
| 0: A | 2: A | 4: A | 6: A | 8: A |
| 1: A | 3: A | 5: A | 7: A | 9: A |

Screen 7-8. Digit Absorption form (page 1 of 1)

- **List Number** — A display-only field when accessed during administration using a command such as change or display. When completing a paper form, enter a list number **0**, **1**, **2**, **3**, or **4**. The list number is referenced via field entry on the associated trunk group. Up to five different Digit Absorption forms may be administered.
- **ABSORPTION TREATMENT ASSIGNMENT** — Enter a desired treatment letter (**A** through **F**); default is **A**. All choices for the digits 0 through 9 must be taken from the same group (Group I or Group II).

## ISDN Numbering — Private

This form supports Private Numbering Plans (PNP). It allows you to specify the digits to be put in the Calling Number IE, Connected Number Information Element (IE), and the QSIG Party Number for extensions in the Private Numbering Plan.

### Administration commands

Use the following commands to administer the ISDN Numbering - Private form

| Action  | Object | Qualifier         |
|---------|--------|-------------------|
| change  | isdn   | private-numbering |
| display | isdn   | private-numbering |

### Form instructions

Page 1 of 1

ISDN NUMBERING - PRIVATE FORMAT

|                                     |                                      |
|-------------------------------------|--------------------------------------|
| Network Level: <input type="text"/> | PBX Identifier: <input type="text"/> |
| Level 2 code: <input type="text"/>  | Deleted Digits: <input type="text"/> |
| Level 1 code: <input type="text"/>  |                                      |

Screen 7-9. ISDN Number — Private Format form (page 1 of 1)

- Network Level** — Enter the value of the highest regional level employed by the PNP network. Valid entries are **0**, **1**, **2**, or blank (default). Use the following table to find the relationship between the network level and the Numbering Plan Identification/Type of Number (NPI/TON) encoding used in the Calling Number and/or Connected Number IEs in addition to the QSIG Party Number.

| Network Level | NPI | TON              |
|---------------|-----|------------------|
| 0             | PNP | local            |
| 1             | PNP | Regional Level 1 |
| 2             | PNP | Regional Level 2 |

 **NOTE:**

If `Network Level` is left blank and `Send Calling Number` and/or `Send Connected Number` is **y** or **r** with **private** specified for `Numbering Format` on the ISDN Trunk Group form, the `Calling Number` and/or `Connected Number IEs` will not be sent. If the field is left blank but **private** has been specified in `Numbering Format` on the ISDN Trunk Group form, the `Identification Number` (PartyNumber data type) is sent for QSIG PartyNumbers encoded in ASN.1-defined APDUs. In this case, the ASN.1 data type containing the PartyNumber (PresentedAddressScreened, PresentedAddressUnscreened, PresentedNumberScreened, or PresentedNumberUnscreened) is sent marked as “PresentationRestricted” with “NULL” for the associated digits.

- **Level 2 Code** — Enter the switch’s second level regional code in the network. You can enter up to 5 numbers (**0 - 9**), or you can enter a blank (default). You can enter numbers only if `Network Level` is **2**. Administer this field carefully. The system will not check to ensure that you have entered a Level 2 Code that supports the network level you entered in `Network Level`. You will be restricted from administering a non-blank entry if the `Network Level` specified above is less than **2** or blank. However, because blank regional codes are valid, an entry is not required if `Network Level` is **2**.
- **Level 1 Code** — Enter the switch’s first level regional code in the network. You can enter up to 5 numbers (**0 - 9**) or you can enter a blank (default). You can enter a non-blank value only if `Network Level` is **1** or **2**. Administer this field carefully. The system will not check to ensure that you have entered a Level 1 Code that supports the network level you entered in `Network Level`. You will be restricted from administering a non-blank entry if the `Network Level` specified above is less than **1** or blank. However, because blank regional codes are valid, an entry is not required if `Network Level` is **1** or **2**.
- **PBX Identifier** — Similar to a Listed Directory Number in the public network, this field prepended with the regional codes administered above allows the PBX to be uniquely identified in the network. Enter up to 5 numbers (**0 - 9**), or you can enter a blank (default).
- **Deleted Digits** — Enter the number of digits to be deleted from the most significant digits of local extensions prior to sending in the `Calling` and/or `Connected Number IEs` as well as the QSIG PartyNumber. This allows UDP network numbers to be converted to PNP Complete Numbers. Valid entries are **0** (default), **1**, or **2**.

## ISDN Numbering — Public/ Unknown

This form supports the ISDN Call Identification Display feature. The feature provides a name/number display for display-equipped stations within an ISDN network. The system uses the caller's name and number and displays it on the called party's display. Likewise, the called party's name and number can be displayed on the caller's display.

The form allows you to specify the desired digits for the Calling Number IE and the Connected Number IE (in addition to the QSIG Party Number) for any extension in the Public and/or Unknown Number Plans.

Administer these forms if either Send Calling Number, Send Connected Number is specified, or Supplementary Service Protocol is **b** on the trunk group form.

### NOTE:

If the table is not properly administered and Send Calling Number or Send Connected Number is **y** or **r** and Numbering Format on the ISDN Trunk Group form is **public** or **unknown**, the Calling Number and Connected Number IE are not sent. If the table is not administered, but Send Calling Number or Send Connected Number is **public** or **unknown**, the Identification Number (PartyNumber data type) is not sent for QSIG PartyNumbers. In this case, the ASN.1 data type containing the PartyNumber (PresentedAddressScreened, PresentedAddressUnscreened, PresentedNumberScreened, or PresentedNumberUnscreened) will be sent marked as "PresentationRestricted" with "NULL" for the associated digits.

## Administration commands

Use the following commands to administer the ISDN Numbering - Public Unknown form

| Action  | Object | Qualifier                |
|---------|--------|--------------------------|
| change  | isdn   | public-unknown-numbering |
| display | isdn   | public-unknown-numbering |

**Form instructions**

---

**Pages 1 of the form**

| ISDN NUMBERING - PUBLIC/UNKNOWN FORMAT |          |            |                  |         |          |            |                  |
|--|----------|------------|------------------|---------|----------|------------|------------------|
| Ext Len                                | Ext Code | CPN Prefix | Total CPN Length | Ext Len | Ext Code | CPN Prefix | Total CPN Length |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |
| -                                      | _____    | _____      | —                | -       | _____    | _____      | —                |

Screen 7-10. ISDN Numbering Public/Unknown form (page 1 of 8)

- **Ext Len** — Specifies the number of digits the extension can have. Enter a number from **0–5** that corresponds to the extension lengths allowed by the dial plan, or leave blank.
- **Ext Code** — Allows for groups of extensions to be administered. The Ext Code can be up to 5-digits long depending on the Ext Len field entry. The entry cannot be greater than the Ext Len field entry. For example, in the case of a 4-digit Ext Len field entry, an Ext Code of 12 is the equivalent of all extensions of the form 12xx, excluding any explicitly listed longer codes. If a code of 123 is also listed, the 12 code is equivalent of all extensions of the form 12xx except extensions of the form 123x. The coding precludes having to list all the applicable 12xx extensions. Valid entries are digits **0–9**, **attd** for attendant, or blank.

 **NOTE:**  
 When "0" alone is entered, the Ext Len field must be 1 and the DDD number must be 10-digits.

- **CPN Prefix** — Specifies the number that is added to the beginning of the extension to form a 10-digit CPN number. The CPN Prefix can be a 6- to 10-digit number, or can be blank. If it is a 10-digit number, the extension number is not used to formulate the 10-digit CPN number. Only digits are allowed in the CPN Prefix column. Leading spaces, or spaces in between the digits, are not allowed.

If the number of digits in the CPN Prefix plus the extension length exceeds 10, excess leading digits of the extension are deleted when formulating the 10-digit CPN number. If the number of CPN Prefix digits plus the extension length is less than 10, the entry is disallowed except for a blank entry. If the CPN Prefix entry is left blank, no calling party number information is provided to the called party and no connected party number information is provided to the calling party.

- **Total CPN Length** — Enter the total number of digits to send. Valid entries are **0–15**, or blank.

## ISDN TSC Gateway Channel Assignments

---

This form is required when the switch is to act as a gateway between a switch that supports the Temporary Signaling Connections (TSC) feature and a non-TSC-compatible switch. The gateway provides interface protocols necessary for communications to exist between a switch administered with Non-Call Associated TSCs in a Signaling Group on the ISDN side and a processor channel (BX.25) on the non-ISDN side. A NCA-TSC is a type of virtual connection established for exchanging user information messages on ISDN-PRI D-channels. There is no B-channel related to the connection.

### Administration commands

---

Use the following commands to administer the ISDN TSC Gateway Channel Assignments form

| Action  | Object           | Qualifier <sup>1</sup> |
|---------|------------------|------------------------|
| change  | isdn tsc-gateway |                        |
| display | isdn tsc-gateway | ['print']              |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.

**Form instructions**

---

| 12: -                               | ---             |     | ---               | -----         | 28: -     | ---             |     | ---               | -----         |
| 13: -                               | ---             |     | ---               | -----         | 29: -     | ---             |     | ---               | -----         |
| 14: -                               | ---             |     | ---               | -----         | 30: -     | ---             |     | ---               | -----         |
| 15: -                               | ---             |     | ---               | -----         | 31: -     | ---             |     | ---               | -----         |
| 16: -                               | ---             |     | ---               | -----         | 32: -     | ---             |     | ---               | -----         |

Screen 7-11. ISDN TSC Gateway Channel Assignment form

- **Sig Group** — Used to indicate the Signaling Group to which the NCA-TSC belongs. Default is blank.
- **Adm'd NCA TSC Index** — Used to indicate the administered NCA-TSC that acts as one endpoint of the gateway. Default is blank.
- **Processor Channel** — Used to indicate the processor channel to which the administered NCA-TSC index will be mapped. This processor channel is used as another endpoint of the connection in this gateway assignment. The default is blank.
- **Application** — Used to indicate the feature this gateway is used for. Gateway channels can be used for DCS+ or ISDN-PRI DCS AUDIX feature. Valid entries are **audix** or **dcs**; default is blank.

The Network-Facilities form displays the AT&T Switched Network Services in Predefined Services/Features. See [“ISDN-BRI trunk group” on page 7-198](#) or [“ISDN-PRI trunk group” on page 7-219](#) for a list of predefined Services Types.

- **Name** — Contains up to 15 alphanumeric characters to specify the name of the indicated Service/Feature.
- **Facility Type** — A **0** indicates that the associated entry is a feature, and a **1** indicates the associated entry is a service. A **2** indicates that the associated entry is of type incoming. A **3** indicates that the associated entry is of type outgoing.

**NOTE:**

Types 2 and 3 can be administered if `Usage Allocation Enhancements` on the `System-Parameters Customer-Options` form is enabled.

- **Facility Coding** — Contains five binary values that specify the ISDN encoding value of the associated Service/Feature.

**NOTE:**

This field does not display if `Facility Type` is either **2** or **3**.

The additional Services/Features area on the form is available for new services and features. The number of entries available depends on system memory and configuration.

## PRI Endpoint

---

This form administers PRI Endpoints for the Wideband Switching feature.

### NOTE:

A PRI Endpoint with a width greater than 1 may be administered only if the Wideband Switching feature has been enabled on the System-Parameters Customer-Options form.

A PRI Endpoint is an endpoint application connected to line-side ISDN-PRI facilities and has standard ISDN-PRI signaling interfaces to the system. For information on endpoint applications connected to line-side non-ISDN T1 or E1 facilities, see [“Access Endpoint” on page 7-72](#) in this module.

A PRI Endpoint is defined as 1–31 adjacent DS0s/B-channels, addressable via a single extension, and signaled via a D-channel (Signaling Group) over a standard T1 or E1 ISDN-PRI interface.

### Administration commands

---

Use the following commands to administer the PRI Endpoint form.

| Action  | Object       | Qualifier <sup>1</sup>                       |
|---------|--------------|--|
| add     | pri-endpoint | extension or 'next'                          |
| change  | pri-endpoint | extension                                    |
| display | pri-endpoint | extension ['print' or 'schedule']            |
| list    | pri-endpoint | extension ['count' X]['print' or 'schedule'] |
| remove  | pri-endpoint | extension                                    |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.

## Form instructions

```

add pri-endpoint next                                     Page 1 of 1
                                                    PRI ENDPOINT

      Extension: 300
      Name: 27 character PRI Endpoint 1
      (Starting) Port:                               Width: 1
      Originating Auto Restoration? n                Signaling Group:
      COR: 1                                         COS: 1
      TN: 1                                         Simultaneous Calls? n
      Maintenance Tests? y

                                                    WIDEBAND SUPPORT OPTIONS

      H0? n
      H11? n
      H12? n
      NXDS0? y   Contiguous? n
    
```

### Screen 7-13. PRI Endpoint form

- **Extension** — Display-only field when the form is accessed using an administration command such as **change** or **display**. This is the extension number used to access the PRI endpoint. Enter a valid unassigned extension number when completing a paper form. Default is blank.
- **Name** — Enter up to 27 alphanumeric characters to identify the endpoint. Default is blank.
- **(Starting) Port** — Enter the seven-character starting port of the PRI Endpoint.

The entry breaks down as follows:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 22 (R5r and later configurations)  |
|            |                | 01 through 03 (R5si and later configurations) |
|            |                | 01 through 02 (G3s)                           |
| 3          | Carrier        | A through E                                   |
| 4-5        | Slot Number    | 01 through 20                                 |
| 6-7        | Circuit Number | 01 through 31 (DS1 Interface ports)           |

- **Width** — Enter the number of adjacent DS0 ports (**1** to **31**), beginning with the specified Starting Port, that make up the PRI Endpoint. A width of **6** defines a PRI Endpoint that can support data rates up to 384 Kbps. This field cannot be blank.

- **Originating Auto Restoration** — Enter **y** to automatically restore calls originating from this PRI Endpoint (while maintaining endpoint call status) in the case of network failure if the call is over SDDN network facilities. Default is **n**.
- **Signaling Group** — Enter the D-channel or D-channel pair that will provide the signaling information for the set of B-channels that make up the PRI Endpoint.  
  
Valid entries are: **1** to **166** (R5r and later configurations), **1** to **8** (R5si and later configurations), and **1** to **4** (G3s). Default is blank.
- **COR** — Enter the appropriate class of restriction (COR) number from **0–95**, to determine calling and called party privileges. Default is **1**.
- **COS** — Enter the appropriate COS number from **0–15**. The COS is administered (see COS form instructions) to determine a certain class of features that can be activated by, or on behalf of, the endpoint. Default is **1**.
- **Maintenance Tests** — Enter **y** (default) to run hourly maintenance tests on this PRI Endpoint. Entering **n** disables the hourly maintenance tests for this PRI Endpoint.
- **Simultaneous Calls** — Enter **y** to specify that multiple simultaneous calls can be placed to/from the PRI Endpoint. Default is **n**.
- **H0** — Enter **y** to specify the ISDN information transfer rate for 384 Kbps of data, which is comprised of six B-channels. When a PRI Endpoint is administered to support H0, the hunt algorithm to satisfy a call requiring 384 Kbps of bandwidth uses a fixed allocation scheme. Default is **n**.
- **H11** — Enter **y** to specify the ISDN information transfer rate for 1536 Kbps of data, which is comprised of 24 B-channels. When a PRI Endpoint is administered to support H11, the hunt algorithm to satisfy a call requiring 1536 Kbps of bandwidth uses a fixed allocation scheme. Default is **n**.
- **H12** — Enter **y** to specify the ISDN information transfer rate for 1920 Kbps data, which includes 30 B-channels. When a PE is administered to support H12, the hunt algorithm to satisfy a call requiring 1920 Kbps of bandwidth uses a fixed allocation scheme. Default is **n**.
- **NXDS0** — Enter **y** to specify the NXDS0 multi-rate service. Default is **n**.

- **Contiguous?** — Specifies whether to hunt contiguous NXDS0 channels. This field only appears if **y** is entered in NXDS0.

The hunt algorithm to satisfy an NXDS0 call is as follows:

- Enter **y** to specify the "floating" scheme. NXDS0 calls are placed on a contiguous group of B-channels large enough to satisfy the requested bandwidth without constraint on the starting channel (no fixed starting point trunk).

 **NOTE:**

H0 and NXDS0 "floating" scheme cannot both be **y**.

- Enter **n** to specify the "flexible" scheme. NXDS0 calls are placed on any set of B-channels on the same facility as long as the requested bandwidth is satisfied. There are no constraints, such as contiguity of B-channels or fixed starting points.

## Signaling Group

---

This form identifies groups of ISDN-PRI DS1 interface B-channels for which a given D-channel or D-channel pair carries associated signaling information. The Non-Facility Associated Signaling (NFAS) feature allows a D-channel to convey signaling information for B-channels that are located on DS1 facilities other than the one containing the D-channel. With NFAS, a signaling group does not necessarily correspond to a single DS1 interface. The Signaling Group form is administered to show how B-channels and D-channels are related.

The Signaling Group form also supports Facility Associated Signaling (FAS). The form establishes the fact that a D-channel carries signaling information for all B-channels on its associated DS1 interface, and for no others.

In addition, the form administers Temporary Signaling Connections (TSC) used in support of DCS Over ISDN-PRI D-channel (includes ISDN-PRI D-channel DCS AUDIX).

### Administration commands

---

Use the following commands to administer the Signaling Group form

| Action  | Object          | Qualifier <sup>1</sup>        |
|---------|-----------------|-------------------------------|
| add     | signaling-group | 1-MAX or 'next'               |
| change  | signaling-group | 1-MAX                         |
| display | signaling-group | 1-MAX ['print' or 'schedule'] |
| list    | signaling-group | 1-MAX ['print' or 'schedule'] |
| remove  | signaling-group | 1-MAX                         |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

The port number assigns the primary D-channel in the Signaling Group. For 24-channel facilities, the 24th port is assigned as the D-channel. For 32-channel facilities, the 16th port is assigned as the D-channel. Default is blank.

- **Secondary D-channel** — Displays when Associated Signaling is **n** (indicates NFAS). Enter a 6- to 7-character port number associated with the DS1 Interface circuit pack port used for secondary D-channel signaling:

The entry breaks down as follows:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)  |
|            |                | 01 through 03 (R5si and later configurations) |
|            |                | 01 (R5vs and later configurations)            |
| 3          | Carrier        | A through E                                   |
| 4-5        | Slot Number    | 01 through 20                                 |
| 6-7        | Port           | 16 or 24                                      |

The port number assigns the secondary D-channel in the Signaling Group. For 24-channel facilities, the 24th port is assigned as the D-channel. For 32-channel facilities, the 16th port is assigned as the D-channel. Default is blank.

- **Max Number of NCA TSC** — The maximum number of simultaneous Non-Call Associated Temporary Signaling Connections (NCA-TSCs) that can exist in the Signaling Group. This number includes all NCA-TSCs that are administered on this form and those NCA-TSCs that tandem through the switch in-route to another switch in the network. Default is **0**.
- **Max number of CA TSC** — The maximum number of simultaneous Call Associated Temporary Signaling Connections (CA-TSCs) that can exist in the Signaling Group. Typically, the number of ISDN-PRI trunk group members controlled by the Signaling Group. Default is **0**.
- **Trunk Group For NCA TSC** — The ISDN-PRI trunk group number whose incoming call handling table will be used to handle incoming NCA-TSCs through the Signaling Group. Enter the assigned ISDN-PRI trunk group number whose call handling table will be used to route the incoming NCA TSCs. (An ISDN-BRI trunk group may not be used.) Default is blank.
- **Trunk Group for Channel Selection** — Enter the assigned trunk group number. (An ISDN-BRI trunk group may not be used.) Default is blank.
- **Supplementary Service Protocol** — Determines whether AT&T NCA TSCs or QSIG NCA TSCs are sent over the interface. Valid entries are **a** (AT&T protocol) or **b** (QSIG protocol). Blank is not a valid entry. Default is

a. This field may be set to **b** only if `Basic Supplementary Services` on the `System-Parameters Customer-Options` form is **y**. If this field is **b**, pages 2 through 5 do not appear.

To change this field from **a** to **b**, first check the `Adm'd NCA TSC Index` field on the ["ISDN TSC Gateway Channel Assignments" on page 7-98](#). Make sure no NCA TSC on the `Signaling Group` form is administered as a Gateway Channel. If they are, you must remove the NCA TSC Gateway assignment first before this field can be changed to **b**.

- **Trunk Brd** — Displays when `Associated Signaling` is "n" (indicates NFAS). Default is blank. Enter a 5-character DS1 Interface circuit pack number that has trunk members belonging to this Signaling Group.

The entry breaks down as follows:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)  |
|            |                | 01 through 03 (R5si and later configurations) |
|            |                | 01 (R5vs and later configurations)            |
| 3          | Carrier        | A through E                                   |
| 4-5        | Slot Number    | 01 through 20                                 |

- **Interface ID** — Displays when `Associated Signaling` is "n" (indicates NFAS). Enter an interface ID for the corresponding DS1 Interface circuit pack. In an NFAS Signaling Group, an Interface ID must be assigned to each DS1 facility so that it can be referenced by both interfacing switches. When a call is established between switches, the Interface ID at each end is used to determine which B-channel is to be used to establish the call. The Interface ID numbers on both ends must be the same.

Pages 2 through 5 of the form

| Service/Feature: _____ |            | ADMINISTERED NCA TSC ASSIGNMENT |             |              |  | Page 2 of 5 |          |
|------------------------|------------|---------------------------------|-------------|--------------|--|-------------|----------|
| TSC Index              | Local Ext. | Enabled                         | Established | Dest. Digits | As-needed Inactivity Time-out (min): _____ | Adj. Name   | Mach. ID |
| 1:                     | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 2:                     | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 3:                     | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 4:                     | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 5:                     | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |

| 10:                    | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 11:                    | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 12:                    | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 13:                    | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 14:                    | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 15:                    | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |
| 16:                    | _____      | -                               | _____       | _____        | _____                                      | _____       | _____    |

Screen 7-15. Signaling Group form Administered NCA TSC Assignment (page 2 of 5)

- **Service/Feature** — The service type for all administered NCA-TSCs assigned in this Signaling Group. Valid entries are: **accunet**, **i800**, **inwats**, **lds**, **mega800**, **megacom**, **multiquest**, **nca-tsc**, **operator**, **sdn**, **sub-operator**, **wats-max-bnd**, and Facility Type 0 and 1 user-defined services. Default is blank.
- **As-needed Inactivity Time-out (min)** — The inactivity time-out for as-needed NCA-TSCs assigned in the Signaling Group. An as-needed administered NCA-TSC staying inactive in this time period will be removed from service. Default is blank.
- **TSC Index** — Display-only field. Specifies the administered NCA-TSCs assigned. The administered NCA TSC index represents one DCS or DCS AUDIX logical channel connecting any two switches. The Index number ranges from 1–64.
- **Local Ext** — Used to assign an extension on the switch to the administered NCA-TSC. Enter an unassigned extension number.

**NOTE:**

The extension cannot be previously assigned to another administered NCA-TSC, station, or data module, and so on.

- **Enabled** — Enter "y" to enable the administered NCA-TSC.
- **Establish** — Used to indicate the strategy for establishing this administered NCA-TSC. Valid entries are **permanent** and **as-needed**. An entry of **permanent** means that the administered NCA-TSC can be established by either the near end or the far end. An entry of **as-needed**

means the administered NCA-TSC will be established the first time the administered NCA-TSC is needed. It can be set up either by the near end or far end switch. Default is blank.

- **Dest. Digits** — Used to route the administered NCA-TSC to the far end switch. Valid entries are digits **0** through **9** and the **+**, **\***, and **#** special characters, and can include up to 15 digits. Default is blank.

**NOTE:**

These digits are sent as entered to the destination switch; no routing or other digit manipulation is performed.

- **Appl.** — Specifies the application this administered NCA-TSC is going to be used for. Valid entries are **audix**, **dcs**, and **gateway**. The **audix** entry is used for ISDN-PRI D-channel DCS AUDIX feature. The **dcs** entry is used for the DCS Over ISDN-PRI D-channel feature. The "gateway" entry is used when the administered NCA-TSC will be used as one end in the gateway channel connecting to a BX.25 link. If **gateway** is entered, then the ISDN TSC Gateway Channel Assignments form must be completed. Default is blank.
- **Adjunct Name** — Only displays for R6r and later configurations. Displays when `App1` is **audix**. Enter the name of the AUDIX as it appears on the "Adjunct Names" form.
- **Machine ID** — Used to indicate the far-end PBX or the AUDIX machine to which this administered NCA-TSC will be connected. Default is blank.

## Synchronization Plan

---

This form assigns primary and secondary external synchronization sources. This provides synchronization between the switch and digital facilities that the switch is connected to. When the switch is connected to digital facilities, the switch (both Processor Cabinets and Expansion Cabinets) must be synchronized to the incoming data rate of 8,000 frames-per-second. This timing information reference may be derived from DS1 facilities or from a Stratum 3 external clock. Loss of the reference signal, excessive phase changes, and variation in timing frequency can cause loss of data or dropped data connections. When no external digital facilities, including Stratum 3 external clocks, are present or when a switch is the "master" node of a network providing timing to the rest of the network, the timing can come from an oscillator on the switch's tone/clock circuit pack.

 **NOTE:**

The Synchronization Plan may not be required for some digital connections. The switch's internal clock may suffice.

### Administration commands

---

Use the following commands to administer the Synchronization Plan form.

| Action  | Object          | Qualifier <sup>1</sup>  |
|---------|-----------------|-------------------------|
| change  | synchronization | —                       |
| display | synchronization | ['print' or 'schedule'] |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.

**Form instructions**

**Page 1 of the form**

Page 1 of X

SYNCHRONIZATION PLAN

SYNCHRONIZATION SOURCE (circuit pack location)

Stratum:   

Port Network:   

Primary:                           Secondary:     

| Location                    | Name                        | Slip      | Type                        | Location                    | Name                        | Slip      | Type      |
|-----------------------------|-----------------------------|-----------|-----------------------------|-----------------------------|-----------------------------|-----------|-----------|
| 01C17                       | <u>                    </u> | D         | UDS1-BD                     | <u>                    </u> | <u>                    </u> | <u>  </u> | <u>  </u> |
| 01C18                       | <u>                    </u> | Y         | TBRI-BD                     | <u>                    </u> | <u>                    </u> | <u>  </u> | <u>  </u> |
| <u>                    </u> | <u>                    </u> | <u>  </u> | <u>                    </u> | <u>                    </u> | <u>                    </u> | <u>  </u> | <u>  </u> |
| <u>                    </u> | <u>                    </u> | <u>  </u> | <u>                    </u> | <u>                    </u> | <u>                    </u> | <u>  </u> | <u>  </u> |
| <u>                    </u> | <u>                    </u> | <u>  </u> | <u>                    </u> | <u>                    </u> | <u>                    </u> | <u>  </u> | <u>  </u> |
| <u>                    </u> | <u>                    </u> | <u>  </u> | <u>                    </u> | <u>                    </u> | <u>                    </u> | <u>  </u> | <u>  </u> |
| <u>                    </u> | <u>                    </u> | <u>  </u> | <u>                    </u> | <u>                    </u> | <u>                    </u> | <u>  </u> | <u>  </u> |

NOTE: TN722B & TN464B DS1 sources result in stratum 4, type II synchronization

**Screen 7-16. Synchronization Plan form (page 1 of X)**

- **Stratum** — Enter the stratum level to be used for synchronization. Valid entries are **3** or **4** (default).

**NOTE:**

Stratum 3 capability is only possible when using a TN780 Tone Clock circuit pack.

- **Port Network** — Only displays when **Stratum** is **3**. This is a display-only field.
- **Primary** — Only displays when **Stratum** is **4**. Note that the Primary and Secondary synchronization sources (DS1 or BRI trunk facilities) must be on the same Port Cabinet (that is, PPN, EPN1, or EPN3). Enter a 4- or 5-character circuit pack location number for the circuit pack that will function as the primary synchronization source.

The entry breaks down as follows:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)<br>01 through 03 (R5si and later configurations)<br>01 (R5vs and later configurations) |
| 3          | Carrier        | A through E   |
| 4-5        | Slot Number    | 01 through 20   |

A blank entry means no external source. The clock circuit pack's internal source is the implicit last choice. Only one switch in the network can function as the primary synchronization source.

- **Secondary** — Only displays when *Stratum* is 4. Note that the Primary and Secondary synchronization sources (DS1 or BRI trunk facilities) must be on the same Port Cabinet (that is, PPN, EPN1, or EPN3). Enter a 4- or 5-character circuit pack location number for the circuit pack that will function as a secondary synchronization source.

The entry breaks down as follows:

| Characters | Meaning        | Value   |
|------------|----------------|---|
| 1-2        | Cabinet Number | 01 through 44 (R5r and later configurations)<br>01 through 03 (R5si and later configurations)<br>01 (R5vs and later configurations) |
| 3          | Carrier        | A through E   |
| 4-5        | Slot Number    | 01 through 20   |

The system will select automatically the secondary circuit pack if the primary circuit has a failure.

### Pages 1–X of the form

- **Location/Name** — Only displays if *Stratum* is 4. Identifies the location and name for each DS1 or BRI trunk circuit pack administered via the DS1 or BRI Trunk Circuit Pack form. These fields are display only.
- **Slip** — Displays as **y** if *Slip Detection* has been enabled for any of the 8 ports on the DS1 Circuit Pack form.
- **Type** — Contains a value for each displayed circuit pack that indicates the circuit pack's maintenance name. For example, UDS1-BD appears for a TN464 circuit pack, and TBR1-BD appears for a TN2185 circuit pack.

Instructions for administering a DS1/DMI interface are provided in *AT&T Generic 1 and System 75 and System 85 DS1/DMI/ISDN-PRI Interface Service Manual*, 555-025-101.

### Implementation notes

---

This is a 6-page form for R6r and later configurations and a 2-page form for R6si and later configurations.

## Trunk Groups — General

---

This section contains the forms and instructions required to administer trunk groups in DEFINITY ECS. See the *DEFINITY ECS System Description Pocket Reference* for capacity information on the maximum number of trunks and trunk groups for each system configuration.

### What are trunks?

---

Communication links called trunks connect two switching systems. These trunks are grouped together through trunk group administration when trunks of the same type are used for the same application.

Trunk group administration allows the system administrator to assign service characteristics to a group of trunks rather than to each trunk individually. Changes can be made and characteristics can be removed on a group basis.

Trunks and access endpoints consume the same resource. Therefore, the sum of trunks and access endpoints cannot exceed the total number of trunks allowed for a particular DEFINITY ECS configuration.

### Trunk group types

---

This section addresses forms for the following trunk group types:

- Access trunk group
- Advanced Private Line Termination (APLT) trunk group
- Centralized Automatic Message Accounting (CAMA) trunk group
- Central Office (CO) trunk group
- Customer Provided Equipment (CPE) trunk group
- Digital Multiplex Interface Bit-Oriented Signaling (DMI-BOS) trunk group
- Direct Inward Dialing (DID) trunk group
- Direct Inward/Outward Dialing (DIOD) trunk group
- Foreign Exchange (FX) trunk group
- Integrated Services Digital Network-Basic Rate Interface (ISDN-BRI) trunk group. (The ISDN-BRI has the same group type as the ISDN-PRI. The difference is in the trunk member ports. The ISDN-BRI ports belong to the ISDN-BRI circuit packs (TN2185). The ISDN-PRI ports belong to the DS1 circuit packs (TN464).)
- Integrated Services Digital Network-Primary Rate Interface (ISDN-PRI) trunk group
- Personal Central Office Line (PCOL) trunk group
- Release Link Trunk (RLT) group

- Tandem trunk group
- Tie trunk group
- Wide Area Telecommunications Service (WATS) trunk group

## **Introduction to trunk groups**

---

This section contains three types of material.

- An overview of various trunk-related terms and concepts
- Descriptions of fields displayed on many of the various trunk group forms, organized alphabetically, by the form on which they appear
- Trunk group forms and fields unique to a particular trunk group

For specific technical information about trunk groups, see the *DEFINITY Communications System Generic 1 and System 75 and System 85 DS1/DMII/ISDN-PRI Reference*.

## **Trunk characteristics**

---

A trunk is named for its transmission characteristics and can be analog or digital depending on the type of signals it carries. One transmission characteristic is signaling, which is the transmission of supervision, address, alerting, or other switching information.

A trunk is further classified as one of the following:

- One-way incoming trunk — A local trunk that can be selected (seized) by the far-end connected switch.
- One-way outgoing trunk — A trunk that can be seized by the local switch to call the far-end switch.
- Two-way trunk — A trunk that can be seized at either end of the connected switches.

## **Supervisory signaling**

---

Supervisory signaling establishes or sets up the connection of the local switch to the distant switch. In general, supervisory signaling can be thought of in two phases:

- Seizure signal — The originating office's signal for a request for service from the distant office.
- Start dial signal — The distant office's acknowledgment that it is ready to accept dialing from the originating office.

## Types of supervisory signaling

The following types of supervision signaling are used in trunks.

- **Ear & Mouth (E&M) supervision** — A symmetric signaling scheme used on private network trunks in which dc voltage levels are sent over E&M leads. The E&M leads are separate from the transmission path. E & M signals indicate on-hook/off-hook states of each end of the connection path.
- **Ground Start (GS) supervision** — A supervisory signaling scheme used on public network trunks in which ground is applied on the tip (T) lead by the CO and on the ring (R) lead by the switch. For example, the calling switch on a call to a CO using an outgoing trunk interface seizes the outgoing trunk by placing a ground on the trunk interface R lead. The CO recognizes the trunk seizure as a request for service and grounds the trunk T lead to indicate to the calling switch that the CO is ready to receive digits. Ground Start trunks are preferred over trunks using Loop Start signaling (description follows) for the following reasons:
  - The tip ground seizure that the distant switch sends minimizes the interval during which a two-way trunk can be seized from both ends (called glare) since the switch can make trunks busy to outgoing calls almost immediately.
  - Ground Start trunks provide a positive indication of a distant switch's disconnect. The removal of the tip ground can be acted on:
    - To prevent a station line from being connected to CO dial tone by remaining off-hook after completing a call. This prevents a restricted station from making an unauthorized call after placing an authorized call via the attendant.
    - To hold the trunk busy until the CO disconnects so that another switch cannot seize the trunk and be connected to the CO party of the previous call.
- **Loop Start (LS) supervision** — A supervisory signaling scheme used between a telephone and a switch in which the telephone or far-end office completes the loop current path formed by the trunk leads (wires). The circuit provides one signaling state when it is open and another when it is closed. A third signaling state is achieved by changing the direction or magnitude of current in the loop. The most preferred method of loop start signaling is reverse battery signaling. Disconnect times when using loop start signaling can result in delays of up to 10–20 seconds. In addition, glare, as described in ground start, is possible.
- **Reverse Battery (RB) supervision** — A supervisory technique on one-way trunks that uses open and closure signals from the originating end and reversals of battery and ground from the terminating end (normally used on direct inward dialing trunks).

## Transmission of address

With signaling there are three types of transmission of address. Transmission of address is the method of signaling used to represent digits and/or characters for called numbers, calling numbers, and so on. The methods of addressing are dial pulse (DP), dual tone multifrequency (DTMF), and multifrequency (MF) addressing.

- **DP addressing** — A means of signaling that consists of regular momentary interruptions of a direct or alternating current at the sending end. The number of interruptions corresponds to the value of a digit or character (alternating current is not used by switches). The interruptions usually are produced by a rotary telephone dial, or may be produced by a sender in a switching system.
- **DTMF addressing** — Signaling arrangements (commonly known as touch-tone) that consist of two, simultaneous, dialing signals. One tone is from a low group of four frequencies. The other tone is from a high group of four frequencies. Both tones correspond to digits, letters, or characters (0–9, A–Y, or \* and #). One of the tones (1,633 Hz) from the high group is a spare.
- **MF addressing** — Signaling arrangements that make use of only 2 frequencies out of 6 to represent 10 decimal digits (0–9) and 5 auxiliary signals. MF signals are used for called number addressing, calling number identification. They also report whether the far end is ringing or busy.

## Transmission of alerting

Network trunks operate as automatic, immediate start, dial tone, wink start, or delay dial according to the type of start dial signal (alerting) the switch sends out or expects to receive. The different transmissions of alerting are as follows:

- **Automatic** — The originating switch sends no digits or start dial signal and expects the terminating switch to complete the call. The call usually is completed by the attendant or other service such as Centralized Attendant Service (CAS).
- **Immediate start** — The originating switch sends digits immediately without waiting for a start dial signal from the terminating switch.
- **Dial tone** — The terminating switch sends precise dial tone to the originating switch. This indicates the terminating switch is ready to receive digits.
- **Wink start** — The terminating switch sends a wink start (momentary off-hook) signal to the originating switch. This indicates the terminating switch is ready to receive digits.
- **Delay dial** — The terminating switch sends a delay dial signal (an off-hook signal followed by an on-hook signal) to the originating switch. This indicates the terminating switch is ready to receive digits.

With digital trunks, signaling schemes are basically the same as for analog trunks when establishing a call. Supervisory, addressing, and alerting have been carried over to the digital trunks. These schemes are handled in a variety of ways to indicate particular calling states, such as on-hook, off-hook, ringing, not ringing, and so on, by using A and B bit-timed signaling. A and B bits carry a 0 or 1 depending on the type of trunk, the near-end channel unit type, far-end channel type, trunk condition (open loop, loop closure, reverse battery, and so on), and whether it is transmit or receive signaling. In addition to the above, see [“DS1 Circuit Pack form” on page 7-79](#) for trunk-related terms associated with DS1 trunk interfaces.

## **Private network trunks**

---

Tie trunks and tandem trunks are private network trunks. The tie trunks that interconnect the switches of a private network are universal. This means the trunks can be administered with a variety of translation encodes. The originating switch can recognize any start dial signal (precise dial tone, wink start, or delay dial) that the terminating switch sends. If the originating switch does not receive one of these start dial signals, it can be administered to send digits after an administered time-out interval. The time-out interval is the amount of time the originating switch waits before sending digits.

Tie trunks are further classified according to the type of signal (analog or digital) they carry.

## **Analog tie trunks**

Analog tie trunks are communications paths that carry voice and voiceband data communication. The term voice implies that sound is transferred into electrical form and transmitted within an approximate voiceband of 300 Hz to 3,400 Hz. Voiceband data implies that data is transmitted within the voiceband and requires a conversion resource (modem) at both ends of the connection. The data-transmission rate for analog tie trunks depends on the data-handling capability of the modems in the connection.

Other factors that affect the data rate are the number of tie trunks in the connection and the technology of any multiplex systems used in the facilities. Generally, for data rates up to 300 bps, a connection can have five tie trunks in tandem. For data rates greater than 300 bps up to 2,400 bps, a connection can have up to three tie trunks in tandem. For data rates greater than 2,400 bps up to 4,800 bps, a connection can have up to two tie trunks in tandem.

Analog tie trunks, used in unswitched connections, can support up to 9,600 bps.

## **Release Link trunk**

A special type of private network tie trunk is a Release Link Trunk (RLT). RLTs are used between a central or main location and a branch location to provide Centralized Attendant Service. It functions as a one-way outgoing circuit from the

branch locations and a one-way incoming to the main location. RLTs participate in the redirection of incoming calls originally directed to the branch location to attendants at the main location, and handle call completion back to the branch location.

### **Advanced Private Line Termination trunk**

Another special type of trunk is the Advanced Private Line Termination (APLT) trunk. APLT provides access to and termination from CO-based private networks; namely, Common Control Switching Arrangements (CCSA) and Enhanced Private Switched Communications Service (EPSCS). APLT trunks are physically the same as those used for analog tie trunks, where the trunk signaling is compatible with EPSCS and CCSA network switches. The outgoing APLT trunk repeats any number of digits to the private network as dialed. APLT trunks can tandem through the PBX from EPSCS network only; CCSA networks require an attendant to complete the call.

### **Digital Tie trunk**

The digital tie trunk is a high-speed and a high-volume trunk interface to a T1 or E1 carrier. It uses a digital signal (DS1). By multiplexing 24 64-kbps digital channels onto a single 1.544-Mbps T1 carrier, or 32 64-kbps digital channels onto a single 2.048-Mbps E1 carrier, DS1 offers an economical alternative to the analog tie trunk as well as a high-speed fully digital (without modems) connection between the switches.

The maximum per-channel data rate for DS1 is 64 Kbps, and it can carry voice, voiceband data, or high-speed data communications.

### **Digital Multiplex interface**

The DS1 tie trunk is also used for Digital Multiplex Interface Bit-Oriented Signaling (DMI-BOS). DMI-BOS provides high-speed communications over digital transmission facilities between a host computer and a DEFINITY ECS. The DMI-BOS trunk uses the A bit for signaling to provide wink-start dial-repeating into the switch and automatic out or two-way wink start.

## **Public network trunks**

---

Public network trunks are used to connect a private network switch to a public network switch (central office). They can be analog or digital trunks.

In reference to a central office, the term local applies to a switch within the local exchange area. An exchange area has a single-uniform set of charges for telephone service and may be served by more than one CO. Within an exchange area, a call between any two points is a local call.

Public network trunks also function as special access to AT&T Communications (AT&T-C) toll network. AT&T-C provides such services as MEGACOM, MEGACOM 800, and ACCUNET.

## Public network trunks

The following are public network trunks:

- **Central Office (CO) Trunk** — A one-way outgoing, one-way incoming, or two-way trunk. It connects the switch to a CO within the local exchange area. A direct outward dialing (DOD) trunk connects the switch to a CO. These trunks allow terminal (station) users to place calls to a public network central office directly (without attendant assistance).
- **Foreign Exchange (FX) Trunk** — A one-way outgoing, one-way incoming, or two-way trunk. It connects the switch to a CO outside the local exchange area. These trunks give a caller direct access to a central office outside the local exchange area without having to use the public network.
- **Wide Area Telecommunications Service (WATS) Trunk** — A one-way outgoing or one-way incoming trunk. It connects the switch to a CO equipped to handle WATS calls. The outgoing trunks allow a customer, for a monthly charge, to place outgoing station-to-station calls to telephones in a defined service area. The service area has one or more geographic areas known as WATS bands. Incoming trunk calls are completed by the attendant or other service.

A one-way incoming trunk connecting the switch to a CO equipped to handle 1-800 service calls is an inward WATS. For a monthly charge, customers can receive incoming station-to-station calls from telephones in a defined service area without charge to the caller.

- **Direct Inward Dialing (DID) Trunk** — A one-way incoming trunk. It connects the switch to a local CO. These trunks allow calls from the public network to complete to terminals (stations) assigned to a private network switch without attendant assistance.
- **Direct Inward/Outward Dialing (DIOD) Trunk** — A trunk that allows both DID and CO functionality on a single trunk port. On outgoing calls, it is a CO call. On incoming and two-way calls, it is either a DID or CO call. See the appropriate category in this list for further definition.

## Digital public network trunks

The digital public network trunk provides a DS1 interface to the central office over T1 or E1 carrier. The DS1 public network trunk provides an interface to CO, FX, WATS, and DID. The DS1 interface supports incoming and outgoing dial types of ground start, loop start, auto/auto, auto/delay, auto/immed, and auto/wink. Signaling may be robbed-bit or common-channel depending on the trunk type and whether the dial-type is incoming or outgoing. The interface may be used to connect the switch to a toll office directly using wink-start tie trunks for two-way access to the toll network.

## Field descriptions — trunk group forms

---

See the following for descriptions of fields displayed on many of the various trunk group forms. Descriptions are organized by the form they appear on and are listed alphabetically within each form. Fields unique to a particular form are presented under that form.

Page 1 of the form

- **Analog Gain** — Displays if `Country` is **15** and `Trunk Type (in/out)` is **2-wire-ac**, **2-wire-dc**, or **3-wire**. This field allows you to specify a boost in analog gain for the TN2199 port in the direction toward the switch. Enter **a** (-3dB gain boost), **b** (-6dB gain boost), **c** (-8dB gain boost), or **none** (default). This applies *only* to the TN2199 port.
- **Answer Supervision Timeout** — Used for all trunk types, except DID, to indicate the amount of time in seconds the system allows for a call to be answered before beginning a CDR record of a call. This interval begins as soon as the outgoing trunk is seized. Valid entries are **0** to **250**; default is **10**. For OCM applications, set Answer Supervision for trunks supporting network answer supervision to **y**. For trunks that do not receive a real answer, this field determines when the CallVisor Adjunct-Switch Application Interface (ASAI) connect event is sent.

### NOTE:

This timeout does not override answer supervision sent from the network or other firmware (DS1 port circuit timers). DS1 firmware sent answer supervision is administered in `Outgoing End of Dial (sec)` on the Administrable Timers page of the trunk group form.

- **Auth Code** — Only displays if `Direction` is **incoming** or **two-way**. Enter **y** if an authorization code must be dialed to complete incoming calls on the trunk group. This field can only be **y** if `Authorization Codes` is enabled on the System-Parameters Customer-Options form. Default is **n**.
- **Auto Guard** — Enter **y** to prevent repeated seizures of a defective trunk. This field is effective only for TN438B, TN465B, and TN2147 ports. TN438B ports have hardware support for detecting a defective trunk. TN465B and TN2147 ports consider a trunk defective if no dial tone is detected on an outgoing call, and `Outpulse Without Tone` is **n** on the Feature-Related System Parameters form. Default is **n**.
- **BCC (Bearer Capability Class)** — Displays when `Comm Type` is **data**, **avd**, or **rbavd**. Used by the Generalized Route Selection feature and identifies the type of traffic on trunks in the group. The BCC entry is used by far-end tandem switches to select outgoing routing facilities with equivalent BCC classes. Valid entries are **0**, **1**, **2**, **3**, and **4**. Default is **0** for **avd** or **rbavd**, and **2** for **data**.

- **Bit Rate** — Displays when `Comm Type` is **avd** or **rbavd**. It also appears if the `Comm Type` is **data**, but only if `ISDN-PRI` is enabled on the System-Parameters Customer-Options form. Specifies the baud rate to be used by pooled modems. Valid entries are **300**, **1200** (default), **2400**, **4800**, **9600**, and **19200**.
  - **Busy Threshold** — Enter the number of trunk group members that must be busy before the attendant is alerted by the Warning lamp on the Attendant Console. For a TN790, the default is **99**. For a UN331B, the default is **255**.
  - **Call Still Held** — Enter **y** to prevent call collisions by not allowing an outgoing seizure for a period of not less than 140 seconds. This field is used only at the end of an incoming call where the disconnect is initiated by the switch. It effectively will extend the Incoming Glare Guard timer by 140 seconds. This field is effective only for TN438B, TN465B, and TN2147 ports and is used primarily when `Country Code` is 2. Default is **n**.
  - **CDR Reports** — Valid entries are:
    - **y** (default) — CDR records will be generated by completed outgoing calls terminated on this trunk group. If incoming calls are being recorded (`Record Outgoing Calls Only` on the CDR System Parameters form is **n**), then a single CDR record will be generated for answered calls with the call duration.
    - **n** — no CDR records will be generated by calls originated by or terminated on this trunk group.
    - **r** (ring-intvl) — CDR records will be generated for both incoming and outgoing calls. In addition, the following ringing interval CDR records are generated:
      - Abandoned calls — A condition code of “H” is generated indicating the time until the call was abandoned.
      - Answered calls — A condition code of “G” is generated for the interval of start of ring to answer.
      - Calls to busy stations — A condition code of “I” is generated with a recorded interval of 0.
-  **NOTE:**  
For ISDN trunk groups, the `Charge Advice` field affects CDR information. For CO, DIOD, FX, and WATS trunk groups, the `Analog PPM` field affects CDR information.
- **CO Type** — Displays when `Country` is **14** and is applicable only if the trunk group members are administered on a TN464D vintage 2 or greater. This field specifies the type of CO the trunk group is attached to. Valid entries are **analog** (default) and **digital**.

- **Comm Type** — Indicates if the trunk is to be used for voice, data, alternate voice-data (avd), or alternate voice/voice grade data and 56-kbps digital data (rbavd) calls. Valid entries are **avd**, **rbavd**, **voice** (default), or **data**. Type **rbavd** supports access to voice/data SDN service on robbed-bit transmission facilities.

 **NOTE:**

Comm Types of **avd** and **rbavd** require trunk member ports on a DS1 circuit pack. An **rbavd** type requires that the DS1 circuit pack be administered for robbed-bit, or (if mixed mode signaling is allowed on the DS1 circuit pack) ISDN-EXT, or ISDN-PRI. An **avd** type requires that the DS1 circuit pack be administered for either common-chan or CAS signaling.

- **Connected to Toll** — Indicates a loss plan. Enter **y** if connected to a CO toll office. This field displays when `Trunk Type` contains an entry of **auto/...**, **delay/...**, **wink/...**, or **immed/...**. If **n**, `STT Loss` displays.
- **COR** — Enter a class of restriction (COR) number (**0–95**) that reflects the desired restriction; default is **1**.
- **Country** — This field specifies the Country Code for each subscriber line. Valid values are any number between **1–23**, inclusive. The value of this field, in conjunction with the values of `Trunk Termination` and `Trunk Gain`, determines the input and trans-hybrid balance impedance requirements for TN465B, TN2146, and TN2147 ports.
  - If `Country` is **18**, DEFINITY ECS can be administered for Public Network Call Priority (Mode of Release Control, Forced Disconnect, and Rering).
  - If `Country` is **11**, DEFINITY ECS is administered for Public Network Call Priority (Call Retention and Rering).
  - If `Country` is **15**, DEFINITY ECS is administered for Public Network Call Priority (Intrusion and Rering). Also, `Protocol Type` appears for Group Type DID or DIOD.
  - If `Country` is **23** and `Group Type` is either **CO** or **DID**, DEFINITY ECS is administered for Block Collect Calls.
  - If `Country` is **14**, `CO Type` appears for Group Type DID or DIOD.
- **Cut-Through** — Displays when `Outgoing Dial Type` is either **rotary** or **tone**. Enter **y** to allow “cut-through” to the CO trunk.

If the dialed digits are restricted:

- The connection to the CO trunk is dropped.
- Intercept treatment is applied.

Enter **n** (default) and the user will receive switch dial tone. Instead of digits being sent to the CO as they are dialed, they are collected, checked for restrictions, and, if there are no restrictions, the digits are sent to the CO.

- **Cyclical Hunt** — Displays when `Direction` is **two-way** and `Trunk Type` is **loop-start**. Enter **y** (default) if a preferential hunting algorithm is to be used. Otherwise, a linear hunting algorithm will be used.
- **Dial Access** — Enter **y** to allow the trunk group to be accessed via a TAC. Access via the ARS feature is allowed regardless of this entry. Default is **n**.
- **Dial Detection** — Applies only to TN2199 ports. Enter **A-wire** (default) or **B-wire**, as appropriate. The `Country` field must be **15**.
- **Digit Absorption List** — Enter a digit list absorption number, if required, when this trunk group terminates at a step-by-step office. This field specifies the type of absorption as specified on the System Digit Absorption form. Up to five different forms (lists 0 to 4) may be administered. Default is blank.
- **Digit Treatment** — Indicates if digits are to be absorbed or inserted. A blank indicates no digit absorption or insertion. Valid entries are **absorption** or **insertion**, or leave blank. If you enter **absorption** or **insertion**, then you must enter a value in `Digits`.

**NOTE:**

DCS features that use the remote-tgs button (on the remote switch) do not work when the local trunk group deletes or inserts digits on the incoming call. These buttons try to dial a local TAC. Adding or deleting digits defeats this operation and renders the remote feature inoperable. If digit manipulation is needed, use it on the outgoing side, based on the routing pattern. One reason for digit manipulation is insertion of the AAR feature access code (FAC).

- **Digits** — Indicates the digits to be inserted or number of digits to be absorbed. This field is used with `Digit Treatment`; if `Digit Treatment` is not blank, then this field cannot be blank. No entry indicates that no digit absorption or insertion is done. Valid entries are the number of digits to be absorbed (**1–5**) or the actual digits to be inserted (up to 4 digits including the characters **\*** and **#**).
- **Direction** — Enter whether the trunk group is **incoming**, **outgoing**, or **two-way** (default). Note `Direction` administered affects which timers appear on the Administrable Timer page.
- **Disconnect Supervision-In** — Displays when `Direction` is either **incoming** or **two-way**. Default is **y**. Internally, the field is set to **n** if `Direction` is **outgoing**. Enter **y** to indicate that the far-end has the ability to release a trunk when the calling party releases from a call and the system is able to recognize the release signal.
- **Disconnect Supervision-Out** — Displays when `Direction` is either **outgoing** or **two-way**. Default is **n**. Internally, the field is set to **n** if `Direction` is **incoming**. If the field is set to **y**, a warning message appears to alert the user of possible trunk lockups. This field specifies whether trunks in this trunk group provide disconnect supervision when seized outgoing (that is, whether these trunks should be allowed to

participate in outgoing trunk to outgoing trunk calls). This field is set independently of the trunk-to-trunk transfer system parameter, although both options must be set appropriately if outgoing trunk to outgoing trunk transfers are desired.

- **Disconnect Timing (msec)** — Specifies the minimum time period in ms that is required for recognition of disconnect by the serving central office or far-end switch. The time interval must be in increments of 10 (from **140–2550** ms); default is **500**. This timer is not used for ports on a circuit pack that can receive the administrable Incoming Disconnect and Outgoing Disconnect timers. These latter two timers replace the former.
- **Disconnect Type** — Displays only if `Country` is **15** and `Trunk Type` is **2-wire-ac**, **2-wire-dc**, or **3-wire**. This field indicates which side or user controls the disconnect, where A refers to the *calling* party and B refers to the *called* party. Enter **AandB** or **AorB** (default). This applies *only* to the TN2199 port.
- **Drop Treatment** — Setting to **intercept** indicates that intercept tone is applied on the talk path of DID calls dropped by the terminating party when the originating party is still on the call. Entering **busy** indicates busy tone will be applied, and **silence** (default) indicates no tone will be applied.

**NOTE:**

In Italy, `Drop Treatment` must be administered as **intercept** for all DID trunk groups.

- **DTT to DCO Loss** (Digital Tie to Digital CO Trunk Loss) — Specifies the loss plan used for the trunk group that connects a DIU-CO (Digital Interface Unit at a Central Office) to a DIU-DTT (Digital Interface Unit for a Digital Tie Trunk Interface). Displays when `Trunk Type` is **auto/...**, **delay/...**, **wink/...**, or **immed/..**

This option affects the transmission performance of public network access via a private switch network. Enter **low** if private network users complain about too much loss on calls to the public network, otherwise, **normal** should be used. Valid entries are **normal** (default) and **low**. The entry is based on the following:

- **normal** — Corresponds to a (0, -6) dB gain pair and is used as the default option. (This corresponds to the DTT/EIA DCO port to port configuration as described in *DEFINITY Communications System Generic 1 and System 75 and System 85 DS1/DMI/ISDN-PRI Reference*.)
- **low** — Corresponds to (+3, -3) dB gain pair. Low is used for internetwork applications in which no significant configuration will encounter echo, stability, or overload problems because of reduced loss. With the low gain pair, subscriber station DTMF signals transmitted through the digital class 5 office into the customer network may experience non-recoverable digit mutilation in secondary signaling applications (that is, DTMF signaling after

the connection has been established). (This corresponds to the DTT/ISL DCO port to port configuration as described in *DEFINITY Communications System Generic 1 and System 75 and System 85 DS1/DMI/ISDN-PRI Reference*.)

- **Duplex** — Displays when `Comm Type` is **avd** or **rbavd**. It also appears if `Comm Type` is **data**, but only if `ISDN-PRI` is enabled on the System-Parameters Customer-Options form. Specifies either full or half duplex for the trunk group. Valid entries are **full** (default) or **half**.
- **Expected Digits** — Only displays if `Trunk Signaling Type` is left blank, `Direction` is **incoming** or **two-way**, and `Incoming Dial Type` is **mf**. This field specifies the number of digits that the far-end sends for an incoming connection. If `Digit Treatment` is **absorption**, this field must have a value greater than that in `Expected Digits`. Valid values are between **1** and **18** inclusive.

⇒ **NOTE:**

When you leave `Expected Digits` blank, you cannot administer digit absorption

- **Group Name** — Enter a unique name that identifies the trunk group. Up to 27 characters can be used; default is **OUTSIDE CALL**.
- **Group Number** — Enter a group number when completing a paper form. This is a display-only field when the form is accessed using an administration command such as **add** or **change**.

⇒ **NOTE:**

When supporting DCS, it is required that the far-end node trunk group be assigned the same group number.

- **Group Type** — Enter the trunk group type.

⇒ **NOTE:**

A Group Type of `isdn-pri` can be entered only if `ISDN-PRI` or `ISDN-BRI Trunks` on the System-Parameters Customer-Options form has been enabled.

- **Incoming Destination** — Displays when `Direction` is **incoming** or **two-way**. Indicates where incoming calls will terminate. Valid entries are an extension number, the attendant group access code (**attd**), **VDN**, or leave blank if `Trunk Type (in/out)` is not **auto/...** If **attd** is entered, a call is treated as a Listed Directory Number (LDN) call.
- **Incoming Dial Tone** — Indicates whether or not the trunk group will pass on incoming dial tone to the calling party. Valid entries are **y** (default) or **n**.
- **Incoming Dial Type** — Indicates the type of pulses required on an incoming trunk group. If using Inband ANI feature, enter **tone**. Valid entries are **tone** (default), **rotary**, or (if `Trunk Signaling Type` is blank), **mf**.

⇒ NOTE:

The `Multifrequency Signaling` field must be enabled on the System-Parameters Customer-Options form before a value of `mf` may be administered.

The `Incoming Dial Type` field may not be `mf` if `Used for DCS` (Page 2 of the form) is `y`.

The value in this field impacts the appearance of `Incoming Partial Dial (sec)` on the `Administrable Timer Page`.

- **Incoming Rotary Timeout (sec)** — The timing interval required by the far-end to which the system is connected. If the system is connected to a Step-by-Step office, 18 seconds or more must be used; if the system is not connected to a Step-by-Step office, 5 seconds or more may be used. Valid entries are **5** through **99**, or blank; default is **5**.
- **ITC** (Information Transfer Capability) — Displays when `Comm Type` is **data**, **avd**, or **rbavd** and `BCC` is not **0**. Used by the GRS feature and enables the system to route calls to restricted (default) or unrestricted facilities according to the endpoint's information transfer capability. A trunk member is said to be restricted if the circuit pack it belongs to is administered as **ami-bsic** or **ami-zcs** in `Line Coding` of the DS1 form. A trunk member is said to be unrestricted if the circuit pack it belongs to is administered as **b8zs** or **hdb3** in `Line Coding` of the DS1 form. A restricted trunk member can carry only restricted calls. An unrestricted trunk member may carry restricted or unrestricted calls. A trunk group with a transfer capability of **unrestricted** may have only unrestricted trunk members.
- **Night Service** — Enter the extension number assigned to Night Service. The extension number entered receives all incoming calls when Night Service is activated and the individual trunk member `Night` field is not administered to override this group extension. Valid entries are an extension number (can be a VDN extension), the attendant group access code (**attd**), or leave blank (default) if `Trunk Type (in/out)` is not **auto/...**

⇒ NOTE:

The following trunk groups do not support night service: CPE, DID, and DIOD.

- **Outgoing Dial Type** — Identifies the type of pulsing required on an outgoing call. Valid entries are **tone** (default), **rotary**, or (if `Trunk Signaling Type` is blank) **mf**.

⇒ NOTE:

`Multifrequency Signaling` must be enabled on the System-Parameters Customer-Options form before a value of `mf` may be administered.

Outgoing Dial Type may not be set to **mf** if Used for DCS (Page 2 of the form) is **y**.

- **Outgoing Display** — Specifies whether the trunk group name displays on a terminal placing an outgoing call. It controls what displays before the call is connected. Valid entries are **y** or **n** (default). When **n**, the dialed number displays. When **y**, the trunk group name and number replace the dialed number.
- **Prefix-1** — Indicates if the prefix 1 is required for NXX FNPA calls (where N is 2 through 9, and X is 0 through 9). Valid entries are **y** (default) and **n**.
- **Protocol Type** — For DID and DIOD trunk groups. Only displays when `Country` is **15** and is applicable only if the trunk group members are administered on a TN2199 or TN464D vintage 3 or greater. This field specifies the type of line signaling protocol (Incoming Local or Incoming Toll) to be used. Valid entries are **inloc** (default) and **intol**. Only the inloc protocol provides ANI.
- **Queue Length** — Only displays when `Direction` is **outgoing** or **two-way**. Enter the number of outgoing calls that can be held waiting. A **0** (default) indicates that no calls are held in queue. Enter **0** for DCS trunks. Valid values are **0-100**. This field turns off if `Direction` is **incoming**.
- **RA Trunk Loss** (Remote Access Trunk Loss) — Displays when `Terminal Balanced` is **n**. Specifies the type of dB loss to be applied to non-terminally balanced trunks. If experiencing unsatisfactory echo performance (hollowness), enter **2dB**. Valid entries are **0db** (default) and **2db**.
- **Receive Answer Supervision** — Specifies whether the network provides answer supervision for the trunks. Answer supervision refers to notification from the far-end that the called party has gone off-hook to answer the call. When answer supervision is not provided, the originating switch can classify a call as answered using the `Answer Supervision Timeout` field entry (for domestic circuit packs) or, for circuit packs that take administrable timers, by using `Outgoing End of Dial (sec)`. For trunks over which answer supervision is provided by the network, set this field to **y** (default) and `Answer Supervision Timeout` to **0** to disable the firmware timeout. The firmware timeout is set automatically to **0** on circuit packs that take the administrable `Outgoing End of Dial (sec)` field. Receive Answer Supervision must be **n** if `Direction` is **incoming**.
- **Receive Release Ack** — Displays only when `Trunk Signaling Type` is either **cont** or **dis**. (Thus, this field only applies to TN2140 ports.) Enter **y** (default) if the switch should expect to receive a release acknowledgment in response to a forward or backward release signal.
- **Send Answer Supervision** — Displays when `Trunk Signaling Type` is **cont** or **dis** and only applies to TN2140 ports. Enter **y** (default) if the switch should signal that the destination party has answered.

- **Send Release Ack** — Displays when `Trunk Signaling Type` is **cont** or **dis** and only applies to TN2140 ports. Enter **y** (default) if the switch must send a release acknowledgment in response to a forward or backward release signal.
- **Sig Bit Inversion** — This field allows the user to administer the signaling bit inversion (the A-bit and B-bit inversion) on a per-port basis and applies only to TN464B or later circuit packs. The CCITT standards define on-hook to be “1” in the A-bit and off-hook to be “0.” This definition is the opposite of the EIA definition. The default in the TN464 firmware for signaling bit inversion is to use the CCITT standard for 32-channel mode and to use the EIA standard for 24-channel mode. Valid entries are **A**, **B**, **A&B** and **none** (default).
- **STT Loss** (Satellite Switch Tie Trunk Loss) — Displays when `Connected to Toll` is **n**. Specifies the loss plan to be used for the trunk group. Valid entries are **normal** (default) or **low**. This option affects the transmission performance of a private network.

Although the use of this option has wider applications, only for the simplest network arrangements (such as co-located DCS) should this field be administered without Network Engineering advice. The **low** option (described as the ISL digital low loss plan in *DEFINITY Communications System Generic 1 and System 75 and System 85 DS1/DMI/ISDN-PRI Reference*) should be used when:

1. Stations on the satellite switch complain of too much loss on calls to the public network.
2. The network consists of **no more** than three switches: one main and one or two satellite switches.
3. All switches have the **low** option available.
4. The total DS1 trunk connection length is less than 100 miles.

If the preceding conditions are not met, obtain Network Engineering assistance. The field entry is based on the following:

- **normal** — Applies to AIU-TT (Analog Interface Unit at Customer Switching System for Tie Trunk — 4-wire E&M interface), and DIU-TT (Digital Interface Unit at Customer Switching System for Tie Trunk — voice or AVD DS1 interface) loss plans.
  - **low** — Applies to AIU-TTS (same as AIU-TT, but suitable for private network connections that can be connected in tandem with public network connections) and DIU-TTS (same as DIU-TT, but suitable for private network connections that can be connected in tandem with public network connections). These interfaces were formerly referred to as DIU DTT ISL.
- **Synchronization** — Enter whether the trunk group will use synchronous or asynchronous communications. Valid entries are **async** (default) and **sync**.
    - Displays when `Group Type` is **dmi-bos** or **isdn-pri**.

- Displays when `Group Type` is **access**, **co**, **fx**, **tandem**, **tie**, or **wats** and `Comm Type` is **avd** or **rbavd**.
- Displays when `Group Type` is **access**, **co**, **fx**, **tandem**, **tie**, or **wats**, `Comm Type` is **data**, and `ISDN-PRI` or `ISDN-BRI Trunks` is enabled on the `System-Parameters Customer-Options` form.
- **TAC** — Enter the trunk access code (TAC) that must be dialed to access the trunk group. CDR also uses the TAC to identify the trunk group on associated CDR reports. A different TAC must be assigned to each trunk group. Valid entries are TACs that are compatible with the System Dial Plan (1–4 digits; 1–3 digits for DCS or to remotely control it).
- **Terminal Balanced** — Displays when `Trunk Type` is **ground-start**, **loop-start**, **immed-start**, or **wink-start**. Enter **y** for terminally balanced trunks or **n** (default) for unbalanced trunks. Typically, a `Trunk Termination` field of **600ohm** signifies a balanced trunk group and a field of **rc** signifies a non-balanced trunk group. If the trunks in this group pass the Low Frequency Return Loss test requirements, then they are terminally balanced, and this field should be **y**.
- **TN** — Enter the Tenant Partition number. For TN790 (Release 6si and later configurations), valid values are **1–20**. For UN331B (Release 6r and later configurations), valid values are **1–100**. Default is **1**.
- **Toll Restricted** — Enter **y** (default) if this trunk group is to be toll restricted. This field only applies for outgoing TAC calls if the originating party is toll restricted. Trunks with an `Outgoing Dial Type` field of **automatic** should have this field set to **n**.
- **Trunk Flash** — Enter **y** or **n** (default) to indicate if access to customized services provided by a far-end (such as Central Office) is permitted for this trunk group. The switch must be directly connected to a far-end that provides such services via an analog or digital trunk.
- **Trunk Gain** — This value specifies the gain of the trunk, and can be **high** (default) or **low**, in conjunction with the values of `Trunk Termination` and `Country`, determine the input and trans-hybrid balance impedance for TN465B, TN2146, TN2147, and TN2184 ports. All other CO and DID circuit packs are set automatically to **high**.
- **Trunk Signaling Type** — Specifies the kind of signaling to use for members in the trunk group, and if administered to a non-blank value, severely restricts the ports that can be administered in the trunk group.

Valid values are **cont** (continuous), **dis** (discontinuous), or blank (default). Entering one of these values indicates that only ports from a TN2140 Italian tie trunk may be administered as trunk group members. Entering one of these values causes `Send Release Ack`, `Receive Release Ack`, and `Send Answer Supervision` to appear. If the field is blank, ports from any other Tie trunk circuit pack may be added as trunk group members.

If `Group Type` is **tie**, valid values include **tge**, **tgi**, and **tgu**. Entering one of these three values indicates that only ports from a TN497 Italian Tie trunk can be administered as trunk group members.

 **NOTE:**

The value in this field also affects which timers will appear on the Administrable Timer Page.

- **Trunk Termination** — Specifies how the trunk group is terminated. Valid entries are **600ohm** or **rc** (default). Enter **600ohm** when the switch trunk port is connected to terminal equipment (for example, SLC carrier or compensators optioned for 600 ohms input impedance) and the distance to the terminal equipment from the switch is less than 3000 feet.
- **Trunk Type** — Identifies the physical type of trunk. It may differ for incoming and outgoing types. Valid entries are **ground-start**, **loop-start**, **auto/auto**, **auto/delay**, **auto/immed**, and **auto/wink**. If `Country` is **15**, additional valid entries are **2-wire-ac**, **2-wire-dc**, and **3-wire**. These three trunk types must be on a TN2199 circuit board.
- **Trunk Type (in/out)** — Identifies the physical type of incoming and outgoing trunks. The trunks may be automatic, immed-start, wink-start or delay-dial; additionally, they may be **cont** (continuous-seize-ack) if `Trunk Signaling Type` is **cont**; if `Trunk Signaling Type` is **dis**, only **disc** (discontinuous-seize-ack is used instead of **wink**) and **immed** are allowed. It may differ for incoming and outgoing directions.
- When the `Trunk Signaling Type` is **dis**, the valid values are **immed** and **disc**:

disc/disc | disc/immed | immed/disc | immed/immed

When the `Trunk Signaling Type` is “cont,” the valid values are:

|            |            |             |             |            |
|------------|------------|-------------|-------------|------------|
| auto/auto  | auto/cont  | auto/delay  | auto/immed  | auto/wink  |
| cont/auto  | cont/cont  | cont/delay  | cont/immed  | cont/wink  |
| delay/auto | delay/cont | delay/delay | delay/immed | delay/wink |
| immed/auto | immed/cont | immed/delay | immed/immed | immed/wink |
| wink/auto  | wink/cont  | wink/delay  | wink/immed  | wink/wink  |

Otherwise, the valid values are:

|            |             |             |            |
|------------|-------------|-------------|------------|
| auto/auto  | auto/delay  | auto/immed  | auto/wink  |
| delay/auto | delay/delay | delay/immed | delay/wink |
| immed/auto | immed/delay | immed/immed | immed/wink |
| wink/auto  | wink/delay  | wink/immed  | wink/wink  |

⇒ NOTE:

For **immed/immed** trunks (on incoming trunks), the far-end switch seizes the trunk and then sends digits without waiting for acknowledgment from the receiving switch. When heavily loaded, the receiving switch may incur a short delay in attaching a Touch Tone Receiver to this call and, therefore, cause it to lose digits. Using wink-start trunks or increasing the dial-guard timer value on the far-end switch avoids this problem.

- **Version** — Displays only if `Country` is **5**. The Version indicates the type of signaling to be used and applies only to TN2147 ports. Enter **a** (default) if `Country 5` signaling is to be used. Enter **b** if `Country 1` signaling is to be used. The value **b** is appropriate if connected to an Ericsson AXE-10 switch.
- **Wink Timer (msec)** — Displays when the trunk type for the “outgoing” side of the in/out field is **wink** or **delay**. Enter a number from **300** (default) to **5000** in increments of 50. This timer is sent only to TN760C (vintage 4 or later), TN767, and TN464C (or later) circuit packs.

⇒ NOTE:

This value is the same for each member of the trunk group where the timing is administered. That is, if members from TN760B ports are mixed with members from TN760C V4 ports, only the TN760C V4 ports are set to this value. (The TN760B ports use a default value on the circuit pack itself.)

United States domestic requirements state that for a “wink” start trunk, the wink must begin within five seconds (the “wait-for-wink-to-start” time) and must end within 290 ms (the “wait-for-wink-to-end” time). For a “delay” dial trunk, the wink must begin within 140 ms (the “wait-for-wink-to-start” time) and end when the switch is ready to receive digits.

For trunk types with an outgoing type Wink, the call is rejected if the wink starts more than 5 seconds after the seize, and if the wink lasts longer than the wink timer setting.

For trunk types with an outgoing type Delay, the Delay Dial signal is ignored if it starts after the wink timer setting after the seize, and if it lasts longer than 5 seconds.

Page 2 of the form

- **Abandoned Call Search** — Administered when `Trunk Type` is **ground-start**. Enter **y** if this trunk group will conduct an Abandoned Call Search to identify a ghost call.

⇒ NOTE:

Abandoned Call Search is designed to work with CO trunks (ground start - analog) that *do not* provide disconnect supervision. Central offices that provide disconnect supervision do not require use of the Abandoned Call Search feature. The CO must support Abandoned Call Search for the feature to work properly.

- **ACA Assignment** — Specifies whether Automatic Circuit Assurance (ACA) measurements will be taken for this trunk group. Valid entries are **y** or **n** (default). If **y** is entered, complete the **Long Holding Time**, **Short Holding Time**, and **Short Holding Threshold** fields.
- **Charge Conversion** — Displays when **Direction** is **outgoing** or **two-way**. For ISDN trunk groups, it displays when **Charge Advice** is *not none*. Used to set the value of a charge unit in terms of currency. DEFINITY ECS multiplies the number of charge units by the value of this field and displays it as a currency amount. If there is no value in this field, DEFINITY ECS displays the number of charge units without conversion to currency. Valid entries are from **1–64,500**. Default is **1**.
- **Charge Type** — Displays when **Direction** is **outgoing** or **two-way**. For ISDN trunk groups, it displays when **Charge Advice** is *not none*. Entry in this field displays on the end-user voice-terminal display. It is a text string you use to describe charges related to a phone call. Default is **units**.
- **Connected to CO** — Displays when the software is R6 or later configurations and **Group Type** is **tie**. Permits overlap sending to a Central Office. Valid entries are **y** and **n** (default).
- **Currency Symbol** — Displays when **Direction** is **outgoing** or **two-way**. For ISDN trunk groups, it displays when **Charge Advice** is *not none*. Entry in this field displays on the end-user voice-terminal display. It is a symbol you want to display in front of the charge amount. Valid values are any character (to a maximum of 3) that you can enter from your keyboard. The default is blank.
- **Data Restriction** — Used to prevent features from generating tones on a data call that would cause erroneous data transmission. Valid entries are **y** or **n** (default).
- **Decimal Point** — Displays when **Direction** is **outgoing** or **two-way**. For ISDN trunk groups, it displays when **Charge Advice** is *not none*. Entry in this field displays on the end-user voice-terminal display. You use it to set a decimal point indicator. Valid values are **comma**, **period**, or **none** (default).
- **Glare Handling** — Only displays when **Direction** is **two-way** and the outgoing side of **Trunk Type** is either **wink** or **delay**. This field determines how glare situations should be treated. Valid entries are **control**, **backoff**, or **none** (default).

Warnings are generated if the field is changed to either **control** or **backoff** and ports for the trunk group are not capable of detecting glare. The following circuit packs can detect glare situations: TN767 (all releases), TN760C (or later releases), and TN464C (or later releases).

- **Incoming Tone (DTMF) ANI** — Displays only when `Incoming Dial Type` on page 1 is **tone**. Valid entries are **\*ANI\*DNIS\***, **ANI\*DNIS\***, or **no** (default).

With the **\*ANI\*DNIS\*** option, the far end must provide a leading “\*.” With the **ANI\*DNIS\*** option, the far end does not provide a leading “\*.”

These ANI digits are printed on a CDR record, passed to the Audix Intuity and ASAI interface, and displayed on the station set (and on tandem calls if the outgoing trunk requires ANI). Then this received ANI is sent to the outgoing trunk.

- **Internal Alert** — Specifies if internal ringing and coverage will be used for incoming calls. Valid entries are **y** or **n** (default).
- **Long Holding Time (hours)** — Displays only when `ACA Assignment` is **y**. This field is the length (in hours) that the system will consider as being a long holding time. If **0** is entered, the system will not consider long holding calls. Valid entries are **0** to **10**; default is **1**.
- **Maintenance Tests** — Indicates whether hourly maintenance tests will be made on this trunk group. Valid entries are **y** (default) or **n**.

**NOTE:**

The value administered is not saved when the form is submitted unless one or more trunk members are administered.

- **Measured** — Indicates if the system will transmit data for this trunk group to the Call Management System (CMS). Valid entries are **internal**, **external**, **both**, or **none** (default). Enter **internal** if the data can be sent to the Basic Call Management System (BCMS) [which is internal to the switch] the VuStats data display, or both. Enter **external** to send the data to the CMS adjunct. Enter **both** to collect data internally and to send the data to the CMS adjunct reports. Enter **none** if trunk group measurement reports are not required. Note that you cannot use **internal** and **both** unless either `BCMS (Basic)` or `VuStats` is enabled on the System-Parameters Customer-Options form.
- **PBX ID** — Displays when `Used for DCS` is **y**. Enter the ID of the switch at the other end of this trunk. Identifies the remote switch within the network with which the trunk will communicate on a DCS signaling link. Valid entries are **1** to **63**; default is blank.
- **Per Call CPN Blocking Code** — (For Access, APLT, CO, DIOD, FX, Tandem, Tie, and WATS trunk groups only.) Enter 1 to 4 digit number and \* and # may be used as the first digit.

- **Per Call CPN Unblocking Code** — (For Access, APLT, CO, DIOD, FX, Tandem, Tie, and WATS trunk groups only.) Enter 1 to 4 digit number and \* and # may be used as the first digit.
- **Receive Analog Incoming Call ID** — Delays ringing on the trunks to collect Incoming Call Line Identification (ICLID) information. This field displays when the Analog Trunk Incoming Call ID field on the System-Parameters Customer-Options form is **y**, Group Type field on the Trunk Group form is **co**, **did**, or **diod**, and the Direction field is **incoming** or **two-way** (the Direction field on DID trunks does not display because all calls are incoming; on DIOD trunks, it defaults to **two-way**). Valid entries are **Bellcore** (used for U.S.), **NTT** (used for Japan), and **disabled** (default).
- **Request Category** — Displays when Country is **15** and Shuttle is **y**. Enter **y** when the switch should request a call category from the CO. Default is **n**.
- **Seize When Maintenance Busy** — This field is effective only for ports on TN760C (or later release), TN767, and TN464C (or later release) circuit packs. It indicates whether an outgoing seize is generated when a trunk is maintenance busied, and whether the far-end switch is administered to do likewise. This supports the Electronic Tandem Network Busyout feature. The intended use of this feature is to prevent the far-end switch from reporting problems concerning a trunk that has been removed from service at the near end. The setting of this field has no effect on the behavior of the far-end machine; it controls the behavior of the near end switch and the *expected* far-end behavior.

If the administered value of this field is either **near-end** or **both-ends**, an outgoing seize will be initiated whenever a trunk in this trunk group is maintenance busied. The seize is maintained until the maintenance busyout is released. This action will likely cause alarms at the far-end switch, perhaps leading to a far-end maintenance busy out, unless the far-end switch is administered to expect this behavior.

If the administered value of this field is either **far-end** or **both-ends**, any abnormally long incoming seize (including failure to drop from a completed call) is *assumed to be the result of a far-end maintenance busy condition*.

Note that this assumption may be incorrect, since the abnormally long seize may actually be due to a transient or permanent failure of the trunk circuit. Regardless of the cause of the abnormally long seize, the near end response is to:

1. Generate a warning alarm indicating that the trunk is assumed to be maintenance busy at the far-end,
2. Remove the trunk from service, and
3. Keep the trunk out of service until a far-end disconnect is received.

The values allowed depend on Direction. When Direction is **incoming**, the valid values are **far-end** and **neither-end**.

When *Direction* is **outgoing**, the valid values are **near-end** and **neither-end**.

When *Direction* is **two-way**, the valid values are **both-ends**, **far-end**, **near-end**, and **neither-end**.

- **Short Holding Threshold** — Displays when *ACA Assignment* is **y**. Number of times the system records a short holding call before an attendant is alerted to the possibility of a faulty trunk. Valid entries are **0** to **30**; default is **15**.
- **Short Holding Time (seconds)** — Displays when *ACA Assignment* is **y**. Specifies the length (in seconds) that the system considers as being a short holding time. If **0** is entered, the system will not consider short holding calls. Valid entries are **0** to **160**; default is **10**.
- **Shuttle** — Displays when *Country* is **15** and *Outgoing Dial Type* is **rotary**. Enter **y** to enable MF shuttle signaling. Default is **n**. Can be administered on TN 464D (or later release) or TN2199 circuit packs.
- **Start B Signal** — Displays when *Country* is **15** and the *Shuttle* field is **y**. Enter **1 - 3** to indicate which B signal should be used to start a call. Default is **1**. Each of the three entries are described below:
  - **1** = Start calls with signal B1 (first digit)
  - **2** = Start calls with signal B2 (next digit)
  - **3** = Start calls with signal B3 (previous digit)

The value administered in this field must be coordinated with the CO-equivalents of *Start Position*.

- **Start Position** — Displays when *Country* is **15** and *Shuttle* is **y**. Enter **1 - 9** to indicate which digit in the digit string is considered to be the “previously sent” digit. Values and their meanings must be agreed upon by the system administrator and the CO. Default is **1**.
- **Suppress # Outpulsing** — Indicates end-to-end signaling begins with (and includes) the “#” when **y** is entered here. The final “#” is suppressed in cases where the system would normally outpulse it. This field should be **y** when the Central Office (for example, rotary) or any other facility treats “#” as an error; default is **n**.
- **Used for DCS** — Specifies whether the trunk group will send and receive messages on a DCS signaling link. Valid entries are **y** or **n** (default). If this field is **y**, you can administer ISDN-BRI trunk groups unless *DCS Signaling* is **d-chan**. In that case, remove the BRI trunks or set *DCS Signaling* to **bx.25** before submitting the form.

 **NOTE:**

This field cannot be activated if the trunk group number is greater than 255 or if the Trunk Access code is more than 3-digits long.

## Administrable Timers form

- **Answer Send (msec)** — Enter the duration (in msec) of the answer signal pulse. This field appears only if `Trunk Signaling Type` is **dis** and the trunk group `Direction` is **incoming** or **two-way**. Valid entries are **10** to **2550** in increments of 10. Default is **80**. Only TN2140 and TN2199 ports receive this timer.
  - **Break (msec)** — Enter the duration of the break interval (the pulse duration) while the system is outpulsing digits using dial pulse signaling.  
  
If `PPS` is **10**, the sum of `Make (msec)` and `Break (msec)` must equal 100. Valid entries are **20** to **80** in increments of 5. The field cannot be blank. The default is **60**.  
  
If `PPS` is **20**, the sum of `Make (msec)` and `Break (msec)` must equal 50. Valid entries are **10** to **40** in increments of 5. The field cannot be blank. The default is **30**.
  - **Disconnect Signal Error (sec)** — Enter the time (in sec) within which a disconnect signal from the far-end is expected after the internal party (a station or a tie trunk) goes on-hook. If the timer expires, the system can assume a disconnect failure and take an appropriate action (such as an error message). This field appears for ground-start trunk groups. Valid entries are **1** to **255** in increments of 1; default is **240**.
  - **Flash Length (msec)** — Specifies the length of the flash signal to be generated toward the Central Office. Valid entries are **10** to **2550** in increments of 10; default is **540**. This timer is sent to TN436B, TN459B, TN464C (or later), TN465B (or later), (TN753 if Country is **23**), TN2146, TN2147, TN2184, and TN2199 circuit boards.
  - **Frequency** — Displays if `Direction` is **outgoing** or **two-way** and `PPM` is **y**. Identifies the PPM pulse frequency(ies). Circuit packs can listen for up to three different frequencies, (12kHz, 16kHz, and 50Hz), plus two frequency combinations, (50Hz/12kHz and 50Hz/16kHz). Valid entries are **12k**, **16k**, **50**, **50/12k** (default), and **50/16k**. This field is sent to the TN465B, TN2138, and TN2184 circuit packs.
-  **NOTE:**  
The TN465B (or later) and TN2184 can only detect 12k and 16kHz PPM. Therefore, if **50/12k** or **12k** is administered, the circuit pack will be set to detect 12kHz. If **16k**, **50**, or **50/16k** is administered, the circuit pack will be set to detect 16kHz.
- **Glare** — Enter the minimum time (in msec) between sending an outgoing seizure and receiving a seizure acknowledgment. If seizure acknowledgment is received before expiration of the timer, a glare condition is assumed. It is only administrable if `Trunk Signaling Type` is **cont** and the trunk group `Direction` is **two-way** or **outgoing**. Valid entries are **40** to **100** in increments of 10. Default is **40**. Only TN2140 ports receive this timer.

- **Incoming Dial Guard (msec)** — Enter the interval between the detection of an incoming seizure and the acceptance of the first digit. The switch will not accept digits before this timer expires. Valid entries are **10–2550** in increments of 10; default is **70**.

 **NOTE:**

This timer is never sent to TN429 ports.

- **Incoming Disconnect (msec)** — A disconnect signal on an incoming call is considered valid only if it continues at least for the time specified by this timer. Valid entries are **50–2550** in increments of 10. The field cannot be blank; default is **500**. The field appears only for an incoming or two-way trunk group when *Trunk Signaling Type* is either blank or **cont**.
- **Incoming Disconnect Send (msec)** — Calls may be cleared by either the calling switch (forward release) or the called switch (backward release). Backward release is signaled by the called switch by grounding the M-lead for the duration specified by this timer. It is only administrable if *Trunk Signaling Type* is **dis** and the trunk group *Direction* is **incoming** or **two-way**. Valid entries are **500–1200** in increments of 100. Default is **800**. Only TN2140 ports receive this timer.
- **Incoming Glare Guard (msec)** — Enter the minimum time (in msec) between the time an incoming trunk is released and the same trunk can be seized for an outgoing call. This guard time ensures the far-end has released all equipment after the incoming trunk is released. Valid entries are **100** to **25500** in increments of 100. The field cannot be blank. Default is **1500**. This field only appears when the trunk group *Direction* is **two-way**.
- **Incoming Incomplete Dial Alarm (sec)** — Enter the maximum time (in sec) allowed between incoming seizure and receipt of all digits. Intervals greater than this generate an inline error. Valid entries are **1** to **255** (default) in increments of 1. Only the TN436 (all), TN459 (all), TN464C (or later), TN760Dv15 (or later), TN767, TN2140, TN2146, TN2184, and TN2199 circuit packs.
- **Incoming Partial Dial (sec)** — Enter the time (in sec) allowed between digits. Valid entries are **5** to **255** in increments of 1; default is **18**. This timer appears only if *Incoming Dial Type* is **rotary**.

 **NOTE:**

This timer is never sent to TN429 ports.

- **Incoming Seizure (msec)** — Enter the minimum time (in msec) required for recognition of incoming ringing signal from the far-end. Valid entries are **20** to **2550** in increments of 10. The field cannot be blank. Default is **500**. This field appears when *Trunk Signaling Type* is **cont** and *Direction* is **incoming** or **two-way**. Only TN429, TN438 (any release), TN 447, TN464C (or later), TN465 (any release), TN767, TN2138, TN2140, TN2147, TN2184, and TN2199 ports receive this timer.

- **Make (msec)** — Enter the duration of the make interval (the pause between pulses) while the system is outpulsing digits using dial pulse signaling.  
  
If PPS is **10**, the sum of Make (msec) and Break (msec) must equal 100. Valid entries are **20 to 80** in increments of 5. The field cannot be blank. The default is **40**.  
  
If PPS is **20**, the sum of Make (msec) and Break (msec) must equal 50. Valid entries are **10 to 40** in increments of 5. The field cannot be blank. The default is **20**.
- **Normal Outgoing Seize Send (msec)** — Outgoing seizure is signaled by the calling switch momentarily grounding the M-lead for the duration specified by this timer. This field appears only if Trunk Signaling Type is **dis** and the trunk group Direction is **two-way** or **outgoing**. Valid entries are **10 to 990** in increments of 10. Default is **70**. Only TN2140 ports receive this timer.
- **Outgoing Dial Guard (msec)** — This timer specifies the minimum time between seizure acknowledgment of a trunk and the outpulsing of digits. For trunks that do not provide seizure acknowledgment, the timer specifies the minimum time between seizure and the outpulsing of digits. Any digit dialed by the station user after they lift the receiver, but before the timer times out, is not outpulsed until the timer expires. Valid entries are **100–25500** in increments of 100. The field cannot be blank. Default is **1600**.
- **Outgoing Disconnect (msec)** — A disconnect signal on an outgoing call is considered valid only if it continues at least for the time specified by this timer. This timer begins timing when a disconnect signal has been detected on an outgoing call over the trunk, and resets when the signal is no longer detected. If the timer times out, the trunk drops. Valid entries are **50 to 2550** in increments of 10. The field cannot be blank. Default is **500**.
- **Outgoing Disconnect Send (msec)** — Forward release is signaled by the calling switch by grounding the M-lead for the duration specified by this timer. It is administrable only if Trunk Signaling Type is “**dis**” and the trunk group Direction is **two-way** or **outgoing**. Valid entries are **100 to 9900** in increments of 100. Default is **800**. Only TN2140 ports receive this timer.
- **Outgoing End of Dial (sec)** — Enter the maximum time (in sec) a trunk may wait for answer supervision after dialing an outgoing call. During a cut-through operation, timing begins after each outgoing digit is sent by the switch and timing ceases after the far-end sends answer supervision. If the timer expires, the switch acts as if it had received answer supervision. On senderized operation, the timer begins after the last digit collected is sent by the switch. The timer ceases when the far-end sends answer supervision. If the timer expires, the switch acts as if it has received answer supervision. This field appears when Direction is **outgoing** or **two-way** and Receive Answer Supervision is **n**. This

field will not appear if `Receive Answer Supervision` is **y**, but a zero (0) value will be sent down to the firmware to disable the timer. Valid entries are **1** to **254** in increments of 1. Default is **10**.

 **NOTE:**

This field controls the firmware answer-supervision timer on ports that take the administrable timers; `Answer Supervision Timeout` on Page 1 of the Trunk Group form controls answer supervision for ports that do not take administrable timers. This field and the value administered in `Answer Supervision Timeout` on the Trunk Group form should be the same value.

- **Outgoing Glare Guard (msec)** — Enter the minimum time (in msec) between the time an outgoing trunk is released and the same trunk can be seized for another outgoing call. This guard time will ensure that the far-end has released all equipment after the outgoing trunk is released. Valid entries are **100** to **25500** in increments of 100. The field cannot be blank. Default is **1500**. This field only appears for **outgoing** and **two-way** trunk groups.
- **Outgoing Last Digit (sec)** — Enter the maximum time (in seconds) to wait for the next digit dialed. After the timer expires, no more digits are accepted by the circuit pack. It will only be administrable if `Trunk Signaling Type` is **dis** or **cont** and the trunk group `Direction` is **two-way** or **outgoing**. Valid entries are **1** to **40**; default is **10**. Only TN497 and TN2140 ports receive this timer.
- **Outgoing Rotary Dial Interdigit (msec)** — Enter the interval (in msec) between rotary dial digits being outpulsed by the switch. Valid entries are **150** to **2550** in increments of 10. The field cannot be blank. Default is **800**. This field only appears when `Outgoing Dial Type` is **rotary**.
- **Outgoing Seizure (msec)** — Displays when `Country` is **15**, `Direction` is **outgoing** or **two-way**, and `Trunk Type` is **2-wire-ac**, **2-wire-dc**, or **3-wire**. This timer specifies the duration (in milliseconds) of the outgoing seizure signal. Enter a number between **20** and **2550** in increments of 10; default is **200**. This timer is sent only to the TN2199 circuit pack.
- **Outgoing Seizure Response (sec)** — Enter a maximum time (in sec) by which the switch should receive the proceed-to-dial indication from the far-end after sending the seize signal. If the indication is not received in this time, a seizure failure response is uplinked. Valid entries are **1** to **255** in increments of 1. Default is **5**. This timer is sent to the TN438B, TN439, TN447, TN458, TN464B (or later), TN465B (or later), TN760Dv15 (or later), TN767, TN2140, TN2147, TN2184, and TN2199 circuit packs.
- **Pause (msec)** — Enter the minimum length of a pause between tones being sent in response to button depressions at a hybrid station set. It is administrable only if the `Trunk Signaling Type` is blank. Valid entries are **20** to **2550** in increments of 10; default is **150**. All CO, DIOD, and Tie circuit packs that accept administrable timers accept this timer. However, this

timer is sent only to the following DID circuit packs: TN464B (or later), TN767, TN436B, TN459B, TN2146, TN2199, and TN429 and TN2184 ports in a DID trunk group.

- **PPM** — (For CO, DIOD, FX, PCOL, and WATS trunks.) Appears for outgoing and two-way CO trunks. Enter **y** if Periodical Pulse Metering (PPM) pulses should be collected from the public network to determine call cost. If this field is **y**, `Frequency` displays.
- **PPS** — Enter either **10** or **20** to specify the PPS (pulses per second) assigned to rotary dial pulse trunk groups. Valid entries are **10** (default) or **20**.

**NOTE:**

The TN439, TN458, TN497, TN747Bv12 (or later), and TN767 circuit packs can do only 10pps.

- **Programmed Dial Pause (msec)** — Enter the length (in msec) of a pause during abbreviated dialing, ARS outpulsing, and terminal dialing operations. This timer is administrable for all outgoing and two-way trunk groups. Valid entries are **100** to **25500** in increments of 100. Default is **1500**. This timer is sent to the TN464B (or later), TN760Dv15 (or later), TN767, TN458, and TN2140 tie circuit packs. All CO circuit packs that accept administrable timers accept this timer.
- **Release Ack Send (msec)** — Enter the duration (in msec) of the forward release acknowledgment signal. After receiving a forward release signal, the called switch must send the forward release acknowledgment signal. This signal is sent by grounding the M-lead for the duration specified by this timer. This field appears only if `Trunk Signaling Type` is **dis** and the trunk group `Direction` is **incoming** or **two-way**. Valid entries are **500** to **1200** in increments of 100. Default is **600**. Only TN2140 ports receive this timer.
- **Ringling Monitor (msec)** — Enter the minimum time required to determine if the trunk disconnects. If the ringing signal disappears for a duration longer than the time specified in this field, the call will be assumed to be disconnected. Valid entries are **200** to **51000** in increments of 200. The field cannot be blank; default is **5200**. This timer is sent to TN464C (or later), TN767, TN438 (all), TN447, TN465 (all), TN2138, TN2147, TN2184, and TN2199 CO circuit packs.
- **Seize Ack Delay (msec)** — Enter the maximum time (in msec) between receiving a seizure and the sending of seizure acknowledgment by the called switch. This field appears only if `Trunk Signaling Type` is **dis** and the trunk group `Direction` is **incoming** or **two-way**. Valid entries are **40** to **120** in increments of 10. Default is **100**. Only TN2140 ports receive this timer.

- **Seize Ack Send (msec)** — Enter the duration (in msec) of the seize acknowledge pulse. This field appears only if `Trunk Signaling Type` is **dis** and the trunk group `Direction` is **incoming** or **two-way**. Valid entries are **10** to **990** in increments of 10. Default is **80**. Only TN2140 ports receive this timer.
- **Tone (msec)** — Enter the length of a DTMF tone sent in response to a button depression at a hybrid station set. Valid entries are **20–2550** in increments of 10; the default is **350**. This field appears only if `Trunk Signaling Type` is blank. This timer is sent only to the TN2184 circuit boards. All CO, DIOD, and Tie circuit packs that accept administrable timers accept this timer. However, this timer is only sent to the following DID circuit packs: TN464B (or later), TN767, TN436B, TN459B, TN2146, TN2199, and TN429 and TN2184 ports in a DID trunk group.

## ATMS Thresholds form

### NOTE:

This form appears when `Direction` on Page 1 is **outgoing** or **two-way** and `ATMS` is enabled on the Feature-Related System Parameters form.

- **Allow ATMS Busyout, Error Logging and Alarming** — Enter **y** to allow ATMS error logging and alarming (subject to filtering depending on the service organization used to deal with alarms); default is **n**.
- **Far-End Test No.** — Enter the access number (1 to 20 digits) dialed to reach the TTL.
- **Marginal and Unacceptable Thresholds**
  - **Marginal Threshold - Max - 1004 Hz Loss** — Enter the maximum signal loss (**0** to **21**) for a 1004 Hz test tone (in dB) allowed before reporting a trunk as out of tolerance; default is **21**. A smaller dB value is more restrictive.
  - **Marginal Threshold - Min - 1004 Hz Loss** — Enter **-2** (default), **-1**, or **0** to **21** to indicate the minimum signal loss for a 1004 Hz test tone (in dB) allowed before reporting a trunk as out of tolerance. A larger dB value is more restrictive.
  - **Unacceptable Threshold - Max - 1004 Hz Loss** — Enter the maximum signal loss (**0** to **21**) for a 1004 Hz test tone (in dB) allowed before reporting a trunk as unacceptable; default is **21**. A smaller dB value is more restrictive.
  - **Unacceptable Threshold - Min - 1004 Hz Loss** — Enter **-2** (default), **-1**, or **0** to **21** to indicate the minimum signal loss for a 1004 Hz test tone (in dB) allowed before reporting a trunk as unacceptable. A larger dB value is more restrictive.

- **Marginal Threshold - -Dev - 404 Hz Loss** — Enter the maximum negative deviation of measured loss (**0 to 9**) at 404 Hz from the 1004 Hz test tone noise level (in dB) allowed before reporting a trunk as out of tolerance; default is **9**. Smaller dB values are more restrictive.
- **Marginal Threshold - +Dev - 404 Hz Loss** — Enter the maximum positive deviation of measured loss (**0 to 9**) at 404 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as out of tolerance; default is **9**. Smaller dB values are more restrictive.
- **Unacceptable Threshold - -Dev - 404 Hz** — Enter the maximum negative deviation of measured loss (**0 to 9**) at 404 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable; default is **9**. Smaller dB values are more restrictive.
- **Unacceptable Threshold - +Dev - 404 Hz** — Enter the maximum positive deviation of measured loss (**0 to 9**) at 404 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable; default is **9**. Smaller dB values are more restrictive.
- **Marginal Threshold - -Dev - 2804 Hz** — Enter the maximum negative deviation of measured loss (**0 to 9**) at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as out of tolerance; default is **9**. Smaller dB values are more restrictive.
- **Marginal Threshold - +Dev - 2804 Hz** — Enter the maximum positive deviation of measured loss (**0 to 9**) at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as out of tolerance; default is **9**. Smaller dB values are more restrictive.
- **Unacceptable Threshold - -Dev - 2804 Hz** — Enter the maximum negative deviation of measured loss (**0 to 9**) at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable; default is **9**. Smaller dB values are more restrictive.
- **Unacceptable Threshold - +Dev - 2804 Hz** — Enter the maximum positive deviation of measured loss (**0 to 9**) at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable; default is **9**. Smaller dB values are more restrictive.
- **Marginal Threshold - Maximum C Message Noise** — Enter the maximum C-message noise interference (**15 to 55**) in dBmC above reference noise terminating on a voice terminal as measured within the voice band frequency range (500 to 2500 Hz) allowed before reporting a trunk as out of tolerance. The default is **55**. Smaller values are more restrictive.

- **Unacceptable Threshold - Maximum C Message Noise** — Enter the maximum C-message noise interference (**15 to 55**) in dBmC above reference noise terminating on a voice terminal as measured within the voice band frequency range (500 to 2500 Hz) allowed before reporting a trunk as unacceptable. The default is **55**. Smaller values are more restrictive.
- **Marginal Threshold - Maximum C Notched Noise** — Enter the maximum C-notched signal dependent noise interference (**34 to 74**) in dBmC allowed before reporting a trunk as out of tolerance. The default is **74**. Smaller values are more restrictive.
- **Unacceptable Threshold - Maximum C Notched Noise** — Enter the maximum C-notched signal dependent noise interference (**34 to 74**) in dBmC allowed before reporting a trunk as unacceptable. The default is **74**. Smaller values are more restrictive.
- **Marginal Threshold - Minimum SRL-HI** — Enter the minimum high-frequency signaling return loss (**0 to 40**) in dB allowed before reporting a trunk as out of tolerance. The default is **0**. Larger values are more restrictive.
- **Unacceptable Threshold - Minimum SRL-HI** — Enter the minimum high-frequency signaling return loss (**0 to 40**) in dB allowed before reporting a trunk as unacceptable. The default is **0**. Larger values are more restrictive.
- **Marginal Threshold - Minimum SRL-LO** — Enter the minimum low-frequency signaling return loss (**0 to 40**) in dB allowed before reporting a trunk as out of tolerance. The default is **0**. Larger values are more restrictive.
- **Unacceptable Threshold - Minimum SRL-LO** — Enter the minimum low-frequency signaling return loss (**0 to 40**) in dB allowed before reporting a trunk as unacceptable. The default is **0**. Larger values are more restrictive.
- **Marginal Threshold - Minimum ERL** — Enter the minimum low-frequency echo return loss (**0 to 40**) in dB allowed before reporting a trunk as out of tolerance. The default is **0**. Larger values are more restrictive.
- **Unacceptable Threshold - Minimum ERL** — Enter the minimum low-frequency echo return loss (**0 to 40**) in dB allowed before reporting a trunk as unacceptable. The default is **0**. Larger values are more restrictive.
- **Maximum Percentage of Trunks Which Can Be Removed From Service by ATMS** — Enter the highest percentage of trunks from the trunk group (**0 to 100**) that can be removed from service at one time because of unacceptable transmission measurement results; default is **0**.

- **Trunk Contact** — Enter up to 25 alphanumeric character name and/or number of the trunk vendor contact (the name and/or telephone number of someone from the trunk vendor who can be contacted in the event of problems with the trunks); default is blank.
- **Trunk Length** — Enter 0–4 digits followed by **k** (for kilometers) or **m** (for miles) showing the length of the trunk. This field is not required. It can be used to assist with threshold establishment, since noise on a trunk increases with the length of the trunk. The default is **0m**.
- **Trunk Vendor** — Enter up to 22 alphanumeric character name of the trunk vendor name (who to notify in the event of problems with the trunks); default is blank.
- **TTL Contact** — Enter the 0 to 25 alphanumeric character TTL vendor contact (the name and/or telephone number of someone from the TTL vendor who can be contacted in the event of problems with the TTL); default is blank.
- **TTL Type** — Specifies the type of TTL selected for testing trunks. The TTL type determines what ATMS tests can be completed and thus which threshold values need to be administered. The different TTLs supported are 105 with return loss (**105-w-rl**) (default), 105 without return loss (**105-wo-rl**), high-level tone source (**high-lts**), low-level tone source (**low-lts**), 100 type (**100**), and 102 type (**102**).

The following table explains the differences between TTL Types:

| Type TTL               | Description   | Example   |
|------------------------|---|---|
| <i>105-w-rl</i>        | Full range of 18 measurements or some defaults for return loss used (56A) | TN771B, ZLC12 and SN261B circuit packs and new 56A mini-responder |
| <i>105-wo-rl</i>       | Cannot return default values for far-end return loss                      | Older 56A mini-responder  |
| <i>high-level-tone</i> | Sends a fixed sequence of tones at 0 dBm                                  | ZLC12 and SN261B circuit packs                                    |
| <i>low-level-tone</i>  | Sends a fixed sequence of tones at -16dBm                                 | SN261B circuit pack   |
| <i>100</i>             | Up to 5 measurements that sends a 1004 Hz tone then a quiet termination   |   |
| <i>102</i>             | One measurement that sends a 1004 Hz tone                                 |   |

The far-end switch containing the TTL may be any of the following:

- System 85 R2 switch, equipped with the Maintenance/Test Board (TN771B)
- System 75 R1V2 and beyond, all of which contain the circuitry required to perform the TTL function
- System 85 R2 switch, equipped with the Analog/Digital Facility Test Circuit (ADFTC, SN261)
- DIMENSION FP8, equipped with the Analog Facility Test Circuit (AFTC, ZLC-12)
- Central Office switches, equipped with various TTL equipment that provide 100, 102, or 105 test line capabilities (56A)

Other vendor switches *may* be supported if compatible test lines are provided by these switches.

Four different versions of the ATMS Threshold Administration page can occur depending upon the measurements allowed by the TTL type selected. The four possibilities are:

1. 105-w-rl and 105-wo-rl — All thresholds appear.
  2. high-lts and low-lts — All thresholds (except maximum C-notched noise) appear.
  3. 100 — All thresholds (except maximum c-notched noise, 404Hz loss, and 2804 Hz loss) appear.
  4. 102 — Only 1004 Hz loss threshold appears.
- **TTL Vendor** — Enter the 0 to 22 alphanumeric character TTL vendor name (the name of the vendor supplying the terminating test line); default is blank.
  - **Unacceptable Thresholds** — See Marginal and Unacceptable Thresholds on page [7-143](#).

## Group Member Assignments form

### NOTE:

The total number of pages, and the first page of the Group Member Assignments, vary depending on whether the Administrable Timers and ATMS Thresholds pages display.

- **Administered Members (min/max)** — Indicates the minimum and maximum member numbers that have been administered for the particular trunk group. This field displays on all member pages.

- **Ans Delay** — Specifies the length of the wait for answer supervision delay (in ms) for trunks using the TN722A or later, TN760 (B, C, or D), TN767, TN464 (any suffix), TN437, TN439, TN458, or TN2140 circuit packs. Valid entries are **20** to **5100** in increments of 20; default is blank and internally treated as a zero. This delay serves two purposes:
    - Used to ensure that the answer supervision signal is valid and not a secondary delay-dial or wink-start signal.
    - Used to bridge over momentary off-hook signals resulting from connections made off-network through certain No. 5 Crossbar CCSA switches as the connection is being established.
  - **Code** — Display-only field. Displays the type of circuit pack physically installed or logically administered at the location to which this member has been assigned. If a circuit pack is neither installed nor administered at the member's location, the field is blank.
  - **Mode** — Specifies the signaling mode used on Tie Trunks with TN722A or later release, TN760B or later release, TN767, TN464 (any suffix), TN437, TN439, TN458, or TN2140 circuit packs. Valid entries are **e&m** (interface), **simplex** (phantomed), or **protected**. This entry must correspond to associated dip switch settings on the circuit pack.
  - **Name** — Enter up to ten characters to identify the member of the trunk group. The name can be a 7-digit telephone number or a 10-digit Trunk Circuit Identification number (provided by the trunk supplier).
  - **Night** — Enter the extension of the night destination for the trunk. This individual night destination overrides the group night service destination on the first page of the trunk group form. Incoming calls are routed to this destination when the system is placed in night service mode. (If **attd** is entered, night service will be to the attendant.)
  - **Port** — Enter seven characters. The first two characters identify the cabinet (01 to 44 [R6r], 01 to 03 [R6si]); the third character identifies the carrier (A through E); the fourth and fifth identify the slot number in the carrier (01 to 20 for multi-carrier cabinets or 01 to 18 for single-carrier cabinets); the last two characters identify the circuit number (01 to 31).
-  **NOTE:**  
When supporting DCS, it is required that the trunk be the same member number on both nodes. The member number of the trunk is the display-only field at the far left of the screen, just before the `Port` field.
- **Sfx** — (Display-only field) Displays the type of circuit pack (suffix only) physically installed at the location to which this member has been assigned. Field is blank if a circuit pack has not been physically installed.
  - **Total Administered Members** (Display-only field) — Indicates the total number of members administered in the trunk group. This field appears on all trunk group member pages.

- **Type** — Specifies the signaling type to be used. This field should be used only with TN760B (or later release), TN722 (with any suffix), TN767, TN2140 (when Trunk Signaling Type is **cont**), TN437, TN439, TN464 with any suffix, or TN458 circuit packs.

The Type column displays when Trunk Signaling Type is blank or **cont**. The Type column does not display if Trunk Signaling Type is **dis**.

The value of **t5 rev** is allowed only for the TN760D vintage 10 or later. When Type is **t5 rev**, Mode must be **e&m**.

Valid entries are **t1 stan**, **t1 comp**, **t5rev**, or **type 5**. Default is blank.

## Access trunk group

---

This form provides the ability to communicate with another switch as either a main or tandem switch in an Electronic Tandem Network (ETN). However, this trunk group does not send or receive Traveling Class Marks.

An ISDN trunk group whose `Service Type` is **access** can also function as an access trunk group.

### Administration commands

---

Use the following commands to administer the Access trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or TAC X...   |
| display | trunk-group | 1-MAX ['number' X]['to-number' X]['count' N]<br>['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']   |
| remove  | trunk-group | 1-MAX or TAC X...   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

A port is required on a TN464D, TN722B, TN760C, or TN767 circuit pack for each trunk assigned in the Access trunk group. A TN464D provides 24 or 32 ports, a TN722B or TN767 provides 24 ports, and a TN760C provides 4 ports.

### Field descriptions

---

The fields on the following forms are described in [“Trunk Groups — General” on page 7-115](#).

## Access trunk group form page 1

Screen 7-22. Access Group Member Assignments form

## APLT trunk group

---

This form provides access to and termination from advanced private line termination (APLT) networks. APLT trunks are used with a Common Control Switching Arrangement (CCSA) or Enhanced Private Switched Communications Service (EPSCS) network. If the trunk group is assigned as external, incoming calls have a 2-burst distinctive-ringing signal.

### ⇒ NOTE:

On the Class of Restriction form, you must enter **n** in APLT to allow access to APLT trunk group CCSA and EPSCS networks.

## Administration commands

---

Use the following commands to administer the APLT trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or TAC X...   |
| display | trunk-group | 1-MAX ['number' X][ 'to-number' X][ 'count' N]<br>[ 'tac' assigned TAC][ 'print' or 'schedule'] |
| list    | trunk-group | [ 'print' or 'schedule']  |
| remove  | trunk-group | 1-MAX or TAC X...   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

## Hardware requirements

---

A port on a TN760C circuit pack or TN464D, TN722B, or TN767 DS1 circuit pack is required for each trunk assigned in the APLT trunk group. A TN760C provides 4 ports for 4-wire E&M lead signaling. A TN722B or TN767 provides 24 ports, and the TN464D provides either 24 or 32 ports, for Tie trunk groups, RLT groups, and APLT trunk groups.

## Field descriptions

---

The fields on the following forms are described in ["Trunk Groups — General"](#).

## CAMA - E911 trunk group

---

This form administers the Centralized Automatic Message Accounting (CAMA) trunks and provides Caller's Emergency Service Identification (CESID) information to the local community's Enhanced 911 system through the local Tandem Office.

When the CAMA feature is administered and a 911 call is placed from a DEFINITY ECS station, DEFINITY software searches for the proper CAMA Touch-Tone Receiver (TTR) resource in the port network (PN) where the CAMA trunk group is located.

If the proper CAMA TTR resource is not available in that PN, the software checks any other available PNs for the proper CAMA TTR resource. If this resource is not found in the entire system, a busy tone is returned to the calling party. However, if another trunk group is in the same routing pattern as the CAMA trunk group, the call routes to the next available trunk group in the pattern. For example, if a CO trunk group is used, then any available TTR resource can be used and the call routes as a normal call over the CO trunk and the public switched telephone network (PSTN).

### Administration commands

---

The ability to change and display CAMA numbering is restricted to Administrators with add/change permission.

Use the following commands to administer the CAMA - E911 trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or TAC X...   |
| display | trunk-group | 1-MAX ['number' X]['to-number' X]['count' N]<br>['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']   |
| remove  | trunk-group | 1-MAX or TAC X...   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

## Hardware requirements

---

- TN429C CO circuit pack

### NOTE:

CAMA requires at least one of the following two circuit packs in the port network's supporting CAMA trunk groups.

- TN2182BV1 or TN2182BV2 Tone Clock/Call Classifier - Detector circuit pack or later configuration.
- TN744DV1 or TN744DV2 Call Classifier - Detector circuit pack or later configuration.

The following touch-tone receivers (TTRs) are not compatible:

- TN748 any vintage
- TN756

Lucent recommends all TTR-equipped circuit packs in the PN with CAMA trunk groups be either TN2182BV1/TN2182BV2 or TN744DV1/TN744DV2 or later configurations.

## How to administer CAMA - E911 trunk groups

| Trunk Group (CAMA)       | ■ All                                    |      |

- Trunk Group (CAMA) — Complete all fields as required.
  - **Group Type** — Enter **cama**.

## Field Descriptions

---

Many of the fields on the following forms are described in [“Trunk Groups — General”](#). If a field on this form is unique, it is listed and defined in the following paragraphs.

## Form instructions

---

Make assignments as required for the following fields on the form.

### Page 1 of the form

                          Trunk Gain: high
```

### Screen 7-28. CAMA Trunk Group form

## Fields unique to this form

---

The following fields are unique to the CAMA - E911 trunk group form:

- **CESID I Digits Sent** — The CESID Information (I) digits sent by the PBX to tell the Central Office or E911 tandem switch how to interpret the received ANI or CESID digits and is part of the E911 signaling protocol. Valid entries are from 1 to 3 digits, or leave blank (default).
- **Outgoing Dial Type** — Enter **r1mf** (default).

TRUNK GROUP

ADMINISTRABLE TIMERS

Outgoing Disconnect (msec): 400  
Cama Outgoing Dial Guard (msec): 75  
Outgoing Glare Guard (msec): 1000

Outgoing End of Dial (sec): 1      Cama Wink Start Time (msec): 5000  
Outgoing Seizure Response (sec): 4  
Disconnect Signal Error (sec): 30

### Screen 7-30. Administrable Timers form

## Implementation notes

---

- **Outgoing Disconnect (msec)** — Used to disconnect signal for an outgoing trunk call. It begins when the disconnect signal is detected and reset when the signal is no longer detected. The disconnect signal is considered valid if it lasts at least for the time specified by this timer. The trunk is dropped when the timer is expired. Enter a number between **50** and **2550** in increments of 10 or enter **400** (default). Blank is not a valid entry.

- **Cama Outgoing Dial Guard (msec)** — Specifies the minimum time between seizure acknowledgment of a trunk and the outpulsing of digits. Enter a number between **25** and **6375** in increments of 25 or enter **75** (default). Blank is not a valid entry.
- **Outgoing Glare Guard (msec)** — Specifies the minimum time between release of a trunk after an outgoing call and seizure of the same trunk for an outgoing call. Enter a number between **100** and **25500** in increments of 100 or enter **1000** (default). Blank is not a valid entry.
- **Outgoing End of Dial (sec)** — Specifies how long the PBX has to wait before an answer supervision can be assumed for those CO trunks which do not provide call answer supervision. Enter a number between **1** and **254** in increments of 1 or enter **1** (default).
- **Outgoing Seizure Response (sec)** — Specifies the time by which the switch should receive the proceed to dial indication from the far end after sending the seize signal. If the indication is not received in this time, the seizure failure response message is uplinked. A different value is required for the Cama trunk type. Enter a number between **1** and **255** in increments of 1 or enter **4** (default).
- **Cama Wink Start Time (msec)** — Specifies the wait-for-wink-to-end time for the wink start Cama trunk. The wink must begin within the value of the Outgoing Seizure Response timer. Enter a number between **20** and **5100** in increments of 20 or enter **5000** (default).
- **Disconnect Signal Error (sec)** — Specifies how long to wait for the far end to release a call after the PBX sends a disconnect signal, before logging error of lacking release from the far end. Enter a number between **1** and **255** in increments of 1 or enter **30** (default).

Screen 7-32. List Trunk Groups form

### Interactions

- When an Expert Agent Selection (EAS) agent dials 911, the CESID outpulsed will be of the physical station, not the logical agent.

**7** Trunk Group Administration  
*CAMA - E911 trunk group*

*Page 7-167*

- CAMA/E911 will only work on DEFINITY ECS if TN429C and TN2182BV1/TN2182BV2 (or TN744DV1/TN744DV2) or later configuration TTR-equipped circuit packs are used. This feature will not always work properly if other circuit packs providing Touch-Tone Receiver (TTR) or General-Purpose Tone Receiver (GPTR) are in the same port network as the TN429C circuit packs used to interface with CAMA trunks.
- Lucent does not recommend the tandeming of 911 calls.
- 911 calls from a bridged extension will report the CESID of the principle station.
- The CAMA/E911 Interface feature is compatible with the Attendant Crisis Alert feature.
- The CAMA/E911 feature does not impact the functionality of the XTEND, Telident, and Proctor adjuncts.
- Class of Restriction (COR), Tenant Partitioning, and Facilities Restriction Level (FRL) restrictions apply to CAMA trunks and 911 calls.
- When a Personal Station Access/Terminal Translation Initialization (PAS/TTI) station is associated with a physical station, the CESID outpulsed when dialing 911 is that of the PSA/TTI station, not of the physical station.

## CO trunk group

---

This form connects the system to the public telecommunications network via a local central office (CO).

If the CO is a step-by-step office, complete the Digit Absorption form. Digit Absorption List on this form must reference the Digit Absorption List Number.

### Administration commands

---

Use the following commands to administer the CO trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or TAC X...   |
| display | trunk-group | 1-MAX ['number' X][ 'to-number' X][ 'count' N]<br>[ 'tac' assigned TAC][ 'print' or 'schedule'] |
| list    | trunk-group | [ 'print' or 'schedule']  |
| remove  | trunk-group | 1-MAX or TAC X...   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

A port on an analog CO or digital DS1 circuit pack is required for each CO trunk assigned. For example, a TN747B provides 8 analog ports, a TN767 provides 24 digital ports, and a TN464D provides either 24 or 32 digital ports. Other circuit packs may also be used. See *System Description Pocket Reference* for the complete list of trunk circuit packs and their capabilities.

For Republic of China: This feature utilizes the TN2147C Analog CO Trunk circuit pack. Customers wishing to receive Periodic Pulse Metering (PPM) will continue to use the TN465C LS CO Trunk circuit pack because the TN21477C does not detect Chinese PPM.

## How to administer CO trunk groups

### Required forms

| Form                             | Field | Page                  |
|----------------------------------|-------|-----------------------|
| Trunk Group (CO)                 | ■ All | <a href="#">7-168</a> |
| Digit Absorption                 | ■ All | <a href="#">7-91</a>  |
| DS1 Circuit Pack                 | ■ All | <a href="#">7-79</a>  |
| ARS and ARS Digit Analysis Table | ■ All | <a href="#">8-54</a>  |

- Trunk Group (CO) — Complete all fields as required.
- Digit Absorption — If required, complete this form when the central office is a step-by-step office. `Digit Absorption List` on the Central Office trunk group form must reference the Digit Absorption List Number entered on the form.
- DS1 Circuit Pack form — Complete all fields as required if the DS1 circuit pack is used.
- ARS Analysis Table form — Complete all fields as required. The table controls the dialing patters that can be used with Central Office Trunk Groups.

### Interactions

For Republic of China: When `Country` is set to **18**, the TN2147C provides the same signaling characteristics of the TN465C including:

- Dual Tone Multi-frequency (DTMF) tone-on timing
- DTMF tone-off timing
- Signaling protocol

For Republic of China: When `Country` is set to **18**, the TN2147C provides the same transmission characteristics of the TN465C including:

- DTMF high frequency gain
- DTMF low frequency gain
- Ring detector impedace
- Transmission gain or loss

**Screen 7-38. CO Group Member Assignments form**

## CPE trunk group

---

This form provides access between DEFINITY ECS and customer-provided equipment (CPE).

The auxiliary trunk ports that are used to connect CPE to the switch are administered as CPE trunk group members. Some features can be assigned to the system using other system forms. For example, trunk port interfaces can be assigned on system forms for such features as Music-on-Hold Access (Feature-Related System Parameters form) and Loudspeaker Paging and Code Calling Access (Loudspeaker Paging and Code Calling Access form).

### Administration commands

---

Use the following commands to administer the CPE trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or TAC X...   |
| display | trunk-group | 1-MAX ['number' X][ 'to-number' X][ 'count' N]<br>[ 'tac' assigned TAC][ 'print' or 'schedule'] |
| list    | trunk-group | [ 'print' or 'schedule']  |
| remove  | trunk-group | 1-MAX or TAC X...   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

A port on a TN763C auxiliary trunk circuit pack is required for each trunk assigned to the CPE trunk group. A TN763C provides 4 ports.

### Field descriptions

---

The fields on the following forms are described in ["Trunk Groups — General"](#).

## CPE Trunk Group form page 1

```

                                                                 Page 1 of X

  End-to-End Signaling: 60_

  Answer Supervision Timeout: _10
```

### Screen 7-39. CPE Trunk Group form (Page 1)

#### Fields unique to this form

The following field is unique to the CPE Trunk Group form.

- **End-to-End Signaling** — Specifies the duration (in ms) of touch-tone signal tone that is sent to the far-end for interpretation by devices at that location. Valid entries are **60** to **360** in increments of 10, or leave blank; default is **60**.

#### NOTE:

For trunks that do not receive real answer supervision, a “connect” Event report is sent when the Answer Supervision Timeout occurs.

## DID trunk group

---

The Direct Inward Dialing (DID) trunk group form allows an incoming call from the exchange network to reach a specific extension number directly without attendant intervention. DID features are also supported over Main/Satellite TGU/TGE trunks.

On the Feature-Related System Parameters form, you can set DID/Tie/ISDN Intercept Treatment to handle calls that do not complete.

### Administration commands

---

Use the following commands to administer the DID trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>   |
|---------|-------------|--|
| add     | trunk-group | 1—MAX (or 'next')  |
| change  | trunk-group | 1—MAX or TAC X...  |
| display | trunk-group | 1—MAX ['number' X][ 'to-number' X][ 'count' N] [ 'tac' assigned TAC][ 'print' or 'schedule'] |
| list    | trunk-group | [ 'print' or 'schedule']   |
| remove  | trunk-group | 1—MAX or TAC X...  |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

The following 8-port circuit packs are available:

- TN753 (used with Country code 1 and 23)
- TN436 (used with Country code 2)
- TN459 (used with Country code 10)
- TN2139 (used with Country code 4)
- TN2146 (used with Country code 5 and 8)
- TN2184 (used with Country code 13)
- TN464 DS1 and TN767 DS1
- TN2199

## How to administer DID trunk groups

### Required forms

| Form                              | Field  | Page                  |
|-----------------------------------|--|-----------------------|
| Trunk Group (DID)                 | ■ All  | <a href="#">7-178</a> |
| Feature-Related System Parameters | ■ DID/Tie/ISDN Intercept Treatment<br>DID Busy Treatment | <a href="#">5-123</a> |

- Trunk Group (DID) — Verify or complete all fields.
- Feature-Related System Parameters — Complete DID/Tie/ISDN Intercept Treatment and DID Busy Treatment to specify call handling for invalid DID calls or DID calls that terminate to a busy station.

### Field descriptions

The fields on the following forms are described in [“Trunk Groups — General”](#).

#### DID trunk group form page 1

## DIOD trunk group

---

This form assigns a Direct Inward and Outward Dialing (DIOD) trunk group and associated trunk ports. It allows non-attendant-assisted incoming and outgoing calls from a local exchange. DIOD trunk groups support both voice and data transmissions. To use data transmissions over digital DIOD trunk groups, set the `Comm Type` field to **data** or **avd**.

On the Feature-Related System Parameters form, you can set DID/Tie/ISDN Intercept Treatment to handle calls that do not complete.

### Administration commands

---

Use the following commands to administer the DIOD trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1—MAX (or 'next')   |
| change  | trunk-group | 1—MAX or TAC X...   |
| display | trunk-group | 1—MAX ['number' X][ 'to-number' X][ 'count' N]<br>[ 'tac' assigned TAC][ 'print' or 'schedule'] |
| list    | trunk-group | [ 'print' or 'schedule']  |
| remove  | trunk-group | 1—MAX or TAC X...   |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

- TN429 analog (with Country code 3)
- TN2184 analog with PPM detection (with Country code 13)
- TN464D digital with a bit rate of at least 2.048 Mbps

## How to administer DIOD trunk groups

### Required forms

| Form                              | Field  | Page                  |
|-----------------------------------|--|-----------------------|
| Trunk Group (DIOD)                | ■ All  | <a href="#">7-183</a> |
| Feature-Related System Parameters | ■ DID/Tie/ISDN Intercept Treatment<br>■ DOD Busy Treatment | <a href="#">5-123</a> |

- Trunk Group (DIOD) — Verify or complete all fields. The group type field must contain “diod.”
- Feature-Related System Parameters — Complete DID/Tie/ISDN Intercept Treatment and DID Busy Treatment to specify call handling for invalid DID calls or DID calls that terminate to a busy station.

### Field Descriptions

The fields on the following forms are described in [“Trunk Groups — General”](#).

### DIOD trunk group form page 1

Answer Supervision Timeout: 10_                 Receive Answer Supervision? n
```

## Implementation notes

---

Terminal Balanced and Cyclical Hunt only display when Trunk Type is **loop-start**.

Enter **loop-start** in Trunk Type for analog DIOD trunk ports. All analog members of this group must be on TN429 (Japan) or TN2184 (Germany) circuit packs. All digital members of this group must be TN464Dv2 or later.

Enter **immed-start** or **wink-start** in Trunk Type for digital DIOD trunk ports.

Screen 7-52. DIOD Group Member Assignments form

### Implementation note

All DIOD analog trunk group members must be on TN429 (Japan) or TN2184 (Germany) circuit packs. All digital members of this group must be TN464Dv2 or later.

## DMI-BOS trunk group

---

The Digital Multiplexed Interface Bit-Oriented Signaling (DMI-BOS) trunk group form allows communications to/from the system using DMI-BOS protocol.

### Administration commands

---

Use the following commands to administer the DMI-BOS trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or TAC X...   |
| display | trunk-group | 1-MAX ['number' X]['to-number' X]['count' N]<br>['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']   |
| remove  | trunk-group | 1-MAX or TAC X...   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Field descriptions

---

The fields on the following forms are described in ["Trunk Groups — General"](#).

wink-start trunks or increasing the dial-guard timer value on the far-end switch avoids this problem.

## DMI-BOS trunk group form page 2

```

Screen 7-57. DMI-BOS Group Member Assignments form

## FX trunk group

The Foreign Exchange (FX) trunk group allows a connection between a distant central office and DEFINITY ECS.

If the CO is a step-by-step office, complete the Digit Absorption form. The Digit Absorption List field on the Central Office trunk group form must reference the Digit Absorption List Number.

### Administration commands

Use the following commands to administer the FX trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>  |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or TAC X...   |
| display | trunk-group | 1-MAX ['number' X]['to-number' X]['count' N]<br>['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']   |
| remove  | trunk-group | 1-MAX or TAC X...   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

A port is required on a TN747B CO trunk, or TN464D or TN767 DS1 circuit pack for each trunk assigned to a FX trunk group. A TN747B provides 8 ports, a TN767 provides 24 ports, and a TN464D provides either 24 or 32 ports.

### How to administer FX trunk groups

#### Required forms

| Form             | Field | Page                  |
|------------------|-------|-----------------------|
| Trunk Group (FX) | ■ All | <a href="#">7-193</a> |
| Digit Absorption | ■ All | <a href="#">7-91</a>  |

- Trunk Group (FX) — Complete all fields.
- Digit Absorption — If required, complete this form when the far-end central office is a step-by-step office. Digit Absorption List on the Foreign Exchange trunk group must reference the Digit Absorption List number entered on the form.

## Field descriptions

The fields on the following forms are described in [“Trunk Groups — General”](#).

### FX trunk group form page 1

### Screen 7-62. FX Group Member Assignments form

## ISDN-BRI trunk group

This form assigns an Integrated Services Digital Network-Basic Rate Interface (ISDN-BRI) trunk group that supports the ISDN-BRI and Call-by-Call Service Selection features. The trunk group provides end-to-end digital connectivity and supports a wide range of services including voice and non-voice services, to which users have access by a limited set of CCITT-defined, standard multipurpose interfaces.

Calls can be processed to a variety of switched nodal services such as MEGACOM telecommunications service, WATS, and ACCUNET digital service and calls destined for different interexchange carriers.

### Administration commands

When an ISDN-BRI trunk connects two switches, the trunk options should be set identically at both ends of the administer connection. Use the following commands to administer the ISDN-BRI trunk group form connection.

| Action  | Object      | Qualifier   |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or tac X...   |
| display | trunk-group | 1-MAX ['number' X]['to-number' X]['count' N]<br>['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']   |
| remove  | trunk-group | 1-MAX or tac X...   |

### Hardware requirements

ISDN-BRI is supported by the TN2185 Trunk-side BRI circuit pack (for implementing the user side of the BRI interface) and by the TN556B or TN556C ISDN-BRI Line circuit pack or the TN2198 ISDN BRI (U-LT) Line circuit pack (for the network side of the BRI interface).

- For R6si and later configurations and R6vs and later configurations, the D-channel switches through the TN778 Packet Control (PACCON) circuit pack. See [Table 7-8](#).
- For R6r and later configurations, the D-channel switches through the TN1655 Packet Interface (PKTINT) circuit pack. See [Table 7-9](#).
- A TN780 or TN2182 Tone Clock circuit pack provides synchronization for the ISDN-BRI Trunk circuit pack.

## How to administer ISDN-BRI trunk groups

**Table 7-8. Required forms for the TN778 Packet Control (PACCON) for an R6si and later configurations**

### Notes for Above Tables

- **System-Parameters Customer-Options** — ISDN-BRI Trunks should be enabled. The QSIG Optional Features fields may be enabled to allow appropriate administration for the Supplementary Service Protocol.
- **Feature-Related System-Parameters Features** — Set Send Non-ISDN Trunk Group Name as Connected Name and Display Connected Name/Number for ISDN DCS Calls. Default is **n**.
- **ISDN-BRI Trunk Circuit Pack** — Assign all fields as required.
- **Maintenance-Related System-Parameters** — Use this form only for a TN778. Set Packet Bus Maint to **y**.
- **ISDN-BRI Trunk Group** — Enter information in all the fields except the trunk group members. Enter the members after you establish the signaling links.

- ISDN Numbering - Public/Unknown — Complete all fields. This form supports the ISDN Call Identification Display.
- ISDN Numbering - Private — Complete all fields. This form supports the ISDN Call Identification Display.
- Routing Pattern — Complete all fields including the Supplemental ISDN Routing Information fields as required.
- Hunt Group — Complete `ISDN Caller Display` by entering either **grp-name** or **mbr-name** to specify whether the hunt group name or member name, respectively, is sent to the originating user (supports the ISDN Call Identification Display feature).
- Terminating Extension Group — Complete `ISDN Caller Display` by entering either **grp-name** or **mbr-name** to specify whether the group name or member name, respectively, is sent to the originating user (supports the ISDN Call Identification Display feature).
- Synchronization Plan — Assigns primary and secondary external synchronization sources for the ISDN-BRI Trunk circuit pack. Complete all form fields as required.

## Design Considerations

ISDN-BRI and ISDN-PRI trunks cannot be mixed in the same trunk group. Therefore, consider the following:

- The earliest trunk member (the lowest numbered one) administered will be considered correct.
- If an offending member is subsequently found (meaning the first member was BRI and a later member was PRI, or vice versa), the cursor positions on the offending member, and the following error message appears:

Cannot mix BRI and PRI ports in the same trunk group.

## Field descriptions

Many of the fields on the following forms are described in [“Trunk Groups — General”](#). If a field on this form is unique, it is listed and defined.

## ISDN-BRI trunk group form

## Screen 7-63. ISDN-BRI Trunk Group form (page 1)

Fields unique to this form

These fields are unique to the ISDN-BRI trunk group form.

- **Calling Number** — These three fields comprise the administrable fields for the Calling Line Identification Prefix feature. They display when Direction is **incoming** or **two-way**.
  - Delete — The number of digits to delete from the calling party number for all incoming calls on this trunk group. Valid values are any number from **1-15**, **all** or blank.
  - Insert — The specific digits prefixed to incoming calls when the calling party is a member of this trunk group. Valid values are any string of **1-15** digits or blank.
  - Numbering Format — Indicates TON/NPI encoding applied to CPN information modified by the CLI Prefix feature. This encoding does not apply to calls originating locally. Numbering Format on page two of this form applies to calls originated from this switch.

If this field is blank, DEFINITY ECS passes on the encoding received in the incoming setup message. If the incoming setup message did not contain CPN information, and digits are added, the outgoing message will contain these digits. If Numbering Format is blank in this case, the value defaults to **pub-unk**.

If `Numbering Format` on page two of this form is also administered as **unknown**, the trunk group is modified to “unk-unk” encoding of the TON/NPI. Therefore, this field also must contain a value other than “unknown.”

 **NOTE:**

The values for this field map to the Type of Numbering (TON) and Numbering Plan Identifier (NPI) values shown in [Table 7-10](#).

**Table 7-10. Numbering Format Valid Values**

| Numbering format valid values | Type of numbering (TON) | Numbering plan identifier (NPI) |
|-------------------------------|-------------------------|---------------------------------|
| blank                         | incoming TON unmodified | incoming NPI unmodified         |
| natl-pub                      | national(2)             | E.164(1)                        |
| intl-pub                      | international(1)        | E.164(1)                        |
| locl-pub                      | local/subscriber(4)     | E.164(1)                        |
| pub-unk                       | unknown(0)              | E.164(1)                        |
| lev0-pvt                      | local(4)                | Private Numbering Plan - PNP(9) |
| lev1-pvt                      | Regional Level 1(2)     | Private Numbering Plan - PNP(9) |
| lev2-pvt                      | Regional Level 2(1)     | Private Numbering Plan - PNP(9) |
| unk-unk                       | unknown(0)              | unknown(0)                      |

- **Charge Advice** — Allows you to accumulate and access charge information about a call. You must have already set `CDR Report` to **y** or **r** (ring-intvl) before changing this field from its default of **none**. You may specify one of the following options.
  - **none** — No Advice of Charge information is collected by the system.
  - **automatic** — Advice of Charge is enabled automatically for all outgoing calls over this trunk group.
  - **end-on-request** — DEFINITY ECS will request information at the end of the call for each outgoing call over this trunk group.
  - **during-on-request** — DEFINITY ECS will request information during and at the end of the call for each outgoing call over this trunk group.

Remember that receiving Advice of Charge during the call (administered as “automatic” or “during-on-request”) affects system performance because of the increased ISDN message activity on the signaling channel, which may reduce the maximum call capacity.

- **Codeset to Send Display** — This field defines the codeset for sending the information element for Display. The value depends on the type of switch the user is connected to as follows.
  - 0 — CCITT
  - 6 — Any other than CCITT or System 85 R2V4, 4E11 (default)
  - 7 — System 85 R2V4, 4E11
- **Codeset to Send TCM, Lookahead** — This field defines the codeset for sending the information element for Traveling Class Marks and Lookahead Interflow. The value depends on the type of switch the user is connected to. Valid entries are **7** for System 85 R2V4, 4E11, or newer switch types, or **6** (default) for other types.

**NOTE:**

A Traveling Class Mark (that is, the user’s FRL or the user’s trunk group FRL) is passed between tandem nodes in an ETN in the setup message only when the *Service Type* is **tandem**. It then is used by the distant tandem switch to permit access to facilities consistent with the originating user’s privileges.

- **Digit Handling (in/out)** — This field defines whether overlap receiving and overlap sending features are enabled. Set the field to overlap when you want overlap receiving or overlap sending. Set to **enbloc** when you do not want these features enabled. The first field value indicates digit receiving and the second value indicates digit sending. There are 4 possible combinations: **enbloc/enbloc** (default), **enbloc/overlap**, **overlap/enbloc**, and **overlap/overlap**.

Without overlap receiving or sending enabled, the digits on incoming and outgoing calls are sent enbloc. If *Digit Handling* is **overlap/enbloc** or **overlap/overlap**, the following results:

- Incoming Call Handling Treatment table does not appear
- *Digit Treatment* and *Digits* appear
- Warning message indicates that all Incoming Call Handling entries are removed when form is submitted
- When form is submitted with these values, all Incoming Call Handling entries are removed

- **Far End Test Line No.** — Specifies the number sent to the far-end’s ISDN test line extension. When the **test trunk long** command is issued, this exact number is sent to the far-end to establish a call that tests the integrity of the trunk member under test. The number does not pass through routing or undergo digit manipulation. The digits entered must be

what the far-end expects. For example, for an ISDN tandem trunk, the far-end test number should be a 7-digit ETN (Electronic Tandem Network) number. Up to 15 digits may be entered in this field.

- **Max Message Size to Send** — Defines the maximum size of ISDN messages sent by the switch. Currently, the system can receive 260 byte messages. Valid entries are **128, 244, 256, and 260** (default).
- **Service Type** — Indicates the service for which this trunk group is dedicated. [Table 7-11](#) provides a listing of predefined entries. In addition to the Services/Features listed in this table, any user-defined Facility Type of **0** (feature) or **1** (service) on the Network Facilities form is allowed. An entry of **cbc** is also allowed, which indicates this trunk group is used by the Call-By-Call Service Selection feature.

Up to 10 (R6si, R6vs) or 200 (R6r) ISDN-BRI and/or ISDN-PRI trunk groups can have this field administered as **cbc**.

**Table 7-11. Predefined Services/Features — ISDN**

| Administration mnemonic | Description   |
|-------------------------|---|
| access                  | A tie trunk giving access to an Electronic Tandem Network — See <a href="#">“Access trunk group”</a>  |
| accunet                 | ACCUNET Switched Digital Service — part of ACI (AT&T Communications ISDN) phase 2.  |
| cbc                     | Call-by-Call service — provides different dial plans for different services on an ISDN-BRI trunk group.   |
| dmi-mos                 | Digital multiplexed interface — message oriented signaling — See <a href="#">“DMI-BOS trunk group”</a> . Do not use for DCS with Rerouting.                                   |
| i800                    | International 800 Service — allows a subscriber to receive international calls without a charge to the call originating party.  |
| inwats                  | INWATS — provides OUTWATS-like pricing and service for incoming calls.  |
| lds                     | Long-Distance Service — part of ACI (AT&T Communications ISDN) phase 2.   |
| megacom                 | MEGACOM Service — an AT&T communications service that provides unbanded long-distance services using special access (switch to 4ESS switch) from an AT&T communications node. |
| mega800                 | MEGACOM 800 Service — an AT&T communications service that provides unbanded 800 service using special access (4ESS switch to switch) from an AT&T communications node.        |

*Continued on next page*

Table 7-11. Predefined Services/Features — ISDN — *Continued*

| Administration mnemonic | Description   |
|-------------------------|---|
| multiquest              | AT&T MULTIQUEST Telecommunications Service — dial 700 service. A terminating-user's service that supports interactive voice service between callers at switched-access locations and service provides directly connected to the AT&T Switched Network (ASN).  |
| operator                | Network Operator — provides access to the network operator.   |
| outwats-bnd             | OUTWATS Band — WATS is a voice-grade service providing both voice and low speed data transmission capabilities from the user location to defined service areas referred to as bands; the widest band is 5.  |
| public-ntwrk            | Public network calls — It is the equivalent of CO (outgoing), DID, or DIOD trunk groups. If Service Type is public-ntwrk, Dial Access can be set to <b>y</b> .  |
| sddn                    | Software Defined Data Network — provides a virtual private line connectivity via the AT&T switched network (4ESS switch). Services include voice, data, and video applications. These services complement the SDN service. Do not use for DCS with Rerouting. |
| sdn                     | Software Defined Network (SDN) — an AT&T communications offering that provides a virtual private network using the public switched network. SDN can carry voice and data between customer locations as well as off-net locations.                             |
| sub-operator            | Presubscribed Common Carrier Operator — provides access to the presubscribed common carrier operator.   |
| tandem                  | Tandem tie trunks integral to an ETN — See <a href="#">“Tandem trunk group”</a> .   |
| tie                     | Tie trunks — general purpose — See <a href="#">“Tie trunk group”</a> .  |
| wats-max-bnd            | Maximum Banded Wats — a WATS-like offering for which a user's calls are billed at the highest WATS band subscribed to by users.   |

- **Supplementary Service Protocol** — Indicates which supplementary service protocol to use for services over this trunk group. *Supplementary Service protocols are mutually exclusive.* Enter one of the following. Default is **a**.
  - a National public network/Shared UUI
  - b ISO/ETSI QSIG Private Network
  - c ETSI public network
  - d European Computer Manufacturer's Association (ECMA) QSIG private network (supports only Name Identification and Additional Network Feature Transit Counter (ANF-TC))
  - e DCS with Rerouting
    - Do not use `Service Type` of **dmi-mos** or **sddn** with this option.
    - Set `Used for DCS` (on page 2) to **y**.
- **Test Call BCC** — Indicates the Bearer Capability Code (BCC) used for the ISDN test call. Valid entries and their definitions are as follows:
  - **0** — Voice
  - **1** — Mode 1
  - **2** — Mode 2 Asynchronous
  - **3** — Mode 3 Circuit
  - **4** — Mode 0 (default)
- **Testcall ITC** — Controls the encoding of the Information Transfer Capability (ITC) codepoint of the bearer capability IE in the SETUP message when generating an ISDN test call. Allowed values are **rest** (restricted) and **unr** (unrestricted). Default is **rest**.  
  
 **NOTE:**  
ISDN Testcall feature has no routing, so a testcall is never blocked due to an incompatible ITC.
- **Testcall Service** — Specifies the call-by-call selection for an ISDN-BRI test call. Only appears if `Service Type` is **cbc**. Valid entries are all of the services listed in [Table 7-13](#) excluding **sddn** or any new `Facility Type` of **0** (feature), **1** (service), or **3** (outgoing) that is defined by users on the Network Specific Facility Encoding form.
- **Trunk Hunt** — The switch performs a trunk hunt when searching for available channels within a facility in an ISDN-BRI trunk group.  
  
Enter **cyclical** to enable a circular trunk hunt based on the sequence the trunks were administered within the trunk group.

- **Usage Alloc** — Displays when *Service Type* is **cbc**. Specifies whether users want to allocate the services provided by the trunk group. Valid entries are **y** and **n** (default). If **y** is entered, two additional CBC-related forms display. They are the CBC Trunk Group Usage Allocation Plans form and the CBC Trunk Group Usage Allocation Plan Assignment Schedule.

## Implementation notes

Answer Supervision Timeout defaults to **0**.

Queue Length displays when *Direction* is **outgoing** or **two-way**.

### Screen 7-64. ISDN-BRI Trunk Group form (page 2)

## Fields unique to this form

These fields are unique to the ISDN-BRI trunk group form.

- **DCS Signaling** — Specifies the means used to send the DCS message. This field only displays if *Used for DCS* entry is **y** and *Service Type* is anything except **dmi-mos** or **sddn**. Valid entries are **bx.25** for the traditional DCS feature or **d-chan** for the DCS over ISDN-PRI D-channel feature. Allows you to administer an ISDN trunk group with BRI trunk members unless the DCS Signaling field is d-chan.
- **Hop Dgt** — The Tandem Hop Limitation and QSIG Additional Network Feature Transit Counter (ANF-TC) features provide a counter that reflects the number of switches (that is, the number of hops) that a call has gone through. The counter increments as a call leaves DEFINITY ECS using tandem facilities. Valid values are **y** and **n** (default). One or both of the features can be applied to the trunk group depending on the following:
  - If you enter **y** and *Group Type* is **tandem** or *Group Type* is **isdn** and *Service Type* is **tandem**, the Tandem Hop Limitation feature is applied to the trunk group.

- If you enter **y** and you set `Group Type` to **isdn**, set `Service Type` to **access**, **dmi-mos**, **public-ntwrk**, **tandem**, **tie**, or any of the craft-defined services allowed in the field. Set `Supplementary Service Protocol` to **b** or **d**, then the ANF-TC feature is applied to calls on the trunk group.

 **NOTE:**

The above conditions overlap. If `Group Type` is **isdn**, `Service Type` is **tandem**, and `Supplementary Service Protocol` is **b** or **d**, then both the Tandem Hop Limitation and ANF-TC features are applied to calls on the trunk group.

- If both features are applied to calls on the trunk group, ANF-TC takes precedence. In situations where DEFINITY ECS is an Incoming or Outgoing Gateway, either feature uses the hop count and transit information provided by the other.
- **Maximum Size of UUI IE Contents**—This field appears when the `UUI Treatment` field is set to **shared**. Enter the maximum number of bytes of user information that the network supports. The default is **128**.
- **NCA-TSC Trunk Member** — Identifies the trunk member whose D-channel will be used to route tandem NCA-TSCs. Value range for this field is from **1** to the maximum number of members per trunk group supported on the switch. Default is blank.
- **Numbering Format** — This field appears if `Send Calling Number` is **y** or **r** or `Send Connected Number` is **y** or **r**. This specifies the encoding of the `Numbering Plan Indicator` field for identification purposes in the Calling Number and/or Connected Number IEs, and in the QSIG Party Number. Valid entries are **public** (default), **unknown**, and **private**. **Public** indicates that the number plan according to CCITT Recommendation E.164 is used and that the Type of Number is **national**. **Unknown** indicates the `Numbering Plan Indicator` is **unknown** and the Type of Number is **unknown**. **Private** indicates the `Numbering Plan Indicator` is **PNP** and the Type of Number is determined from the ISDN Private-Numbering form.
- **Outgoing Channel ID Encoding** — Displays only if `Group Type` is **isdn**, `Used for DCS` is **y**, and `Service Type` is anything except **dmi-mos** or **sddn**. Determines whether to encode the Channel ID IE as **preferred** or **exclusive**. Blank is not a valid entry. Defaults are determined as follows:
  - If `Group Type` is **isdn** and `Used for DCS` is **y**, default is **exclusive**.
  - If `Group Type` is **isdn** and `Used for DCS` is **n**, default is **preferred**.
  - If `Group Type` is not **isdn** or it is **isdn**, but `Used for DCS` does not appear, default is **preferred**.
- **Send Calling Number** — Specifies whether the calling party's number is sent on outgoing or tandemed ISDN calls. Valid entries are **y**, **n** (default), or **r** (restricted). If **y** is entered, the ISDN Numbering - Public/Unknown

Format form is accessed to construct the actual number to be sent, or the ISDN Numbering-Private form (based on `Numbering Format`) is used. If `r` is entered, the calling number is sent “presentation restricted.”

 **NOTE:**

The ISDN Numbering - Public/Unknown Format form can override `Send Calling Number` entry for any administrable block of extensions.

- **Send Codeset 6/7 LAI IE?**—Specifies whether the ISDN trunk should transmit information in Codeset 6/7. If the `UUI IE Treatment` field is **shared**, then this field should be **n**. Otherwise, the same information will be sent twice and may exceed the message size. Default is **y** for pre-DEFINITY 6.3 compatibility.
- **Send Connected Number** — Specifies if the connected party’s number is sent on incoming or tandemmed ISDN calls. Valid entries are **y**, **n** (default), or **r** (restricted). If **y** is entered, the ISDN Numbering - Public/Unknown Format form is accessed to construct the actual number sent, or the ISDN Numbering-Private form (based on `Numbering Format`) is used. If the value is **r**, the connected number is sent “presentation restricted.”

 **NOTE:**

The ISDN Numbering - Public/Unknown Format form overrides `Send Connected Number` entry for any administrable block of extensions.

- **Send Name** — Specifies whether the calling/connected/called/busy party’s administered name is sent to the network on outgoing/incoming calls. Valid entries are **y**, **n** (default), or **r** (restricted). The value **r** indicates that the calling/connected name will be sent by the switch but will be marked “presentation restricted.” The value **r** is only valid if `Supplementary Services Protocol` is **b** (for called/busy only) or **d** for the QSIG Global Networking Supplementary Services Protocol. When `Supplementary Service Protocol` is **e** (DCS with Rerouting), only values of **y** and **n** permitted.

 **NOTE:**

If name information is not administered for the calling station or the connected/called/busy station, the system sends the extension number in place of the name.

- **Send UCID**—Specifies whether or not the trunk should transmit Universal Call IDs. The valid entries are **y** and **n** (default).
- **UUI IE Treatment**—Specifies whether the user information is shared. Enter **shared** if the trunk is connected to a DEFINITY 6.3 (or later) switch. Enter **service-provider** (default) if the trunk is connected to a pre-DEFINITY 6.3 switch or service provider functionality is desired.

- **Wideband Support** — Specifies whether or not Wideband Switching is supported by this trunk group. The only valid entry for ISDN-BRI trunk groups is **n** (default).

## Implementation notes

---

Internal Alert only displays if Service Type is **tie**.

DCS Signaling and PBX ID display when Used for DCS is **y**.

The Used for DCS is not displayed if Service Type is **dmi-mos** or **sddn**.

Hop Dgt displays if the Service Type is **tandem**. It also displays when the Supplementary Service Protocol is **b** and the Service Type is **access**, **dmi-mos**, **public-ntwrk**, **tandem**, **tie**, or any Type 0 or Type 1 craft defined service.

Numbering Format displays if Send Calling Number and/or Send Connected Number are **y** or **r**.

## Shared UII Feature Priorities Page

---

This page appears on the trunk group form **only** when the UII IE Treatment field is **shared**. The fields in this page show the priorities for each type of information to be forwarded in the Shared UII.

```
SHARED UII FEATURE PRIORITIES

ASAI: 1

Universal Call ID: 2

MULTI SITE ROUTING (MSR)

    In-VDN Time: 3
    VDN Name: 4
    Collected Digits: 5
    Other LAI Information: 6
```

### Screen 7-65. Shared UII Feature Priorities Page

#### Fields unique to this form

Changing the priorities in this form may affect whether or not certain information will be sent. For more information about setting priorities, see [Information Forwarding](#).

- **ASAI** — User information from ASAI. Valid entries are 1 to 6 and blank. If blank, that field's information is not forwarded.
- **Universal Call ID** — Unique tag to identify each call. Valid entries are 1 to 6 and blank. If blank, that field's information is not forwarded.
- **In-VDN Time** — Number of seconds the call has spent in vector processing. Valid entries are 1 to 6 and blank. If blank, that field's information is not forwarded.
- **VDN Name** — Name of the active VDN (also called LAI DNIS). Valid entries are 1 to 6 and blank. If blank, that field's information is not forwarded.
- **Collected Digits** — Digits collected from caller (not including dial-ahead digits). Valid entries are 1 to 6 and blank. If blank, that field's information is not forwarded.
- **Other LAI Information** — Includes the time stamp of when the call entered the current queue, the call's priority level in its current queue, and the type of interflow. Valid entries are 1 to 6 and blank. If blank, that field's information is not forwarded.

### Incoming Call Handling Treatment Table

| Service/<br>Feature | Called<br>Len | INCOMING CALL HANDLING TREATMENT |     |        | Page y of x        |               |
|---------------------|---------------|----------------------------------|-----|--------|--------------------|---------------|
|                     |               | Called<br>Number                 | Del | Insert | Per Call<br>CPN/BN | Night<br>Serv |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |
|                     |               |                                  |     |        |                    |               |

Screen 7-66. Incoming Call Handling Treatment Table form

**NOTE:**  
 This table does not appear if Digit Handling (in/out) is **overlap** on the "in" side or if Direction is **outgoing**.

The Incoming Call Handling Treatment Table can (optionally) provide unique call treatment for different incoming calls on any ISDN-BRI trunk group. The number of unique treatments that can be specified in this table and the number of pages vary depending on whether the Usage Allocation Enhancements feature is enabled and on the amount of available system memory.

Unique digit manipulation capabilities, CPN/BN requests, and night service destinations are possible for different types of incoming calls. The unique digit manipulation capabilities can be particularly useful to accommodate different dial plans for different services on an ISDN-BRI trunk type with a *Service Type* (field entry) of **cbc** (Call-by-Call). The table can also be used for ISDN-BRI trunk groups that are not Call-by-Call. For example, an ISDN-BRI group with *Service Type* set to **mega800** could use the Incoming Call Handling Treatment table to distinguish treatment of calls to different 800 numbers based on the Dialed Number Identification Service (DNIS) number that is incoming to the switch.

Each row in the table consists of seven columns. The first three columns (*Service/Feature*, *Called Len*, and *Called Number*) constitute a key that together select which row or unique treatment should apply for an incoming call on the group. The remaining four columns (*Del*, *Insert*, and so on) specify the treatment to be provided for a call that matches the key.

If an incoming call is for a service listed in a row on the table, then that row may specify the treatment for the call, depending on the other two columns of the key. *Called Len* is used to continue the row determination. If the number of digits received with the incoming call matches the number of digits in *Called Len* for calls to the matched service, then this row may apply. If no other row also contains a matching service and called length, then this row does apply. If another row does exist with the same service and number length, then *Called Number* will be used to continue the row determination.

If the leading digits received with the incoming call match the digits specified in *Called Number*, then this row applies to the call. Therefore, with this table, a unique treatment can be given to any incoming call, even if these calls are to the same service or have the same length of digits. The remaining four fields specify the unique treatment for the call once the row has been determined. Together, the *Del* and *Insert* fields can be used to manipulate the incoming number that will be used to route the call. *Per Call CPN/BN* can be used to request CPN/BN for specific calls incoming on the group. The *Night Serv* field is used to have calls of different types routed to different night destinations when night service is in effect.

 **NOTE:**

DCS features that use the remote-tgs button (on the remote switch) do not work when the local trunk group deletes or inserts digits on the incoming call. These buttons try to dial a local TAC. Adding or deleting digits defeats this operation and renders the remote feature inoperable. If digit manipulation is needed, use it on the outgoing side, based on the routing pattern. One reason for digit manipulation is insertion of the AAR feature access code (FAC).

## Fields unique to this form

These fields are located on the Incoming Call Handling Treatment Table form.

- **Service/Feature** — Specifies the ISDN Services/Features for an incoming call type. See *Service Type* description for a list of predefined Services/Features that can be received. Or, use Type 0, Type 1, and Type 2 user defined services. The identifier “other” can be used for any Services/Features not explicitly specified.
- **Called Len** — Specifies the number of digits received for an incoming call. A blank entry is used as a “wild card” entry and, when used, means that any length of digits associated with the specified Service/Feature can match in this field. Valid entries are **0** to **21**, or leave blank.
- **Called Number** — Specifies the leading digits received for an incoming call. A blank entry is used as a “wild card” entry and, when used, means that any number associated with the specified Service/Feature can match in this field. Valid entries are 1 to 16 digits, or leave blank.
- **Del** — Specifies the number of leading digits to be deleted from the incoming Called Party Number. Calls of a particular type may be administered to be routed to a single destination by deleting all incoming digits and then administering *Insert* with the desired extension. Valid entries are **1** to **21**, **all**, or leave blank.
- **Insert** — Specifies the digits to be prepended to the front of the remaining digits after any (optional) digit deletion has been performed. The resultant number formed from digit deletion/insertion is used to route the call, provided night service is not in effect. Valid entries are up to 16 characters consisting of a combination from the following: 0 through 9, \*, #, or leave blank.
- **Per Call CPN/BN** — Specifies when and how to request Calling Party Number (CPN) or Billing Number (BN) for calls of this type. Leave blank when connected to another switch, or when connected to a public network outside North America. Within North America, leave blank when connected to a public network that does not permit customer equipment to request CPN or BN for individual incoming calls. The AT&T Switched Network offers this service under the titles “CPN/BN to Terminating End on a Per-Call Basis” and “ANI (BN) on Request.” An entry of **none** indicates the switch will not request either CPN or BN for any incoming calls of this type. Valid entries are **cpn-only**, **bn-only**, **bn-pref** (prefer BN, but accepts CPN), **cpn-pref** (prefer CPN, but accepts BN), **none**, or leave blank (default). Leave blank when connected to another switch or to a network other than the AT&T Switched Network.

### NOTE:

A 4-second delay occurs in terminating the call to the far-end station if the connecting switch does not respond to the request.

- **Night Serv** — Specifies a night service extension (can be a VDN extension) per Service/Feature. An entry other than blank overrides *Night Service* entry on page 1 of the form. This entry can be overridden by the Trunk/Member Night Service entry when provided. Valid entries are an assigned extension, the attendant group access code (**attd**), or leave blank.

### Implementation notes

---

When *Service Type* is **cbc**, incoming call handling and digit manipulation are handled on a per *Service/Feature* basis.

For ISDN trunk groups with **cbc** entered in *Service Type*, *Service/Feature* cannot be any of the following: **access**, **dmi-mos**, **public-ntwrk**, **sddn**, **tandem**, or **tie**.

When *Service Type* is not **cbc**, *Service/Feature* must match *Service Type* entered.

Screen 7-67. CBC Trunk Group Usage Allocation form

## Fields unique to this form

The CBC Trunk Group Usage Allocation form sets a minimum and maximum number of members for up to ten different Services/Features for up to three different Usage Allocation Plans (1–3).

### NOTE:

See "[Call-by-Call Service Selection](#)" for a detailed description of Usage Allocation Plans.

- **Service/Feature** — Specifies the ISDN Services/Features that can be requested at call setup time when using this trunk group. See *Service Type* description for a list of predefined Services/Features that can be received on a call by call basis. In addition, the user defined service types can also be used. The identifier "other" is used for all Services/Features not explicitly specified.
- **Min# Chan** — Indicates the minimum number of members of an ISDN-BRI trunk group with a *Service Type* of **cbc** that a particular Service/Feature can use at any given time. The sum of the minimum number of members for all Service/Features must not exceed the total number of members of the trunk group. Valid values are **0-99** or blank (default).
- **Max# Chan** — Indicates the maximum number of members of a ISDN-BRI trunk group with a *Service Type* of **cbc** that a particular Service/Feature can use at any given time. This field must be completed if a Service/Feature has been entered in the Incoming Call Handling Treatment Table form. Valid values are **0-99** or blank (default).

## Implementation note

This form displays when *Service Type* is **cbc** and *Usage Alloc* is **y**.

Screen 7-68. CBC Service Trunk Group Allocation Plan Assignment Schedule form

### Fields unique to this form

The CBC Service Trunk Group Allocation Plan Assignment Schedule form provides for administering a fixed schedule or administering a schedule that can change up to six times a day for each day of the week. This form determines which CBC Service Trunk Group Allocation Plan will be in use at any given time.

- **Fixed** — Indicates whether the allocation plan will be fixed. If **y** is entered, the plan number entered in Allocation Plan Number will be enabled. Default is **n**.
- **Allocation Plan Number** — Specifies the CBC Trunk Allocation Plan (1 through 3) that is in effect if a fixed usage method has been selected. This field must be assigned if Fixed is **y**. Valid entries are **1** through **3** or blank (default).
- **Scheduled** — Indicates whether or not the allocation plans will be in effect according to the schedule found on this page. If **y** is entered in this field then there must be at least one entry in the schedule.
- **Act Time** — Indicates the time the usage allocation plan administered in the next field (Plan #) will become effective. Enter the time in military time. There must be at least one entry per day. Valid entries are **00:00** through **23:59**.
- **Plan #** — Specifies the number of the usage allocation plan that will be in effect from the activation time until the activation time of the next scheduled plan change. Valid entries are **1** to **3** or blank (default).

## Implementation notes

This form displays when Service Type is **cbc** and the Usage Alloc is **y**.

Allocation Plan Number only displays if Fixed is **y**.

## Group Member Assignments form

| GROUP MEMBER ASSIGNMENTS |       |       |      |       |       |       |
|--------------------------|-------|-------|------|-------|-------|-------|
| Port                     | Code  | Sfx   | Name | Night | Sig   | Grp   |
| 1:                       | _____ | _____ | -    | _____ | _____ | _____ |
| 2:                       | _____ | _____ | -    | _____ | _____ | _____ |

Screen 7-69. ISDN-BRI Group Member Assignment form

## Fields unique to this form

These fields are unique to the ISDN-BRI Trunk Group Member Assignment form.

 **NOTE:**

The total number of pages, and the first page of Group Member Assignments, will vary depending on whether the CBC and Wideband Support pages display.

- **Port** — Specifies the B-channel port numbers with B-channel 2 being the port number plus 16. For example, if B-channel 1's port number is 01A1002, then B-channel 2's port number would be 01A1018.
- **Sig Grp** — When an ISDN-BRI trunk port is administered, this field becomes unadministrable.

## ISDN-PRI trunk group

---

This form assigns an Integrated Services Digital Network-Primary Rate Interface (ISDN-PRI) trunk group that supports the ISDN-PRI and Call-by-Call Service Selection features. The trunk group provides end-to-end digital connectivity and supports a wide range of services including voice and non-voice services, to which users have access by a limited set of CCITT-defined, standard multipurpose interfaces. Calls can be processed to a variety of switched nodal services such as MEGACOM telecommunications service, WATS, and ACCUNET digital service and calls destined for different interexchange carriers.

The ISDN-PRI trunk group may also be used to support the Wideband Switching feature. This is intended to work with the H0 (384 Kbps), H11 (1536 Kbps), H12 (1920 Kbps), and NXDS0 (128 to 1984 Kbps) data services, and to support high-speed video conferencing and data applications.

### Administration commands

---

When an ISDN-PRI trunk connects two switches, set the trunk options identically at both ends of the connection, with the exception of Trunk Hunt. It is acceptable for both ends to have `Trunk Hunt` administered as **cyclical**, but if one end is administered as **ascend**, the other end must be administered as **descend**. This helps avoid the possibility of glare conditions.

Use the following commands to administer the ISDN-PRI trunk group form.

| Action  | Object      | Qualifier   |
|---------|-------------|---|
| add     | trunk-group | 1-MAX (or 'next')   |
| change  | trunk-group | 1-MAX or tac X...   |
| display | trunk-group | 1-MAX ['number' X]['to-number' X]['count' N]<br>['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']   |
| remove  | trunk-group | 1-MAX or tac X...   |

### Hardware requirements

---

ISDN-PRI is supported by the TN767 circuit pack (for assignment of a T1 signaling link and up to 24 ISDN-PRI trunk group members), or the TN464C or later circuit pack (for assignment of a T1 or E1 signaling link and up to 24 or 31 ISDN-PRI trunk group members, respectively). The TN2207 circuit pack can also be used with ISDN-PRI.

- For R6si and later configurations and R6vs and later configurations, the D-channel switches through either the TN765 Processor Interface (PI) circuit pack or the TN778 Packet Control (PACCON) circuit pack.

- For R6r and later configurations, the D-channel switches through the TN1655 Packet Interface (PKTINT) circuit pack.
- A TN780 or TN2182 Tone Clock circuit pack is required to provide synchronization for the DS1 circuit pack.

**NOTE:**

The TN767 cannot be used to carry the D-channel if either the TN778 (PACCON) or TN1655 (PKTINT) circuit packs are used to switch the D-channel. However, in these circumstances, the TN767 can be used for NFAS interfaces carrying only B-channels.

**How to administer ISDN-PRI trunk groups**

## Notes for the Above Tables

---

- **System-Parameters Customer-Options** — ISDN-PRI should be enabled. For a TN778, set `PRI Over PACCON` to **y**. The `QSIG Optional Features` fields may be enabled to allow appropriate administration for the `Supplementary Service Protocol`.
- **System-Parameters Features** — Set `Send Non-ISDN Trunk Group Name as Connected Name` and `Display Connected Name/Number for ISDN DCS Calls`. (Default is **n**.)
- **DS1 Circuit Pack** —
  - **DS1 (T1) Circuit Pack**

Assign all fields as required. For Facility Associated Signaling, up to 23 ports are available for administration as trunk members in an associated ISDN-PRI trunk group. The 24th port is used as a signaling channel. For Non-Facility Associated Signaling, all 24 ports may be used on certain DS1 circuit packs. The D-channel signaling function for these packs must be provided by a designated DS1 pack on its 24th channel.
  - **E1 Circuit Pack**

Assign all fields as required. For Facility Associated Signaling, up to 30 ports are available for administration as trunk members in an associated ISDN-PRI trunk group. Port number 16 is used as a signaling channel.
- **System-Parameters Maintenance-Options** — Use this form only for a TN778. Set `Packet Bus Maint` to **y**.
- **ISDN-PRI Trunk Group** — Enter information in all the fields except the trunk group members. Enter the members after you establish the signaling links.
- **Signaling Group** — Complete all fields. This form identifies groups of ISDN-PRI DS1 interface B-channels for which a given D-channel (or D-channel pair) will carry the associated signaling information (supports the Facility and Non-Facility Associated Signaling feature). Each DS1 board that is required to have a D-channel must be in a different signaling group by itself (unless D-channel backup is needed, in which case a second DS1 is administered as a backup D-channel). You are not required to select a channel for a trunk group, but if you do, you must have already defined the trunk group as type ISDN.

### NOTE:

The following three forms, Processor Interface Data Module, Communication Interface Links, and Communication Processor Channel Assignment are used only to implement the ISDN-PRI feature using PI TN765.

- Processor Interface Data Module — Use this form only for a TN765. Assign up to 8 interface links using 8 Processor Interface Data Module forms for multi-carrier cabinet systems, and up to 4 links for single-carrier cabinet systems. One Processor Interface Data Module form must be completed for each interface link to be assigned.
- Communication Interface Links — Use this form only for a TN765. Assign link numbers 01 to 08 for a multi-carrier cabinet system or links 01 to 04 for a single-carrier cabinet system as required. When first administering this form in DEFINITY ECS for ISDN, do not administer the Enable field.
- Communication Processor Channel Assignment — Use this form only for a TN765. Enter assigned link numbers and assign associated channel numbers to each link. Complete all fields of the form as required. When first administering this form in DEFINITY ECS for ISDN, you need to:
  - First, administer the Interface Links form, except the Enable field.
  - Second, administer the ISDN fields on the Processor Channel form.
  - Last, go back to the Interface Links form and administer the Enable field.
- ISDN Numbering - Public/Unknown — Complete all fields. This form supports the ISDN-PRI Call Identification Display.
- ISDN Numbering - Private — Complete all fields. This form supports the ISDN-PRI Call Identification Display.
- Routing Pattern — Complete all fields including the Supplemental ISDN Routing Information fields as required.
- Hunt Group — Complete `ISDN Caller Display` by entering either **grp-name** or **mbr-name** to specify whether the hunt group name or member name, respectively, is sent to the originating user (supports the ISDN-PRI Call Identification Display feature).
- Terminating Extension Group — Complete `ISDN Caller Display` by entering either **grp-name** or **mbr-name** to specify whether the group name or member name, respectively, is sent to the originating user (supports the ISDN-PRI Call Identification Display feature).
- Synchronization Plan — Assigns primary and secondary external synchronization sources for the DS1 circuit pack. Complete all form fields as required.

## Design Considerations

ISDN-BRI and ISDN-PRI trunks cannot be mixed in the same trunk group. Therefore, consider the following:

- The earliest trunk member (the lowest numbered one) administered is considered correct.
- If an offending member is subsequently found (meaning the first member was BRI and a later member was PRI, or vice versa), the cursor positions on the offending member, and the following error message appears:

**Cannot mix BRI and PRI ports in the same trunk group.**

## Field descriptions

Many of the fields on the following forms are described in [“Trunk Groups — General” on page 7-115](#). If a field on this form is unique, it is listed and defined.

### ISDN-PRI trunk group form page 1

```

Screen 7-70. ISDN-PRI Trunk Group form (page 1)

## Fields unique to this form

These fields are unique to the ISDN-PRI trunk group form.

- **Calling Number** — These three fields comprise the administrable fields for the Calling Line Identification Prefix feature. They display when *Direction* is **incoming** or **two-way**.
  - Delete — The number of digits to delete from the calling party number for all incoming calls on this trunk group. Valid values: any number from **1-15**, **all** or blank.
  - Insert — The specific digits prefixed to incoming calls when the calling party is a member of this trunk group. Valid values: any string of 1-15 digits or blank.
  - Numbering Format — Indicates TON/NPI encoding applied to CPN information modified by the CLI Prefix feature. This encoding does not apply to calls originating locally. *Numbering Format* on page two of this form applies to calls originated from this switch.

If this field is blank, DEFINITY ECS passes on the encoding received in the incoming setup message. If the incoming setup message did not contain CPN information, and digits are added, the outgoing message will contain these digits. If *Numbering Format* is blank in this case, the value defaults to **pub-unk**.

If *Numbering Format* on page two of this form is also administered as **unknown**, the trunk group is modified to “unk-unk” encoding of the TON/NPI. Therefore this field also must contain a value other than **unknown**.

**⇒ NOTE:**

The values for this field map to the Type of Numbering (TON) and Numbering Plan Identifier (NPI) values shown in [Table 7-12](#).

**Table 7-12. Numbering Format Valid Values**

| Numbering format valid values | Type of numbering (TON) | Numbering plan identifier (NPI) |
|-------------------------------|-------------------------|---------------------------------|
| blank                         | incoming TON unmodified | incoming NPI unmodified         |
| natl-pub                      | national(2)             | E.164(1)                        |
| intl-pub                      | international(1)        | E.164(1)                        |
| locl-pub                      | local/subscriber(4)     | E.164(1)                        |

*Continued on next page*

Table 7-12. Numbering Format Valid Values — *Continued*

| Numbering format valid values | Type of numbering (TON) | Numbering plan identifier (NPI) |
|-------------------------------|-------------------------|---------------------------------|
| pub-unk                       | unknown(0)              | E.164(1)                        |
| lev0-pvt                      | local(4)                | Private Numbering Plan - PNP(9) |
| lev1-pvt                      | Regional Level 1(2)     | Private Numbering Plan - PNP(9) |
| lev2-pvt                      | Regional Level 2(1)     | Private Numbering Plan - PNP(9) |
| unk-unk                       | unknown(0)              | unknown(0)                      |

- **Charge Advice** — Allows you to accumulate and access charge information about a call. You must have already set `CDR Report` to **y** or **r** (ring-intvl) before changing this field from its default of **none**. You may specify one of the following options:
  - none — No Advice of Charge information is collected by the system.
  - automatic — Advice of Charge is enabled automatically for all outgoing calls over this trunk group.
  - end-on-request — DEFINITY ECS will request information at the end of the call for each outgoing call over this trunk group.
  - during-on-request — DEFINITY ECS will request information during and at the end of the call for each outgoing call over this trunk group.

Remember that requesting “during-on-request” affects system performance because the option increases message activity on the signaling channel which may reduce the maximum call capacity.

- **Codeset to Send Display** — This field defines the codeset for sending the information element for Display. The value depends on the type of switch the user is connected to.
  - 0 — CCITT
  - 6 — Any other than CCITT or System 85 R2V4, 4E11 (default)
  - 7 — System 85 R2V4, 4E11

- **Codeset to Send TCM, Lookahead** — This field defines the codeset for sending the information element for Traveling Class Marks and Lookahead Interflow. The value depends on the type of switch the user is connected to. Valid entries are **7** for System 85 R2V4, 4E11, or newer switch types, or **6** (default) for other types.

**NOTE:**

A Traveling Class Mark (that is, the user's FRL or the user's trunk group FRL) is passed between tandem nodes in an ETN in the setup message only when the `Service Type` is **tandem**. It is then used by the distant tandem switch to permit access to facilities consistent with the originating user's privileges.

- **Digit Handling (in/out)** — This field defines whether overlap receiving and overlap sending features are enabled. Set the field to **overlap** when you want overlap receiving or overlap sending. Set the field to **enbloc** when you do not want these features enabled. The first field value indicates digit receiving and the second value indicates digit sending. There are 4 possible combinations: **enbloc/enbloc** (default), **enbloc/overlap**, **overlap/enbloc**, and **overlap/overlap**.

Without overlap receiving or sending enabled, the digits on incoming and outgoing calls are sent enbloc. If `Digit Handling` is **overlap/enbloc** or **overlap/overlap**, the following results:

- Incoming Call Handling Treatment table does not appear.
  - `Digit Treatment` and `Digits` appear.
  - Warning message indicates that all Incoming Call Handling entries are removed when form is submitted.
  - When form is submitted with these values, all Incoming Call Handling entries are removed.
- **Far End Test Line No.** — Specifies the number sent to the far-end's ISDN test line extension. When the **test trunk long** command is issued, this exact number is sent to the far-end to establish a call that tests the integrity of the trunk member under test. The number does not pass through routing or undergo digit manipulation. The digits entered must be what the far-end expects. For example, for an ISDN tandem trunk, the far-end test number should be a 7-digit ETN (Electronic Tandem Network) number. Up to 15 digits may be entered in this field.

- **Max Message Size to Send** — Defines the maximum size of ISDN-PRI messages sent by the switch. Currently, the system can receive 260 byte messages. Valid entries are **128**, **244**, **256**, and **260** (default). The following table indicates the expected message size from several Lucent Technologies products.

| Products         | Message Length (octets) Received |
|------------------|----------------------------------|
| 4ESS (4E11)      | 256                              |
| 4ESS (4E13)      | 256                              |
| 4ESS (4E14)      | 256                              |
| 5ESS (5E4)       | 244                              |
| 5ESS (5E5)       | 244                              |
| 5ESS (5E6)       | 244                              |
| System 75 (all)  | 260                              |
| System 85 (R2V4) | 128                              |
| System 85 (R2V5) | 260                              |
| System 85 (R2V6) | 260                              |

- **Service Type** — Indicates the service for which this trunk group is dedicated. [Table 7-13](#) provides a listing of predefined entries. In addition to the Services/Features listed in this table, any user-defined Facility Type of Type 0 (feature) or Type 1 (service) on the Network Facilities form is allowed. An entry of **cbc** is also allowed, which indicates this trunk group is used by the Call-By-Call Service Selection feature.

Up to 10 (R6si, R6vs) or 200 (R6r) ISDN-BRI and/or ISDN-PRI trunk groups can have this field administered as **cbc**.

**Table 7-13. Predefined Services/Features — ISDN**

| Administratio<br>n mnemonic | Description  |
|-----------------------------|--|
| access                      | A tie trunk giving access to an Electronic Tandem Network — See <a href="#">“Access trunk group” on page 7-150</a> |
| accunet                     | ACCUNET Switched Digital Service — part of ACI (AT&T Communications ISDN) phase 2.                                 |
| cbc                         | Call-by-Call service — provides different dial plans for different services on an ISDN-PRI trunk group.            |

*Continued on next page*

Table 7-13. Predefined Services/Features — ISDN — *Continued*

| Administratio<br>n mnemonic | Description   |
|-----------------------------|---|
| dmi-mos                     | Digital multiplexed interface — message oriented signaling — See <a href="#">“DMI-BOS trunk group” on page 7-188</a> . Do not use with DCS with Rerouting.  |
| i800                        | International 800 Service — allows a subscriber to receive international calls without a charge to the call originating party.  |
| inwats                      | INWATS — provides OUTWATS-like pricing and service for incoming calls.  |
| lds                         | Long-Distance Service — part of ACI (AT&T Communications ISDN) phase 2.   |
| megacom                     | MEGACOM Service — an AT&T communications service that provides unbanded long-distance services using special access (switch to 4ESS switch) from an AT&T communications node.   |
| mega800                     | MEGACOM 800 Service — an AT&T communications service that provides unbanded 800 service using special access (4ESS switch to switch) from an AT&T communications node.  |
| multiquest                  | AT&T MULTIQUEST Telecommunications Service — dial 700 service. A terminating-user’s service that supports interactive voice service between callers at switched-access locations and service provides directly connected to the AT&T Switched Network (ASN).  |
| operator                    | Network Operator — provides access to the network operator.   |
| outwats-bnd                 | OUTWATS Band — WATS is a voice-grade service providing both voice and low speed data transmission capabilities from the user’s location to defined service areas referred to as bands; the widest band is 5.  |
| public-ntwrk                | Public network calls — It is the equivalent of CO (outgoing), DID, or DIOD trunk groups. If Service Type is public-ntwrk, Dial Access can be set to <b>y</b> .  |
| sddn                        | Software Defined Data Network — provides a virtual private line connectivity via the AT&T switched network (4ESS switch). Services include voice, data, and video applications. These services complement the SDN service. Do not use for DCS with Rerouting. |
| sdn                         | Software Defined Network (SDN) — an AT&T communications offering that provides a virtual private network using the public switched network. SDN can carry voice and data between customer locations as well as off-net locations.                             |

*Continued on next page*

Table 7-13. Predefined Services/Features — ISDN — *Continued*

| Administratio<br>n mnemonic | Description   |
|-----------------------------|---|
| sub-operator                | Presubscribed Common Carrier Operator — provides access to the presubscribed common carrier operator.                           |
| tandem                      | Tandem tie trunks integral to an ETN — See <a href="#">“Tandem trunk group”</a> .   |
| tie                         | Tie trunks — general purpose — See <a href="#">“Tie trunk group”</a> .  |
| wats-max-bnd                | Maximum Banded Wats — a WATS-like offering for which a user's calls are billed at the highest WATS band subscribed to by users. |

- **Supplementary Service Protocol** — Indicates which supplementary service protocol should be used for services over this trunk group. *Supplementary Service protocols are mutually exclusive.* Enter one of the following Supplementary Service Protocols. Default is **a**.
  - a national public network
  - b ISO/ETSI QSIG Private Network
  - c ETSI public network
  - d European Computer Manufacturer's Association (ECMA) QSIG private network (supports only Name Identification and Additional Network Feature Transit Counter (ANF-TC))
  - e DCS with Rerouting
    - Do not use `Service Type` of **dmi-mos** or **sddn** with this option.
    - Set `Used for DCS` (on page 2) to **y**.
- **Test Call BCC** — Indicates the Bearer Capability Code (BCC) used for the ISDN-PRI test call. Valid entries and their definitions are as follows:
  - 0 — Voice
  - 1 — Mode 1
  - 2 — Mode 2 Asynchronous
  - 3 — Mode 3 Circuit
  - 4 — Mode 0 (default)

- **Testcall ITC** — Controls the encoding of the Information Transfer Capability (ITC) codepoint of the bearer capability IE in the SETUP message when generating an ISDN test call. Allowed values are **rest** (restricted) and **unre** (unrestricted); default is **rest**.

 **NOTE:**

ISDN Testcall feature has no routing, so a testcall is never blocked due to an incompatible ITC.

- **Testcall Service** — Specifies the call-by-call selection for an ISDN-PRI test call. Only appears if `Service Type` is **cbc**. Valid entries are all of the services listed in [Table 7-13](#) excluding **sddn** or any new Facility Type of Type 0 (feature), Type 1 (service), or Type 3 (outgoing) that is defined by users on the Network Specific Facility Encoding form.
- **Trunk Hunt** — The switch performs a trunk hunt when searching for available channels within a facility in an ISDN-PRI trunk group. Enter **ascend** to enable a linear trunk hunt search from the lowest to highest numbered channels, or **descend** for a linear trunk hunt search from the highest to lowest numbered channels. With both **ascend** and **descend**, all trunks within an ISDN-PRI trunk group are selected based on this field and without regard to the order in which trunks are administered within the trunk group.

Enter **cyclical** (default) to enable a circular trunk hunt based on the sequence the trunks were administered within the trunk group.

 **NOTE:**

The **cyclical** option cannot be set if the trunk group is to be used for Wideband operations (`wideband Support` set to **y**).

The search can be administered per ISDN-PRI trunk group, but it infers the direction of search within all ISDN-PRI facilities (or portions of those facilities) administered within the trunk group.

- **Usage Alloc** — Displays when `Service Type` is **cbc**. Specifies whether the users want to allocate the services provided by the trunk group. Valid entries are **y** and **n** (default). If **y** is entered, two additional CBC-related forms display. They are the CBC Trunk Group Usage Allocation Plans form and the CBC Trunk Group Usage Allocation Plan Assignment Schedule.

## Implementation notes

`Answer Supervision Timeout` defaults to **0**.

`Digit Treatment` and `Digits` display when `Digit Handling (in/out)` is **overlap** on the “in” side.

Queue Length displays when Direction is **outgoing** or **two-way**.

Usage Alloc and Testcall Service display when Service Type is **cbc**.

### Screen 7-71. ISDN-PRI Trunk Group form (page 2)

#### Fields unique to this form

These fields are unique to the ISDN-PRI trunk group form.

- **DCS Signaling** — Specifies the means used to send the DCS message. This field only displays if *Used for DCS* entry is **y** and *Service Type* is anything except **dmi-mos** or **sddn**. Valid entries are **bx.25** for the traditional DCS feature or **d-chan** for the DCS over ISDN-PRI D-channel feature.
- **Hop Dgt** — The Tandem Hop Limitation and QSIG Additional Network Feature Transit Counter (ANF-TC) features provide a counter that reflects the number of switches (that is, the number of hops) that a call has gone through. The counter increments as a call leaves DEFINITY ECS using tandem facilities. Valid values are **y** and **n** (default). One or both of the features can be applied to the trunk group depending on the following:
  - If you enter **y** and *Group Type* is **tandem** or *Group Type* is **isdn** and *Service Type* is **tandem**, the Tandem Hop Limitation feature is applied to the trunk group.
  - If you enter **y** and you set *Group Type* to **isdn**, set *Service Type* to **access**, **dmi-mos**, **public-ntwrk**, **tandem**, **tie**, or any of the craft-defined services allowed in the field. Set *Supplementary Service Protocol* to **b** or **d**, then the ANF-TC feature is applied to calls on the trunk group.

⇒ NOTE:

The above conditions overlap. If `Group Type` is **isdn**, `Service Type` is **tandem**, and `Supplementary Service Protocol` is **b** or **d**, then both the Tandem Hop Limitation and ANF-TC features are applied to calls on the trunk group.

— If both features are applied to calls on the trunk group, ANF-TC takes precedence. In situations where DEFINITY ECS is an Incoming or Outgoing Gateway, either feature uses the hop count and transit information provided by the other.

- **Maximum Size of UII IE Contents**—Appears when UII Treatment is shared.
- **NCA-TSC Trunk Member** — Identifies the trunk member whose D-channel will be used to route tandem NCA-TSCs. Value range for this field is from **1** to the maximum number of members per trunk group supported on the switch. Default is blank.
- **Numbering Format** — This field appears if `Send Calling Number` is **y** or **r** or `Send Connected Number` is **y** or **r**. This specifies the encoding of the “Numbering Plan Indicator” field for identification purposes in the Calling Number and/or Connected Number IEs, and in the QSIG Party Number. Valid entries are **public** (default), **unknown**, and **private**. **Public** indicates that the number plan according to CCITT Recommendation E.164 is used and that the `Type of Number` will be **national**. **Unknown** indicates the `Numbering Plan Indicator` is **unknown** and that the `Type of Number` is **unknown**. **Private** indicates the `Numbering Plan Indicator` is **PNP** and the `Type of Number` is determined from the ISDN Private-Numbering form.
- **Outgoing Channel ID Encoding** — Displays only if `Group Type` is **isdn**, `Used for DCS` is **y**, and `Service Type` is anything except **dmi-mos** or **sddn**. Blank is not a valid entry. Defaults are determined as follows:
  - If `Group Type` is **isdn** and `Used for DCS` is **y**, default is **exclusive**.
  - If `Group Type` is **isdn** and `Used for DCS` is **n**, default is **preferred**.
  - If `Group Type` is not **isdn** or it is **isdn**, but `Used for DCS` does not appear, default is **preferred**.
- **Send Calling Number** — Specifies whether the calling party’s number is sent on outgoing or tandemed ISDN calls. Valid entries are **y**, **n** (default), or **r** (restricted). If **y** is entered, the ISDN Numbering - Public/Unknown Format form is accessed to construct the actual number to be sent, or the ISDN Numbering-Private form (based on `Numbering Format`) is used. If the value is **r**, the calling number is sent “presentation restricted.”

⇒ NOTE:

The ISDN Numbering - Public/Unknown Format form can override the `Send Calling Number` entry for any administrable block of extensions.

- **Send Codeset 6/7 LAI IE?**—Specifies whether the ISDN trunk should transmit information in Codeset 6/7. If the `UUI IE Treatment` field is **shared**, then this field should be **n**. Otherwise, the same information will be sent twice and may exceed the message size. Default is **y** for pre-DEFINITY 6.3 compatibility.
- **Send Connected Number** — Specifies if the connected party's number is sent on incoming or tandemmed ISDN calls. Valid entries are **y**, **n** (default), or **r** (restricted). If **y** is entered, the ISDN Numbering - Public/Unknown Format form is accessed to construct the actual number sent, or the ISDN Numbering-Private form (based on `Numbering Format`) is used. If the value is **r**, the connected number is sent "presentation restricted."

 **WARNING:**

*The AT&T Switched Network Protocol does not support restricted displays of connected numbers. Therefore, if you administer the 1a country-protocol/protocol-version combination on the DS1 form, you should not administer Send Connected Number to "r" (restricted) on the ISDN-PRI Trunk Group form, as this causes display problems.*

 **NOTE:**

The ISDN Numbering - Public/Unknown Format form overrides the `Send Connected Number` entry for any administrable block of extensions.

- **Send Name** — Specifies whether the calling/connected/called/busy party's administered name is sent to the network on outgoing/incoming calls. Valid entries are **y**, **n** (default), or **r** (restricted). The value **r** indicates that the calling/connected name will be sent by the switch but will be marked "presentation restricted." The value **r** is only valid if the `Supplementary Services Protocol` is **b** (for called/busy only) or **d** for the QSIG Global Networking Supplementary Services Protocol. When `Supplementary Service Protocol` is **e** (DCS with Rerouting), only values of **y** and **n** permitted.

 **NOTE:**

If name information is not administered for the calling station or the connected/called/busy station, the system sends the extension number in place of the name.

- **Send UCID**—Specifies whether or not the trunk should transmit Universal Call IDs. The valid entries are **y** and **n** (default).
- **UUI IE Treatment**—Specifies whether the Information Element (IE) is shared. Enter **shared** if the trunk is connected to a DEFINITY 6.3 (or later) switch. Enter **service-provider** (default) if the trunk is connected to a pre-DEFINITY 6.3 switch or service provider functionality is desired.

- **Wideband Support** — Specifies whether or not Wideband Switching is supported by this trunk group. Valid entries are **y** or **n** (default). You can administer this field only if `Wideband Switching` is enabled on the System-Parameters Customer-Options form. If set to **y**, the Wideband Support Options page displays. All trunk members must be from TN464C (or later) circuit packs.

**NOTE:**

Wideband trunk calls are treated as a single trunk call when Automatic Circuit Assurance (ACA) measurements are taken. This way, if an ACA referral call is generated (for short or long holding time), the wideband call only triggers a single referral call using the lowest B-channel trunk member associated with the wideband channel.

## Implementation notes

Internal Alert only displays if Service Type is **tie**.

DCS Signaling and PBX ID display when Used for DCS is **y**.

Used for DCS does not display if Service Type is **dmi-mos** or **sddn**. Set value to **y** to use with DCS with Rerouting

Hop Dgt displays if Service Type is **tandem**. It also displays when Supplementary Service Protocol is **b** and Service Type is **access**, **dmi-mos**, **public-ntwrk**, **tandem**, **tie**, or any Type 0 or Type 1 craft defined service.

## Shared UUI Feature Priorities Page

This page appears on the trunk group form **only** when the UUI IE Treatment field is **shared**. The fields in this page show the priorities for each type of information to be forwarded in the Shared UUI.

SHARED UI FEATURE PRIORITIES

ASAI: 1

Universal Call ID: 2

MULTI SITE ROUTING (MSR)

In-VDN Time: 3

VDN Name: 4

Collected Digits: 5

Other LAI Information: 6

## Screen 7-72. Shared UI Feature Priorities Page

### Fields unique to this form

Changing the priorities in this form may affect whether or not certain information will be sent. For more information about setting priorities, see [Information Forwarding](#).

- **ASAI** — User information from ASAI. Valid entries are **1** to **6** and blank. If blank, that field's information is not forwarded.
- **Universal Call ID** — Unique tag to identify each call. Valid entries are **1** to **6** and blank. If blank, that field's information is not forwarded.
- **In-VDN Time** — Number of seconds the call has spent in vector processing. Valid entries are **1** to **6** and blank. If blank, that field's information is not forwarded.
- **VDN Name** — Name of the active VDN (also called LAI DNIS). Valid entries are **1** to **6** and blank. If blank, that field's information is not forwarded.
- **Collected Digits** — Digits collected from caller (not including dial-ahead digits). Valid entries are **1** to **6** and blank. If blank, that field's information is not forwarded.
- **Other LAI Information** — Includes the time stamp of when the call entered the current queue, the call's priority level in its current queue, and the type of interflow. Valid entries are **1** to **6** and blank. If blank, that field's information is not forwarded.

### Incoming Call Handling Treatment Table

| Service/<br>Feature | Called<br>Len | INCOMING CALL HANDLING TREATMENT |            | Per Call<br>CPN/BN | Night<br>Serv |
|---------------------|---------------|----------------------------------|------------|--------------------|---------------|

Screen 7-73. Incoming Call Handling Treatment Table form

**⇒ NOTE:**

This table does not appear if Digit Handling (in/out) is **overlap** on the “in” side or if Direction is **outgoing**.

The Incoming Call Handling Treatment Table can (optionally) provide unique call treatment for different incoming calls on any ISDN-PRI trunk group. The number of unique treatments that can be specified in this table and the number of pages vary depending on whether the Usage Allocation Enhancements feature is enabled and on the amount of available system memory.

Unique digit manipulation capabilities, CPN/BN requests, and night service destinations are possible for different types of incoming calls. The unique digit manipulation capabilities can be particularly useful to accommodate different dial plans for different services on an ISDN-PRI trunk type with a Service Type (field entry) of **cbc** (Call-by-Call). The table can also be used for ISDN-PRI trunk groups that are not Call-by-Call. For example, an ISDN-PRI group with Service Type set to **mega800** could use the Incoming Call Handling Treatment table to distinguish treatment of calls to different 800 numbers based on the Dialed Number Identification Service (DNIS) number that is incoming to the switch.

Each row in the table consists of seven columns. The first three columns (Service/Feature, Called Len, and Called Number) constitute a key that together select which row or unique treatment should apply for an incoming call on the group. The remaining four columns (Del, Insert, and so on) specify the treatment to be provided for a call that matches the key.

If an incoming call is for a service listed in a row on the table, then that row may specify the treatment for the call, depending on the other two columns of the key. `Called Len` is used to continue the row determination. If the number of digits received with the incoming call matches the number of digits in `Called Len` for calls to the matched service, then this row may apply. If no other row also contains a matching service and called length, then this row does apply. If another row does exist with the same service and number length, then `Called Number` will be used to continue the row determination.

If the leading digits received with the incoming call match the digits specified in `Called Number`, then this row applies to the call. Therefore, with this table, a unique treatment can be given to any incoming call, even if these calls are to the same service or have the same length of digits. The remaining four fields specify the unique treatment for the call once the row has been determined. Together, the `Del` and `Insert` fields can be used to manipulate the incoming number that will be used to route the call. `Per Call CPN/BN` can be used to request CPN/BN for specific calls incoming on the group. `Night Serv` is used to have calls of different types routed to different night destinations when night service is in effect.

#### ⇒ NOTE:

DCS features that use the remote-tgs button (on the remote switch) do not work when the local trunk group deletes or inserts digits on the incoming call. These buttons try to dial a local TAC. Adding or deleting digits defeats this operation and renders the remote feature inoperable. If digit manipulation is needed, use it on the outgoing side, based on the routing pattern. One reason for digit manipulation is insertion of the AAR feature access code (FAC).

### Fields unique to this form

These fields are located on the Incoming Call Handling Treatment Table form.

- **Service/Feature** — Specifies the ISDN Services/Features for an incoming call type. See the `Service Type` field description for a list of predefined Services/Features that can be received. Or, use Type 0, Type 1, and Type 2 user defined services. The identifier "other" can be used for any Services/Features not explicitly specified.
- **Called Len** — Specifies the number of digits received for an incoming call. A blank entry is used as a "wild card" entry and, when used, means that any length of digits associated with the specified Service/Feature can match in this field. Valid entries are **0** to **21**, or leave blank.
- **Called Number** — Specifies the leading digits received for an incoming call. A blank entry is used as a "wild card" entry and, when used, means that any number associated with the specified Service/Feature can match in this field. Valid entries are 1 to 16 digits, or leave blank.

- **Del** — Specifies the number of leading digits to be deleted from the incoming Called Party Number. Calls of a particular type may be administered to be routed to a single destination by deleting all incoming digits and then administering the Insert field with the desired extension. Valid entries are **1** to **21**, **all**, or leave blank.
- **Insert** — Specifies the digits to be prepended to the front of the remaining digits after any (optional) digit deletion has been performed. The resultant number formed from digit deletion/insertion is used to route the call, provided night service is not in effect. Valid entries are up to 16 characters consisting of a combination from the following: **0** through **9**, **\***, **#**, or leave blank.
- **Per Call CPN/BN** — Specifies when and how to request Calling Party Number (CPN) or Billing Number (BN) for calls of this type. Leave blank when connected to another switch, or when connected to a public network outside North America. Within North America, leave blank when connected to a public network that does not permit customer equipment to request CPN or BN for individual incoming calls. The AT&T Switched Network offers this service under the titles “CPN/BN to Terminating End on a Per-Call Basis” and “ANI (BN) on Request.” An entry of **none** indicates the switch will not request either CPN or BN for any incoming calls of this type. Valid entries are **cpn-only**, **bn-only**, **bn-pref** (prefer BN, but accepts CPN), **cpn-pref** (prefer CPN, but accepts BN), **none**, or leave blank (default). Leave blank when connected to another switch or to a network other than the AT&T Switched Network.

 **NOTE:**

A 4-second delay occurs in terminating the call to the far-end station if the connecting switch does not respond to the request.

- **Night Serv** — Specifies a night service extension (can be a VDN extension) per Service/Feature. An entry other than blank overrides the `Night Service` entry on page 1 of the form. This entry can be overridden by the Trunk/Member Night Service entry when provided. Valid entries are an assigned extension, the attendant group access code (**attd**), or leave blank.

## Implementation notes

---

When `Service Type` is **cbc**, incoming call handling and digit manipulation are handled on a per Service/Feature basis.

For ISDN trunk groups with **cbc** entered in `Service Type`, `Service/Feature` cannot be any of the following: **access**, **dmi-mos**, **public-ntwrk**, **sddn**, **tandem**, or **tie**.

When `Service Type` is not **cbc**, `Service/Feature` must match the `Service Type` field entered.

### CBC Trunk Group Usage Allocation form

| CBC TRUNK GROUP USAGE ALLOCATION |      |      |                         |      |      | Page y of X             |      |      |

|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |
|                                  |      |      |                         |      |      |                         |      |      |

Screen 7-74. CBC Trunk Group Usage Allocation form

#### Fields unique to this form

The CBC Trunk Group Usage Allocation form sets a minimum and maximum number of members for up to ten different Services/Features for up to three different Usage Allocation Plans (1–3).

 **NOTE:**  
 See [“Call-by-Call Service Selection”](#) for a detailed description of Usage Allocation Plans.

- **Service/Feature** — Specifies the ISDN Services/Features that can be requested at call setup time when using this trunk group. See the `Service Type` field description for a list of predefined Services/Features that can be received on a call by call basis. In addition, the user defined service types can also be used. The identifier “other” is used for all Services/Features not explicitly specified.
- **Min# Chan** — Indicates the minimum number of members of an ISDN-PRI trunk group with a `Service Type` of **cbc** that a particular Service/Feature can use at any given time. The sum of the minimum number of members for all Service/Features must not exceed the total number of members of the trunk group. Valid values are **0-99** or blank (default).
- **Max# Chan** — Indicates the maximum number of members of a ISDN-PRI trunk group with a `Service Type` of **cbc** that a particular Service/Feature can use at any given time. This field must be completed if a Service/Feature has been entered in the Incoming Call Handling Treatment Table form. Valid values are **0-99** or blank (default).

**Implementation note**

This form displays when Service Type is **cbc** and Usage Alloc is **y**.

**CBC Service Trunk Group Allocation Plan Assignment Schedule form**

Screen 7-75. CBC Service Trunk Group Allocation Plan Assignment Schedule form

**Fields unique to this form**

The CBC Service Trunk Group Allocation Plan Assignment Schedule form provides for administering a fixed schedule or administering a schedule that can change up to six times a day for each day of the week. This form determines which CBC Service Trunk Group Allocation Plan will be in use at any given time.

- **Fixed** — Indicates whether the allocation plan will be fixed. If **y** is entered in this field, the plan number entered in Allocation Plan Number will be enabled. Default is **n**.
- **Allocation Plan Number** — Specifies the CBC Trunk Allocation Plan (1 through 3) that is in effect if a fixed usage method has been selected. This field must be assigned if Fixed is **y**. Valid entries are **1** through **3** or blank (default).
- **Scheduled** — Indicates whether or not the allocation plans will be in effect according to the schedule found on this page. If **y** is entered in this field then there must be at least one entry in the schedule.

- **Act Time** — Indicates the time the usage allocation plan administered in the next field (Plan #) will become effective. Enter the time in military time. There must be at least one entry per day. Valid entries are **00:00** through **23:59**.
- **Plan #** — Specifies the number of the usage allocation plan that will be in effect from the activation time until the activation time of the next scheduled plan change. Valid entries are **1** to **3** or blank (default).

## Implementation notes

---

This form displays when `Service Type` is **cbc** and the `Usage Alloc` is **y**.

`Allocation Plan Number` only displays if `Fixed` is **y**.

## Wideband Support Options form

```
Wideband Support Options                                     Page Y of X
H0? n
H11? n
H12? n
NxDS0? y           Contiguous? n
```

### Screen 7-76. Wideband Support Options form

## Fields unique to this form

---

The Wideband Support Options form appears immediately before the trunk group member pages. The actual page number will vary.

### ⇒ NOTE:

All B-channels that comprise the wideband call must reside on the same ISDN-PRI facility. Also, all trunk members in an ISDN-PRI trunk group with `Wideband Support` set to **y** must be from a TN464C (or later) circuit pack.

- **H0** — Enter **y** to specify the ISDN information transfer rate for 384-kbps of data, which is comprised of six B-channels. When a trunk group is administered to support H0, the trunk/hunt algorithm to satisfy a call requiring 384-kbps of bandwidth uses a fixed allocation scheme. Default is **n**.

- **H11** — Enter **y** to specify the ISDN information transfer rate for 1536-kbps of data, which is comprised of 24 B-channels. When a trunk group is administered to support H11, the trunk/hunt algorithm to satisfy a call requiring 1536-kbps bandwidth uses a fixed allocation scheme. Default is **n**.
- **H12** — Enter **y** to specify the ISDN information transfer rate for 1920-kbps of data, which is comprised of 30 B-channels. When a trunk group is administered to support H12, the trunk/hunt algorithm to satisfy a call requiring 1920-kbps bandwidth uses a fixed allocation scheme. Default is **n**.
- **NxDS0** — Enter **y** to specify the “N by DS-zero” multi-rate service. Default is **n**.
- **Contiguous?** — Specifies whether or not to hunt contiguous NXDS0 channels. This field only appears if **NXDS0** is **y**.

The trunk/hunt algorithm to satisfy an **NXDS0** call is as follows:

- Enter **y** to specify the “floating” scheme. **NXDS0** calls are placed on a contiguous group of B-channels large enough to satisfy the requested bandwidth without constraint on the starting channel (no fixed starting point trunk).

 **NOTE:**

H0 and **NXDS0** “floating” scheme cannot both be **y**.

- Enter **n** to specify the “flexible” scheme. **NXDS0** calls are placed on any set of B-channels on the same facility as long as the requested bandwidth is satisfied. There are no constraints such as contiguity of B-channels or fixed starting points.

## Implementation notes

This form displays when the `Wideband Support` is **y**.

`Contiguous` only displays if **NXDS0** is **y**.

## Group Member Assignments form

| GROUP MEMBER ASSIGNMENTS |       |       | TRUNK GROUP |  | Page Y of X |       |
|--------------------------|-------|-------|-------------|--|-------------|-------|
|                          |       |       |             | Administered Members(min/max): xxx/yyy |             |       |
|                          |       |       |             | Total Administered Members: xxx        |             |       |

Screen 7-77. ISDN-PRI Group Member Assignment form

### Fields unique to this form

This field is unique to the ISDN-PRI Trunk Group Member Assignment form.

**⇒ NOTE:**

When supporting DCS, Member Number Assignments must be the same between nodes (Member #1 must be Member #1 at the far-end trunk group).

For BX.25 signaling, Trunk Group numbers must be the same between nodes (trunk group 1 must be trunk group 1 at the far-end).

The trunk access code (TAC) must be less than four digits.

The total number of pages, and the first page of Group Member Assignments, will vary depending on whether the CBC and Wideband Support pages display.

- Sig Grp** — Enter the appropriate signaling group number. If a DS1 interface appears in one signaling group, then the number of that signaling group appears as a default in the Sig Grp column for any trunk on that interface after the form is submitted. This value cannot be altered without adding a DS1 interface to another signaling group. If a DS1 circuit pack appears in more than one signaling group, then Sig Grp cannot be left blank. One of the signaling group members must be entered. Valid values are 1-0 or 1-166 depending on the amount of system memory. Default is blank.

## PCOL trunk group

---

The Personal Central Office Line (PCOL) Trunk Group form provides a dedicated trunk circuit between multiappearance voice terminals and a CO or other switch via the network.

Each PCOL can have an appearance at multiple multiappearance voice terminals. Users assigned this feature press the PCOL feature button to answer and place calls — dial access is not provided. The status lamp associated with the PCOL button indicates the busy or idle status of the trunk. PCOLs are not assigned a COR.

An incoming PCOL call rings all voice terminals assigned the feature (ringing can be either audible or silent, depending on administration). The PCOL button status lamp flashes even if all call appearances at the voice terminal are active. If a call appearance is idle, the status lamp associated with that appearance also flashes.

CO, FX, and WATS trunks can be assigned as PCOLs.

### Administration commands

---

Use the following commands to administer the PCOL trunk group form.

| Action  | Object           | Qualifier <sup>1</sup>  |
|---------|------------------|---|
| add     | personal-co-line | 1—MAX (or 'next')   |
| change  | personal-co-line | 1—MAX   |
| display | personal-co-line | 1—MAX ['number' X]['to-number' X]['count' N]<br>['tac' assigned TAC]['print' or 'schedule'] 1—<br>MAX (or 'next') |
| list    | personal-co-line | ['print' or 'schedule']   |
| remove  | personal-co-line | 1—MAX   |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

Requires a port on a TN747B Central Office Trunk circuit pack for each CO, FX, or WATS trunk assigned as a PCOL.

## How to administer PCOL trunk groups

### Required forms

| Form                               | Field   | Page                  |
|------------------------------------|---|-----------------------|
| Personal Central Office Line Group | ■ All   | <a href="#">7-168</a> |
| Station (multiappearance)          | ■ Button/Feature Button Assignments<br>— per-COline (Grp: __)<br>— aut-msg-wt (Ext: ____) | <a href="#">6-14</a>  |

- Personal Central Office Line Group (PCOLG) — Verify or complete all fields.
- Station — Assign (per CO line) buttons to voice terminals in group. If Leave Word Calling (LWC) messages are to be stored for the PCOLG, assign a LWC Remote Message Waiting (aut-msg-wt) feature button with status lamp to one of the voice terminals in the group.

### Field descriptions

The fields on the following forms are described in [“Trunk Groups — General” on page 7-115](#).

### **PCOL trunk group form page 1**

Page 1 of X

```

```

## Fields unique to this form

The following field is unique to the PCOL trunk group form.

- **Coverage Path** — Enter the number of the Call Coverage Path used to redirect the incoming calls on this PCOL Group. This field may be blank.
- **Security Code** — Enter a 4-digit code (or leave blank) that users must dial to retrieve voice messages and to use the Demand Print Message feature.
- **Data Restriction** — Is used to restrict DEFINITY ECS features from causing overriding tones on a PCOL. This provides permanent protection. Valid entries are **y** or **n** (default).
- **Trunk Direction** — Identifies the direction of the trunks in the PCOL Group. Valid entries are **incoming**, **outgoing**, or **two-way** (default) for CO and FX group types. For WATS Group Types, only **incoming** or **outgoing** may be entered.
- **Trunk Port** — Enter seven characters. The first two characters identify the cabinet (01 to 44 [R5r and later configurations], 1 to 3 [R5si and later configurations]); the third character identifies the carrier (A through E); the fourth and fifth identify the slot number in the carrier (01 to 20); the last two characters identify the circuit number (01 to 31).
- **Trunk Name** — A 10-character name that identifies the PCOL group.

## Implementation notes

Call Still Held displays when Group Type is **co**, **fx**, or **wats**.

RA Trunk Loss only displays when Terminal Balanced is **n**.

Disconnect Supervision In only displays when Direction is **incoming**, **outgoing**, or **two-way**.

Outgoing Disconnect and Incoming Disconnect display when Trunk Type is **loop-start** or **ground-start** and Direction is **two-way** or **outgoing**.

Prefix-1 and Call Still Held only display when Group Type is **co** or **fx**.

### Implementation note

---

This is a display-only form. The PCOL trunk groups are assigned on the Station form. The number of fields displayed varies depending on the DEFINITY ECS configuration and the amount of system memory available.

## Administrable Timers form

Page Y of X

### ADMINISTRABLE TIMERS

|                                   |  |
|-----------------------------------|--|
| Incoming Glare Guard(msec): 1500  | Outgoing Dial Guard(msec): 160             |
|                                   | Outgoing Glare Guard(msec): 1500           |
|                                   | Outgoing Rotary Dial Interdigit(msec): 800 |
| Ringling Monitor(msec): 5200      | Incoming Seizure(msec): 500                |
| Outgoing End of Dial(sec): 10     | Outgoing Seizure Response(sec): 5          |
| Programmed Dial Pause(msec): 1500 |  |
| Flash Length(msec): 540           |  |

### END TO END SIGNALING

|                 |                  |
|-----------------|------------------|
| Tone(msec): 350 | Pause(msec): 150 |
|-----------------|------------------|

### OUTPULSING INFORMATION

|         |                |                 |         |                   |
|---------|----------------|-----------------|---------|-------------------|
| PPS: 10 | Make(msec): 40 | Break(msec): 60 | PPM?: y | Frequency: 50/12k |
|---------|----------------|-----------------|---------|-------------------|

## Screen 7-80. PCOL Trunk Group Administrable Timers form

## Implementation notes

---

PPM only displays when CDR Reports is **y**.

Incoming Disconnect only displays when Trunk Type is **ground-start** or **loop-start** and Direction is **incoming** or **two-way**.

Outgoing Disconnect only displays when Trunk Type is **ground-start** or **loop-start** and Direction is **outgoing** or **two-way**.

Outgoing Glare Guard and Outgoing End of Dial only display when Direction is **outgoing** or **two-way**.

## Considerations

---

The following features cannot be used with the PCOL feature: ARS, Call Forwarding All Calls, and Ringback Queuing.

## Interactions

---

- Abbreviated Dialing  
Abbreviated Dialing can be used with the PCOL feature. However, the accessed lists are associated with the individual voice terminals.
- Auto Hold  
Auto Hold does not work between PCOL calls.
- Bridged Call Appearance  
If a user is active on his or her primary extension number on a PCOL call, bridged call appearances of that extension number cannot be used to bridge onto the call. The call can only be bridged onto if another voice terminal is a member of the same PCOL group and has a PCOL button.
- Call Coverage  
AUDIX cannot be in the coverage path of a PCOL group.
- Hold  
When a user, active on a PCOL call, puts the call on Hold, the status lamp associated with the PCOL button does not track the busy/idle status of the PCOL.
- LWC  
LWC cannot be used with a PCOL call.

- Call Detail Recording

CDR can be activated for PCOL calls, but the CDR record does not specifically identify the call as PCOL. A PCOL call can, however, be identified by the trunk access code used on the call. The call is recorded to the extension number assigned to the voice terminal where the call was originated or answered.

- Send All Calls

Send All Calls cannot be activated for a PCOL group.

- Temporary Bridged Appearance

When a PCOL is shared (assigned to a group), any group member can bridge onto a PCOL call through the Temporary Bridged Appearance feature. The Privacy — Manual Exclusion feature can be activated on such a call if the voice terminal is assigned an Exclusion button.

- Transfer

A PCOL can be transferred to an extension that does not have a button for that PCOL.

## RLT trunk group

---

The Release Link Trunk (RLT) Group form implements the Centralized Attendant Service (CAS) feature, and connects attendant-seeking calls from a branch location to a main location.

### Administration commands

---

Use the following commands to administer the RLT trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>   |
|---------|-------------|--|
| add     | trunk-group | 1-MAX (or 'next')  |
| change  | trunk-group | 1-MAX or TAC X...  |
| display | trunk-group | 1-MAX ['number' X]['to-number' X]['count' N] ['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']  |
| remove  | trunk-group | 1-MAX or TAC X...  |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

A port is required on a TN722B, TN767, or TN464D circuit pack for each trunk to be assigned in the Trunk Group. A TN722B or TN767 provides 24 ports, and a TN464D provides 24 or 32 ports.

### Field descriptions

---

The fields on the following forms are described in [“Trunk Groups — General”](#).

Otherwise, the valid values are:

|            |             |             |            |
|------------|-------------|-------------|------------|
| auto/delay | auto/immed  | auto/wink   | delay/wink |
| delay/auto | delay/delay | delay/immed | immed/wink |
| immed/auto | immed/delay | immed/immed | wink/wink  |
| wink/auto  | wink/delay  | wink/immed  |            |

**NOTE:**

For “immed/immed” trunks (on incoming trunks), the far-end switch seizes the trunk and then sends digits without waiting for acknowledgment from the receiving switch. When heavily loaded, the receiving switch may incur a short delay in attaching a Touch-Tone Receiver to this call and, therefore, cause it to lose digits. Using wink-start trunks or increasing the dial-guard timer value on the far-end switch avoids this problem.

### Screen 7-83. RLT Trunk Group Administrable Timers form

#### Implementation notes

---

Incoming Dial Guard is administrable when Trunk Signaling Type is blank.

Incoming Seizure displays when Trunk Signaling Type is **cont** and Direction is **incoming**.

Outgoing End of Dial only displays when Direction is **outgoing** and Receive Answer Supervision is **n**.

Incoming Disconnect only displays when Direction is **incoming** and Trunk Signaling Type is blank or **cont**.

Outgoing Disconnect displays if Trunk Signaling Type is **blank** or **cont** and Direction is **outgoing**.

#### NOTE:

TN760Dv15 (or later) ports used in a Release Link Trunk group will have their incoming and outgoing disconnect timer value internally forced to 280 ms. All other ports in the group that take administrable timers will receive the value administered in this field. All other ports in the group that do not take administrable timers will have their disconnect timing forced to 280 ms.

Screen 7-85. RLT Group Member Assignments form

## Tandem trunk group

---

This form interconnects tandem nodes in an ETN network. The trunk group provides the system with the ability to act as an intermediate switch (through switch) in a private network and is capable of transmitting and receiving Traveling Class Marks as well as outputting 7-digit RNX-XXXX dialed numbers. A Traveling Class Mark represents a user's Facility Restriction Level (FRL) or the FRL of the user's trunk group.

### Administration commands

---

Use the following commands to administer the Tandem trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>   |
|---------|-------------|--|
| add     | trunk-group | 1—MAX (or 'next')  |
| change  | trunk-group | 1—MAX or TAC X...  |
| display | trunk-group | 1—MAX ['number' X]['to-number' X]['count' N] ['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']  |
| remove  | trunk-group | 1—MAX or TAC X...  |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

A port is required on a TN722B, TN760D, TN767, or TN464D circuit pack for each trunk to be assigned in the Access Trunk Group. A TN760D provides four ports, a TN722B or TN767 provides 24 or 32 ports, and a TN464D provides 32 ports.

### Field descriptions

---

The fields on the following forms are described in ["Trunk Groups — General" on page 7-115](#).

### Screen 7-87. Tandem Trunk Group form (Page 2)

#### Fields unique to this form

---

The definition of the following field is unique to the Tandem trunk group form.

- **Hop Dgt** — The Tandem Hop Limitation feature provides a counter that reflects the number of switches (i.e., the number of hops) that a call has gone through; the counter is incremented as a call leaves DEFINITY ECS using tandem facilities. Enter **y** if you want the Tandem Hop Limitation feature applied to this trunk group; enter **n** (default) if you do not.

**NOTE:**

Never use Tandem-tie trunks to transport UDP numbers (the Hop count will not be recognized as such following the extension received at the receiving switch).

## Administrable Timers form

**Screen 7-90. Tandem Group Member Assignments form**

## Tie trunk group

---

This form provides private access between DEFINITY ECS and another switch or network. The trunks are used to interconnect a satellite, tributary, and a main switch in an ETN. The trunk group can also be used to interface a 4ESS switch in support of MEGACOM, MEGACOM 800, and MEGACOM 800 DNIS.

### Administration commands

---

Use the following commands to administer the Tie trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>   |
|---------|-------------|--|
| add     | trunk-group | 1—MAX (or 'next')  |
| change  | trunk-group | 1—MAX or TAC X...  |
| display | trunk-group | 1—MAX ['number' X]['to-number' X]['count' N] ['tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']  |
| remove  | trunk-group | 1—MAX or TAC X...  |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

A port is required on a TN722B, TN760D, TN767, or TN464D circuit pack for each trunk to be assigned in the Trunk Group. A TN760D provides four ports, a TN722B or TN767 provides 24 or 32 ports, and a TN464D provides 32 ports.

### Field descriptions

---

The fields on the following forms are described in [“Trunk Groups — General”](#).

## Tie trunk group form page 1

### Screen 7-91. Tie Trunk Group form (page 1)

#### Fields unique to this form

---

The following field is unique to the Tie trunk group form.

- **Line Length** — This field appears only when Trunk Signaling Type has a value of **tge**, **tgi**, or **tgu**. (Thus, this field only applies to TN497 ports.)

**NOTE:**

The value administered is not saved when the form is submitted unless one or more trunk members are administered.

#### Implementation notes

---

Answer Supervision Timeout defaults to **0**.

BCC displays when the Comm Type is **avd** or when ISDN-PRI is optioned on the System-Parameters Customer-Options form and Comm Type is **avd**, **rbavd**, or **data**.

Synchronization displays when Comm Type is **avd** or **rbavd**.

Outgoing Disconnect displays if Trunk Signaling Type is **blank** or **cont** and Direction is **outgoing** or **two-way**.

Trunk Type, Outgoing Dial Type, Incoming Dial Type, and Receive Answer Supervision do not display if Trunk Signaling Type is **tge**, **tgi** or **tgu**.

Line Length only displays if Trunk Signaling Type is **tge**, **tgi** or **tgu**.

When Trunk Signaling Type is **dis**, the valid values are:

disc/disc | disc/immed | immed/disc | immed/immed

When Trunk Signaling Type is “**cont**,” the valid values are:

|            |            |             |             |            |
|------------|------------|-------------|-------------|------------|
| auto/auto  | auto/cont  | auto/delay  | auto/immed  | auto/wink  |
| cont/auto  | cont/cont  | cont/delay  | cont/immed  | cont/wink  |
| delay/auto | delay/cont | delay/delay | delay/immed | delay/wink |
| immed/auto | immed/cont | immed/delay | immed/immed | immed/wink |
| wink/auto  | wink/cont  | wink/delay  | wink/immed  | wink/wink  |

Otherwise, the valid values are:

|            |             |             |            |
|------------|-------------|-------------|------------|
| auto/auto  | auto/delay  | auto/immed  | auto/wink  |
| delay/auto | delay/delay | delay/immed | delay/wink |
| immed/auto | immed/delay | immed/immed | immed/wink |
| wink/auto  | wink/delay  | wink/immed  | wink/wink  |

 **NOTE:**

For “immed/immed” trunks (on incoming trunks), the far-end switch seizes the trunk and then sends digits without waiting for acknowledgment from the receiving switch. When heavily loaded, the receiving switch may incur a short delay in attaching a Touch Tone Receiver to this call and, therefore, cause it to lose digits. Using wink-start trunks or increasing the dial-guard timer value on the far-end switch avoids this problem.

#### Implementation notes

The Type column displays when Trunk Signaling Type is **blank** or **cont**. The Type column does not display if Trunk Signaling Type is **dis**.

The Ans Delay column displays when Trunk Signaling Type is **blank**, **cont**, or **dis**.

Mode, Type, and Ans Delay do not display if Trunk Signaling Type is **tge**, **tgi**, or **tgu**.

## WATS trunk group

---

This form provides access to and/or from a portion of the DDD network via dedicated trunks to and/or from a wide area telecommunications service (WATS) serving office.

### Administration commands

---

Use the following commands to administer the WATS trunk group form.

| Action  | Object      | Qualifier <sup>1</sup>   |
|---------|-------------|--|
| add     | trunk-group | 1—MAX (or 'next')  |
| change  | trunk-group | 1—MAX or TAC X..   |
| display | trunk-group | 1—MAX ['number' X]['to-number' X]['count' N]<br>'tac' assigned TAC]['print' or 'schedule'] |
| list    | trunk-group | ['print' or 'schedule']  |
| remove  | trunk-group | 1—MAX or TAC X..   |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Hardware requirements

---

A port on a TN747B CO Trunk, or TN767 or TN464 DS1 Interface circuit pack is required for each WATS trunk to be assigned. A TN747 provides eight ports, a TN767 provides 24 ports, and a TN464D can provide either 24 or 32 ports.

### Field descriptions

---

The fields on the following forms are described in [“Trunk Groups — General” on page 7-115](#).

## **Automatic Routing — General**

---

DEFINITY ECS provides a variety of automatic-routing features for public and private networks. Automatic Alternate Routing (AAR) and Automatic Route Selection (ARS) are the foundation for these automatic-routing features. They route calls based on the preferred (normally the least expensive) route available at the time the call is placed. Generally, AAR routes calls over a private network and ARS routes calls using the public network numbering plan. However, both AAR and ARS support public and private networks.

When you use AAR and ARS, you can also use the following additional features:

- AAR/ARS Overlap Sending
- AAR/ARS Partitioning
- Facility Restriction Levels (FRL) and Traveling Class Marks (TCM)
- Alternate Facility Restriction Levels (AFRL)
- Generalized Route Selection (GRS)
- Look Ahead Routing (LAR)
- Subnet Trunking
- Time of Day (TOD) Routing

## AAR and ARS

---

### AAR

AAR supports private networks. Private network calls originate and terminate at one or many customer locations without accessing the public network. When you dial an access code and phone number, AAR selects the most desirable route for the call and performs any necessary digit conversion. If the first choice is unavailable, another trunk group, if administered, is chosen automatically.

The numbers you call using AAR are normally private-network numbers. However, you can call a public-network number, a service code, an international number, operator access code, or an operator-assisted dialing number. With AAR and Subnet Trunking, you have a convenient way to place international calls to frequently-called foreign cities. Such calls route as far as possible over the private network, and then access the public network. This saves toll charges and allows you to use your private network as much as possible.

Certain domestic calls may reach a point on a private network where they can route no further because tie trunks to the next switch are unavailable. In this case, subnet trunking can delete the location code and insert the appropriate public-network code. Calls of this type route off of the private network to a central office (CO). The CO may be connected to either a private-network tandem or main switch. Toll charges, if any, are from the final ETN switch to the destination.

### ARS

ARS selects carriers automatically and routes calls inexpensively over the public network. When there are one or more long-distance carriers or services, DEFINITY ECS selects the most preferred route for the call. Long-distance carrier-code dialing may not be required on routes selected by the system. You assign long-distance carrier-codes and DEFINITY ECS translates them. The system can insert codes as needed to guarantee automatic carrier selection.

ARS can route calls to a variety of types-of-numbers (TON):

- Local dialing
- National dialing
- International dialing
- Operator-assisted dialing
- Service codes
- Inter-exchange carrier (IXC)

ARS can access a variety of types of public-network and private-network trunk groups including CO, FX, ISDN, tie, and WATS. See each trunk group type in other sections of this manual for additional information.

## How to administer AAR and ARS

### Required forms for AAR

| <u>Form</u>                             | <u>Field</u>  | <u>Page</u>                                    |
|---|---|--|

## **Detailed description**

---

A detailed description of AAR and ARS follows. Included is information on dialing, digit analysis, digit conversion, and route pattern. Considerations and interactions that involve implementation are addressed.

More detailed information is provided in Expanded Technical Information. Included is an explanation of AAR dialing, ARS dialing, call processing, and electronic tandem networks (ETN). Finally, the following additional related features are addressed: AAR/ARS Partitioning, Facility Restriction Levels and Traveling Class Marks, Alternate Facility Restriction Levels, Generalized Route Selection, Look Ahead Routing, Overlap Sending, Subnet Trunking, and Time of Day Routing.

Review [Figure 8-1](#) for an overview of the automatic routing.

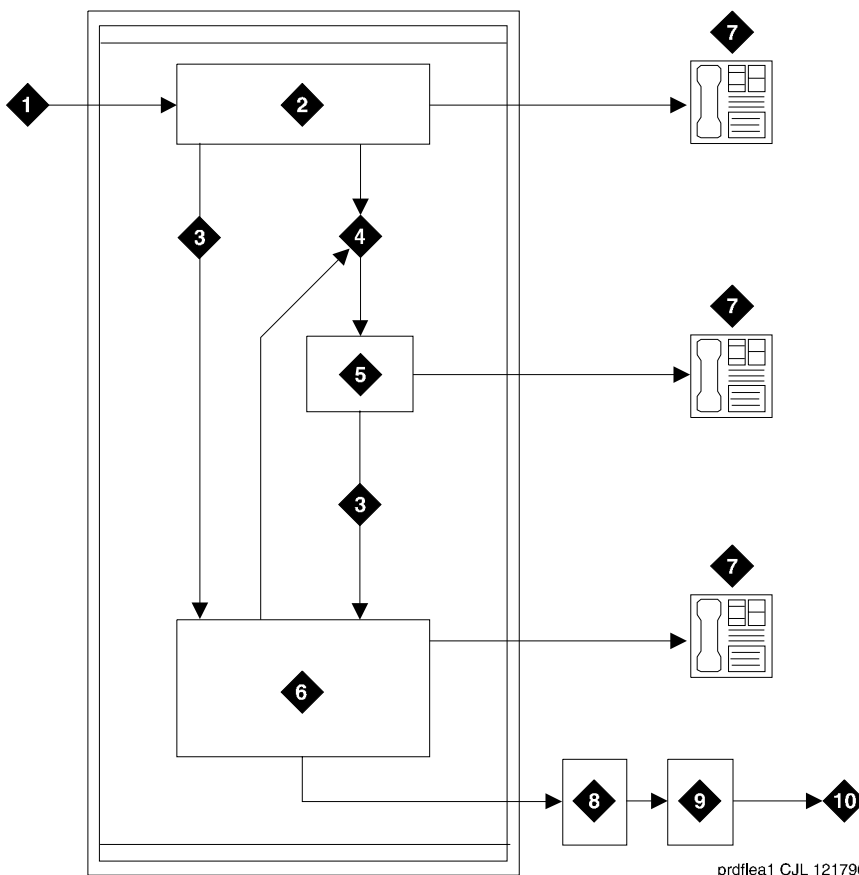

Figure Notes

1. Input from voice terminal, public network trunk, or private network trunk
2. Analyze digits to determine address type (First Digit Table)
3. Direct to AAR/ARS
4. Direct to Uniform Dial Plan (UDP)
5. Analyze digits using UDP to determine route
6. Delete and insert digits (AAR and ARS Digit Conversion Tables)
7. Terminate call at voice terminal
8. Analyze digits (AAR and ARS Digit Analysis Tables) and determine route pattern (Route Pattern, Node Number Routing, Extended Trunk Access forms)
9. Select outgoing trunk group and delete and insert digits
10. Output to public network trunk or private network trunk

Figure 8-1. Automatic Routing

## Dialing

Automatic routing starts when you dial a feature access code followed by the number to be called. For AAR, this access code is usually the digit 8. For ARS, this access code is usually the digit 9 in the US and 0 outside of the US.

As soon as you dial the AAR or ARS access code, the system checks to see if your voice-terminal extension has been origination restricted or outward restricted by its assigned Class of Restriction (COR). The system also checks to see if you have a controlled restriction of either outward or total. If any of these restrictions exist, intercept treatment is applied to the call. Otherwise, the AAR or ARS call continues and you can enter the number to be called.

A second dial tone may or may not be heard after the AAR or ARS access code is dialed, depending on system administration. For more detailed information, see Expanded Technical Information.

### Interdigit timeout

DEFINITY ECS uses a long interdigit timer and a short interdigit timer during the dialing process. Normally, a long, 10-second interdigit timer is used between each digit. This timer waits for another digit when the digits dialed are not a valid destination. If this timer runs out, you receive timeout and an intercept tone.

If the digits dialed point to a valid destination, but there is a similar string of digits that is of different length, the short, 3-second interdigit timer is started.

If dialing does not continue before the timers expire, the system assumes that no more digits are to follow, and appends # to indicate end of dialing. You also may override the timer by dialing #. This results in faster call processing.

When no length ambiguity exists and all digits are collected, the call is routed, and no timer or # is required.

## Digit analysis

Digit analysis compares the dialed number (or incoming digit string) with entries in the AAR or ARS Digit Analysis Table depending on which Dial Access Code was utilized. When DEFINITY ECS finds a dialed-string entry in the table that matches the incoming digit string, the AAR or ARS Digit Analysis Table maps the incoming digit string to a specific route pattern and call type. The selected route pattern and call type are used to route the call. The AAR or ARS Digit Analysis Table also shows the minimum and maximum number of digits required for the analysis of each incoming digit string. Node-number routing can also be specified on this form.

A dialing pattern can be mapped directly to a specific route pattern and call type. Or, it can be changed in the AAR or ARS Digit Conversion Table. During digit conversion, digits may be inserted or deleted from the digit string. For instance, private network numbers may be converted to other private network

numbers or public network numbers or extensions. This new dialed string is analyzed again in the appropriate analysis table for routing. Matching criteria are (most important first):

- Number of digits (between min and max)
- Most number of matching digits
- Exact match over wildcard match (from left to right)

## Digit conversion

When an access code and number are dialed, the dialed string is compared to entries in the `Matching Pattern` field of the ARS or AAR Digit Conversion Table. If all or part of the dialed string matches one of the Matching Patterns, the matching part of the dialed string is replaced by a new number from the Replacement String field. This new number then is used to route the call. The new number is analyzed using the AAR or ARS Digit Analysis Table or is routed directly to an extension. An intercept tone is supplied if a match is not found or if the call fails to route.

Review the following examples. These conditions are assumed for the examples: ARS Access Code = 9, AAR Access Code = 8, Home RNX (Private Network Office Code) = 222, Prefix 1 is required on all long-distance DDD calls, Dashes (-) shown in [Table 8-1](#) are for readability only. The dialed digits are mapped to the matching pattern that most closely matches the dialed number.

### Example:

If the dialed string is 957-1234 and matching patterns 957-1 and 957-123 are in the table, the match is on pattern 957-123. The call is routed as dialed.

Table 8-1. ARS Digit Conversion Examples

| Operation  | Actual Digits Dialed           | Matching Pattern     | Replacement String | Modified Address | Notes   |
|--|--------------------------------|----------------------|--------------------|------------------|---|
| DDD call to ETN  | 9-1-303-538-1345               | 1-303-538            | 362                | 362-1345         | Call routes via AAR for RNX 362   |
| Long-distance call to presubscribed carrier                                    | 9-10222+DDD                    | 10222                | (blank)            | (blank)          | Call routes as dialed with DDD # over private network   |
| Terminating a local DDD call to an internal station                            | 9-1-201-957-5567 or 9-957-5567 | 1-201-957-5 or 957-5 | 222-5              | 222-5567.        | Call goes to home RNX 222, ext. 5567  |
| Unauthorized call to intercept treatment                                       | 9-1-212-976-1616               | 1-XXX-976            | #                  | (blank)          | "#" means end of dialing. ARS ignores digits dialed after 976. User gets intercept treatment.   |
| International calls to an attendant  | 9-011-91-672530                | 011-91               | 222-0111#          | 222-0111         | Call routes to local switch (RNX 222), then to attendant (222-0111). Call can route to an announcement by replacing 0111 with an announcement extension. <sup>1</sup> |
| International call from certain European countries needing dial tone detection | 0-00-XXXXXXXX                  | 00                   | +00+ <sup>2</sup>  | 00+XXXX          | The first 0 denotes ARS, the second pair of 0s denotes an international call, the pluses denote "wait" for dial tone detection.                                       |

1. This method may also be used to block unauthorized IDDD calls.
2. This can be done via subnet trunking

## Route pattern

DEFINITY ECS selects a route pattern for a call as a result of the digit analysis performed on the number dialed. The AAR or ARS Digit Analysis Table analyzes up to 28 digits. An RHNPA Table **is used to screen 3 additional digits after an area code**. A route pattern is a sequence of trunk groups that are used to route the call. (More than one combination of dialed digits can point to the same route pattern.)

You relate a Dialed String (number dialed) to a Rte Pat (route pattern) on the AAR or ARS Digit Analysis Table. You set up the Rte Pat on the Route Pattern form. Usually, you arrange the trunk groups in a route pattern by preference. The least expensive route pattern is generally the preferred route. To select a route pattern, DEFINITY ECS considers preference order and FRL compatibility.

You also assign an FRL to a routing-pattern preference. FRLs are assigned to both trunk groups and voice terminals via the COR. The caller's FRL must be greater than or equal to the preference FRL. See the section on Facility Restriction Levels and Traveling Class Marks for additional information.

When AAR and ARS route calls over ISDN trunk groups, overlap sending can be administered. This allows you to send and receive digits one digit at a time instead of enbloc (digits are not sent until the entire group of digits is received). In countries with complex public-network numbering plans, this decreases call setup time significantly. When overlap receiving is enabled, this is especially significant for tandemed calls.

If AAR routes the call to another switch over a trunk with ISDN overlap sending, the system seizes the outgoing ISDN trunk and starts sending digits while DEFINITY ECS continues to collect (receive) the remaining incoming digits. After receiving the number of digits administered in the Max. digit field of the AAR Digit Conversion Table (or a timeout), the system sends an end-of-dial signal backward to the originating switch. With overlap sending, it also is no longer necessary to enter # to indicate end of dialing. Additional information is provided in the section on Overlap Sending.

Look-Ahead Routing allows you to maximize your route-pattern preferences. It allows you to continue to try to reroute an outgoing ISDN call when initial attempts fail because of congested trunks. You can indicate the next route-pattern preference or indicate that the current route-pattern preference should be attempted a second time before going to the next preference. Additional information is provided in the section on Look-Ahead Routing.

## **Expanded technical information**

---

The following paragraphs contain further information about AAR dialing and translations, ARS dialing and translations, and trunking facilities.

### **AAR dialing**

Typically, AAR simplifies dialing. You dial the AAR access code (normally 8) followed by a private network or public network number. AAR selects the route and performs whatever digit manipulation is necessary. In addition, AAR selects the most cost-effective public-network or private-network route. If the first-choice preference is not available, another preference is chosen automatically. For outgoing ISDN calls, route selection is dependent on Bearer Capability Class (BCC), Facility Restriction Level (FRL), and type of facility.

AAR allows you to dial a private network number to reach a specific public network. The call can be routed via a private network to an appropriate exit point, where digit insertion is used for conversion to the appropriate access code, country code, city code, and exchange.

You can administer DEFINITY ECS to include RN, RNX, and RXX dial plans, where R = 2 to 9, N = 2 to 9, and X = 0 to 9 (and any other forms). See the following table for default translations associated with AAR Digit Analysis.

**Table 8-2. AAR Digit Analysis Default Translations**

| Dialed String | Total Digits |      | Call Type |
|---------------|--------------|------|-----------|
|               | Min.         | Max. |           |
| 2             | 7            | 7    | aar       |
| 3             | 7            | 7    | aar       |
| 4             | 7            | 7    | aar       |
| 5             | 7            | 7    | aar       |
| 6             | 7            | 7    | aar       |
| 7             | 7            | 7    | aar       |
| 8             | 7            | 7    | aar       |
| 9             | 7            | 7    | aar       |

### ARS dialing

You can administer DEFINITY ECS to recognize different types of dialing patterns on outgoing calls and route the call accordingly. The following dialing patterns are supported.

- **Operator Assistance Calls** — The first digit following the ARS access code is a 0. If a 0 is dialed by itself to access an operator, a special interdigit timeout occurs, the route for dial 0 calls is selected and a 0# is outpulsed. If the user dials another 0, the route for 00 is selected, and a 00# is outpulsed. The call is routed to the toll operator (if one exists) instead of the local operator in this case.
- **DDD Calls with Prefix Digit 1 Required** — The `Pfx Mrk` (Prefix Mark) field (on the Route Pattern form) is administered as follows for each of the 6 possible routing choices on the form:

The digit 1 may or may not be required at the public network office to which the call is routing. (If 1 is dialed on 7-digit calls at a stand-alone system (non-ETN), the 1 is outpulsed by the system.) In the other cases, the 1 outpulsing requirements are indicated in the system. Since any given call may have a choice of routes, some of which may require a 1 and some of which may not, this indication is associated with each route. Five

choices are available and are identified in translations by a Prefix Mark. Digit 1 outpulsing only applies to calls administered as "fnpa" or "hnpa" in the ARS Digit Analysis table. The values and meanings of the Prefix Marks are as follows:

- Prefix Mark 0 — Suppress a user-dialed Prefix digit 1 for 10-digit FNPA calls, but leave a user-dialed Prefix digit 1 for the following types of calls:
  - 10-digit calls that are not administered as FNPA or HNPA types in the ARS Routing Table.
  - 7-digit HNPA calls
- Prefix Mark 1 — Send a 1 on 10-digit calls, but not on 7-digit calls.
- Prefix Mark 2 — Send a 1 on all toll calls (for example, all 10-digit calls and 7-digit toll calls).
- Prefix Mark 3 — Send a 1 on all toll calls and keep or insert the NPA to ensure that all toll calls are 10-digit calls. Note that a user-dialed Prefix digit 1 for a 7-digit call makes it a toll call and, hence, NPA is also inserted in this case.
- Prefix Mark 4 — Always suppress a user-dialed Prefix digit 1.

**NOTE:**

This capability is required, for example, when routing ISDN calls to an Lucent Technologies 4ESS. If the prefix digit 1 were not suppressed, then the 4ESS would reach calls.

Which of the five possible treatments of the 1 prefix digit should be administered on a given route is based on the characteristics of the distant office. Prefix Mark 0 prevents the system from sending a 1 prefix digit for 10-digit FNPA calls. However, the system leaves a user-dialed prefix digit 1 for 7-digit HNPA calls and 10-digit calls that are not administered as FNPA or HNPA types in the ARS Routing Table. In some areas, all toll calls must be dialed as 1+10 digits. Check with your local network provider.

Prefix Mark 1 causes the system to send a 1 prefix on all 10-digit FNPA calls.

With Prefix Marks 2 and 3, the decision is based on whether the call is a toll call. Toll Lists are provided in the system to furnish this information. A Toll List simply indicates if the office code associated with the call constitutes a toll call from the interconnecting office (not from the local system). Up to 32 Toll Lists are provided. The applicable list number, if any, for the call is assigned in the Routing Pattern.

Prefix Marks are only applicable on 7- or 10-digit DDD public network calls. Requirements for outpulsing a 1 are specified via Prefix Marks and go into effect when the call accesses is outpulsed. Digit 1 outpulsing only applies to calls administered as "fnpa" or "hnpa" in the ARS Digit Analysis table.

- **DDD Calls with Prefix Digit 1 Not Required** — The first digit of a long-distance call following the ARS access code may or may not be a 1 (dialing the 1 prefix before a 10-digit call is optional). In systems where the 1 prefix is dialed (even though not required), the prefix is ignored if no match is found with the “1” included. The default ARS translations include entries starting with “1.”
- **Operator Assisted and International Calls** — The first digits following the ARS access code are a 0 (operator), 00 (toll operator), and optionally followed by a 10-digit DDD number, or by 01 or 010 (international operator) for international dialing and optionally followed by international destination address digits. Because of the variable number of digits required for these calls, an interdigit timeout is used to recognize end of dialing.
- **International Direct Distance Dialing** — An international telephone number consists of a country code (CC) plus the national number (NN). The NN is simply the number used when calling within the country. In the North American Numbering Plan (NANP), NN is a 10-digit address. In the NANP, special prefix codes alert DEFINITY ECS that an international number is being dialed. These codes are outlined as follows:
  - 011 — Indicates that the caller is making a station paid direct international call and CC plus NN digits follow. The term IDDD (International Direct Distance Dialing) is normally associated with 011 plus (011+) station calls.
  - 01 — Indicates that the caller desires operator assistance in an international call, such as person-to-person, credit card, collect call, and so on, and CC and NN digits follow. The term ICDOS (International Customer-Dialed and Operator-Serviced) reflects the nature of 01+ dialing options.

A 01+ (ICDOS) call is similar to 0+ or 00+ (operator-assisted North American Network) call, whereas a 011+ (IDDD) call is similar to a 1+ call.
- **Special Service Codes** — The first digit following the ARS Access Code is a special system or service code. In North America, such codes consist of only three digits in the form N11 (where N = 2 to 9) with or without dialing the “1” prefix digit. These are recognized as complete addresses, and even if no further digits are dialed, are routed to the appropriate facility. The interdigit timeout determines whether the call is a 3- or 7-digit call. For example, if the user dials 911, the call routes to the police or emergency operator, and if the user dials 811-XXXX, the call is translated as a 7-digit call for the repair bureau corresponding to the last 4 digits (811 is a service code for repair).
- **Call Dialed with Inter-Exchange Carrier (IXC) Access** — The IXC Code, if dialed, is comprised of the first digits following the ARS Access Code, usually a 5- or 7-digit IXC code. IXC codes are defined in the Inter-Exchange Carrier Codes form on page [5-177](#). DEFINITY ECS decides the number of digits to collect based on the digits following the

code. The IXC code may be followed by a DDD or IDDD number. This gives you control over which carriers or which facilities are used for routing the call. The call may be routed based on administration of the IXC code in the ARS Digit Analysis Table.

DEFINITY ECS supports three general IXC access arrangements that are commonly referred to as Feature Group A, B, and D (FG A, FG B, FG D). From a caller's perspective, the major differences between use of the various groups are:

- To select an IXC, FG A and FG B require the dialing of 7 digits (NXX-XXXX or 950-0/1XXX, respectively) but FG D requires just 5 digits (10XXX).
- Single-stage dialing is supported for FG D, but FG A and FG B require 2-stage dialing. (Two-stage dialing means that there is a pause for dial tone between the 2 groups of dialed digits.) FG A and FG B calls are analyzed and routed just like normal calls.
- No customer identification digits are required for FG D.
- A touch-tone telephone is required to enter a Personal Identification Number code when using FG A or FG B. (These digits are not collected or analyzed by the switch.) A dial pulse or touch-tone telephone may be used with FG D.

See [Table 8-3](#) for default translations associated with ARS digit analysis.

**Table 8-3. ARS Digit Analysis Default Translations**

| Dialed String | Total Digits |      | Route Pattern | Call Type |
|---------------|--------------|------|---------------|-----------|
|               | Min.         | Max. |               |           |
| 0             | 1            | 1    | den           | op        |
| 0             | 8            | 8    | den           | op        |
| 0             | 11           | 11   | den           | op        |
| 00            | 2            | 2    | den           | op        |
| 01            | 9            | 17   | den           | iop       |
| 011           | 10           | 18   | den           | intl      |
| 10XXX0        | 6            | 6    | den           | op        |
| 10XXX0        | 16           | 16   | den           | op        |
| 10XXX1        | 16           | 16   | den           | fnpa      |
| 10XXX01       | 14           | 22   | den           | iop       |
| 10XXX011      | 15           | 23   | den           | intl      |

*Continued on next page*

**Table 8-3. ARS Digit Analysis Default Translations — Continued**

| Dialed String | Total Digits |      | Route Pattern | Call Type |
|---------------|--------------|------|---------------|-----------|
|               | Min.         | Max. |               |           |
| 1XXX555       | 11           | 11   | den           | fnpa      |
| 1XXX976       | 11           | 11   | den           | fnpa      |
| 18000555      | 11           | 11   | den           | fnpa      |
| 1809          | 11           | 11   | den           | fnpa      |
| 1900555       | 11           | 11   | den           | fnpa      |
| 411           | 3            | 3    | den           | svct      |
| 555           | 7            | 7    | den           | hnpa      |
| 611           | 3            | 3    | 1             | svcl      |
| 811           | 3            | 3    | 1             | svcl      |
| 911           | 3            | 3    | 1             | svcl      |
| 976           | 7            | 7    | den           | hnpa      |
| N             | 7            | 7    | 2             | hnpa      |
| 1N00          | 11           | 11   | den           | fnpa      |
| 1NX           | 11           | 11   | den           | fnpa      |

Legend:

- N - 2 through 9
- X - any digit (0 - 9)
- den - deny
- fnpa - foreign number plan area (10-digit call)
- hnpa - home number plan area (7-digit call)
- intl - international
- iop - international operator
- op - operator
- svcl - service (local)
- svct - service (toll)

## Trunking facilities

Automatic routing uses a combination of public and private trunking facilities. Off-net facilities include trunks such as CO, FX, and WATS. These trunks carry public network calls. On-net facilities include trunks such as tie, tandem, and private ISDN trunks. These trunks are dedicated to your private network.

DEFINITY ECS can serve as an electronic tandem network (ETN). An ETN is a hierarchical network of privately-owned trunk and switching facilities that provide a cost-effective alternative to toll calling between locations. Tandem trunks are used to interconnect two tandem nodes in an ETN.

An ETN consists of tandem switches, the intertandem tie trunks that interconnect them, the access- or bypass-tie trunks from a tandem switch to a main switch, and the capability to control call routing over these facilities. Within an ETN, each switching facility is identified by a unique private-network office code. Private-network office codes may be 1–8 digits.

Traveling Class Marks (TCM) are appended to AAR and ARS numbers outpulsed on ETNs. Remember, TCMs represent the caller's FRL or the FRL of the caller's access trunk group. Access trunks are used to connect a subtending main switch to a tandem node. Tie trunks are used to interconnect a satellite or tributary and the homing main switch. An ETN tandem node can, however, directly access main and tributary switches that are homed on another tandem node using bypass-access trunks.

## Considerations

---

- ARS and AAR can access the same trunk groups and share the same route patterns, toll lists, and RHNPA tables. ARS calls can be converted to AAR calls and vice-versa.
- Internal memory resources used for digit analysis are shared by ARS and AAR Digit Conversion and Toll Analysis. The Percent Full field on the ARS Digit Analysis and AAR Digit Analysis screens indicates how many of these resources are used for both AAR and ARS.

## Interactions

---

- Abbreviated Dialing  
FRL checking is bypassed on ARS and AAR calls made via a privileged Abbreviated Dialing Group List.
- Attendant Control of Trunk Group Access  
Attendant control of a trunk group, in effect, removes the trunk group from the route pattern. ARS and AAR do not access controlled trunk groups.
- CAS  
A CAS Attendant can extend a call out of a branch switch using ARS and AAR. When you dial the feature access code and number, the call is routed according to the AAR and ARS administration at the branch switch.

- CDR
  - A CDR account code may be required for an AAR call if it crosses over and becomes an ARS call.
  - An ARS or AAR call using a trunk group marked for CDR is indicated by the dialed access code and by a condition code. It is possible to record either the dialed number or the outpulsed number. If the dialed number is recorded, subnet trunking does not affect CDR.
  - Outpulsed digits can be recorded.
  - If CDR generation is administered for a trunk group assigned to a route pattern, data is collected for all calls routed through the trunk group.
  - If a CDR account code is to be dialed with an ARS or AAR call, it must be dialed before the ARS or AAR access code is dialed.
- Controlled Restriction, Origination Restriction, and Outward Restriction

These features prohibit access to ARS and AAR.
- Forced Entry of Account Codes

Prefix marks and other digits inserted from route patterns are not used to determine whether a call is a toll call. See Forced Entry of Account Codes below for more information.
- ISDN-BRI Stations

An ISDN-BRI station does not recognize the conference or transfer buttons until a call is ready to be routed. For calls that require an interdigit timeout, you must delay dialing for 3 seconds or dial a # to indicate that the call is ready to be routed. The routing operation is completed by the switch and then the ISDN-BRI station recognizes the conference or transfer buttons.
- Miscellaneous Trunk Restrictions

Miscellaneous Restrictions are not checked on ARS and AAR calls.
- Personal Central Office Line (PCOL) Trunk

A PCOL trunk group cannot be assigned to a route pattern.
- Ringback Queuing
  - Ringback Queuing can be used on ARS and AAR calls when they originate at a switch that provides the queuing. Incoming tie trunk calls do not queue on an outgoing trunk group.
  - Ringback Queuing is activated automatically when you have an Automatic Callback button, make an ARS or AAR call, and all trunks are busy.

- Toll Restriction

Toll Restriction is checked if calls are dialed as ARS calls; it is not checked on AAR calls even if they digit convert to ARS calls.

- Voice Terminal Display

- The voice terminal display shows the dialed digits (not outpulsed digits) on AAR and ARS calls and then may change to the name of the trunk group.
- On ARS calls, the called party shown on the display is that of the trunk group actually used. The Miscellaneous Call Identification field on the display shows ARS. By administering trunk groups, you can replace the dialed digits with the name of the trunk group and trunk access code (TAC).
- Outgoing AAR calls display the trunk name and TAC.
- An ISDN-BRI station may format these display fields differently, and the timing of display updates may be different.

## AAR and ARS Overlap Sending

DEFINITY ECS supports overlap sending for AAR and ARS calls that are routed over ISDN trunk groups. ISDN call-address information is sent one digit at a time instead of enbloc — in other words, all address information in one block. In countries with complex public-network numbering plans, this allows for a significant decrease in call setup time. When overlap receiving is enabled, this is especially significant for tandemed calls.

If AAR or ARS determines that the call is to be routed to another switch over a trunk with ISDN overlap sending, the system seizes the outgoing ISDN trunk and starts sending digits while DEFINITY ECS continues to collect (receive) the remaining incoming digits. After receiving the number of digits administered in the `Max` field of the AAR or ARS Digit Analysis form (or a timeout), the system sends an end-of-dial signal backward to the originating switch. It is no longer necessary to enter # to indicate end of dialing.

### How to administer AAR and ARS Overlap Sending

#### Required forms

| Form                 | Field                     | Page                  |
|----------------------|---------------------------|-----------------------|
| ISDN-PRI Trunk Group | ■ Digit Handling (in/out) | <a href="#">7-219</a> |
| ISDN-BRI Trunk Group | ■ Digit Handling (in/out) | <a href="#">7-198</a> |

## AAR and ARS Partitioning

AAR and ARS can be partitioned into 8 user groups within a single DEFINITY ECS. AAR and ARS Partitioning provides individual routing treatment for each of these user groups.

User groups share the same Partition Group Number (PGN). The PGN is not a restriction; it indicates the choice of routing tables used on a particular call. Each Class of Restriction (COR) is assigned a specific PGN or Time of Day specification. Different CORs may be assigned the same PGN.

### How to administer AAR and ARS Partitioning

#### Required forms

| <u>Form</u>                         | <u>Field</u>               | <u>Page</u>          |
|-------------------------------------|----------------------------|----------------------|
| Class of Restriction                | ■ Partitioned Group Number | <a href="#">5-72</a> |
| Time of Day Routing Plan (optional) | ■ All                      | <a href="#">8-78</a> |
| AAR and ARS Digit Analysis Table    | ■ Partitioned Group Number | <a href="#">8-54</a> |

- Different Digit Analysis tables must be administered for each partitioned user group.
- A PGN must be assigned to each COR table. A Time of Day Plan Number is assigned to the COR instead of the PGN if Time of Day Routing is used.

### Detailed description

This feature allows you to divide users into groups and restrict or allow different access to facilities depending upon the group. In motels, for instance, AAR and ARS Partitioning allows you to group employees and guests and give them different access to facilities. When a guest places an interstate call, the guest user-group's ARS tables can route the call to a telephone-billing information system that bills back or allocates long-distance charges. A similar call placed by an employee can route over a direct-distance dialing (DDD) trunk.

All partitioned user groups share the same pool of route patterns. The translation tables that specify the route-pattern number are unique for each partitioned user group. Route patterns may be shared among the user groups or may be dedicated to a particular user group. Once you activate AAR or ARS and dial enough digits for the system to search for the route pattern, the PGN of the caller's COR is used to select the table to look up the route pattern.

The following can use AAR and ARS Partitioning:

- Voice terminals
- Attendant consoles
- Remote-access users
- Data endpoints
- Incoming trunks

## Considerations

- The following situations may require AAR and ARS Partitioning:
  - User groups with different routing preferences for calls to a given area due to special billing needs
  - User groups that have dedicated use of a particular network facility
  - User groups in different businesses in one or more buildings serviced by a single system
  - Data users who require special facility types on outgoing calls
- Partition user groups are only used with AAR, and ARS, and UDP. There is no capability to access the partitioned user groups directly. Operation is transparent to the user.

## Interactions

- Bridged Call Appearance

If a Bridged Call Appearance is used for an AAR or ARS call, the system uses the bridged extension's PGN instead of the caller's PGN.
- Call Detail Recording (CDR)

The PGN used to route the call is not recorded in CDR.
- Call Forwarding All Calls

If a call terminates at a voice terminal that has Call Forwarding activate and the forwarded-to number uses AAR or ARS, the caller's COR is used to look up the PGN for the call.
- DCS

When a call routes over DCS, PGN information is not sent to the far-end switch. The far-end switch is only capable of using the incoming trunk's PGN to route the call.
- Remote Access

If a remote-access user activates ARS, the COR assigned to the barrier code dialed (or the Authorization Code, if required) is used to select the PGN for the call.

- Straightforward Outward Completion and Through Dialing

If the attendant assists or extends a call and activates ARS, the attendant's COR is used to select the PGN for the call if the individual extension number is assigned, otherwise it refers to the COR set on the console parameter.

- Time of Day Routing

TOD Routing allows different AAR and ARS Partitions to be used at different times of the day and different days of the week. If you wish to assign certain users to a particular partition at all times, you must use a default Time-Of-Day Routing Plan that points to the same PGN # at all times.

- Uniform Dial Plan

Since UDP calls expand the dialed digits into 7-digit numbers and then use AAR to route the call, these calls use partitioning. Once the call is handled by AAR, the caller's COR is used to select the PGN for the call.

## Facility Restriction Levels and Traveling Class Marks

---

Facility Restriction Levels (FRL) and Traveling Class Marks (TCM) allow certain calls to specific users, while denying the same calls to other users. For example, certain users may be allowed to use central office (CO) trunks to other corporate locations while other users may be restricted to less expensive private-network lines.

FRLs and TCMs provide up to 8 levels of restriction for users of AAR and ARS.

### How to administer FRLs and TCMs

---

#### Required forms

| Form                 | Field       | Page                 |
|----------------------|-------------|----------------------|
| Class of Restriction | ■ FRL       | <a href="#">5-72</a> |
| Route Pattern        | ■ FRL (0-7) | <a href="#">8-67</a> |

#### NOTE:

FRLs are important to system security. Assign the most restrictive (7) FRL consistent with the FRLs to be used on the COR form and the least restrictive (0) FRL on the Route Pattern form in order to help prevent unauthorized use of system features.

### Detailed description

---

FRLs and TCMs are transparent to the user. The appropriate values are predetermined and programmed into the system. Dialing procedures are unaffected.

Call routing for each call is determined by the dialed area code or office code (either public or private network) or by the administered dial string. Analysis of the called number yields a route pattern. More than one dialed string can point to the same pattern. Each route preference includes:

- Trunk group number
- Minimum FRL required to access the trunk group

Each facility, such as a trunk or voice terminal, that is capable of originating a call also has an associated FRL. Whether a call is allowed or not depends on 2 things: compatibility between FRLs and availability of an idle trunk.

Compatibility is determined by a comparison of the minimum FRL associated with the route preference and the originating-side FRL. Either can have a value of 0–7. Access to the associated trunk group is permitted if the originating-side FRL is greater than or equal to the minimum FRL of the preference. Note that lower originating-side FRLs can access to fewer routing preferences, whereas lower minimum FRLs on the Route Pattern permit greater access. Stated another way, a 0 originating-side FRL is the most restricted and a 7 is the least restricted. A 0 minimum FRL is the least restrictive, and a 7 is the most restrictive (when applied to the route pattern's FRL). Compatibility checking begins with the first-choice route (the first one in the pattern). Assuming that access is permitted, availability is checked; that is, is there an idle trunk in the group? If so, the call continues. If not, compatibility is checked on the next-choice route. The intercept treatment is not received unless all possible routes are inaccessible.

If the compatibility check fails on the next-choice or subsequent route, or if all accessible trunk groups are busy, the call may queue on the first routing preference or first compatible trunk group if trunk queueing is provided.

If the trunk group selected for a call is an intertandem tie-trunk group, then a TCM is outpulsed as the last digit. A TCM is equivalent to the originating-side FRL. At the next tandem switch, compatibility and availability checking are done, as before. In this case, the FRL assigned to the incoming intertandem tie-trunk group is used as the originating-side FRL (to compare with the minimum FRL). If it is sufficient, then the call continues and no comparison between the TCM and minimum FRL is made. If it is not sufficient, then the TCM is compared with the minimum FRL to see if the call is allowed to continue. If this fails to yield a route and if the TCM is higher than the tie-trunk FRL, then the TCM is used in another attempt to complete the call.

## Call-originating facilities

At a switch serving as the call-origination point, any of the following can be the originator of an ARS or AAR call:

- Voice terminal
- Remote Access user
- Attendant
- Incoming tie-trunk group from a subtending location
- Data terminal capable of keyboard dialing

At a tandem switch, either of the following can be the originator of an ARS or AAR call:

- Incoming intertandem tie-trunk group
- Incoming access tie-trunk group — links a remote main switch to a tandem switch

Each of these facilities is assigned an FRL via an associated COR, either directly or indirectly.

Voice terminals and all incoming tie-trunk groups use the FRL within the assigned COR. Attendants use the FRL within the COR assigned to the attendant group for extended calls. If Individual Attendant Access is assigned, the individual attendant's COR FRL is used. Data terminals use the FRL within the COR assigned to the associated data module.

Remote Access can be accessed via the following trunk groups: DID, ISDN, tie, dedicated CO, 800-service, or dedicated FX. The applicable originating FRL is contained in the COR assigned to the dialed barrier code. If a barrier code is not required on remote access calls, the applicable FRL is the default (none).

## **Call terminating facilities**

Any of the following trunk types can serve as the termination point for an ARS or AAR call:

- Tie trunk — excluding Release Link Trunks (RLT), but including Common Control Switching Arrangement (CCSA) and Enhanced Private Switched Communications Services (EPSCS) access trunks
- Wide Area Telecommunications Service (WATS)
- CO
- Foreign exchange (FX)
- Integrated Services Digital Network - Primary Rate Interface (ISDN-PRI)

Each of these outgoing trunk groups has an assigned COR that contains an FRL. However, this FRL is never used. Terminating-side FRLs are assigned in the route pattern, not to the outgoing trunk group.

## **Considerations**

---

- FRLs restrict certain users from placing selected calls while allowing other users to place the same calls.
- A COR is assigned to each trunk group. If the COR specifies an FRL, the FRL is ignored. The minimum FRL specified in the route pattern is the only FRL used on the terminating side of the call.
- On attendant-extended calls, the attendant-group FRL is used rather than the FRL of the calling party.

## Guidelines and examples

The following guidelines and examples illustrate some practical aspects of FRLs.

FRLs on the terminating end of a call are not checked unless the terminating facility is a trunk group in a route pattern. This simplifies assignments. At each switch, the trunk groups available to handle a given AAR or ARS call can be listed in any order within the route pattern. Access to each listed trunk group must be determined via an FRL. On a scale of 0–7, the relative value is determined and assigned. Decisions are normally based on the cost, or appropriateness, of using the facility. The same FRL value can be assigned to more than one trunk group if there is no reason to prefer one trunk group over another.

If some users within the system are not allowed to make outside calls, use some value other than 0 for the first-choice route. Then assign these users an FRL of 0 to deny access to any trunk group, because all trunk-group FRLs are greater than 0.

Each route pattern must be individually constructed. The same trunk group can be used in more than one pattern. The associated FRL is assigned within the pattern and is not associated with the trunk group itself. The same trunk group can have a different FRL in a different pattern.

Be consistent in FRL assignments. Do not use a range of 0–5 in one pattern and 2–7 in another pattern if all users can access the first-choice route. Admittedly, the trunk group with an FRL of 2 may be more expensive than the trunk group with an FRL of 0, but there is no reason to assign 2 to a trunk group that everyone can access. For ease of assignments, always use 0 for such a trunk group.

Establish COR for each FRL in a route pattern. Assign the appropriate COR to users who can access the routes restricted by the FRL. For example, a middle executive might be able to access all routes with an FRL of 5 or lower, whereas the president can access all routes. In this case, the executive is assigned a COR with an FRL of 5 and the president is assigned a COR with an FRL of 7.

Remote access users can access system features and services the same as an on-premises user. FRL assignment is via remote-access barrier codes. Up to 10 barrier codes, each with its own COR (and FRL), can be assigned. Although the COR defines other restrictions, 10 barrier codes are enough to provide a range of FRL assignments. Assign barrier code FRLs as if the user were on-premises. The simplest way to assign these FRLs is to duplicate the on-premises FRLs, then relate the appropriate barrier code to users who need remote access.

The following is an example of how FRLs can be assigned in a COR:

- FRL0 — 911 access only
- FRL1 — Local calls only
- FRL2 — FRL1 plus home area-code calls using WATS
- FRL3 — FRL2 plus use of local lines for all calls in the home area code
- FRL4 — FRL3 plus calls to all the USA, using WATS only
- FRL5 — FRL4 plus calls to all the USA, using local lines
- FRL6 — FRL5 plus international calls
- FRL7 — Reserved

## **Interactions**

---

- AAR and ARS  
FRLs apply only on ARS and AAR calls (including Uniform Dial Plan).
- Authorization Codes  
Authorizations Codes can be used to raise a user's FRL.
- Call Detail Recording  
If 15-digit CDR account codes are used, the FRL field in the CDR record is overwritten.
- Intercept Treatment  
The TCM containing the originating facility's FRL is sent over ISDN facilities in the SETUP message.

## Alternate Facility Restriction Levels

---

Alternate Facility Restriction Levels (AFRL) allows DEFINITY ECS to adjust facility restriction levels or authorization codes for lines or trunks. Each line or trunk is normally assigned an FRL. With this feature, alternate FRLs are also assigned. Attendants or System Administrators can change to the alternates, thus changing access to lines and trunks. For example, a company might want to use this feature to disable most long-distance calling at night to prevent unauthorized staff from making long-distance calls.

### CAUTION:

*AFRL impacts AAR and ARS call routing because it may change the routing preferences. Using AFRL on tandem and tie-trunk applications affects entire networks. Calls that may be part of a cross-country private network may be blocked.*

## How to administer AFRL

## Detailed description

---

AFRLs affect two types of users: the attendant or System Administrator (who enables and disables the AFRL feature) and a voice-terminal user (who places outgoing trunk calls).

## Attendant perspective

You can administer an ALT-FRL button to any attendant console or any station. Pressing the ALT-FRL button activates or deactivates AFRL. Pressing the ALT-FRL button on any console or station may affect the status of other buttons.

When AFRL is activate, the user may notice a sudden change in calling privileges. For example, the user may have been able to make long-distance calls but AFRL (which have been administered to add restrictions to the calling

parties) can no longer do so. When AFRL is active, you can be any one of 3 types of alterable FRL entities:

- An originating line
- An originating trunk (for example, an incoming trunk call)
- A dialed authorization code

### Terminal-user perspective

If you use AFRL to restrict calling at certain hours, make sure that users know about those restrictions.

### Trunk originator case

In this case, the originator is in reality an incoming trunk. Incoming trunk calls can be direct inward dialing (DID) calls to a station, incoming calls on access tie-trunks, or possibly intertandem tie-trunk calls. The FRL of the device is first used to determine if it is at a high enough level to select the outgoing device. If it is not, then the FRL associated with this signaling entity, called a Traveling Class Mark (TCM), is used. Tandem trunk groups are administered to pass along the FRL level associated with the other switch as part of the interoffice signaling protocol. This can be done inband as part of the addressing information which is sent between two switches using tone sending on the trunk itself, or can be done using special ISDN Q.931 messaging. In either case, the seizure of the outgoing trunk is not done until either the TCM is received or (in the case of inband signaling) an interdigit timeout occurs while waiting for the TCM digit.

If AFRLs are active, the FRL associated with the incoming trunk group is set to a new FRL. If after doing so, the originator is blocked from the trunk facility due to insufficient FRL, the TCM, if any, is used. The TCM, which is in reality just another FRL, is also set to a new FRL value. Therefore, the TCM information recorded in the billing data (CDR) is the AFRL value, not the original TCM.

Due to the application of AFRL on tandem and tie trunk applications, entire networks can be affected by the application of the AFRL feature. Use caution to engineer AFRLs as *now calls* that may be part of a cross-country switch network and that may be blocked from completion due to the engineering of a restrictive AFRL arrangement.

### Considerations

---

- Consider the impact on your operations when there are sudden changes in the calling privileges of your system users. Consider announcing changes and preparing your telecommunications department to handle inquiries.

## Guidelines and examples

The following examples should help you understand AFRLs and should illustrate some of their practical aspects.

### AFRL mapping

FRLs are used to determine the privileges that an originating party can have when making an outgoing trunk call. This party can be either a line or a trunk. An FRL is assigned to each device and/or device group through its associate COR.

When a device originates an outgoing trunk call, its FRL is compared to the FRL of either the terminating trunk group or (for AAR or ARS) the preference. If the FRL of the originator is greater than or equal to the terminating FRL, the call proceeds. Otherwise, the call is blocked. FRLs restrict outgoing calls by destination, by time of day, or by facility problem (such as trunk outages).

For example, a technician could remap FRLs less than 3 to 3 and FRLs greater than 3 to 7. Any attendant or station with an AFRL button can control whether the original FRL or the AFRL is used.

### Authorization codes

Authorization codes prevent unauthorized access to various facilities. You can use them, for example, to restrict access to certain trunk groups or to remote access trunk groups. When a user dials an authorization code, it is validated by the system. If it is not valid, the call routes to an assignable intercept. If the code is valid, the system determines an associated COR. This COR has an FRL associated with it. If AFRL is activated, it is the AFRL level and not the FRL that is used in mapping the AFRL.

For example, a user whose FRL is 1 attempts a toll call. AFRL is active and maps as shown in [Figure 8-2](#) (that is, FRL = 1 maps to AFRL=3). The desired trunk has an FRL of 7, and so the user is blocked. If Authorization Codes are enabled, the user is prompted to dial an authorization code to obtain greater calling privileges. As shown in [Figure 8-2](#), an Auth Code set to 1234567 has a COR set to 3 and, therefore, an FRL set to 5. This is still not high enough to permit access to the desired trunk except when the user presses the active AFRL button. Then the AFRL feature is active and maps the FRL of 5 to 7, thus allowing the call to complete.

| Authorization code to COR Table |     | COR to FRL Table |     | FRL to AFRL Table |      |
|---------------------------------|-----|------------------|-----|-------------------|------|
| Authorization Code              | COR | COR              | FRL | FRL               | AFRL |
| 1234567                         | 3   | 1                | 1   | 0                 | 3    |
| 1234568                         | 2   | 2                | 3   | 1                 | 3    |
| 1234569                         | 3   | 3                | 5   | 2                 | 3    |
| 2222222                         | 3   | 4                | 7   | 3                 | 3    |
|                                 |     |                  |     | 4                 | 7    |
|                                 |     |                  |     | 5                 | 7    |
|                                 |     |                  |     | 6                 | 7    |
|                                 |     |                  |     | 7                 | 7    |

Originator COR is 1  
 Trunk Desired COR is 4

Figure 8-2. Example of authorization codes with AFRLs

### Interactions

- AAR/ARS
  - ARFL can change route preferences and affect the cost of usage-sensitive calls.
- Facility Restriction Levels and Traveling Class Marks
  - AFRL sets up alternate levels to those normally provided by FRL.

## Generalized Route Selection

---

Generalized Route Selection (GRS) provides voice and data call-routing capabilities. You use it to select not only the least-cost routing, but also the most optimal routing over the appropriate facilities.

GRS is a capability built onto the AAR and ARS features. In AAR or ARS, routing is based on the dialed number, the FRL of the caller, the partition group number, and the time of day. GRS provides additional parameters in the routing decision. It enhances AAR and ARS and maximizes the chance of using the right facility to route the call. Also, if an endpoint incompatibility exists, it provides a conversion resource (such as a modem from a modem pool) to attempt to match the right facility with the right endpoint.

### How to administer GRS

---

### Detailed description

---

GRS allows customers to use separate routes for voice and data calls. For data calls, DEFINITY ECS distinguishes between restricted and unrestricted digital transmissions. This allows the switch to route data calls onto the appropriate facilities. With GRS, you can integrate voice and data on the same trunk group.

GRS allows the system to use the ISDN Call-by-Call Service Selection feature to access public network services. It also provides interworking between ISDN and non-ISDN entities.

ISDN interworking is the mixture of ISDN trunks and non-ISDN trunks in a call. A mixture of these signaling procedures is required to provide end-to-end connectivity when different type trunking facilities are used.

ISDN services add 5 routing parameters that are specified on each trunk group preference of the route pattern. These parameters are:

- Bearer Capability Class (BCC) — Identifies the type of call, such as voice calls and different types of data calls. For all trunk groups, the BCC is checked to see if the route selected is compatible.
- Information Transfer Capability (ITC) — Identifies the type of data transmission (restricted, unrestricted, or both). For all trunk groups, the ITC is checked to see if the route selected is compatible.
- Network Specific Facility — Identifies the services and features to be used to complete a call.
- Band — Identifies the OUTWATS band (US only). WATS is a voice-grade service providing both voice and low-speed data transmission calls to defined areas (bands) for a flat rate charge.
- Inter-Exchange Carrier (IXC) — Identifies the specific common carrier, such as AT&T, to be used for a call.

In GRS, there are 5 BCCs. Customers may specify routing for each BCC according to their particular transmission needs. See the Expanded Technical Information portion of this section for more information on BCCs and ISDN BCC Parameters.

## Expanded technical information on BCC

### BCCs

BCCs are the mechanisms by which specialized routing is provided for the various type data calls and voice calls. Each trunk group preference in the AAR or ARS route patterns contains a BCC parameter. When a call is originated, a route is selected based on the BCC of the originating facility. BCCs are used to classify the type of traffic permitted on this trunk in the outgoing direction. Details on how a trunk group preference is determined are given in Guidelines and examples.

A set of ISDN bearer capability and low-layer compatibility parameters are defined by a BCC.

The system will determine the originating endpoint's BCC from one of the following:

- For an ISDN-BRI set, the switch determines the BCC by using information from the Bearer Capability Information Element (IE) and Low-Layer Compatibility IE in the ISDN SETUP message.
- For a non-BRI terminal, the switch creates a BCC by using information about the station administration for the terminal and information obtained by performing a terminal query.
- From the administered value of the incoming trunk. For a non-ISDN trunk group, the switch uses the administered BCC value.
- From the ISDN bearer capability and low-layer compatibility parameters, if the call is an ISDN trunk-originated call.

The BCC associated with the routing preference in the route pattern is administered by the system administrator. More than one BCC can be associated with each preference and the same facility can appear multiple times in a route pattern and in multiple route patterns.

The BCC of the originating endpoint (trunk or terminal) is matched with the BCCs of the routing preferences. An exact match is not always required. The system determines when conversion/insertion resources must be used to successfully complete a call via a compatible, but not identical, BCC.

GRS recognizes one or more of 5 BCCs for each trunk group preference in the route pattern (DCP/DMI mode is explained later). See [Table 8-4](#).

**Table 8-4. BCC Assignment**

| Endpoint                         | Voice/<br>Data Mode | BCC   | Comments                             |
|----------------------------------|---------------------|-------|--------------------------------------|
| Voice Terminal                   | Voice               | 0     |                                      |
| Data Line Circuit Pack           | 2                   | 2     |                                      |
| Voice Data Set                   | 2                   | 2     |                                      |
| Modular Processor Data Module    | 0,1,2               | 1,2,4 | See Note                             |
| Modular Processor Data Module-M1 | 1                   | 1     | For ACCUNET Switched 56 kbps Service |
| Modular Trunk Data Module        | 2                   | 2     |                                      |
| Digital Terminal Data Module     | 2                   | 2     |                                      |

*Continued on next page*

**Table 8-4. BCC Assignment — Continued**

| Endpoint                                  | Voice/<br>Data Mode | BCC   | Comments |
|---|---------------------|-------|----------|
| 510D Personal Terminal                    | 2                   | 2     |          |
| Digital Communications Protocol Interface | 0,2,3               | 2,3,4 | See Note |
| 7400A Data Module                         | 2                   | 2     |          |
| 3270T Data Module                         | 3                   | 3     |          |
| 3270C Data Module                         | 3                   | 3     |          |
| 3270A Data Module                         | 2,3                 | 2,3   | See Note |

**Legend**

| BCC | Type                       | DCP/DMI Mode |
|-----|----------------------------|--------------|
| 0   | Voice-Grade Data and Voice | None         |
| 1   | 56 kbps Data (Mode 1)      | 1            |
| 2   | 64 kbps Data (Mode 2)      | 2            |
| 3   | 64 kbps Data (Mode 3)      | 3            |
| 4   | 64 kbps Data (Mode 0)      | 0            |

 **NOTE:**

For all endpoints, the switch automatically determines its current operating mode when the data module originates. Before any call is originated, the default is Mode 2.

Since call origination from a data module determines the mode used on the call, you should press the Originate/Disconnect button once after changing data options. This way, the right mode is sure to be assigned to the next call.

## ISDN BCC parameters

The ISDN BCC Parameters are:

- Information Transfer Capability
- Low-Layer Compatibility
- DCP/DMI Mode

### Information Transfer Capability

The information to be transferred (or type of call) requires different transmission facilities. For example, transmission needs for voice calls and data calls are generally different. Voice and voice-grade data calls can be sent over analog trunks, while high speed data calls require digital trunks.

The Information Transfer Capability parameter in the Bearer Capability Information Element (BC IE) and Low-Layer Compatibility Information Element (LLC IE) have the following 4 values:

- Voice (speech)
- Voice-grade data (3.1 kHz transmission)
- Unrestricted digital transmission
- Restricted digital transmission.

With data calls, the switch distinguishes the information transfer capability (restricted or unrestricted) of the originating data endpoint (trunk or terminal). It uses the information transfer capability of the data endpoint to route the call to the appropriate facility. For BRI and PRI originating data endpoints, the information transfer capability is contained in the ISDN SETUP message. For non-ISDN data endpoints, the switch uses the information transfer capability specified by the system administrator. The default for the information transfer capability of an endpoint is *restricted*. This can be changed to restricted or unrestricted for each non-ISDN originating endpoint.

More than one Information Transfer Capability can be supported by one BCC. See [Table 8-5](#).

**Table 8-5. Assignment of BCC Based on Information Transfer Capability**

| DCP/DMI MODE    | Information Transfer Capability     | BCC | Comments   |
|-----------------|-------------------------------------|-----|--|
| —               | Speech, 3.1 kHz                     | 0   | Used for Voice/ Voice Grade Data.                          |
| M1              | Unrestricted/<br>Restricted Digital | 1   | Used for Mode 1 Data (56 kbps).                            |
| M2 <sup>1</sup> | Unrestricted/<br>Restricted Digital | 2   | Used for Mode 2 Data (async data speed up to 19.2 kbps).   |
| M3 <sup>1</sup> | Unrestricted/<br>Restricted Digital | 3   | Used for Mode 3 Data (64 kbps).                            |
| M0              | Unrestricted/<br>Restricted Digital | 4   | Used for Mode 0 Data <sup>2</sup> (64 kbps clear channel). |

1. Typically not used outside of North America.
2. Use BCC 4 for an unknown data mode that requires a 64-KBPS channel.

### Low-Layer Compatibility

The low-layer compatibility information element provides remote compatibility checking. This element is used with the bearer capability element and determines the mode of the originating caller. The low-layer compatibility information element is optional and sent only in case of data calls.

 **NOTE:**  
 DCP Mode 0 does not send an LLC IE.

### DCP/DMI Mode

The Digital Communications Protocol (DCP) and the Digital Multiplexed Interface (DMI) modes are data parameters of the originating data facility. These modes are not applicable to voice.

The mode values (0, 1, 2, and 3) are administered for data and Alternate Voice/Data (AVD) non-ISDN trunk groups. These mode values determine the BCC of the trunk groups.

### Determination of BCC at tandeming or terminating system

The BCC parameters received on the signaling channel (D-channel) determine the BCC for an incoming call from an ISDN trunk to a tandem or terminating switch. This includes the ITC (restricted or unrestricted) if the call is a data call.

The BCC for an incoming call from a non-ISDN trunk is determined as follows:

- If the incoming trunk is a voice trunk, then the BCC is defaulted to 0.
- If the incoming trunk is a data, AVD, or RBAVD (robbed-bit AVD) trunk, then the BCC and ITC are administrable.

## Guidelines and examples

---

The AAR/ARS route pattern contains an indication for each trunk group preference showing which BCC or BCCs can use that trunk group. A trunk group preference may have more than one BCC.

GRS uses a *look-ahead* algorithm when determining which preference in a route pattern to choose. GRS first attempts to find an exact match between the originator's BCC and the corresponding allowed BCC for any of the preferences in the route pattern. Therefore, if preference 1 does not have an exact match (even though there are available compatible members in preference 1), it is skipped over if a subsequent preference in the same pattern has an allowed BCC that exactly matches the originator's BCC.

After matching the BCCs, DEFINITY ECS matches the ITCs. The originator's ITC is matched to the route preference ITC.

- Unrestricted (unre) matches on "unr" or "both"
- Restricted (rest) matches on "rest" or "both"

### NOTE:

ITC matching only applies to data calls (BCC 1 through 4).

As an example of how GRS chooses a trunk group preference, assume preference 1 in a pattern has BCC 0 and BCC 2 set to yes, while preference 2 has BCC 1, BCC 3, and BCC 4 set to yes. A voice or Mode 2 data call accessing this pattern uses the first preference, while a Mode 1, Mode 3, or Mode 0 data call uses the second. (This is independent of the availability of trunks in the first preference.)

When an exact match is not found in any of the route-pattern preferences, calls are treated as follows:

- Calls With an Originating BCC of 0

A BCC 0-originated call (such as voice or analog modem) is not denied routing by GRS, even if the route pattern lacks a preference with BCC 0 set to yes. This allows you to use voice transfer to data when making a data call, without the need for data preindication.

- If a BCC 0-originated call accesses a route pattern for which there is no preference for BCC 0 set to yes, then GRS chooses a preference with BCC 2 set to yes (if one exists).

- If none exists, the next preferred order would be a preference with BCC 1 set to yes, followed by BCC 3, and finally, BCC 4.

Since each preference must allow at least one BCC to be passed, a BCC 0 (voice) originated call is never blocked by GRS. The call is of course still subject to other restrictions, such as FRL restrictions. The ITC does not help select a preference.

Since BCC 0 (voice) has no ITC, the switch selects an ITC from the route pattern when a BCC 0 call is being routed as a data call. [Table 8-6](#) shows how the ITC codepoint in the Bearer Capability IE is determined.

**Table 8-6. Determination of ITC Codepoint**

| Originating Endpoint's ITC | Routing Preference's ITC |              |               |                   | ITC codepoint in BC IE |
|----------------------------|--------------------------|--------------|---------------|-------------------|------------------------|
|                            | restricted               | unrestricted | both endpoint | both unrestricted |                        |
| voice                      | x                        |              |               |                   | restricted             |
| voice                      |                          | x            |               |                   | unrestricted           |
| voice                      |                          |              | x             |                   | unrestricted           |
| voice                      |                          |              |               | x                 | unrestricted           |

- Calls With an Originating BCC of 2
  - If a BCC 2 originated call accesses a route pattern for which no preference has BCC 2 set to yes, then GRS chooses a preference with BCC 0 set to yes (if one exists).
  - If none exists, the call is blocked with intercept treatment.

- Calls With an Originating BCC of 1, 3, or 4
 

A DCP/DMI Mode 0 (BCC 4), Mode 1 (BCC 1), or Mode 3 (BCC 3) originated call requires an exact match on at least one preference in a route pattern in order for GRS to allow the call to complete.

For example, a Mode 1 originated call completes only if the accessed route pattern has a preference with BCC 1 set to yes. The ITCs must also match.

When an ISDN trunk group preference is accessed, the BCC information is encoded and sent in the outgoing ISDN SETUP message to the distant-end as shown below. The BCC information sent to the far-end is important. The BCC information that the far-end receives in the SETUP message becomes the originating BCC for the far-end's incoming trunk call.

- If an exact match of the originator's BCC and ITC is found, then that Bearer Capability is encoded and sent in the ISDN SETUP message to the far-end. If the call is a data call, the system uses the ITC of the route pattern to encode the SETUP message as shown in [Table 8-7](#).

Table 8-7. Encoding of Setup message

| Originating Endpoint's ITC | Routing Preference's ITC |              |               |                   | ITC codepoint in BC IE |
|----------------------------|--------------------------|--------------|---------------|-------------------|------------------------|
|                            | restricted               | unrestricted | both endpoint | both unrestricted |                        |
| restricted                 | x                        |              |               |                   | restricted             |
| restricted                 |                          |              | x             |                   | restricted             |
| restricted                 |                          |              |               | x                 | unrestricted           |
| unrestricted               |                          | x            |               |                   | unrestricted           |
| unrestricted               |                          |              | x             |                   | unrestricted           |
| unrestricted               |                          |              |               | x                 | unrestricted           |
| voice <sup>1</sup>         | x                        |              |               |                   | restricted             |
| voice                      |                          | x            |               |                   | unrestricted           |
| voice                      |                          |              | x             |                   | unrestricted           |
| voice                      |                          |              |               | x                 | unrestricted           |

1. A voice originated call without data preindication that is routed to a route pattern with data preferences only.

- If an exact match is not found, but the call is allowed to proceed, then the BCC encoded in the SETUP message sent to the far-end is that of the route pattern.

For example, if a BCC 2 (for example, DTMF) endpoint originates a call and accesses a pattern that has one preference with only BCC 0 set to yes, then the switch automatically inserts a modem pool for this call. In effect, the modem pool is converting BCC 2 to BCC 0. The far-end cannot distinguish this call from a BCC 0-originated call that has no modem pool inserted. Therefore, BCC 0 is sent in the SETUP message. This may in turn determine routing decisions by the far-end. Additional routing decisions are made as shown in [Table 8-8](#) through [Table 8-12](#).

## BCC and ITC Determination on Calls from Endpoints to ISDN Trunks

Table 8-8. Calls from Endpoint to ISDN Trunks

| Originating BCC | Chosen BCC from the Route Pattern |       |       |       |       |
|-----------------|-----------------------------------|-------|-------|-------|-------|
|                 | BCC 0                             | BCC 1 | BCC 2 | BCC 3 | BCC 4 |
| BCC 0           | P                                 | PT    | PT    | PT    | PT    |
| BCC 1           | B                                 | P     | B     | B     | B     |
| BCC 2           | PM                                | B     | P     | B     | B     |
| BCC 3           | B                                 | B     | B     | P     | B     |
| BCC 4           | B                                 | B     | B     | B     | P     |

Legend

|    |  |
|----|--|
| B  | Block the call with intercept treatment  |
| P  | Allow the call and send the originating endpoint's BCC in the SETUP message. Use the ITC as shown in <a href="#">Table 8-9</a> |
| PT | Allow the call and send the BCC and ITC chosen from the route pattern in the SETUP message                                     |
| PM | Insert a pooled modem for the call and send the BCC and ITC chosen from the route pattern in the SETUP message                 |

If BCC 1, 2, 3, or 4 is chosen from [Table 8-8](#), [Table 8-9](#) is used to determine the appropriate ITC.

Table 8-9. Calls from Endpoints to ISDN Trunks

| Originating ITC | Chosen ITC from the Route Pattern |      |            |          |
|-----------------|-----------------------------------|------|------------|----------|
|                 | unr                               | rest | both endpt | both unr |
| unr             | P                                 | B    | P          | PU       |
| rest            | B                                 | P    | P          | PU       |

Legend

|    |   |
|----|---|
| B  | Block the call with intercept treatment                                     |
| P  | Allow the call and send the originating endpoint's ITC in the SETUP message |
| PU | Allow the call and send unrestricted in the SETUP message                   |

## BCC and ITC Determination on Calls from Trunks to ISDN

Table 8-10. Calls from Trunks to ISDN Trunks

| Originating BCC | Chosen BCC from the Route Pattern |       |       |       |       |
|-----------------|-----------------------------------|-------|-------|-------|-------|
|                 | BCC 0                             | BCC 1 | BCC 2 | BCC 3 | BCC 4 |
| BCC 0           | P                                 | PT    | PT    | PT    | PT    |
| BCC 1           | B                                 | P     | B     | B     | B     |
| BCC 2           | PT                                | B     | P     | B     | B     |
| BCC 3           | B                                 | B     | B     | P     | B     |
| BCC 4           | B                                 | B     | B     | B     | P     |

Legend

|    |   |
|----|---|
| B  | Block the call with intercept treatment   |
| P  | Allow the call and send the incoming trunk's BCC in the SETUP message. Use the ITC as shown in <a href="#">Table 8-11</a> |
| PT | Allow the call and send the BCC and ITC chosen from the route pattern in the SETUP message                                |

If BCC 1, 2, 3, or 4 is chosen from [Table 8-10](#), [Table 8-11](#) is used to determine the appropriate ITC.

Table 8-11. Calls from Trunks to ISDN Trunks

| Originating | Chosen ITC from the Route Pattern |      |            |          |
|-------------|-----------------------------------|------|------------|----------|
|             | unr                               | rest | both endpt | both unr |
| unr         | P                                 | B    | P          | PU       |
| rest        | B                                 | P    | P          | PU       |

Legend

|    |   |
|----|---|
| B  | Block the call with intercept treatment                               |
| P  | Allow the call and send the incoming trunk's ITC in the SETUP message |
| PU | Allow the call and send unrestricted in the SETUP message             |

The system does not insert pooled modem for any interworking trunk-to-ISDN trunk calls. The BCC and ITC of an incoming trunk are determined as follows:

- ISDN Trunk BCC and ITC are in the received SETUP message
- AVD Trunk BCC and ITC are the BCC and ITC values administered on the trunk group form
- RBAVD Trunk BCC and ITC are the BCC and ITC values administered on the trunk group form
- Data Trunk BCC and ITC are the BCC and ITC values administered on the trunk group form
- Voice Trunk BCC is 0.

### BCC and ITC Determination on Calls from ISDN Trunks to Endpoints (GRS not Involved)

Table 8-12. Calls from ISDN Trunks to Endpoints

| Originating BCC | Terminating Endpoint BCC |       |       |       |       |
|-----------------|--------------------------|-------|-------|-------|-------|
|                 | BCC 0                    | BCC 1 | BCC 2 | BCC 3 | BCC 4 |
| BCC 0           | P                        | P     | PM    | P     | P     |
| BCC 1           | P                        | P     | P     | P     | P     |
| BCC 2           | P                        | P     | P     | P     | P     |
| BCC 3           | P                        | P     | P     | P     | P     |
| BCC 4           | P                        | P     | P     | P     | P     |

Legend

|    |  |
|----|--|
| P  | Allow the call, and (1) if it is a voice originated call, let the calling user decide whether the terminating endpoint is the correct endpoint or not based on audible feedback (for example, data tone), or (2) if it is a data call, the data handshake procedure will establish or drop the call based on the compatibility of the endpoints. |
| PM | Insert a pooled modem and terminate the call to the endpoint. The ITC defaults to restricted in this case.   |

**NOTE:**

The system does not use ITCs when terminating to an endpoint.

## Look-Ahead Routing

---

Look-Ahead Routing (LAR) provides an efficient way to use trunking facilities. It allows you to continue to try to reroute an outgoing ISDN call that is not completing. When DEFINITY ECS receives a cause value that indicates congestion, LAR tells the system what to do next. For each routing preference, you can indicate if the next routing preference should be attempted or if the current routing preference should be attempted a second time. If the second attempt fails, the next routing preference is attempted.

LAR can be administered at either an origination switch or a tandem switch. However, it also can be turned off at different points in the network to reduce network load. You use LAR with AAR and ARS, GRS, UDP. You can also use it with the Feature Access Code ISDN Access Code. A LAR field is administered on the Route Pattern form.

### How to administer LAR

---

#### Required forms

---

| Form          | Field | Page                 |
|---------------|-------|----------------------|
| Route Pattern | ■ LAR | <a href="#">8-67</a> |

#### NOTE:

When LAR is used in a mixed network of DEFINITY ECS and pre-DEFINITY ECS switches, LAR ends at the pre-DEFINITY ECS switch and calls are rejected the normal way. However, if a LAR-triggering cause value is passed back in the network to a DEFINITY ECS that is enabled for LAR, LAR is attempted from that switch again.

### Detailed description

---

LAR can be administered for each ISDN route preference per Pattern Number. The maximum number of LAR attempts per call per switch is 2 times the number of route preferences in the route pattern. LAR can be administered at each intermediate node that the call may be tandemed through to allow all possible routes to be attempted. You can control LAR by:

- Administering it on a per route-preference basis
- Partitioning trunks
- Limiting the number of hop counts

## LAR activation

LAR is active when a call is rejected with a cause value in the range of #34–#47 and #3 (no route to destination). The range of #34–#47 indicates congestion and that resources are unavailable. The following cause values activate LAR:

| Cause Value | Cause Description                            |
|-------------|--|
| 3           | ■ No route to destination                    |
| 34          | ■ No circuit/channel available               |
| 38          | ■ Network out of order                       |
| 41          | ■ Temporary failure                          |
| 42          | ■ Switching equipment congestion             |
| 43          | ■ Access information discarded               |
| 44          | ■ Requested circuit or channel not available |
| 47          | ■ Resources unavailable                      |

### ⇒ NOTE:

When country code 13, protocol version a, is administered on the DS1 Circuit Pack form, only the cause values #10 and #89 activate LAR.

## LAR termination

LAR terminates when:

- Call is successfully routed
- Call is rejected with a non-LAR-triggering cause value
- No further route preference can be used to route the call

## LAR measurement

You can measure the number of LAR reroutes that are attempted and successful. A new form, Measurements LAR Route Pattern, displays LAR measurements for a particular route pattern. A route pattern must be selected for measurement before data collection. See *DEFINITY Enterprise Communications Server Release 6 System Monitoring and Reporting* for more information.

## Considerations

---

- LAR cannot be activated by dialing an ISDN TAC or via Extended Trunk Access (ETA).
- If LAR is enabled for an ISDN-PRI route preference and AAR, ARS, GRS, or ISDN Access Code is used, LAR can be active on all outgoing calls using that route preference. This includes: Abbreviated Dialing, ACCUNET

Service, Administered Connections, Call-by-Call Service Selection, Call Forwarding, Call Vectoring, Electronic Tandem Networks, Multimedia, Outgoing Call Management, and QSIG Networks.

## Interactions

---

- Automatic Circuit Assurance

LAR rerouting attempts are recorded as short holding time calls.
- Distributed Communications Systems

If a non-DCS trunk preference is selected for rerouting a DCS call, DCS feature transparency is lost. If LAR for a DCS call is done within the same DCS trunk group, feature transparency is not lost.
- Generalized Route Selection

LAR on a route preference does not change or impact GRS feature operation.
- QSIG Networks

If a non-Supplementary Services B (SS B) trunk preference is selected for rerouting a SS B call, QSIG feature transparency is lost. If LAR for a QSIG call is done through either the same or another SS B trunk group, feature transparency is not lost.
- Ringback Queuing

When a call originates and queues at the trunk group queue, the call can be placed in queue multiple times if LAR is active. The call originator can be called back each time the call is continued automatically.
- Satellite Hop Limit

Satellite Hop Limit always takes precedence over LAR. When the maximum hop limit is reached for a route preference, the last call routing attempt is denied and the call is rejected with a cause value of #28 — invalid number format. (This value does not activate LAR.)
- System Measurements

System resource use during LAR attempts are included in existing system measurements and performance reports. They include the following measurements: route pattern, call rate, call summary, performance summary, processor occupancy, trunk group, and call-by-call measurements. For more information about LAR system measurements, refer to *DEFINITY Enterprise Communications Server Release 6 System Monitoring and Reporting*.

## Subnet Trunking

---

Subnet Trunking modifies the number you dial so an AAR or ARS call can route over different trunk groups. These trunk groups frequently terminate in switches with different dial plans.

Subnet Trunking inserts digits, deletes digits, pauses, and/or waits for dial tone in digit outpulsing, as required, so calls route:

- To or through a remote switch
- Over Tie trunks to a private network switch
- Over CO trunks to the serving CO

Subnet Trunking is not required on calls terminating directly to a party at the local switch. AAR handles these calls.

Subnet Trunking is required on calls routing to or through a remote switch, regardless of the call's destination.

### How to administer Subnet Trunking

---

#### Required forms

---

| Form                              | Field                              | Page                  |
|-----------------------------------|------------------------------------|-----------------------|
| Route Pattern                     | ■ No. Del. Digits                  | <a href="#">8-67</a>  |
|                                   | ■ Inserted Digits                  |                       |

|                                   | ■ Interval                         |                       |

---

### Detailed description of Subnet Trunking

---

An AAR or ARS call may ultimately reach a point where it can no longer route on a private network. That is, the call reaches a point where another on-network switch is not available for the call. Assuming the call is not denied at this point, it routes to one of the following:

- Directly to a party at the local switch
- Directly to a WATS serving office
- Directly to a local CO or a FX CO

Calls accessing a local CO or FX CO directly from the terminating switch normally require Subnet Trunking only if access to a long-distance carrier is other than the carrier automatically provided by the CO. In this case, DEFINITY ECS inserts the appropriate dial access code into the digit string. Subnet Trunking is

needed only if the number is modified or if the call passes through some intermediate switch.

Subnet Trunking is used to provide added functionality to the system. For example, it can convert an AAR number into an international number. Also, it can modify a digit string so that a remote access trunk group can be used on calls.

ARS does not use Subnet Trunking to add or delete an area code; it handles it via code conversion.

AAR uses Subnet Trunking to convert an on-network number to a public network number. In this case, the conversion may include an Area Code insertion via Subnet Trunking.

Any of several special characters may be used with Subnet Trunking:

- Pause — Delays outpulsing of subsequent digits for 1.5 seconds
- Wait — Can be administered in one of two ways
  - In the first way, delays outpulsing of subsequent digits for a preprogrammed interval (from 5 to 25 seconds) or, if tone detectors are provided, until dial tone is received from the distant switch or the interval expires, whichever occurs first.
  - In the second way, dial tone must be received before any outpulsing is done.
- Convert-to-tone — Causes all remaining digits to be outpulsed using tone signaling.

## Time of Day Routing

---

Time of Day (TOD) Routing provides the most economical routing of ARS and AAR calls. This routing is based on the time of day and day of the week that each call is made. Up to 8 TOD routing plans may be administered, each scheduled to change up to 6 times a day for each day in the week.

With TOD Routing, you can take advantage of lower calling rates during specific times of the day and week. In addition, companies with locations in different time zones can use different locations that have lower rates at different times of the day or week. This feature is also used to change patterns during the times an office is closed in order to reduce or eliminate unauthorized calls.

### How to administer Time of Day Routing

---

#### Required forms

| Form                                  | Field   | Page                   |
|---------------------------------------|---|------------------------|
| Time of Day Routing Plan              | ■ All   | <a href="#">8-78</a>   |
| AAR and ARS Digit Analysis Table      | ■ All   | <a href="#">8-54</a>   |
| Node Number Routing (optional)        | ■ All   | <a href="#">12-119</a> |
| Class of Restriction                  | ■ Time of Day Plan Number   | <a href="#">5-72</a>   |
| Station (multi-appearance) (optional) | ■ Button/Feature Button Assignments<br>— man-overid<br>— clk-overid | <a href="#">6-28</a>   |
| Attendant Console (optional)          | ■ Feature Button Assignments<br>— man-overid<br>— clk-overid        | <a href="#">5-35</a>   |

- Time of Day Routing can only be used if AAR and ARS Partitioning and AAR or ARS are used. Also, it needs to be enabled on the System-Parameters Customer-Options form.

### Detailed description

---

TOD Routing uses the Time of Day Plan Number assigned by the COR feature. A Time of Day Routing Plan can be administered for each of the 8 Time of Day Plan Numbers. When you make an AAR or ARS call, the call is routed according to the Time of Day Routing Plan associated with your Time of Day Plan Number.

After a call passes through AAR or ARS Digit Conversion (with no matching pattern found) and toll analysis allows the call, the Time of Day Plan Number of the calling party is used to make the choice of an associated Time of Day

Routing form. A PGN is identified and AAR or ARS Partitioning selects the specific partition of the AAR or ARS Digit Analysis form and determines how the call is routed.

When TOD Routing is enabled, it applies to all AAR or ARS outgoing calls: voice terminals, attendants, data terminals, remote access users, incoming tie trunks, ISDN-PRI trunks, and trunks used for call forwarding to external numbers.

## Overriding the Time of Day Routing Plan

An attendant or a voice terminal user with console permission and a display can temporarily override the activating user's current routing plan. This can be accomplished by either of two methods:

- Immediate Manual Override
- Clocked Manual Override

Both types of override cannot be activated simultaneously. If either type is activated while the other is still in effect, the newly activated override goes into effect and the other override is automatically deactivated.

There is no indication via the management terminal that either type of override is activate. Also, since these overrides are temporary, they are not saved to translations.

## Guidelines and examples

Assume the following:

- Jim is the user at extension 1234.
- Extension 1234 is assigned a COR of 2.
- COR 2 is assigned a Time of Day Plan Number of 3.
- The Time of Day Routing Plan table for Time of Day Plan Number 3 is administered as shown in [Screen 8-1](#).

When Jim comes into work on Monday morning at 8:30 and at that time makes an ARS call (dials the ARS access code followed by the number of the person he is calling), the system looks at the Time of Day Plan Number assigned to Jim's COR to determine which Time of Day Routing Plan table is used.

Since Jim has a COR of 2 and COR 2 has a Time of Day Plan Number of 3, the system uses Time of Day Routing Plan 3 to route the call.

According to Time of Day Routing Plan 3, all calls made between 8:00 a.m. and 12:00 p.m. route according to the ARS Digit Analysis Table associated with PGN 2. Therefore, these tables are used to find a route pattern for the call.

If Jim makes a call between 12:00 p.m. and 1:00 p.m. on Monday, the same Time of Day Routing Plan table (number 3) is used and the call is routed according to PGN 1. See [Screen 8-1](#).

Page 1 of 1

TIME OF DAY ROUTING PLAN 3

| Act Time  | PGN # | Act Time   | PGN # | Act Time   | PGN # | Act Time   | PGN # | Act Time   | PGN # | Act Time |
|-----------|-------|------------|-------|------------|-------|------------|-------|------------|-------|----------|

Screen 8-1. Time of Day Routing Plan

## Interactions

- **Abbreviated Dialing**  
 For TOD Routing purposes, a user's own COR Time of Day Plan Number is used when accessing an Abbreviated Dialing privileged list. The call is processed the same as if the call had been dialed directly using AAR or ARS.
- **Attendant Extended Calls**  
 When an attendant extends a call and that call uses AAR or ARS to process the call, the call is routed according to the Time of Day Plan Number of the attendant's COR.
- **Authorization Codes**  
 If a user's FRL is changed using an Authorization Code, the COR FRL associated with the entered Authorization Code is used in route pattern selection.
- **AAR and ARS**  
 When Time of Day Routing is assigned, all AAR and ARS calls use the Time of Day Routing Plans for routing calls.
- **Bridged Call Appearance**  
 The COR Time of Day Plan Number of the primary extension applies to calls originated from a bridged call appearance of the primary extension.
- **Call Detail Recording**  
 Normal CDR records are generated. Information about the Time of Day Plan Number used to route the call is not provided.

- Call Forwarding

If you enable call forwarding and AAR or ARS routes an incoming call to the forwarded-to number, the COR Time of Day Plan Number of the caller is used to route the call.

- DCS

Care should be taken when making Time of Day Routing assignments in a DCS environment. Depending on a user's Time of Day Plan Number, a user may or may not be routed to a DCS trunk group. If a user is not routed to a DCS trunk group, feature transparency is lost.

When a call routes over a DCS trunk, the switch at the far end routes the call according to the COR Time of Day Plan Number of the incoming trunk.

- Individual Attendant Access

When an individual attendant access call is made, the individual attendant's COR Time of Day Plan Number is used for routing the call.

- Remote Access

When an AAR or ARS call is made via remote access, the COR Time of Day Plan Number of the barrier code and/or authorization code that was entered is used for routing the call.

- UDP

The caller's COR Time of Day Plan Number is used to route UDP calls.

This section contains the forms and associated instructions for implementing automatic routing. Included are:

- AAR and ARS Digit Analysis Table
- AAR and ARS Digit Conversion Table
- AAR and ARS Route Pattern form
- ARS Toll Table
- Remote Home Numbering Plan Area (RHNP) Table
- Time of Day Routing Plan

AAR and ARS are implemented using similar forms. When fields and their definitions are the same, they are not repeated. When they are different, the difference is noted. Examples of both forms are provided.

 **NOTE:**

For AAR administration, on the System-Parameters Customer-Options form, either the Private Networking or Uniform Dialing Plan option must be enabled.

For ARS administration, on the System-Parameters Customer-Options form, the Automatic Route Selection must be enabled as well as Time of Day Routing.

## **Automatic Routing Forms**

## AAR and ARS Digit Analysis Table

This form maps customer dialed strings to route patterns. When there is a Remote Home Numbering Plan Area (RHNPA) entry in `Rte Pat`, the RHNPA Table translates the next 3 digits.

If RHNPA translations are required for certain dialed strings, enter r1–r32 in the appropriate `Rte Pat` field on the AAR or ARS Digit Analysis Table. The RHNPA Table is used for translating 3-digit codes in the range 000–999. The RHNPA Table is used typically for the DDD of CO codes in a non-local NPA. For additional information, see [“RHNPA Table” on page 8-76](#).

### Administration commands

Use the following commands to administer the AAR and ARS Digit Analysis Table form.

| Action  | Object                               | Qualifier <sup>1</sup>  |
|---------|--------------------------------------|---|
| change  | aar analysis<br>ars analysis         | Enter digits between 0 to 9, 'x' or 'X' (dialed string) ['part' 1-8] ['min'(1-MAX)]   |
| display | aar analysis<br>ars analysis         | Enter digits between 0 to 9, 'x' or 'X' (dialed string) ['part' 1-8] ['min' (1-MAX)] ['print' or 'schedule']                                |
| list    | aar analysis<br>ars analysis         | ['start' string] ['count' 1-MAX] ['route'(1-MAX or r1-r32)], ['part' (1-8)], ['node' (1-MAX)], ['to-node' (1-MAX)], ['print' or 'schedule'] |
| list    | aar route-chosen<br>ars route-chosen | Enter dialed number, ['partition' (1-8)], ['print' or 'schedule']   |

- Some qualifiers are available with R5si and later configurations only. Brackets [] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

- **Percent Full** — 3-character display-only field. Displays the percentage of the System's memory resources that have been used. A common pool of memory resources is shared between the ARS and AAR Analysis tables.  
  
 If this field display indicates that the System memory resources are in jeopardy of becoming full (100%), perform any of the following to free-up memory resources:
  - Delete unnecessary entries from any of the shared resources tables
  - Use RHNPA Tables for 6-digit screening. Use ARS analysis to screen on the area code. Then use the RHNPA Table to finish the 6-digit screening in the office code.
  - Reduce Dialed String field entries to shortest possible length that accomplishes the desired function.
- **Partitioned Group Number** — Enter the PGN to be associated with this table. Valid entries are 1 (default) to 8.
- **Dialed String** — Enter the dialed string of significant digits. Up to 18 ARS characters consisting of the digits 0 through 9 or \* are allowed. Use a wildcard letter (x or X) to substitute for any digit occurring in the dialed string at the character position where used.

 **NOTE:**

The user-dialed digits are matched to the Dialed String entry that most closely matches the dialed number (referred to as the longest match). For example, if a user dials 297-1234 and the AAR or ARS Analysis Table has dialed string entries of 297-1 and 297-123, the match is on the 297-123 entry. In addition, an exact match is made on dialed string entries of the same number of digits in cases where wildcard characters are used. For example, if 424 is dialed and the table has dialed string entries of 424 and X24, the match is on the 424 entry.

An example of dialed string entries and associated Min and Max entries is provided in the following table. RNxs 200 through 299 can be assigned on the AAR Analysis Table in the following ways:

| Dialed String | Min. # of Digits | Max. # of Digits |
|---------------|------------------|------------------|
| 2             | 7                | 7                |
|               | or               |                  |
| 20            | 7                | 7                |
| 21            | 7                | 7                |
| 22            | 7                | 7                |
| ...           | ...              | ...              |
| 29            | 7                | 7                |

- **Min** — Enter the minimum number of digits needed to validate and route the call. Default is blank.
- **Max** — Enter the maximum number of digits to collect, between **Min** and **28**. Default is blank.
- **Rte Pat** (Route Pattern) — Enter the route pattern number or a pointer to an associated Remote Home Number Plan Area (RHNPA) form (**r1** to **r32**) to be used to route the call once all identifying digits have been received, **nod** to use node number routing, **n/a** to indicate that routing is not applicable to this PGN, **den** to block the call, or blank (default).
- **Call Type** (for AAR only) — Enter **aar** for regular AAR calls. Enter **intl**, or **pubu** if the administered route pattern contains preferences which are public network ISDN trunks requiring Type of Number (TON) encodings "international" or unknown respectively. Enter **lev0**, **lev1**, or **lev2** or leave blank (default) to specify Private Numbering Plan (PNP) number formats. See the ISDN Protocol Table below for the Numbering Plan Identifier (NPI) and Type of Numbering based on Call Type.

| Call Type | Numbering Plan Identifier | Type of Numbering   |
|-----------|---------------------------|---------------------|
| aar       | E.164(1)                  | national(2)         |
| intl      | E.164(1)                  | international(1)    |
| pubu      | E.164(1)                  | unknown(0)          |
| lev0      | PNP(9)                    | local(4)            |
| lev1      | PNP(9)                    | Regional Level 1(2) |
| lev2      | PNP(9)                    | Regional Level 2(1) |

- **Call Type** (for ARS only) — Valid call types are:

| Call Type | Description  | China # 1 Call Type |
|-----------|--|---------------------|
| alrt      | alerts attendant console for emergency   | normal              |
| emer      | emergency call   | normal              |
| fnpa      | 10-digit North American Numbering Plan (NANP) call (11 digits with Prefix Digit "1") | attendant           |
| hnpa      | 7-digit NANP call  | normal              |
| intl      | public-network international number  | toll-auto           |

| Call Type | Description                           | China # 1<br>Call Type |
|-----------|---------------------------------------|------------------------|
| iop       | international operator                | attendant              |
| loc1      | public-network local number           | normal                 |
| lpvt      | local private                         | normal                 |
| nat1      | non-NANP                              | normal                 |
| npvt      | national private                      | normal                 |
| nsvc      | national service                      | normal                 |
| op        | operator                              | attendant              |
| pubu      | public-network number (E.164)-unknown | normal                 |
| svcl      | national(2)                           | toll-auto              |
| svct      | national(2)                           | normal                 |

- **Node Number** — The number of the destination node if node number routing or DCS are used.
- **ANI Rq** — Enter **y** if ANI is required on incoming R2-MFC or Russian MF ANI calls. Default is **n**. This field only applies if the `Request Incoming ANI (non-AAR/ARS)` field on the Multifrequency-Signaling-Related System Parameters form is **n**.

## AAR and ARS Digit Analysis Default Translations

[Table 8-1](#) lists the AAR and ARS Digit Analysis Default Translations.

[Table 8-2](#) lists the ARS Digit Analysis Default Translations.

Table 8-1. AAR Digit Analysis Default Translations

| Dialed String | Total Digits |      | Call Type |
|---------------|--------------|------|-----------|
|               | Min.         | Max. |           |
| 2             | 7            | 7    | aar       |
| 3             | 7            | 7    | aar       |
| 4             | 7            | 7    | aar       |
| 5             | 7            | 7    | aar       |
| 6             | 7            | 7    | aar       |
| 7             | 7            | 7    | aar       |
| 8             | 7            | 7    | aar       |
| 9             | 7            | 7    | aar       |

 **NOTE:**

Any dialed digit-string not accounted for on the table is considered invalid and the call is routed to intercept. These default translations are used for call processing regardless of whether or not AAR or ARS has been optioned for on the switch.

The translations shown in [Table 8-2](#) appear only once in the switch's memory but are displayed in sorted order (including additions) on each of the 8 possible ARS Digit Analysis Tables.

 **NOTE:**

For service outside of North America, these defaults should be deleted. You can delete the defaults by entering **change ARS analysis 0**. Then blank out all of the Dialed Strings with spaces.

Table 8-2. ARS Digit Analysis Default Translations

| Dialed String | Total Digits |      | Route Pattern | Call Type |
|---------------|--------------|------|---------------|-----------|
|               | Min.         | Max. |               |           |
| 0             | 1            | 1    | den           | op        |
| 0             | 8            | 8    | den           | op        |
| 0             | 11           | 11   | den           | op        |
| 00            | 2            | 2    | den           | op        |
| 01            | 9            | 17   | den           | iop       |
| 011           | 10           | 18   | den           | intl      |
| 10XXX0        | 6            | 6    | den           | op        |
| 10XXX0        | 16           | 16   | den           | op        |
| 10XXX01       | 14           | 22   | den           | iop       |
| 10XXX011      | 15           | 23   | den           | intl      |
| 1XXX555       | 11           | 11   | den           | fnpa      |
| 1XXX976       | 11           | 11   | den           | fnpa      |
| 1800555       | 11           | 11   | den           | fnpa      |
| 1809          | 11           | 11   | den           | fnpa      |
| 1900555       | 11           | 11   | den           | fnpa      |
| 411           | 3            | 3    | den           | svc       |
| 555           | 7            | 7    | den           | hnpa      |
| 611           | 3            | 3    | 1             | svc       |
| 811           | 3            | 3    | 1             | svc       |
| 911           | 3            | 3    | 1             | svc       |
| 976           | 7            | 7    | den           | hnpa      |
| N             | 7            | 7    | 2             | hnpa      |
| 1N00          | 11           | 11   | den           | fnpa      |

*Continued on next page*

Table 8-2. ARS Digit Analysis Default Translations  
— *Continued*

---

| Total Digits  |      |      |               |           |
|---------------|------|------|---------------|-----------|
| Dialed String | Min. | Max. | Route Pattern | Call Type |
| 1NX           | 11   | 11   | den           | fnpa      |

---

Legend:

- N - 2 through 9
  - X - any digit (0 - 9)
  - den - deny
  - fnpa - foreign number plan area (10-digit call)
  - hnpa - home number plan area (7-digit call)
  - intl - international
  - iop - international operator
  - op - operator
  - svc - service
-

## AAR and ARS Digit Conversion Table

This form converts private-network numbers to other private-network or to public-network ARS numbers. It is essential for converting home AAR numbers into extension numbers. Using this table, you can:

- Steer some AAR calls to other switches in the private network
- Change the dialed string to a public-network number and route the call via the ARS feature
- Block or intercept certain private-network calls to the attendant group
- Route unauthorized public-network calls to an attendant or give them intercept tone

The form allows for the replacement of all or part of a dialed string with a modified string and/or change of analysis type. The modified string represents an alternative equivalent address and results in call analysis according to the network type. This table is accessed during call-processing.

Digit conversion enhances the capabilities of the AAR and ARS features so that outgoing public-network calls and private-network calls can be changed to local, private, or public network destinations. The calls are then analyzed by the UDP, AAR, or ARS features and routed according to the associated route patterns.

### Administration commands

Use the following commands to administer the AAR and ARS Digit Conversion Table form.

| Action  | Object                                       | Qualifier <sup>1</sup>   |
|---------|--|--|
| change  | aar digit-conversion<br>ars digit-conversion | Enter digits between 0 to 9 'x' or 'X'                                       |
| display | aar digit-conversion<br>ars digit-conversion | Enter digits between 0 to 9 'x' or 'X'<br>['print' or 'schedule']            |
| list    | aar digit-conversion<br>ars digit-conversion | Enter ['start' matching pattern]['count'<br>(1-MAX)] ['print' or 'schedule'] |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

**Form Instructions**

Screen 8-4. ARS Digit Conversion Table Form

 **NOTE:**

When the form is accessed via a **display** or **change** command, the entries are sorted separately in the order of the matching pattern. Specific digits are sorted before the characters “\*,” “X,” or “X.”

- **Percent Full** — 3-character display-only field. Displays the percentage of the used system’s memory resources. A common pool of memory resources is shared between the ARS and AAR Digit Conversion tables.

If this field indicates that the system memory resources are in jeopardy of becoming full (100%), perform any of the following to free-up memory resources:

- Delete unnecessary entries from any of the shared resources tables
- Use RHNPA Tables for 6-digit screening
- Reduce `Dialed String` entries to shortest possible length that accomplishes the desired function

- **Matching Pattern** — Enter a 1–18-digit string to be matched against a dialed number. Matching Pattern entries must be unique within the table. The string may contain the digits 0–9 or a \* and wildcard characters “x” or “X.” These are used to match any digit in the range of 0–9 or \*. If a Prefix Digit is required for 10-digit DDD numbers, then the Prefix Digit “1” must be present in the Matching Pattern string for the match to succeed.

If the associated `Replacement String` has an entry, `Matching Pattern` must also have an entry.

- **Min** — The minimum number of digits in the dialed string
- **Max** — Enter the maximum number of digits to collect, between `Min` and **28**.
- **Del** — The number of digits to delete from the beginning of the dialed string
- **Replacement String** — Enter a 0–18-digit dialed string that replaces the deleted portion of the dialed number. The dialed string may contain the digits 0–9 or \*, a “#” character, or be blank. The “#” character, when used, must be at the end of the digit-string and is used to indicate end-of-dialing.

 **NOTE:**

A blank `Replacement String` has the effect of just deleting the leading digits from the dialed string. Because the “#” character in the `Replacement String` indicates the end-of-dialing, any digits dialed after the inserted portion of the string are ignored. Deletion of digits and blank replacements are used to crossover from ARS to AAR.

8 Automatic Routing Forms  
AAR and ARS Digit Conversion Table

Page 8-66

- **Net** — The network in which to analyze the resulting number. Enter **ext**, **aar**, or **ars**. The resulting digit-string is then analyzed as an extension number, an AAR address, or an ARS address respectively.
- **Conv** — Enter **y** or **n**. To allow further conversion enter **y**.
- **ANI Req** — Enter **y** if ANI is required on incoming R2-MFC or Russian MF ANI calls. Default is **n**. This field only applies if the `Request Incoming ANI (non-AAR/ARS)` field on the Multifrequency-Signaling-Related System Parameters form is **n**.

## Route Pattern form

---

The digit translations performed by the AAR and ARS Digit Analysis and RHNPA Tables cause a specific route pattern to be selected for routing the call. The route pattern contains a sequence of trunk groups on which an attempt is made to route the call.

The Route Pattern form implements one route pattern. Each route pattern can contain alternate trunk groups. The maximum number of route patterns and alternate trunk groups allowed depends on the configuration and memory available in your system.

The route patterns specified on the Route Pattern form are used by the following features: AAR, ARS, GRS, and Call-by-Call Service Selection.

Before a call is routed, DEFINITY ECS checks the Facility Restriction Level (FRL) compatibility to ensure:

- Calling party's FRL is greater than or equal to the routing preference's FRL
- Calling party's BCC matches the BCC specified for the routing preference (ISDN calls only)
- Facility type is okay for the call type
- There is an unused circuit (trunk port) available in the selected trunk group

When all checks are complete and compatibility is ensured, digits are outpulsed over the selected trunk group member.

## Administration commands

---

Use the following commands to administer the Route Pattern form

| Action  | Object        | Qualifier <sup>1</sup>  |
|---------|---------------|---|
| change  | route-pattern | 1-MAX   |
| display | route-pattern | 1-MAX [print]   |
| list    | route-pattern | Enter ['trunk' (1-MAX)] ['service'/feature name string] ['print' or 'schedule'] |

---

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

**Form Instructions**

```

Screen 8-5. Route Pattern form (Page 1 of X)

Make assignments as required for the following fields on the form:

- **Pattern Number** — This is a display-only field when the form is accessed using an administration command such as **change** or **display**.
- **Grp No.** — Enter the desired trunk-group number to specify which trunk-group will be associated with the entries on this line of the form.
- **FRL** — Enter the FRL **0–7** to be assigned this routing preference (this line of parameters on the form). 0 is the least restrictive and 7 is the most restrictive. Trunk-group FRLs are changeable from pattern to pattern. The calling party's FRL must be greater than or equal to this FRL to access the associated trunk-group.

Valid entries are 0 to 7.

 **NOTE:**

For system security reasons, Lucent recommends using the most restrictive FRL possible.

- **NPA** — This entry is not required for AAR. For ARS, enter the NPA of the distant-end (terminating endpoint). For WATS trunks, the NPA is the same as the home NPA unless the LEC wants 10 digits for local NPA calls. For tie trunks, the NPA field is left blank. Valid entries are 3-digits in the form: first digit (**2–9**), second digit (**0–9**), third digit (**0–9**). Default is blank.
- **Prefix Mark** — Not required for AAR. For ARS, enter a number from **0–4** or blank (default) as indicated below. This specifies whether the prefix digit 1 is outpulsed.

For a WAT -trunk, the Prefix Mark is the same as the local CO trunk. Prefix Mark operations only apply to FNPA or HNPA call types (ARS). For tie trunks, leave field this blank.

- 0 Indicates that the Prefix digit 1 is never outpulsed for 10-digit user-dialed FNPA calls, but leaves a user-dialed Prefix digit 1 for 7-digit HNPA calls. Prefix Mark 0 also leaves 1s on 10-digit calls that are not administered as FNPA- or HNPA-types.

 NOTE:

FNPA and HNPA are North American Numbering Plan terms.

- 1 Indicates that the Prefix digit 1 is outpulsed if and only if the call is a 10-digit call. Select Prefix Mark 1 for those HNPAs that require users to dial 1 to indicate a toll-call.
- 2 Indicates that the Prefix digit 1 is outpulsed for all toll calls, 7- and 10-digit. Prefix Mark 2 must refer to a Toll Table. See *Toll List* definition.
- 3 Indicates that the Prefix digit 1 is outpulsed for all toll-calls. These calls are always outpulsed as 10-digit numbers, even if they are within the HNPA. Prefix Mark 3 must refer to a Toll Table. See *Toll List* definition.
- 4 Indicates that the user-dialed Prefix digit 1 is always suppressed.

 NOTE:

This capability is required, for example, when routing ISDN calls to an Lucent Technologies 4ESS. If the prefix digit 1 were not suppressed, then the 4ESS would reject such calls.

- **Hop Lmt** — Controls the number of hops for each preference. A blank in this field indicates that there is no limit to the number of hops for this preference. Enter a number from **1–9** to limit the number of hops if using the tandem hop feature. Enter a number from **1–32** if using the transit feature. DEFINITY ECS blocks a hop equal to or greater than the number you enter.
- **Toll List** — Not required for AAR. For ARS, enter a number that references the ARS Toll Table associated with the terminating NPA of the trunk group. This field must be completed if *Prefix Mark* is **2** or **3**. Default is blank.
- **No. Del. Digits** — Enter the total number of digits to be deleted from the dialed string when selecting this trunk-group for call-routing. Default is blank.

Any nonblank entry in this field (including 0) causes any user-dialed IXC code to be deleted in addition to the number of digits specified.

**NOTE:**

Use 0 (zero) in this field to suppress user-dialed IXC codes. This capability is useful when the call is routed via ISDN trunks to a 4ESS office. The 4ESS will reject a call if the IXC code is sent along with the address digits.

- **Inserted Digits** — Enter the actual digits to be inserted. Up to 52 digits may be outpulsed. This includes 36 digits which you enter here plus up to 18-digits originally dialed. When they are used, special symbols count as two digits each. The special characters used in route patterns are described below.

| Special Character | Description  |
|-------------------|--|
| *                 | digit * (See note below <sup>1</sup> .)  |
| #                 | digit # (See note below <sup>1</sup> .)  |
| ,                 | 1.5 second pause   |
| +                 | Wait for dial tone up to the Off Premises Tone Detection Timer and then either outpulse or intercept tone based on <i>Out Pulse Without Tone y/n</i> (Feature-Related System Parameters form). Outpulsed DTMF digits are sent at the rate specified by the End-to-End Signaling Tone and Pause parameters (Trunk Group Administrable Timers form). |
| %                 | Start End-to-End Signaling. Send digits as DTMF inband tones at the rate specified by the End-to-End Signaling tone and Pause parameters (Trunk Group Administrable Timers form).  |
| !                 | Wait for dial tone without timeout and then outpulse DTMF digits at the rate specified by the End-to-End Signaling Tone and Pause parameters (Trunk Group Administrable Timers form).  |
| &                 | Wait for ANI (used for Russian pulse trunks to indicate where to wait for ANI prompt and send in-band ANI)   |

1. If the outgoing trunk is signaling type "mf," the signal administered as the "end-of-digit" in the Outgoing Group column of the System-Parameters Multifrequency-Signaling form is inserted, and not the "\*" or the "#."

**NOTE:**

Do not use a comma "," (1.5 second pause) as the first character in the string unless absolutely necessary. Misuse of the character can result in calls, such as Abbreviated Dialing or Last Number Dialed, not completing to the far end.

When an asterisk "\*" is translated in the route pattern and the signal "end-of-dial" is translated on the Multifrequency-Signaling form, the MFC tone for the "end-of-digits" is sent out to the CO in place of the asterisk "\*."

- **IXC** — Displays when ISDN-PRI or ISDN-BRI Trunks are enabled on the System-Parameters Customer-Options form. For ISDN Preference trunks, enter the last two-to-four digits to represent an equal access inter-exchange carrier (IXC) code number (such as 10XX or 10XXX).

 **NOTE:**

This length should match the format established on the IXC Codes form.

This field is used by all calls that route via an IXC, and is used also for Call Detail Recording (CDR). If an IXC is not specified, a call is transmitted by the presubscribed common carrier.

 **NOTE:**

The IXC field must be **none** for non-ISDN trunk groups and for Bellcore NI-2 Operator Service Access. If you need to send an IXC code for a non-ISDN trunk group, then enter this IXC value in *Inserted Digits*.

- **BCC Value** (required by GRS feature) — Displays when ISDN-PRI or ISDN-BRI Trunks are enabled on the System-Parameters Customer-Options form. Enter **y** (default) or **n** in the appropriate BCC column (0, 1, 2, 3, 4, or W) to specify whether the BCC is valid for the associated route. The following defines the BCC values:

| BCC Value | Description                      |
|-----------|----------------------------------|
| 0         | Voice-Grade Data and Voice       |
| 1         | 56-kbps Data (Mode 1)            |
| 2         | 64-kbps Data (Mode 2)            |
| 3         | 64-kbps Data (Mode 3)            |
| 4         | 64-kbps Data (Mode 0)            |
| W         | 128 to 1984-kbps Data (Wideband) |

- **TSC** — Enter **y** to allow incoming Non-Call-Associated TSC requests to be tandemed out and to allow the establishment of Call-Associated TSCs associated with B-channel connections of that preference. To achieve feature transparency, DCS+ calls should be routed via a route pattern that has an ISDN-PRI Used for DCS trunk-group as a first preference.

- **CA-TSC Request** — Appears when **TSC** is **y**. A CA-TSC uses the call reference value of the call control data packets to exchange user-information messages associated with an ISDN B-channel connection. CA-TSCs are a finite system and trunk group resource. There is a trade-off between the two possible entries — a small time-lag with the first and usage generated by the second. Valid entries are:

|           |  |
|-----------|--|
| as-needed | (Recommended for most situations.) CA-TSC is not established along with the B-channel call. If a CA-TSC is needed due to feature activation somewhere in the lifetime of this B-channel call, then the CA-TSC is established at that time and remains active for the duration of the call. |
| at-setup  | Causes a CA-TSC to be established at the same time as the initial B-channel connection is established. In other words, a CA-TSC is set up for each and every B-channel call <b>whether CA-TSC is ever needed</b> .   |
| none      | Disallows the establishment of CA-TSCs associated with B-channel connections of the current preference (tandeming of NCA-TSC setup requests, however, are still permitted).  |

 **NOTE:**

With **as-needed**, the need to establish the CA-TSC causes a slight delay in the invocation of the Call-Associated feature. This delay is not present with **at-setup** because the CA-TSC is established already at call-setup and is ready to be used immediately upon feature invocation.

- **ITC** (Information Transfer Capability) — Used to administer the type of traffic (restricted, unrestricted, or both) that is allowed to be carried by this routing preference. If entering **rest** (restricted), then only calls originating from restricted endpoints may access this route pattern. If entering **unre** (unrestricted), then only calls originating from unrestricted endpoints may access this route pattern. If entering **both**, then calls originating from both restricted and unrestricted endpoints may access the route pattern.

This field must be **unre** or **both** if **BCC W** is **y**.

- **BCIE** (Bearer Capability Information Element) — Used to determine how to create the ITC codepoint in the BCIE of the setup message. This field only applies to ISDN trunks and is displayed and administrable only if **ITC** is **both**. Valid entries are **ept** (endpoint) and **unr** (unrestricted). Default is **ept**.

- **Service/Feature** (required by the Call-by-Call Service Selection feature) — Displays when ISDN-PRI or ISDN-BRI Trunks is enabled on the System-Parameters Customer-Options form. Enter up to 15 characters that represent the Service/Feature carried by a call in this route pattern. Default is blank. Valid entries are:
  - accunet
  - i800
  - inwats
  - lds
  - mega800
  - megacom
  - multiquest
  - operator
  - outwats-bnd
  - sdn
  - sub-operator
  - wats-max-bnd
- **Band** (required by the Call-by-Call Service Selection feature) — Displays when ISDN-PRI or ISDN-BRI Trunks is enabled on the System-Parameters Customer-Options form. Enter a number that represents the OUTWATS band number. This field displays when Services/Features is **outwats-bnd**. The default is blank.
- **Numbering Format** — Displays when ISDN-PRI or ISDN-BRI Trunks is enabled on the System-Parameters Customer-Options form. This field specifies the format of the routing-number used for the trunk group administered for the preference. You can leave the field blank (default) or you can enter one of the following values from [Table 8-3](#) if the trunk group specified for preference is ISDN:

**Table 8-3. Numbering Format Values**

| Route Pattern Format | Numbering Plan Identifier | Type of Numbering   |
|----------------------|---------------------------|---------------------|
| blank                | E.164(1)                  | 1-MAX               |
| natl-pub             | E.164(1)                  | national(2)         |
| intl-pub             | E.164(1)                  | international(1)    |
| locl-pub             | E.164(1)                  | local/subscriber(4) |

*Continued on next page*

Table 8-3. Numbering Format Values — *Continued*

| Route Pattern Format | Numbering Plan Identifier       | Type of Numbering   |
|----------------------|---------------------------------|---------------------|
| pub-unk              | E.164(1)                        | unknown(0)          |

| lev1-pvt             | Private Numbering Plan - PNP(9) | Regional Level 1(2) |
| lev2-pvt             | Private Numbering Plan - PNP(9) | Regional Level 2(1) |
| unk-unk              | unknown(0)                      | unknown(0)          |

**NOTE:**

To access Bellcore NI-2 Operator Service Access, Inserted Digits must be **unk-unk**.

- **LAR** — Enter the routing-preference for Look Ahead Routing. The choices are described below.

| LAR Value | DEFINITY ECS Actions   |
|-----------|--|
| next      | Go to the next routing-preference and attempt the call again                             |
| rehu      | Rehunt within the current routing-preference for another trunk to attempt the call again |
| none      | Look Ahead Routing is not enabled for the preference                                     |

**Implementation Notes**

The number of pages displayed depends upon the amount of system memory. Also, many of the fields only display under certain conditions. See field definitions for those conditions.

## ARS Toll Table

This form assigns ARS Toll Tables used by Subnet Trunking. Use it to specify whether calls to CO codes listed on the table are toll or non-toll calls. You specify non-toll calls based on the last 2 digits of the distant-end of the trunk group.

### Administration commands

Use the following commands to administer the ARS Toll Table form.

| Action  | Object   | Qualifier <sup>1</sup>                                    |
|---------|----------|---|
| change  | ars toll | n:xxx (1-MAX:office code) n:xyy: n(1-MAX); ':' ;x(2-MAX); |
| display | ars toll | n:xxx (1-MAX:office code) ['print' or 'schedule']         |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

### Form Instructions

ARS TOLL TABLE: \_\_\_ Page 1 of 1

OFFICE CODES: x00-x99

|       |       |       |       |       |       |       |       |       |       |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 00: y | 10: y | 20: y | 30: y | 40: y | 50: y | 60: y | 70: y | 80: y | 90: y |
| 01: y | 11: y | 21: y | 31: y | 41: y | 51: y | 61: y | 71: y | 81: y | 91: y |
| 02: y | 12: y | 22: y | 32: y | 42: y | 52: y | 62: y | 72: y | 82: y | 92: y |

| 07: y | 17: y | 27: y | 37: y | 47: y | 57: y | 67: y | 77: y | 87: y | 97: y |
| 08: y | 18: y | 28: y | 38: y | 48: y | 58: y | 68: y | 78: y | 88: y | 98: y |
| 09: y | 19: y | 29: y | 39: y | 49: y | 59: y | 69: y | 79: y | 89: y | 99: y |

### Screen 8-6. ARS Toll Table

- **ARS TOLL TABLE** — Enter the ARS Toll Table number. Up to 8 forms may be required for each table, one for each 100-block, 2 to 9.
- **OFFICE CODES** — Enter a 100-block — 200–299 through 900–999. A separate form is required for each 100-block.
- **00:** through **99:** — Enter **n** beside each CO code to be designated as non-toll. These fields represent the last 2 digits of the codes within the 100-block. If no changes are made, the codes are implemented as toll-type codes (default).

## RHNPA Table

---

The Remote Home Numbering Plan Area (RHNPA) Table assigns additional 3-digit screenings (for instance, on the prefix or nxx numbers) and associated route pattern numbers for up to 32 RHNPA Tables (r1–r32). One form is required for each 100-block of codes in the range 000–999. RHNPA Tables can be used with any call-type and a choice of up to 12 route patterns is provided for each 100-block of codes.

RHNPA Tables typically are used for the DDD prefixes.

The ARS Digit Analysis Table performs translations on the first 3 digits of the dialed string. The RHNPA Table performs translations on the next 3-digit dialed string.

### Example

The `Rte Pat` fields on the ARS Digit Analysis Table are set to r1, r10 and r32. These point to the respective RHNPA Tables 1, 10, or 32. Therefore, the next 3 digits dialed represent a CO code in the FNPA. These digits are translated by the RHNPA Table and routed via the assigned route pattern to the CO.

The RHNPA Table can also be used for AAR analysis.

## Administration commands

---

Use the following commands to administer the RHNPA Table form.

| Action  | Object | Qualifier <sup>1</sup>  |
|---------|--------|---|
| change  | rhnpa  | Enter RHNPA and office code n:xyy n(1-MAX) x(0-MAX) y(0-MAX) y(0-MAX)                       |
| display | rhnpa  | Enter RHNPA and office code n:xyy n(1-MAX) x(0-MAX) y(0-MAX) y(0-9) ['print' or 'schedule'] |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

**Form Instructions**

Screen 8-7. RHNPA Table (Page 1 of 1)

- **RHNPA TABLE** — Enter the applicable table number from 1–32. Up to 8 forms may be required for each table, one for each 100-block, 2 to 9.
- **CODE** — Enter the desired 100-block; that is, 000 through 099, 100 through 199, 200 through 299,...800 through 899, 900 through 999. A separate form is required for each 100-block.
- **Pattern Choices** — Enter a pattern number representing the route patterns that can be accessed by the RHNPA's identified on this form. Each form on each RHNPA Table may have 12 different route patterns (Pattern Choices). A Pattern choice listed on one form automatically defaults to the other forms of the same RHNPA Table. If one pattern is used most often (that is, accessed by the greatest number of CO codes in this block), assign that as Pattern Choice 1. Otherwise, the correlation between Pattern Choice Numbers and route patterns is completely arbitrary.
- **Code-Pattern Choice Assignments (from 1-12 above)** — Enter a Pattern Choice number from the list above in the field associated with each CO Code. The Code fields represent the last 2-digits of the codes within the 100-block. This field points to the Pattern Choice above, which contains the route pattern to be used.

## Time of Day Routing Plan

---

Use this form to assign Time of Day Routing Plans. Using this form, you can route AAR and ARS calls based on the time of day each call is made. Up to 8 Time of Day Routing Plans can be administered, each scheduled to change up to 6 times a day, for each day in the week.

The calling party's FRL must be greater than or equal to the FRL assigned in the route pattern. The route pattern is selected by matching on the Time of Day Routing Plan the PGN# with the Partitioned Group Number field on the AAR or ARS Digit Analysis Table. Then, the AAR or ARS Digit Analysis Table selects the route pattern.

### NOTE:

The following optional features must be enabled on the System-Parameters Customer-Options form before this form can be administered: Automatic Route Selection (ARS) or Private Networking, AAR/ARS Partitioning, and Time of Day Routing.

## Administration commands

---

Use the following commands to administer the Time of Day Routing Plan form.

| Action  | Object      | Qualifier <sup>1</sup>                      |
|---------|-------------|---|
| display | time-of-day | ['print' or 'schedule']                     |
| display | time-of-day | 1-MAX (plan number) ['print' or 'schedule'] |
| change  | time-of-day | [time of day routing plan (1-MAX)]          |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

**Form Instructions**

| TIME OF DAY ROUTING PLAN x |       |      |         |      |         |      |         |      |         |      |         | Page 1 of 1 |         |

Screen 8-8. Time Of Day Routing Form (Page 1 of 1)

- **Time of Day Routing Plan** — Specifies the TOD routing plan number. Up to 8 of these plans can be administered. This is a display-only field when the form is accessed using an administration command such as **add** or **change**.
- **Act Time** — Specifies the time of day the route pattern (identified by PGN #) is effective. The time is represented in military time (24:00 hours per day). List times for the same day in increasing order. Valid entries are **00:00–23:59**; default is **00:00**. There must be at least one entry for each day.
- **PGN #** — Enter a PGN that points to the appropriate AAR or ARS Digit Analysis Tables. The AAR or ARS Digit Analysis Tables should have the same PGN #. This is how you point to the route pattern that should be active for the activation time. There must be at least one entry for each day.

The AAR or ARS Digit Analysis Table selected and the route pattern used is based on the dialed string. Default is 1.

**NOTE:**

It is possible to point to an AAR or ARS Digit Analysis Table associated with a PGN that has a different FRL than the FRL assigned to the caller's facility. Proceed with caution when making these assignments.

Before a call is routed, DEFINITY ECS checks to see that the Calling party's FRL is greater than or equal to the routing preference's FRL.

## Call Center

# 9

---

This section contains the following DEFINITY ECS Call Center features. Call Center forms are located at the end of this chapter.

## Abandoned Call Search

---

Abandoned Call Search allows the switch to identify abandoned calls if the central office (CO) does not provide timely disconnect supervision. An abandoned call is one in which the calling party hangs up before the call is answered. Note that Abandoned Call Search is suitable only for older COs that do not provide timely disconnect supervision. Most COs provide timely disconnect supervision and do not require Abandoned Call Search.

Before an incoming Automatic Call Distribution (ACD) split rings a hunt group member or agent, the system checks to make sure that the calling party has not abandoned the call. If the calling party has abandoned the call, the call does not ring the hunt group member or agent.

If a call has been abandoned, the system determines if the calling party is still connected to the ground-start trunk at the CO. To do this, the system flashes (that is, opens the tip-ring loop for 150 to 200 ms) the CO end of the trunk. If the calling party is still connected, the CO does not respond. If the calling party has abandoned the call, the CO sends the system a disconnect signal within 800 ms. The system interprets this as an abandoned call, releases the trunk, and the call does not ring the hunt group member or agent.

Outside of the U.S., a flash of this duration may be handled differently. See [“Trunk Flash” on page 4-603](#) for more information.

### How to administer Abandoned Call Search

---

#### Required forms

---

| Form        | Field                   | Page                  |
|-------------|-------------------------|-----------------------|
| Trunk Group | ■ Abandoned Call Search | <a href="#">7-115</a> |
| — CO        |                         | <a href="#">7-168</a> |
| FX          |                         | <a href="#">7-193</a> |
| WATS        |                         | <a href="#">7-268</a> |

You administer Abandoned Call Search on a per-trunk-group basis. Administer each ground-start CO, FX, and WATS trunk group either having Abandoned Call Search or not having it. Abandoned Call Search is not supported for tie trunks.

## Considerations

---

### NOTE:

Abandoned Call Search works with ground-start analog trunks that *do not* provide disconnect supervision and that *do* react to a 500-ms break.

Some older COs can take as long as two minutes to notify the switch of a disconnect. Thus, the switch must determine within one second whether the call has been abandoned, before extending the call. Even with Abandoned Call Search or disconnect supervision, there is a small probability that a call will be extended to the destination hunt group after the caller has hung up. Abandoned Call Search and disconnect supervision significantly reduce that probability.

Abandoned Call Search allows agents and hunt group members to answer more calls because time is not wasted on abandoned calls. In addition, call-handling statistics that the Call Management System (CMS) generates are more accurate because it is clear when a call is abandoned.

However, be aware that Abandoned Call Search adds an overhead of up to one second to each call delivered to an agent.

## Interactions

---

None.

## Add/Remove Skills

---

Add/Remove Skills allows an agent using Expert Agent Selection (EAS) to add or remove skills. A skill is a numeric identifier in the switch that refers to an agent's specific ability. For example, an agent who is able to speak English and Spanish could be assigned a Spanish-speaking skill with an identifier of 20. The agent then adds skill 20 to his or her set of working skills. If a customer needs a Spanish-speaking agent, the system routes the call to an agent with that skill.

Each agent can have up to 20 skills active at any one time. Agents can dial feature access codes (FACs) to add or remove a skill. Or a supervisor with console permission can enter an agent's login ID and add or remove an agent's skill. If a supervisor adds or removes a skill for an agent, the agent receives a change notification.

To determine if they need to add or remove a skill, agents and supervisors can use queue-status indications, VuStats, or Call Management System (CMS) or Basic Call Management System (BCMS) information. When adding a skill, the agent must specify the skill priority level (1 — 16).

On voice terminals with displays, the system prompts the agent through the process of adding or removing a skill and displays the updated set of skills.

### How to administer Add/Remove Skills

---

#### Required forms

| Form                       | Field  | Page                  |
|----------------------------|--|-----------------------|
| Class of Restriction (COR) | ■ Add/Remove Agent Skills                        | <a href="#">5-72</a>  |

### Considerations

---

- A skill cannot be removed from an agent's skill set if the agent is on a call for that skill or in the After-Call-Work (ACW) state for that skill.
- With EAS, agents cannot remove their Direct Agent Skill.

## Interactions

---

- Auto-Available Splits (AAS)

If an agent adds a skill that is administered as Auto-Available, on the Agent Login ID form, you must set the AAS field to **y** for that agent's login ID.

- BCMS

BCMS begins tracking a new skill as soon as it is added. When an agent removes a skill, the real-time agent information specific to that skill is removed from the real-time reports, but it still appears on the historical reports.

- EAS-PHD

When EAS-PHD is set as an option, agents cannot remove their Direct Agent Skill. In an EAS environment, agents must have at least one skill assigned to them during a login session. With EAS-PHD, agents can specify up to 20 skills.

If EAS-PHD is not enabled, agents can specify only 4 skills.

- VuStats

Because VuStats displays information gathered by BCMS whether BCMS is enabled or not, the BCMS interaction above applies to VuStats.

## Agent Call Handling

---

Agent Call Handling allows you to administer functions that Automatic Call Distribution (ACD) agents use to answer and process ACD calls.

You define the following agent capabilities:

- Agent login and logout
- Agent answering options: Automatic Answer (zip tone) or Manual Answer
- ACD work modes: Auxiliary Work (AUX Work), Auto-In, Manual-In, or After Call Work (ACW)
- Timed ACW
- Agent request for supervisor assistance
- ACD call disconnect (Release button)
- Stroke counts
- Call work codes
- Forced entry of stroke counts and call work codes

[“Agent capacity and related limits” on page 9-15](#) describes agent-capacity planning.

### NOTE:

All of these agent capabilities are also supported through the CallVisor Adjunct/Switch Applications Interface (ASAI). For information, see [“CallVisor Adjunct-Switch Application Interface” on page 4-250](#).

## How to administer Agent Call Handling

## Detailed description

---

This section describes agents capabilities. For details on procedures that agents follow when using these capabilities, see *DEFINITY Enterprise Communications Server Generic 1, Generic 3, and System 75 Automatic Call Distribution (ACD) Agent Instructions*.

### NOTE:

This information applies generally to ACD; see [“Expert Agent Selection” on page 9-72](#) for additional EAS procedures.

## Agent login and logout

To receive ACD calls, an agent must log into the system. An agent can be logged into multiple splits. If a hunt group is measured by Call Management System (CMS) or Basic Call Management System (BCMS) or is a skill, an agent must enter a login ID; otherwise, the login ID is optional.

### Login

To log in, an agent goes off-hook and dials the login feature access code (FAC), followed by the split number and the log-in ID, if required. If login is successful, the agent automatically enters Auxiliary Work mode for that split. The Auxiliary Work button lamp for that split, lights steadily and the agent hears the confirmation tone.

If the split is measured, the system sends messages to CMS or BCMS that the agent (identified by login ID) has logged in and has entered Auxiliary Work mode.

Login is canceled and the agent receives intercept tone if any of the following occur during login:

- The agent dials an invalid login FAC or split number (that is, the number of a split that does not exist or to which the agent is not assigned).
- The agent is already logged into the maximum number of splits.
- The agent dials a split number for a split that he or she is already logged into.

### Logout

The agent should log out when he or she leaves for an extended period of time and is unavailable for ACD calls. If the split is measured by CMS or BCMS and an agent logs out, a message is sent to the CMS or BCMS so that the agent's status is no longer measured. If an agent is logged into multiple splits, he or she should log out of each split.

When temporarily unavailable for calls, an agent should use Auxiliary work mode, rather than logging out. CMS or BCMS can continue tracking the agent's auxiliary work time.

To log out of a split, an agent goes off-hook and dials the logout FAC followed by the split number. If logout is successful, the agent hears confirmation tone and work-mode button lamps darken. The logout is canceled and the agent receives an intercept if any of the following occur during logout:

- The agent dials an invalid logout FAC or split number.
- The agent dials a split number for a split that he or she is not logged into.

If an agent is using a handset in Automatic Answer mode, the agent can log out simply by hanging up or turning off the headset. (This does not mean pressing the release button on a CALLMASTER voice terminal.) This does not apply to quick-disconnect. If the agent pulls the handset to log out, the agent is automatically logged out of all splits that he or she has logged into.

## Agent answering options

An agent can answer ACD calls by using either a headset, handset, or speakerphone. You can assign an agent as either Automatic Answer or Manual Answer.

### NOTE:

Use Automatic Answer with a headset. See [“Considerations” on page 9-17](#) for more information.

## Automatic Answer

The information in this section applies to ACD and EAS environments.

An agent assigned to Automatic Answer hears zip tone and connects directly to incoming calls without ringing.

### NOTE:

You can administer Automatic Answer to apply only to ACD calls or to apply to all calls terminating to the agent's set. If all calls are Automatic Answer and the agent receives direct-extension calls, he or she should always activate Call Forwarding, or Send All Calls when leaving temporarily or for an extended period, so that calls do not terminate to an unstaffed station.

## Manual Answer

An agent assigned to Manual Answer hears ringing, and then goes off-hook to answer the incoming call.

## ACD work modes

At any given time, an agent can be in one of four work modes:

- Auxiliary Work (AUX)
- Auto-In
- Manual-In

- After Call Work (ACW)

An agent can change work modes at any time.

To enter any work mode, an agent presses the button or dials the FAC for that mode, depending on what you have administered. If the agent has no active or held calls, the work-mode button lamp lights steadily and CMS or BCMS is informed of the agent's mode change. If the agent has active or held calls, the lamp flashes until all calls are dropped, then the new work mode's lamp lights steadily and CMS or BCMS is informed of the agent's mode change.

The attempt is canceled and the agent receives an intercept if the agent:

- Tries to enter a work mode for an invalid split
- Tries to enter the work mode for a split of which he or she is not a member
- Dials an invalid FAC

### Auxiliary work mode

An agent should enter Auxiliary Work mode for a split whenever taking a temporary break. This makes the agent unavailable for ACD calls to that split and removes them from the most-idle-agent queue. CMS and BCMS can continue to track the agent.

The agent is no longer available to answer other ACD calls to that split. However, the agent may be available for ACD calls to other splits that the agent is logged into, depending on the agent's state in those splits. The agent is still available for non-ACD calls. CMS or BCMS are notified whenever an agent in Auxiliary Work mode receives an incoming non-ACD call or makes an outgoing call. When an agent logs into a split, he or she automatically enters Auxiliary Work mode for that split.

#### NOTE:

Agents in vector-controlled splits can go into Auxiliary Work mode even if they are the last agent and calls are queued to that split.

### Auto-In mode

In Auto-In mode, the agent automatically becomes available for answering new ACD calls upon disconnecting from an ACD call.

### Manual-In mode

In Manual-In mode, the agent automatically enters ACW mode for that split upon disconnecting from an ACD call and is not available for any ACD calls. To become available for ACD calls, the agent must manually reenter either Auto-In mode or Manual-In mode.

## After Call Work mode

An agent should enter ACW mode when he or she needs to perform ACD-related activities, such as filling out a form as a result of an ACD call. The agent is unavailable for ACD calls to all splits while in ACW mode. Switch administration determines whether the agent remains in the Most Idle Agent queue while in ACW.

When an agent is in the Manual-In mode and disconnects from an ACD call, he or she automatically enters ACW mode. Although no longer available for ACD calls, the agent is still available for non-ACD calls. CMS or BCMS is notified whenever an agent in ACW mode receives an incoming non-ACD call or makes an outgoing call.

## Timed After Call Work

With Timed ACW administered, an Auto-In agent is immediately placed in ACW mode for a specific length of time after completing the currently-active ACD call. When the Timed ACW interval expires, the agent automatically returns to the Auto-In work mode. If the agent activates ACW while not on a call, the agent is placed in ACW (not timed) mode regardless of whether the agent is in Auto-In or Manual-In mode.

Use Timed ACW to allow agents to rest between incoming ACD calls, or to pace agents when they have to complete work from the previous call within an allotted time. In addition, if you have Home Agent, use Timed ACW to allow agents additional time to dial a FAC to place themselves in a different work mode after the current ACD call is completed.

## Timed ACW and VDN

You can administer Timed ACW for all calls to a split/skill and/or to a VDN. Any completed calls to the split/skill or to the VDN, including direct agent calls, are followed by a timed ACW when the answering agent is in Auto-In work mode. If a VDN call routes to a split/skill, the Timed ACW interval for the VDN overrides the Timed ACW interval for the hunt group. VDN override applies to VDN-Timed ACW.

## Cancelling Timed ACW

When an agent activates Auto-In or Manual-In mode during Timed ACW, the agent becomes available and timed ACW is cancelled. An agent can change to Manual-In mode before or during a call. The system cancels Timed ACW and applies ACW (not timed) mode when the call is released. The agent remains in ACW until he or she requests another mode. When the agent releases an ACD call, the ACW lamp (if provided) lights. At the end of the administered Timed ACW interval, the ACW lamp goes dark and the Auto-In lamp lights.

Timed ACW also is canceled when an agent presses the ACW button or dials the ACW FAC.

If an agent activates Auxiliary Work mode during Timed ACW, the agent is placed in that mode and Timed ACW is cancelled.

## Agent request for supervisor assistance

To request assistance from the split supervisor, an agent, with or without an active ACD call, presses the Assist button or puts the call on hold and dials the Assist FAC plus the split number. The agent must be logged into the split. Assist generates 3-burst ringing at the supervisor's station. If a split supervisor is not assigned, the agent receives intercept tone.

Attendants should press the Start button before pressing the Assist button. This allows them to later transfer the call. This rings like a priority call at the supervisor's set.

When the agent presses the Assist button, the following happens:

1. If the agent is active on an ACD call, the ACD call is automatically placed on hold and a call is placed to the split supervisor. If the agent is not active on an ACD call, a call is automatically placed to the supervisor.
2. CMS or BCMS is notified of the request and the supervisor's display shows that the call is a request for assistance. This rings like a priority call at the supervisor's set.
3. The caller hears silence or music on hold.
4. After the agent has talked to the supervisor, the agent can drop the assist call and return to the ACD call, set up a conference call with the supervisor and the calling party, or transfer the call to the supervisor.

When the agent puts the call on hold and dials the Assist FAC plus the split number, the system handles the request as if the agent pressed the Assist button, except that the Assist call does not follow the supervisor's coverage path.

## Stroke counts

Stroke counts allow you to record in CMS the number of times that a particular customer-related event occurs. For example, agents could press a button each time a customer requests information on a certain item.

Stroke counts are reported to CMS in real time. The system does not store stroke counts. Use stroke counts only when CMS is connected and you have defined ACD splits to be measured by CMS.

Stroke counts allow agents to record up to nine administrator-defined events on a per-call basis. You can assign 10 Stroke Count button types. Stroke Count 0 is reserved for tracking Audio Difficulty or poor transmission quality.

For troubleshooting purposes, CMS records the equipment location of the trunk that the agent was using when he or she pressed the Audio Difficulty button.

Make sure that agents are aware that pressing this does not improve audio transmission quality.

To enter a stroke count, an ACD agent presses a Stroke Count button while off-hook. The system validates that the agent is either active on an ACD call or in the ACW mode for an ACD split. If yes, the feature lamp lights steadily for two seconds to indicate activation and the stroke count is sent to CMS. If not, the feature lamp flutters and no message is sent.

## Call work codes

Call work codes are up to 16-digit sequences that ACD agents enter to record such customer-related information as account codes, social security numbers, or phone numbers. You define the codes for your site. Codes that agents enter are sent to CMS for storage for splits measured by CMS and only when the link to the CMS is up. Agents must have multiappearance voice terminals (for example, CALLMASTER) to enter call work codes.

To enter call work codes, the agent must be off-hook and either:

- On an ACD call
- In ACW mode after disconnecting from a call while in Manual-In mode
- In Timed ACW after disconnecting from a call while in Auto-In mode
- In Auto-In mode and pending for ACW mode

The sequence of event is as follows:

1. The agent select Call Work Code (CWC) button.
2. The CWC lamp lights steadily and a C: prompt appears on the agent's display. The agent must wait for the ready indication before entering the call work code or the caller hears the touch-tone digits being dialed.
3. Agent enters up to 16 digits on the dial pad. The agent can press \* to erase digits.
4. The agent presses # to send the code entry to CMS.
5. The Call Work Code lamp goes dark and the display returns to normal.
6. If the agent presses any feature button or hangs up during digit collection, the code entry is cancelled and data is sent to CMS. The CWC lamp goes dark and the display is cleared.

Call work codes may be used by as many as 100 agents simultaneously. If 100 agents are simultaneously using this function, and another agent attempts to enter a call work code, the agent receives a display message to try again later.

## Forced entry of stroke counts and call work codes

You can administer a split so that agents must enter a stroke count and/or a call work code before becoming available for another call using Manual-In mode.

 **NOTE:**

Multiappearance voice terminals or an attendant console are required for agents to enter stroke counts or call work codes.

To enter a stroke count and/or call work code, the agent must be on a call, or in ACW mode after releasing a call in Manual-In mode.

After releasing a call, the agent automatically enters ACW mode and cannot return to Manual-In mode until entering a stroke count or call work code. If the agent presses the Manual-In button or FAC before entering a stroke count or a call work code, the Manual-In lamp flutters or intercept tone is given.

Once the agent enters a stroke count or call work code and presses the Manual-In button or FAC, he or she returns to Manual-In mode and the Manual-In lamp lights.

Any of the agent's splits can have Forced Entry assigned. If the agent goes into Auxiliary Work mode in any split, the Forced Entry requirement for all other splits is removed.

## Expanded technical information

### Agent capacity and related limits

Agent Sizing adds an overriding capacity limit to the number of logged-in ACD agents. It can be used to limit the number of logged-in ACD agents to a number less than (or equal to) the maximum supported by the system configuration.

The logged-in ACD agents limit applies to ACD agents in traditional (or non-EAS) ACD splits or in Expert Agent Selection (EAS) skills. Auto-Available Split/Skill (AAS) agent ports are logged in and counted when they are first assigned, while the non-AAS agents are counted when they actually log in. Each logged-in agent is counted as a single agent independent of the number of splits or skills logged in to for the Logged-in ACD agents limit. AAS and non-AAS agents are counted towards this limit whether they are BCMS/CMS measured or not.

The agent sizing limit is administered by authorized Lucent Technologies personnel via the Logged-in ACD Agents option on the System-Parameters Customer-Options form. The maximum number of allowed logged-in ACD agents is set to correspond to the configuration you purchase.

For agent sizing, if you have agents working in shifts, you should purchase enough agent capacity to allow for a smooth shift change. If agents on a subsequent shift are logging in before agents in the previous shift have logged out, agents could be denied login because too many agents are currently logged in. Additionally, the non-ACD and/or non-agent (AAS/VRU) use of Hunt Group resources must be considered. Call Center managers need to be aware of their logged-in ACD agent and other related limits when adding agents to handle a

traffic peak or when planning a special campaign. Some of the resource utilization is displayed dynamically on the Display Capacities form.

Note that under certain configurations, the limit set in the Logged-In Agents field cannot be reached due to some other system limit being reached. In particular, note that the ECS R5r and later configurations with EAS only supports up to 500 agents logged in if each has the maximum 20 skills assigned due to the 10,000 Hunt Group member limit.

In addition to the logged-in ACD agents limit, the number of agents supported is dependent on the upper limits that the system platform supports. The following limits must also be considered.

- Maximum Hunt Group members
  - Non-ACD members include hunting groups with or without queues, Message Center Service groups, INTUITY/AUDIX groups and Remote AUDIX groups (see [“Hunt Group” on page 5-158](#)). Each line or port in a group is counted once when assigned.
  - ACD members (also called agent-split pairs or agent-skill pairs with EAS). For agents in multiple splits/skills, each combination (pair) is counted as a member (e.g., an EAS agent logged into 4 skills or a non-EAS agent assigned to 4 splits counts as 4 members). Non-EAS ACD members are counted when assigned (note that many more splits can be assigned to an agent than can be logged into but each agent-split pair is still counted towards the limit). EAS ACD members are counted when they log in.
- Hunt Group members per group — Count of non-ACD or ACD members within a group/split/skill. Counting is done as above for maximum Hunt Group members.
- Additional traditional ACD (non-EAS) agents limits:
  - Maximum logged-in agents system limit
  - Maximum splits an agent can log into
- Additional EAS limits:
  - ACD members (skill pairs) administered — Limits skill assignments to agents (each AAS port is counted as one skill pair)
  - Agent Login IDs Administered — Limits number of AAS ports and EAS agents that can be pre-assigned
  - Agent Login IDs Logged-In (staffed) system limit — Upper limit on the number of EAS agents (and AAS ports) that can be logged-in simultaneously
  - Skills per Agent — The maximum number of skills a particular agent can be assigned

- Call Management System (CMS) logged in ACD members (agent-split/skill pairs) limits assigned. Both a Lucent Technologies setup and customer-administered limit is assigned in CMS. These limits are related to the CMS memory/hardware configuration equipped and are passed over the link to the DEFINITY switch to reduce/set the externally measured logged-in ACD member component of the Hunt Group member limit to that supported by CMS.
- BCMS internally measured ACD agents system limit. Non-EAS ACD agents counted when assigned while EAS agents are counted when logged in.

When the maximum number of ACD agents are logged in or any of the other above limits are reached, an agent who attempts to log in hears reorder tone or is otherwise denied log in. Also with EAS, an agent logging in may not have all the assigned skills logged in if the ACD member limit is reached.

The administrator of a non-EAS system also can be blocked from adding agents to splits via the Hunt Group form or the administrator of an EAS system can be blocked from assigning additional Login IDs or skills to an agent via the Login ID form if the relevant system limits are reached.

## Considerations

---

Release button

Agents using Automatic Answer are logged out of all splits when they disconnect from an ACD call by hanging up. Therefore, agents should use the Release button, if provided. This button is in addition to the fixed Release button on the attendant console.

## Timed ACW

To prevent agents from canceling Timed ACW by pressing the Manual-In or ACW buttons, do not assign these buttons to the agents' voice terminals. Timed ACW cannot be assigned to AAS, adjunct-controlled, AUDIX, Remote AUDIX, or Message Center splits. In addition, VDN-Timed ACW does not apply to calls routed to a converse split by way of the *converse-on* vector command. Timed ACW assigned to a converse split hunt group applies.

BCMS and CentreVu CMS track Timed ACW as standard ACW work states. Time spent in Timed ACW is not specifically identified.

## Nonvector-controlled splits

For nonvector-controlled splits, the last available agent in a split cannot enter Auxiliary Work mode if any calls remain in the split queue. (However, the agent can log out.)

When the last available agent tries to enter Auxiliary Work mode, the following occurs:

- The Auxiliary Work button flashes indicating the change is pending.
- New calls on the ACD split either receive busy tone or redirect to coverage. Calls in the queue continue to route to the last available agent until the queue is empty.
- At the last available voice terminal or console, the Auxiliary Work button lamp flashes until the queue is empty. The terminal then enters Auxiliary Work mode and the associated lamp lights steadily.

### **Agents logged into multiple splits**

If an agent is logged into multiple splits, the agent may become unavailable for calls to one split because of activity at another split. For example, if an agent enters After Call Work mode for one split, the agent becomes unavailable for calls to other splits.

An agent should not log into a split while a call is on hold at his or her extension.

### **Agents with Automatic Answer**

Agents who use Automatic Answer should use a headset. The agent hears zip tone through the headset and automatically connects to a call.

If either the incoming trunk group or the agent's extension is data-restricted, the agent does not hear zip tone. Therefore, do not assign data-restriction to a headset user's extension.

It is not recommended that you use Automatic Answer with a handset or speakerphone. The handset or speakerphone must be off-hook (handset lifted or speakerphone turned on) all the time for the agent to hear zip tone.

If automatic answer is assigned for all calls, when a non-ACD call arrives, non-ACD Auto-Answer agents hear Incoming Call ID tone, not ringing.

### **CALLMASTER terminals**

Calls for CALLMASTER digital voice terminals and attendant stations are announced by double tones. The tones that are doubled are zip (Auto-Answer ACD agent calls) and Incoming Call ID (for End of VDN of Origin announcements and all other Auto-Answer calls). The user hears part of the first tone and all of the second tone.

## Agents assigned to hunt-group and ACD calls

Do not use agents for hunt-group calls and ACD split calls simultaneously. Otherwise, all of the calls from one split (either ACD or hunt-group) are answered first.

The oldest call-waiting termination is supported only for agents who are servicing ACD calls only.

## Interactions

---

- **Abbreviated Dialing**

Assign Abbreviated Dialing buttons to make agent login easier. You can program an Abbreviated Dialing button to dial access code, split number, and/or agent login ID. With DEFINITY switches (R4 or later) you can use Autodial feature buttons to assign log and logout feature buttons.
- **Auto-Available Split (AAS)**

An AAS cannot be administered for Timed ACW.
- **Bridging**

ACD split/skill calls are not bridged.

Station calls are bridged and agents are able to bridge onto them. If an agent bridges onto a call, the call is considered a non-ACD extension-in call. The agent is not available for an ACD call unless the agent is a member of a many-forced, one-forced, or one-per-skill MCH split/skill. The agent can put the call on hold and become available to receive ACD calls even in non-MCH splits/skills if only bridged appearances are active.
- **Call Coverage**

If an ACD call routes to an agent as a result of covering to a VDN (where the VDN is the last coverage point in the coverage path), Timed ACW applies as administered for the VDN or split/skill.
- **Call Forwarding**

If an ACD call routes to an agent after being call-forwarded to a VDN, Timed ACW applies as administered for the VDN or split/skill.
- **Call Pickup**

When an ACD agent answers a call via Call Pickup, the call is treated as an incoming non-ACD call. The agent can put the call on hold and become available for additional calls.
- **Call Work Codes**

The call work code 100-agent limit is shared with Reason Codes. Therefore, no more than 100 agents can simultaneously enter either a call work code or reason code.

- CallVisor ASAI Adjunct

If a split/skill hunt group has CallVisor ASAI as the controlling adjunct, you cannot administer Timed ACW for the split/skill. Additionally, if an ACD call is routed to an agent in an adjunct-controlled split/skill, the agent is not placed in Timed ACW when the call ends.

- CentreVu CMS

Timed ACW is reported on CMS reports in the same way as any other ACW. CMS gives exception notification only on ACW intervals that are longer than the defined threshold.

- Conference

If an agent receives an ACD call through a VDN and then conferences in other agents, the agents added to the call use the Timed ACW interval associated with the number dialed to conference them.

An ACD agent on conference with more than three parties may cause inaccurate CMS measurements.

- Expert Agent Selection

When EAS is active, all ACD hunt groups are assigned as vector-controlled skills. Agents log in using Logical Agent IDs. Skills can be preassigned to login IDs, however, assignment on the Login ID form does not actually assign a non-AAS login ID to the skills until the ID is logged in. When the login ID is logged in, each skill is counted as a hunt-group member towards the system hunt-group member limit, the per-group member limit, and each agent is counted as a logged-in ACD agent.

- Multiple Call Handling

If MCH calls are on hold at an agent's terminal and the agent completes a call that normally is followed by Timed ACW, the agent is not placed in ACW. If no MCH calls are on hold, but one is alerting at the station when the Timed ACW call completes, the agent is placed in ACW.

MCH affects when agents can enter different work modes and when calls are delivered to agents in Manual-In or Auto-In work modes. See [“Multiple Call Handling” on page 9-104](#) for detailed information.

- Transfer

If an agent receives an ACD call through a VDN and then transfers the call to another agent, the second agent uses the Timed ACW interval assigned to the number that was dialed to transfer the call.

For an EAS agent, this is the Timed ACW interval associated with his or her Direct Agent skill. For an agent receiving a call transferred to a second VDN, this is the VDN Timed ACW interval of the second VDN. The agent who originally transferred the call uses the ACW associated with the VDN or split/skill that first received the call.

- VDN Override

If a VDN has VDN Override set to no and the vector routes a call to a second VDN, the first VDN's Timed ACW interval is used for Timed ACW. If VDN Override is set to yes, the second VDN's Timed ACW interval is used.

If no interval is set for the second VDN, no Timed ACW is associated with the call.

- Voice Response Integration

If an ACD call routes on a *converse* vector command, any VDN-Timed ACW associated with the call is ignored for agents in the converse split/skill. However, if the converse split/skill has an administered Timed ACW interval, the answering agent associated with the split/skill is placed in Timed ACW when *converse* vector command processing completes.

## Auto-Available Split

---

Auto-Available Split (AAS) allows members of an ACD split to be in Auto-In work mode continuously. An agent in Auto-In work mode becomes available for another ACD call immediately after disconnecting from an ACD call.

Use AAS to bring ACD-split members back into Auto-In work mode after a system restart. Although not restricted to such, this feature is intended to be used for splits containing only nonhuman members — for example, recorders or voice-response units (VRUs).

### How to administer AAS

---

#### Required forms

---

| Form                     | Field | Page                  |
|--------------------------|-------|-----------------------|
| Hunt Group               | ■ AAS | <a href="#">5-158</a> |
| Agent LoginID (EAS only) | ■ AAS | <a href="#">9-193</a> |

ACD must be set as a system option and the ACD field on the Hunt Group form must be set to **y**.

### Detailed description

---

- Agent login with AAS

With AAS, ACD splits generally operate as usual. The major difference is in how work modes are handled.

For ACD splits with AAS, agents are automatically logged in under the following circumstances:

- Call Management System (CMS) completes an Agent Move request into an Auto-Available split.
- A maintenance-busied-out port, which is defined as an agent in an Auto-Available split, is released.
- The system reinitializes and requires agents to log in again.
- You administer a split on the Hunt Group form as AAS = y.
- You administer an agent into an existing AAS split.

Once an agent is logged into an Auto-Available split, it is immediately moved to the Auto-In work mode and subsequent requests to change out of that mode are denied.

- Agent logout with AAS

For ACD splits with AAS, agents are automatically logged out under the following circumstances:

- CMS completes an Agent Move request out of an Auto-Available split.
- The Auto-Available agent's port is unavailable because maintenance is being performed.
- You administer a split as AAS = n.
- You remove an agent from an existing AAS split.
- Redirection on No Answer (RONA) redirects a call that the agent has not answered after an administered number of rings.

## Considerations

---

- AAS is intended primarily for non-BX.25 and non-ASAI PBX adjuncts such as Conversant VIS, that require extra help in getting PBX ports back online after a restart. AUDIX is incompatible with AAS because it uses BX.25 messages to automatically activate its ACD agent ports after a PBX restart.
- Because AAS is intended for nonhuman agents, do not administer an Auto-Answer terminal as a member of an AAS.
- AAS is not intended for any agent port hardware that can change its work mode state since a request to move to any state other than AUTO-IN is denied; however, administration of such terminals is not blocked.

## Interactions

---

- Auto-Answer

Do not administer an Auto-Answer terminal as a member of an AAS.

Auto-Answer was originally implemented for human agents. Currently, if a nonanalog terminal is administered as Auto-Answer and that terminal is logged into a split, when the terminal goes on-hook, the terminal is logged out.

Agents at analog terminals defined as Auto-Answer who are logged into a split must dial a log-out FAC to log out. If a terminal is a member of an AAS, a log-out FAC is denied. To log the agent out, you must either remove the terminal from the split when it is not active on a call or busy-out the terminal.

If an agent in an AAS with an Auto-Answer terminal goes off-hook, his or her terminal is logged into any Auto-Available splits of which it is a member. To log out of the AAS splits, the agent goes on-hook, is placed in AUX work mode, and then presses the RELEASE button on nonanalog

sets or disconnects on analog sets. Because agents are not placed immediately in Auto-In work mode, they may place personal or emergency calls rather than answering ACD calls that may be in queue.

- **CMS**

For each agent, AAS notifies CMS of any login, logout, or change into the Auto-In work mode. In a non-EAS environment, an AAS agent is identified to CMS with a login ID equivalent to the agent's administered extension. With EAS, the AAS login ID and port are assigned on the Login ID form.

With CMS Move Agent, you can move a member from one AAS split to another while that member is logged in.

## Automatic Call Distribution

---

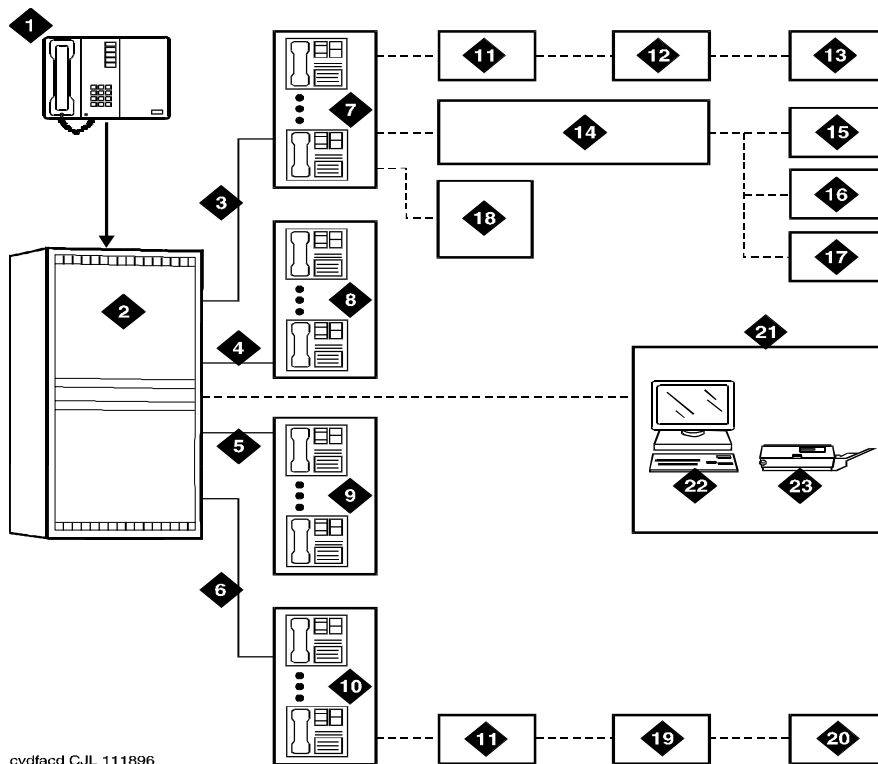

Automatic Call Distribution (ACD) allows incoming calls to connect automatically to specific splits. An ACD split is simply a hunt group that is designed to receive a high volume of similar calls. Calls to a specific split are automatically distributed among the agents, or hunt group members, assigned to that split. Calls queue to the split until an agent is available.

An ACD agent can be a voice-terminal extension, individual attendant extension, or, in an Expert Agent Selection (EAS) environment, an agent login ID. An agent can be logged into multiple splits. However, in a non-EAS environment, agents can be logged into only one split if that split is administered for Multiple Call Handling (MCH).

You can assign a supervisor to each split. The split supervisor can listen in on agent calls, monitor the split queue status, and assist agents on ACD calls. Although split supervisors can assist agents on ACD calls, the supervisors do not normally receive ACD calls unless they are also members of the split.

If you have Call Management System (CMS) or Basic Call Management System (BCMS), you can measure and create reports on the status of ACD agents, splits, and trunks. See [“Agent Call Handling” on page 9-7](#) and [“Call Management System” on page 9-58](#) or [“Basic Call Management System” on page 9-40](#) before setting up your ACD splits. See [“Agent Call Handling” on page 9-7](#) for detail on administering agent functions and operations.

[Figure 9-26](#) shows an a typical ACD arrangement.

- Trunk Group forms — In the Group Number field, assign consecutive Group Numbers to trunk groups when you are using two or more trunk groups to support ACD applications.
- Hunt Group form — When the ACD field is set to y, complete the fields that apply. In the AAS field, enter **y** to enable Auto-Available Split. See [“Auto-Available Split” on page 9-22](#) for more information.

## Detailed description

You can administer an ACD split to use one of three methods to select an available agent:

- Direct Department Calling
- Uniform Call Distribution
- Expert Agent Distribution

### Direct Department Calling

If you administer a split for Direct Department Calling (DDC), an incoming call is routed to the first available agent extension in the administered sequence. If the agent is not available, the call routes to the next available agent, and so on. Incoming calls are always routed to the first agent in the sequence, so calls are not evenly distributed among agents. DDC is not available with EAS.

### Uniform Call Distribution

Uniform Call Distribution (UCD) uses the Most-Idle Agent (MIA) algorithm to route calls. The MIA algorithm creates a queue of agents who are available to receive calls. An incoming call is routed to the agent who has waited the longest time in the queue. When an agent receives a call, the agent is removed from the queue for the split/skill to which the call was delivered. If MIA Across Splits/Skills is active, the agent is also removed from all other agent queues. Otherwise, the agent remains in the MIA queue for any other splits/skills that he or she is logged into.

The agent is returned to the agent queue (or queues if MIA Across Splits/Skills is active), based on how you administer the following:

- If forced Multiple Call Handling applies, the agent is placed in the queue when the call stops alerting.
- If ACW Agents on MIA List is enabled, the agent is queued when the call completes.
- If ACW Agents on MIA List is disabled, the agent is queued when ACW completes.

UCD distributes calls evenly among agents logged in to a particular split/skill. UCD with MIA Across Splits/Skills distributes calls evenly among agents logged into the same splits/skills.

## Expert Agent Distribution

Expert Agent Distribution (EAD) is available only with Expert Agent Selection (EAS). EAD also uses the MIA algorithm to route calls but maintains a queue of idle agents by agent skill level.

When you are using EAS Preference Handling Distribution (EAS-PHD), the agent can enter the MIA queue at one of 16 levels. The lower the level, the higher the level of expertise; so an agent with skill level 1 is the most qualified to answer a call to that skill. Without EAS-PHD, agents enter the MIA queue as either level 1 or level 2 agents.

When agents with a lower skill level become idle, they enter the MIA queue in front of agents with a higher skill level. See [“Expert Agent Selection” on page 9-72](#) for more information about EAS Call Distribution.

## Queuing and announcements

You create a queue for an ACD split by setting Queue to **y** on the Hunt Group form. When all agents are active on calls or in After-Call Work mode, the queue allows incoming calls to wait for an idle agent. The next available agent is automatically connected to the call in the split queue.

For non-vector-controlled splits, calls do not queue to splits in these cases:

- No agents are logged in
- All logged-in agents are in Auxiliary Work mode
- No queue slots are available

The caller gets a busy signal (or busy coverage, if administered) unless a call comes in via an automatic-in central office (CO) facility. In this case, the caller hears ringback from the CO and the system continues trying to place the call in the queue.

You can assign two announcements to each split and administer a second announcement to repeat. When an incoming call is directed to an ACD split, the call is either directed to an agent or is automatically connected to the first announcement. See [“Announcement rules” on page 9-32](#) in this section for information on how announcements are affected by call forwarding and call coverage.

### First announcement

After a call enters a split queue, the caller hears ringing and the first announcement delay interval begins. If an agent becomes available during the first announcement delay interval, the call is connected to the agent. Otherwise, the interval expires and the system tries to connect the incoming call to the first announcement, with one of the following results:

- If the first announcement is available, the caller hears ringing, then the first announcement.
- If the announcement is busy and has no queue, the caller hears ringing and the first announcement delay interval is reset. The system tries to access the announcement again when the interval expires.
- If the announcement is busy and has a queue, then:
  - If the queue is full, the caller hears ringing and the first announcement delay interval is reset. The system tries to access the announcement again when the interval expires.
  - If the queue is not full, the call enters the announcement queue and the caller hears ringing, then the first announcement. The system then tries to connect the call to an agent.
- If the announcement is not busy, but is still unavailable, the second-announcement delay interval begins and the system attempts to connect the call to the second announcement.

If there is no first or second announcement, the call remains in queue until answered or removed from the queue.

### Forced first announcement

The first-announcement delay interval defines how long a call remains in queue before the call is connected to the first announcement. If this interval is 0 seconds, the incoming call is automatically connected to the first announcement. This is a forced first announcement — the call is not routed to an agent until after the caller hears the first announcement.

With a forced first announcement, the following occurs:

- If a first announcement is available, the caller hears ringing and then the first announcement. The system then tries to connect the call to an agent.
- If the announcement is busy and has no queue, the system waits 10 seconds and then tries to access the announcement.
- If the announcement is busy and has a queue, then:
  - If the queue is full, the system waits 10 seconds, then tries to access the announcement.
  - If the queue is not full, the call enters the announcement queue and the caller hears ringing, then the first announcement. The system then tries to connect the call to an agent.
- If the announcement is not busy but is still unavailable (for example, it may have been deleted), then the system tries to connect the call to an agent.

After a forced first announcement, the caller always hears ringback (or music-on-hold, if administered) until the call is answered or is connected to a second delay announcement. After a first or second delay announcement, the caller hears music-on-hold, if administered.

## Second announcement

After the first announcement, the second-announcement delay interval begins and the caller hears ringing (if there is no forced first announcement), or music, if provided. If an agent becomes available during the interval, the call is connected. Otherwise, the interval expires and the system tries to connect the incoming call to the second announcement, resulting in one of the following:

- If the second announcement is available, the caller hears ringing or music, then the second announcement.
- If the announcement is busy and has no queue, the caller hears ringing and the second-announcement delay interval is reset. The system tries to access the announcement again when the interval expires.
- If the announcement is busy and has a queue, then:
  - If the queue is full, the caller hears ringing (only if the first announcement has not been heard) and the second-announcement delay interval is reset. The system tries to access the announcement again when the interval expires.
  - If the queue is not full, the call enters the announcement queue and the caller hears ringing (only if the first announcement has not been heard), then the second announcement. The system then connects the call to an agent.
- If the announcement is not busy but is still unavailable, the call remains in queue until answered or removed from the queue.

After the second announcement, the caller hears music, if provided, or silence and then:

- If you administered the split to repeat the second announcement, the system tries to connect the call to the second announcement after the delay expires.
- If you administered the split not to repeat the second announcement, the call remains in the queue until answered or removed from the queue.

## Forced disconnect

You can connect an incoming call directly to an announcement and then disconnect the call after the announcement has completed in one of two ways:

- Administer an announcement extension as the incoming destination. The caller is directed to the announcement and is disconnected, without being queued for a split.
- Administer an announcement extension as a point in a split's coverage path. Calls that have been in the queue for a long time are forced to go directly to the announcement and are disconnected.

## Announcement rules

The following rules govern announcements a caller hears:

- Calls that reach a split directly always hear a forced first announcement, if assigned, regardless of subsequent call coverage, call forwarding, night service, or busy signal processing. If these calls queue long enough, they hear first and second announcements.
- Calls that reach a split via call coverage receive a second announcement only, if administered. The assumption is that a caller has likely heard a first announcement at the original split or station before being redirected.
- Calls that reach a split via call forwarding receive first and second announcements at the destination split, if administered. These calls can receive a forced first announcement at the original split, if administered, but not at the split they are forwarded to.

## Entering the queue

When a forced first announcement is not assigned, the system tries to connect an incoming call to an available agent. If an agent is available, the call is connected to the agent. If all agents are active (either on an ACD call or in ACW mode), the call enters the split queue.

If no queue is assigned, or if no queue slots are available and the incoming facility is a CO trunk, the caller hears ringing. The system continues trying to queue the call until a queue slot becomes available, or until the call is abandoned or an agent becomes available. When you have administered Intraflow and Interflow with Call Coverage and Call Forwarding All Calls, the caller hears a busy tone or the call is redirected in any of these cases:

- No split queue is assigned.
- The queue is full.
- No agents are logged in.
- All logged-in agents are in AUX work mode, and the incoming facility is a digit-oriented facility (digits are sent to the PBX as in DID, incoming wink, or immediate tie trunks)

### NOTE:

Central office trunk (non-DID) calls receive ringback from the CO, so the PBX cannot give these callers a busy signal. The system tries to put such calls into queue until successful or until the call is abandoned.

## Priority queuing

Priority queuing allows priority calls to be queued ahead of calls with normal priority. You can implement priority queuing in two ways:

- Assign Priority Queuing to a calling party's Class of Restriction (COR).
- Assign Priority on Intraflow to an ACD split. This allows calls from the split, when intraflowed into another split, to be queued ahead of nonpriority calls. For more information, see ["Information Forwarding" on page 9-89](#).

## Queue status indications

You can assign queue status indications on agents' or supervisors' terminals or consoles for ACD calls in queue. For more information, see ["Queue Status Indications" on page 9-110](#).

## Direct Agent Calling

### NOTE:

Direct Agent Calling requires CallVisor Adjunct-Switch Application Interface (ASAI) or EAS. Both originating and called party Class of Restrictions (CORs) must be set to allow Direct Agent Dialing. See ["Expert Agent Selection" on page 9-72](#) for information on Direct Agent Announcements.

Direct Agent Calling (DAC) causes a call to a particular ACD agent to be treated as an ACD call. Agents can enter After Call Work mode for direct agent calls and CMS and BCMS correctly measure these calls as ACD calls.

If an agent is available to answer an ACD call, the direct agent call is delivered to the agent. An agent in Automatic Answer mode hears a zip tone.

An agent with a multifunction voice terminal or who is on-hook and not available to answer an ACD call hears a ring-ping. An agent with a single-line voice terminal and who is off-hook and not available hears the call-waiting tone, even when Call Waiting Termination is not assigned. The ring-ping or call waiting tone is given only once per call when the direct-agent call is queued. The lit work mode button lamp for the split on the agent's voice terminal flashes, indicating that a direct agent call is waiting. Flashing starts when the call queues and stops when all direct agent calls are removed from the queue (that is, they are answered, abandoned, or sent to coverage).

While on a direct-agent call, the agent becomes unavailable for subsequent ACD calls. If the agent logs off by unplugging the headset, he or she can still answer a direct-agent call in the queue by logging back in and becoming available. Agents who have direct-agent calls waiting are not allowed to log off using a FAC. If the agent is in Manual In mode or pushes the After Call Work (ACW) button while on a direct-agent call, the agent goes to ACW mode.

Generally, direct-agent calls are queued and served in first-in, first-out order before other calls, including priority calls. However, if you administer a skill level for Call Handling Preference, direct-agent calls must be assigned the highest priority for them to be delivered before other ACD calls. Otherwise, calls with a higher skill level are distributed before direct-agent calls.

Note that you can use Multiple Call Handling (MCH) to allow agents to answer a direct agent call with another ACD call active.

Direct-agent calls follow the receiving agent's coverage and call forwarding paths, if these features are administered. Once a call goes to coverage or is forwarded, the call is no longer treated as a direct-agent call, and CMS is informed that the call has been forwarded.

## **Considerations**

---

### **Maximum Number of Agents**

If an agent is assigned to more than one split, each assignment applies to the maximum number of agents. When computing the number of agents measured by BCMS, count one agent as one agent regardless of the number of splits that the agent will be logged into. For CMS sizing, count one agent for each agent in each split measured by CMS; one agent logged into three splits counts as three agents.

Using the Number of Agents System Capacity screen, you can view the Used, Available, and System Limit counts.

### **MIA Across Splits/Skills**

MIA Across Splits/Skills distributes calls more equally to agents with multiple splits or skills. When agents handle a call for one split or skill, they go to the back of all their idle agent lists.

With MIA Across Splits/Skills, agents may not receive calls from all of their splits/skills. If, for example, split 20 has a very short average agent idle time and split 22 has a very long average agent idle time, agents with both of these skills may never become the most-idle for skill 22 because they continuously take calls for split 20.

### **Announcements**

Announcements can be analog, aux trunk, DS1, or integrated. Integrated announcements use the 16-channel announcement board and queuing is based on whether one of the 16 channels is available. When a channel becomes available, any announcements on the board can be accessed, including the announcement already being played. A caller may be in queue for an announcement because a channel is not available, even though that

announcement is not being used. The maximum queue length for all digital announcements is shown in the Capacities Table in the *DEFINITY Enterprise Communications Server Release 6 System Description Pocket Reference*. Queues for analog and aux trunk announcements are on a per-announcement basis. You can also install multiple Integrated Announcement boards to allow for more announcements.

If a delay announcement is used, answer supervision is sent to the distant office when the caller is connected to the announcement. Charging for the call, if applicable, begins when answer supervision is returned.

## Storing and retrieving messages

Leave Word Calling messages can be stored for an ACD split and retrieved by a split member, a covering user of the split, or a system-wide message retriever. The message retriever must have a voice terminal display and proper authorization. You can also assign a remote Automatic Message Waiting lamp to a split agent's terminal to indicate when a message has been stored for the split.

## Class of Restriction

Each ACD split and each individual agent is assigned a COR. You can use Miscellaneous Restrictions to prohibit selected users from accessing certain splits. You can use Miscellaneous Restrictions or restrictions assigned through the COR to prevent agents from being accessed individually. Unless you administer such restrictions, each agent can be accessed individually as well as through the split.

An agent with origination and termination restriction can receive ACD calls and use the assist function. A terminal in a COR with termination restriction can receive ACD calls.

If you are using Service Observing, administer a COR for observers and agents being observed.

## Trunk groups and ACD splits

- If you assign an ACD split extension as the incoming destination of a trunk group and that split's extension is later changed, you must also change the trunk group's incoming destination to a valid extension.
- Calls incoming on a non-DID trunk group can route to an ACD split instead of to an attendant. Calls incoming on any non-DID trunk group can have only one primary destination; therefore, the trunk group must be dedicated to the ACD split or a VDN.

- For MEGACOM 800 Service with DNIS over a wink/wink-tie trunk, if all agents are logged out or in AUX work mode, incoming MEGACOM calls receive a busy signal if no coverage path is provided (unlike other automatic-in trunk groups, which receive ringback from the central office).
- CO switches usually drop calls that remain unanswered after two to three minutes. Therefore, if an incoming CO call queues to a split without hearing an announcement or music, and the caller hears CO ringback for two to three minutes, the CO drops the call.

### Agent considerations

- Agents should not be used for hunt group calls and ACD split calls simultaneously. Otherwise, all calls from one split (either ACD or hunt group) are answered first. For example, if ACD calls are answered first, none of the hunt-group calls are answered until all of the ACD calls are answered.
- Agents with multiappearance voice terminals can receive only one ACD call at a time unless Multiple Call Handling is active. Without MCH, a voice terminal is available for an ACD call only if all call appearances are idle. The agent may, however, receive non-ACD calls while active on an ACD call.

### Vector-controlled splits

- You can enhance ACD by using Call Prompting, Call Vectoring and Expert Agent Selection. For detailed information on vector-controlled splits, see the *DEFINITY Enterprise Communications Server Call Vectoring/EAS Guide*. Vector-controlled splits/skills should not be called directly via the split/skill extension (instead of via a VDN mapped to a vector that terminates the call to a vector controlled split/skill). However, if split/skill extensions are called, the calls do not receive any announcements, are not forwarded or redirected to coverage, and do no intraflow/interflow to another hunt group.
- The oldest-call-waiting termination, which is available with Call Vectoring, is supported for agents who are servicing ACD calls only.

### Changing hunt groups from ACD to non-ACD

Before you change a hunt group from ACD to non-ACD, all agents in that hunt group must be logged out. When you change a hunt group from ACD to non-ACD, the system places all agents in that hunt group in busy state. If any voice terminals in the hunt group have an Auxiliary Work button, the button lamp lights. To become available for calls, the agent presses the Auxiliary Work button or dials the Hunt Group Busy Deactivation FAC followed by the hunt-group number.

## Interactions

---

- Attendant Call Waiting

An attendant can originate or extend a call to an ACD split. Attendant Call Waiting cannot be used on such calls. However, such calls can enter the split queue.

- Attendant Intrusion

Attendant Intrusion does not work with ACD split extensions because an ACD extension has many agent extensions. It is not possible to determine which agent extension to intrude upon.

- Automatic Callback

Automatic Callback calls cannot be activated toward an ACD split.

- Call Coverage

Calls can redirect to or from an ACD split. A vector-controlled split cannot be assigned a coverage path.

For a call to an ACD split to be redirected to call coverage on the Busy coverage criterion, one of the following conditions must exist:

- All agents in the split are active on at least one call appearance and the queue, if there is one, is full.
- No agents are logged in.
- All agents are in Auxiliary Work mode.

If the queue is not full, a call enters the queue when at least one agent is on an ACD call or in ACW mode. Queued calls remain in queue until the Coverage Don't Answer Interval expires before redirecting to coverage. If any split agent becomes available, the call is directed to the agent.

Calls that redirect on the Don't Answer coverage criterion are reported to BCMS/CMS as intraflowed calls.

If a call is queued for an ACD split and redirects via Call Coverage directly to an announcement, the call is dropped after the announcement.

Calls to a split that are directed to an agent's voice terminal do not follow the agent's call coverage path. If an agent activates Send All Calls it does not affect the distribution of ACD calls. An ACD split call directed to an agent's station follows the split's call coverage path, once the agent's Don't Answer interval is met.

- Call Forwarding All Calls

Call Forwarding All Calls activated for an individual extension does not affect the extension's ACD functions.

When activated for the split extension, calls directed to the split are forwarded from the split. Calls receive no announcements associated with that split (other than a forced first announcement, if administered). The

system reports to BCMS or CMS that calls are queued on the split. The system reports to CMS when the call is removed from the queue and forwarded.

Calls can be forwarded to an off-premises destination to activate Intraflow and Interflow. See [“Information Forwarding” on page 9-89](#) in this book for more information.

- Data Call Setup

Voice-terminal or data-terminal dialing can be used on calls to or from a member of an ACD split.

- Data Restriction

If the trunk group used for an ACD call has data restriction activated, agents with Automatic Answer activated do not hear the usual zip tone.

- DCS

CMS cannot measure ACD splits on a DCS network as if they were one switch. Agents for a split must be all on the same switch. If a call to an ACD split is forwarded to a split at another DCS node, the caller does not hear the forced first announcement at the second split.

If an ACD split is in night service, with a split at second DCS node as the night service destination, a call to the first split is connected to the second split's first forced announcement.

- Dial Intercom

An agent with origination and termination restriction can receive ACD calls and can make and receive dial intercom calls.

- Hold

If an agent puts an ACD call on hold, information is reported to the CMS via Personal Call Tracking. CMS records the amount of time the agent actually talks on the call.

- Individual Attendant Access

Individual attendant extensions can be assigned to ACD splits. Unlike voice-terminal users, individual attendants can answer ACD calls as long as there is an idle call appearance and no other ACD call is on the console.

- Internal Automatic Answer (IAA)

Internal calls directed to an ACD split are eligible for IAA. You cannot administer IAA and ACD Automatic Answer simultaneously on the same station.

- Intraflow and Interflow

Intraflow and Interflow, when used with Call Forwarding All Calls or Call Coverage, allows splits to be redirected to other destinations on and outside the system. For more information, see [“Information Forwarding” on page 9-89](#).

- Multiappearance Preselection and Preference

All assigned call appearances must be idle before an ACD call is directed to a voice terminal.
- Night Service – Hunt Group

When Hunt Group Night Service is activated for a split and the night-service destination is a hunt group, a caller hears the first forced announcement at the original split. The call is redirected to the night-service destination hunt group. If all agents in the hunt group are busy, the caller hears whatever you have assigned.
- Terminating Extension Group

A TEG cannot be a member of an ACD split.
- Transfer

Calls cannot be transferred to a busy split. The transfer fails and the agent transferring the call is re-connected to the call. If an agent presses the Transfer button, dials the hunt-group extension number, and then disconnects while the split is busy, the call is disconnected.
- Voice Terminal Display

For calls dialed directly to an ACD split extension, the identity of both the calling party and ACD split are shown on the voice terminal display.

## Basic Call Management System

---

Basic Call Management System (BCMS) provides real-time and historical reports to assist you in managing agents, ACD splits (hunt groups), VDNs, and trunk groups. You can display BCMS reports on the Management Terminal or print them on the printer associated with the Management Terminal. In addition, you can schedule historical reports to print on the system printer.

BCMS provides the following reports:

- Real Time Reports
  - Split Status
  - System Status
  - VDN Status
- Historical Reports
  - Agent
  - Agent Summary
  - Split
  - Split Summary
  - Trunk Group
  - Trunk Group Summary
  - VDN
  - VDN Summary

For a detailed description of BCMS and the reports it provides, see *DEFINITY Enterprise Communications Server Release 6 Basic Call Management System (BCMS) Operations*.

## How to administer BCMS

---

### Required forms

| Form                                  | Field  | Page                  |
|---------------------------------------|--|-----------------------|
| System Parameters<br>Customer-Options | ■ BCMS   | <a href="#">5-277</a> |
|                                       | ■ BCMS Service Level   |                       |
|                                       | ■ ACD  |                       |
|                                       | ■ BCMS/VuStats Login ID  |                       |
| Agent LoginID                         | ■ When BCMS is being used with EAS, complete all fields for each agent           | <a href="#">9-193</a> |
| BCMS/VuStats Login ID                 | ■ When BCMS is being used without EAS, enter a Login ID and Name for each agent. | <a href="#">9-200</a> |
| Feature-Related<br>System Parameters  | ■ BCMS Parameters  | <a href="#">5-123</a> |
|                                       | ■ BCMS/VuStats Measurement Interval  |                       |
|                                       | ■ ACD Login Identification Length  |                       |
|                                       | ■ BCMS/VuStats Abandoned Call Timer  |                       |
|                                       | ■ System Printer Extension   |                       |
|                                       | ■ Lines Per Page   |                       |
| Hunt Groups                           | ■ Measured   | <a href="#">5-158</a> |
|                                       | ■ Acceptable Service Level   |                       |
| Trunk Groups                          | ■ Measured   | <a href="#">7-115</a> |
| Vector Directory<br>Number (VDN)      | ■ Measured   | <a href="#">9-214</a> |
|                                       | ■ Acceptable Service Level   |                       |

All agents should log off before any changes are made to the BCMS/VuStats Login ID form.

Measurements can be turned off for a split while agents are logged in, but agents must be logged off to start measurements for a split.

**Interactions**

---

For information about how BCMS records redirected and conferenced calls, see *DEFINITY Enterprise Communications Server Basic Call Management System (BCMS) Operations*.

- **Move Agents From CMS**

If agents are moved from one split to another split by the CMS adjunct, measurements are stopped for the agent's "from" split and started for the agent's "to" split.

If the adjunct CMS attempts to move an agent that is not being measured by BCMS into a split that is being measured by BCMS, and the move would exceed the maximum number of measured agents, the switch rejects the move. Otherwise, internal BCMS measurements are started for the agent. If the adjunct CMS moves an agent from a split that is measured by BCMS to a split that is not BCMS-measured, internal measurements for the agent stop.

- **Night Service**

When night service is activated for a split, new calls go to the alternate destination. BCMS does not record these calls as OUTFLOW. If the destination is a measured split, BCMS treats the calls as new incoming calls (that is, BCMS does not record them as INFLOW).

- **System Measurements**

The system can produce BCMS reports, adjunct CMS reports, and switch traffic measurements simultaneously.

BCMS measurements are not determined in the same way as trunk group and hunt group measurements although some of the information is similar. Therefore, the two reports may represent data differently.

**Table 9-2. System Capacity**

|  | <b>R6vs/csi/si</b> | <b>R6r</b>       |
|--|--------------------|------------------|
| Maximum agents displays by Monitor BCMS Split command            | 100 <sup>1</sup>   | 100 <sup>1</sup> |
| Maximum BCMS terminals   | 3                  | 4                |
| Maximum active maintenance commands for system                   | 1                  | 5                |
| Maximum BCMS terminals in monitor mode at same time <sup>2</sup> | 1                  | 3                |

1. The Monitor Split command will only display status for the first 100 agents logged into the split regardless of how many additional agents log in to the split.

**9** Call Center  
*Basic Call Management System*

*Page 9-43*

2. BCMS monitoring, being a maintenance command, is limited by the active maintenance commands limit, reduced by 2 in the "r" system configuration (since 2 active command slots are reserved for the INADs and SAT logins respectively).
-

## Best Service Routing™

---

Best Service Routing™ (BSR) allows DEFINITY® ECS to compare specified splits or skills, identify the split or skill that will provide the best service to a call, and deliver the call to that resource. If no agents are currently available in that split or skill, the call is queued. To respond to changing conditions and operate more efficiently, BSR monitors the status of the specified resources and adjusts call processing and routing as appropriate.

BSR is available in single and multi-site versions. Single-site BSR compares splits or skills on the DEFINITY ECS where it resides to find the best resource to service a call. Multi-site BSR extends this capability across a network of DEFINITY switches, comparing local splits or skills, remote splits or skills, or both, and routing calls to the resource that will provide the best service.

Best Service Routing is summarized in this chapter. For complete information on how to get the most from BSR, see Chapter 9, “Best Service Routing” in the *DEFINITY® ECS Release 6 Call Vectoring/Expert Agent Selection (EAS)* manual.

### Benefits of Best Service Routing

---

Both single- and multi-site BSR intelligently compare specific resources to find the one that can best service a call. In addition, multi-site BSR allows you to integrate a network of call centers for better load balancing and optimal agent utilization. Depending on your specific application, BSR can yield a variety of other benefits as shown below.

**Table 9-3. Best Service Routing benefits**

---

| <b>You can benefit by...</b>   | <b>As a result of...</b>   |
|--------------------------------|--|
| Improved customer satisfaction | <ul style="list-style-type: none"><li>■ Lower average speed of answer (ASA), thus more calls handled<sup>1</sup></li><li>■ Greater probability that expert agents will be available for a specific call type (for centers with Expert Agent Selection)</li><li>■ Lower abandonment rate</li></ul> <p>By balancing the load between locations in a network, BSR reduces extremes in wait times between the locations.</p> |

---

*Continued on next page*

**Table 9-3. Best Service Routing benefits — Continued**

| You can benefit by...   | As a result of...  |
|---|--|
| Increased revenue   | <ul style="list-style-type: none"> <li>■ Lower average speed of answer (ASA), thus more calls handled</li> <li>■ Lower abandonment rate</li> <li>■ Lower network cost</li> <li>■ Greater probability that high-revenue generating agents will be available for a specific call type (for centers with Expert Agent Selection)</li> </ul>   |
| Improved productivity   | <ul style="list-style-type: none"> <li>■ Increased agent occupancy rates<br/>                     Improve your service without adding staff, or reduce staff while maintaining your current level of service.</li> <li>■ Faster delivery of interflowed calls<br/>                     Agents at one location in a network are less likely to sit idle while calls wait in queue at another location.</li> </ul> |
| Increased operating flexibility, easier staffing and scheduling | <ul style="list-style-type: none"> <li>■ Larger pool of agents available to take calls in a split or skill<br/>                     Spikes in call volume at a single call center can be distributed across all centers. Temporarily understaffed centers can be supported by the other centers in the network.</li> </ul>   |
| Improved service levels   | <ul style="list-style-type: none"> <li>■ Lower average speed of answer (ASA), thus more calls handled</li> </ul>   |
| Increased performance   | <ul style="list-style-type: none"> <li>■ Less messaging and processing required per call</li> </ul>  |
| Operating separate sites as an integrated “virtual call center” | <ul style="list-style-type: none"> <li>■ DEFINITY ECS’s ability to compare resources and queue a call to the best one</li> <li>■ DEFINITY ECS’s enhanced information forwarding capabilities</li> </ul>  |

1. A location’s ASA may be low because the location is underutilized and agents are frequently sitting idle. When BSR is implemented at such a location, ASA may rise because of the rise in incoming call volume.

## Before you Start

For single-site BSR applications, your switch must meet the requirements shown below (except for LAI). To use multi-site BSR applications, both the switches involved and the network connecting them must meet all the requirements described in this section.

### CAUTION:

*To ensure your network meets the requirements for BSR support presented below, contact your Account Executive about BSR network certification.*

## Switch requirements

Your switch has to meet *all* of the requirements shown below to support Best Service Routing. Check the settings shown below before you try to use BSR.

**Table 9-4. Requirements to use Best Service Routing**

| Form   | Page | Field                                | Must be set to...                |
|--|------|--------------------------------------|----------------------------------|
| Software Version                                   | 1    | Memory Resident                      | G3V6i.03 or<br>G3V6r.03          |
| System-Parameters<br>Customer-Options <sup>1</sup> | 1    | G3 Version                           | V6 or higher                     |
|  | 2    | ISDN-BRI Trunks?                     | Y                                |
|  |      | ISDN-PRI Trunks?                     | Y                                |
|  | 3    | Vectoring (G3V4<br>Advanced Routing) | Y                                |
|  |      | Vectoring (Best<br>Service Routing)  | Y                                |
| Lookahead Interflow<br>(LAI) <sup>2</sup>          |      | Y                                    |                                  |
| Feature-Related<br>System Parameters               | 8    | Adjunct CMS Release                  | R3V6 or higher,<br>or left blank |

1. ISDN connectivity is only necessary if you want to use multi-site BSR. One or both of these fields must be set to "Y." Multi-site BSR operates over both BRI and PRI trunks.
2. Lookahead Interflow is only necessary if you want to use multi-site BSR. For status poll and interflow calls used in multi-site BSR applications, set up trunks as you would for LAI. See [Chapter 9, "Look-Ahead Interflow"](#), for more information. Information Forwarding is not required for polling calls

 **NOTE:**

If you begin using BSR and then decide to turn it off, you will not be able to set Vectoring (Best Service Routing) to “N” until you remove all BSR commands from vectors.

## Network requirements

To support BSR, networks must meet both the criteria for LAI call control operation over switched networks (see [“Look-Ahead Interflow” on page 9-98](#)) and the following criteria:

- The network must support end-to-end transport of codeset 0 user data, either as a User-to-User Information Element (UUI IE) or by QSIG Manufacturer Specific Information (MSI IE), in the ISDN SETUP and DISCONNECT messages. (For more information, see [“Information Forwarding” on page 9-89](#).)

Private networks can be configured for either QSIG (transport via MSI packaged in a codeset 0 Facility IE) or non-QSIG (transport via a codeset 0 UUI IE). Currently, public networks do not support QSIG and user data can only be transported via the UUI IE when supported by the network. Future public network offerings may support QSIG, possibly by Virtual Private Network.

- DEFINITY ECS must support the ISDN country protocol.
- The network byte limit for user information contents (the user data portion) must be large enough to carry the data needed for the customer application.

 **NOTE:**

Some public network providers may require service activation and/or fees for user information transport.

- Response time for ISDN signaling should be fast enough that an entire consider series can execute within a single ring cycle.

Enhanced information forwarding has been tested with several major carriers. To find out if these capabilities work with your carrier, check with your account team for the most current information.

If testing has not been done to verify operation over the public networks involved with the preferred specific configuration, use of private ISDN trunking between the nodes should be assumed until successful testing has been completed.

## How to administer Best Service Routing

BSR administration varies, depending on whether your switch is configured for single- or multi-site BSR.

## Single-site BSR

### Required forms for administering single-site BSR

| Form                                  | Field  | Page                  |
|---------------------------------------|--|-----------------------|
| System Parameters<br>Customer-Options | ■ G3 Version   | <a href="#">5-277</a> |
|                                       | ■ Vectoring (G3V4 Advanced Routing)                      |                       |
|                                       | ■ Vectoring (Best Service Routing)                       |                       |
| Feature-Related<br>System Parameters  | ■ Adjunct CMS Release                                    | <a href="#">5-123</a> |
| VDN                                   | ■ BSR Available Agent Strategy                           | <a href="#">9-214</a> |
| Call Vector                           | ■ Complete a form for each vector that uses BSR commands | <a href="#">9-207</a> |

## Multi-site BSR

### Required forms for administering multi-site BSR

| Form                                     | Field   | Page                  |

- 
1. Settings in the fields Codeset to Send TCM, Lookahead and Send Codeset 6/7 LAI IE? on the ISDN trunk forms do not affect BSR.

Multi-site BSR requires that Look-Ahead Interflow (LAI) be enabled. See [“How to administer Look-Ahead Interflow” on page 9-99](#) for a list of required forms and fields. Since BSR can forward information such as VDN name, in-VDN time, and collected digits with interflowed calls, also see [“Administering User-to-User Information Transport” on page 9-90](#) for instructions.

## Detailed description

---

To use Best Service Routing on a single switch, you simply use special commands and command elements that are part of the DEFINITY ECS call vectoring language. As a result, BSR for a single location can be easily added to existing vectors without modifying other parts of DEFINITY ECS.

Multi-site applications work similarly, but additional administration is required. Since steps in a multi-site BSR vector will contact one or more remote locations, you need to define these locations, tell DEFINITY ECS how to contact each one, and set up VDNs and vectors to handle communications between the sending switch and each remote switch.

Three VDN/vector pairs must be used in every multi-site BSR application. The Primary VDN/vector pair, on the sending switch, contacts the specified remote switches, collects information, compares the information, and delivers or queues the call to the resource that is likely to provide the best service. Two VDN/vector pairs are needed on each remote switch. A Status Poll VDN/vector pair provides information about the best resource at its location in response to inquiries from BSR applications on other switches. Finally, an Interflow VDN/vector pair is needed to receive and process the calls interflowed from BSR applications on other switches.

## Call surplus situations

Every BSR application compares a set of predetermined resources (splits or skills) and selects the “best” resource to service the call. In a call surplus situation (no agents available), the best resource is the split or skill with the lowest Expected Wait Time (EWT). For purposes of calculating the best resource in a call surplus situation, BSR allows you to adjust the EWT figure for any split or skill. The actual EWT for calls in queue isn't changed, of course; only the figure used in the calculations performed by the BSR feature is changed. You don't have to enter adjustments, but the ability to adjust the EWT for splits or skills allows you to program preferences in vectors. Because of agent expertise, for example, or the availability or cost of tie trunks, you might prefer that some resources *not* service a call unless doing so significantly decreases the call's time in queue.

## Agent surplus situations

In an agent surplus situation (one or more agents available to take incoming calls), BSR will deliver a new call according to the BSR Available Agent Strategy specified on the VDN form. The “best” resource will be the split or skill that meets the criteria defined by the strategy you’ve chosen for that VDN. BSR can use any of the five strategies shown in the table below to select an agent when agents are available.

**Table 9-5. BSR Available Agent Strategies**

| If BSR Available Agent Strategy is set to... | The call will be delivered to...   |
|--|--|
| 1st-found                                    | the first available agent. BSR will not consider any other resources as soon as it finds an available agent.   |
| ucd-mia                                      | the agent who has been idle the longest. BSR will compare all the splits or skills specified in the vector before delivering the call.   |
| ead-mia                                      | the agent with the highest skill level relevant to the call who has been idle the longest. BSR will compare all the splits or skills specified in the vector before delivering the call. |
| ucd-loa                                      | the least-occupied agent. <sup>1</sup> BSR will compare all the splits or skills specified in the vector before delivering the call.   |
| ead-loa                                      | the agent with the highest skill level relevant to the call who is the least occupied. BSR will compare all the splits or skills specified in the vector before delivering the call.     |

1. LOA is a new agent selection method available as an option on DEFINITY ECS R6.3 and later switches. For more information, please see the *CentreVu® Advocate User Guide* (585-215-855).

When agents are available in one or more of the specified resources, BSR does not consider EWT adjustments in selecting an agent for a call.

**⇒ NOTE:**

The BSR Available Agent Strategy assigned to a VDN should match the agent selection method used in the splits or skills considered by a BSR application.

## Vector commands for single-site BSR

The following table shows the vector commands and command elements used in single-site BSR applications.

**Table 9-6. Vector commands and command elements for single-site BSR**

| Commands and command elements |                             | Use this ...  |
|-------------------------------|-----------------------------|---|
| Commands                      | <i>consider split/skill</i> | to obtain the Expected Wait Time or agent data needed to identify the best local resource. One <i>consider</i> step must be written for each split or skill you want to check. <sup>1</sup> |
|                               | <i>queue-to</i>             | with the <i>best</i> keyword to queue calls to the best resource identified by the <i>consider</i> sequence.  |
|                               | <i>check</i>                | with the <i>best</i> keyword to queue calls to the best resource identified by the <i>consider</i> sequence if the resource meets certain conditions.                                       |

*Continued on next page*

Table 9-6. Vector commands and command elements  
 for single-site BSR — *Continued*

| Commands and command elements |                      | Use this ...  |
|-------------------------------|----------------------|---|
| Key word                      | <i>best</i>          | in <i>queue-to</i> , <i>check</i> , and <i>goto</i> commands that refer to the resource identified as best by a series of consider steps  |
| Conditional                   | <i>wait-improved</i> | to prevent calls from being queued to an additional split or skill when the reduction in Expected Wait Time isn't enough to be useful. "Wait improved" means that a call's EWT must be improved by a specific amount (a figure you specify in seconds) over its current EWT or DEFINITY ECS won't queue it to the additional split or skill.  |
| User adjustment               | <i>adjust-by</i>     | to specify your preferences for the splits or skills that might handle calls in a particular vector. Any time a <i>consider</i> step returns EWT for a local split or skill, you can increase this value. <sup>2</sup> As a result, this split or skill is less likely to service a call unless its EWT is significantly shorter than that of any other available split or skill.<br><br>For example, you may prefer that the main split or skill in a vector handle as many calls as possible but want to use another split or skill as a backup. You can write the <i>consider</i> step that checks the backup split or skill to increase the returned EWT by a set amount. |

1. Since the *consider* command is designed to compare two or more resources, *consider* commands are typically written in sequences of two or more with the sequence terminating in a *queue-to best* step. This set of *consider* commands and a *queue-to best* step is called a consider series.
2. Of course, DEFINITY ECS doesn't increase the actual wait time in a split or skill. It only adjusts EWT in the calculations used to identify the "best" split or skill to which to queue a call.

## Vector commands for multi-site BSR

The following table summarizes the vector commands and command elements that support multi-site BSR applications.

**Table 9-7. Vector commands and command elements for multi-site BSR**

| Commands and command elements |                             | Use this...   |
|-------------------------------|-----------------------------|---|
| Commands                      | <i>consider split/skill</i> | to obtain the Expected Wait Time or agent data needed to identify the best local resource. One <i>consider</i> step must be written for each split or skill you want to check. <sup>1</sup>   |
|                               | <i>consider location</i>    | to obtain the Expected Wait Time or agent data needed to identify the best resource at a remote switch. One <i>consider</i> step must be written for each location you want to check. Routing information is obtained from the BSR Application plan for the active VDN. |
|                               | <i>reply-best</i>           | to return data to another switch in response to a status poll   |
|                               | <i>queue-to</i>             | with the <i>best</i> keyword to queue calls to the best resource identified by the <i>consider</i> sequence.  |
|                               | <i>check</i>                | with the <i>best</i> keyword to queue calls to the best resource identified by the <i>consider</i> sequence if the resource meets certain conditions.   |

*Continued on next page*

Table 9-7. Vector commands and command elements  
 for multi-site BSR — *Continued*

| Commands and command elements |                      | Use this...  |
|-------------------------------|----------------------|--|
| Key word                      | <i>best</i>          | in <i>queue-to</i> , <i>check</i> , and <i>goto</i> commands that refer to the resource identified as best by a series of <i>consider</i> steps  |
| Conditional                   | <i>wait-improved</i> | to prevent calls from being queued to an additional split or skill—local or remote—when the reduction in Expected Wait Time isn't enough to be useful. "Wait improved" means that a call's EWT must be improved by a specific amount (a figure you specify in seconds) over its current EWT or DEFINITY ECS won't queue it to the additional split or skill. |
| User adjustment               | <i>adjust-by</i>     | control long-distance costs and limit trunk usage. Any time a vector polls a local or remote resource, you can increase the EWT returned by that resource by a preset amount. <sup>2</sup> You might want to set this adjustment to reflect factors such as the availability of tie trunks or agent expertise at remote locations.                           |

1. Since the *consider* command is designed to compare two or more resources, *consider* commands are typically written in sequences of two or more with the sequence terminating in a *queue-to best* step. This set of *consider* commands and a *queue-to best* step is called a *consider* series.
2. Of course, DEFINITY ECS doesn't increase the actual wait time in a split or skill. It only adjusts EWT in the calculations used to identify the "best" split or skill to which to queue a call.

## Interactions

---

- Agent Terminal Display  
If collected digits are forwarded with an interflowed call, the forwarded digits are displayed to the answering agent (unless they're overridden with newly collected digits).
- Best Service Routing (BSR)/LAI

Restrictions and interactions that apply to LAI also apply to BSR status poll and interflow calls. See the *DEFINITY® ECS Release 6 Call Vectoring/Expert Agent Selection (EAS) Guide* (555-230-521) or the [“Look-Ahead Interflow”](#) chapter in this manual for more information.

- BCMS

BCMS does not report accumulated in-VDN time.

BCMS does not log LAI attempts and therefore will not log BSR status polls, which are treated as LAI attempts.

- Call Vectoring

The following considerations apply to ALL vectors when BSR is enabled on your switch.

**route-to VDN:** If a call is routed to a new VDN, any “best” resource data defined by a series of consider steps in the previous VDN will be initialized (cleared)

**goto vector:** If a *goto vector* command is executed, any “best” resource data produced by a series of consider steps in the original VDN will remain with the call and can be used in the subsequent vector.

**best keyword:** The *best* keyword cannot be used as a replacement for split/skill in the following vector commands:

- *converse-on split/skill*
- *messaging split/skill*

The *best* keyword can be used in the following commands, but only with the conditionals listed:

- *goto step* or *goto vector* commands using the *expected-wait* or *wait-improved* conditionals
- *check* commands using the *unconditional*, *expected-wait*, or *wait-improved* conditionals

**Consider command:** Don't use other commands within a series of *consider* steps, since these may delay the execution of the series.

Splits or skills used in *consider* commands must be vector controlled.

**Converse command:** Collected digits forwarded with the call will be passed to VRU via the "digits" data passing type.

- Direct Department Calling

BSR will function when the considered splits use DDC call distribution. Once the best resource is determined, the actual call distribution will follow the split's DDC setting regardless of the BSR Available Agent Strategy. DDC may not be used as a BSR Available Agent Strategy.
- Expert Agent Selection

EAS is required to use the EAD-MIA or EAD-LOA Available Agent Strategy. EAS VDN skills (1st, 2nd, 3rd) can be used in *consider skill* commands.
- Facility Restriction Levels

The FRL applies to status poll and interflow calls in the same way it works with the "route-to number" command.
- ISDN

Best Service Routing and globally supported information transport are fully functional over ISDN PRI or ISDN BRI trunking facilities.
- Lucent Distributed Networking via QSIG - Manufacturers Specific Information (MSI)

BSR will not function with systems from other vendors (unless that vendor develops a corresponding capability that works with DEFINITY ECS).
- Multi-Split/Skill Queuing

A call may be queued up to 3 times by *queue-to* or *check* commands in the same vector. One vector may therefore contain up to 3 series of *consider* steps. Each series must be followed by a *queue-to best* step. Each consider series will select the best remote resource from the options you specify and queue the call to that resource.
- Network Access

BSR operates over public, private, or virtual private (for example, SDN) ISDN-BRI and -PRI networks that meet the criteria explained in ["Network requirements" on page 9-47](#). Best Service Routing requires that the network support transport of user-to-user data via MSI or UUI as a codeset 0 Information Element. The numbers administered on the BSR Application Plan form are expected to access VDNs via ISDN trunks.

Administration or call processing will not prevent access to other types of routing numbers, but BSR is only intended to support the types of applications described in this section. Attempts to use the BSR feature for any other purposes may not work.
- Operating Support System Interface (OSSI)

The new administration commands, conditionals, keywords and forms are available via OSSI.

- QSIG

LAI, BSR, and information forwarding function over QSIG trunk facilities if the remote locations are DEFINITY systems. BSR and information forwarding require R3V6.3 or later switch software.
- Redirection on No Answer (RONA)

Calls redirected to a VDN by RONA can be subsequently processed and BSR or LAI applications. When the RONA feature redirects a call to a VDN, any best resource data defined in a previous vector will be initialized (cleared).
- Service Observing

You can observe a call in BSR or LAI processing as long as the call is still connected through the local DEFINITY ECS. All current restrictions on Service Observing still apply.
- Transfer

If a call is transferred to a VDN, any best resource data defined in previous vector processing will be initialized (cleared). In fact, transferred calls do not forward any of the information that is forwarded with interflows (previously collected digits, In-VDN time, etc.).
- Trunk Access Code (TAC)

Use of routing numbers (status poll or interflow) that utilize TACs is not recommended since the required in-band outpulsing slows the setup operation significantly.
- VDN Override

VDN Override applies to the BSR Application Number and the Available Agent Strategy option assigned on the VDN form. It also applies to the VDN name forwarded via Information Forwarding. When a *consider* step is executed, the application number and available agent strategy assigned to the active VDN for the call will be used.
- VDN Return Destination

The best resource data for a call is initialized when the call first leaves vector processing and therefore will not be available should the call return to vector processing.
- VuStats

No enhancements have been added for BSR.

## Call Management System

Call Management System (CMS) allows you to collect and monitor ACD facilities and personnel. You can create reports on the status of agents, splits, trunks, vectors, and vector directory numbers. You can store historical CMS reports or display real-time reports at a terminal.

Unlike Basic Call Management System (BCMS), the CMS resides on an adjunct computer that connects to the switch via a data link. See [Figure 9-1](#) for a typical ACD CMS configuration.

This section describes how to administer the interface between DEFINITY and CMS. See *CentreVu Call Management System Release 3 Version 5 Administration* for more information on CMS.

### How to administer the DEFINITY/CMS Interface

#### Required forms

| Form   | Field                              | Page                  |
|--|------------------------------------|-----------------------|
| Feature-Related System Parameters                                    | ■ Adjunct CMS Release              | <a href="#">5-123</a> |
|  | ■ Automatic Call Distribution      |                       |
|  | ■ ACD Log-in Identification Length |                       |
|  | ■ Minimum Agent Login ID           |                       |
|  | ■ Password Length                  |                       |
| Processor Interface Data Module (R5si and later configurations only) | ■ All (for one CMS link)           | <a href="#">6-246</a> |
| Processor/Trunk Data Module (PDM)                                    | ■ All (for one CMS link)           | <a href="#">6-243</a> |
| X.25 Data Module (R5r and later configurations only)                 | ■ All (for one CMS link)           | <a href="#">6-249</a> |
| Processor Channel Assignment   | ■ All (for one CMS link)           | <a href="#">5-248</a> |
| Interface Links  | ■ All (for one CMS link)           | <a href="#">5-179</a> |
| Hunt Group   | ■ Measured                         | <a href="#">5-158</a> |
| Trunk Group (All)  | ■ Measured                         | <a href="#">7-115</a> |
| Vector Directory Number (VDN)  | ■ Measured                         | <a href="#">9-214</a> |
| Packet Gateway Board (PGATE) (R5r and later configurations only)     | ■ All                              | <a href="#">5-246</a> |

- Feature-Related System Parameters form — In ACD Log-in Identification Length, enter the number of digits the agent must dial to log into the ACD split. Enter the appropriate Adjunct CMS Release number.
- Processor Interface Data Module form — Assign a physical channel and maintenance extension. For the PDM data module, assign a digital line port. For the X.25 data module, assign DTE/DCE as **dte** and Baud Rate as **9600**.
- Processor Channel Assignment form — Enter the CMS link number from the Interface Links Form. Enter the appropriate Interface Channel and Remote Proc Chan. Leave the Machine ID field blank.
- Communication Interface Link form — Enter in Destination Digits the extension assigned to the PDM data module. Set the Prot field **bx25**. Set the DTE/DCE field to **dte**.
- Complete the form that applies (Hunt Group, Trunk Group, and VDN Forms) when the Measured field is set to either external or both. See the *DEFINITY Enterprise Communications Server Release 6 System Description Pocket Reference* for the maximum number of hunt groups, trunk groups, agents, and VDNs that can be measured.
- Packet Gateway (PGATE) form — Enter the board location.

## Considerations

---

CMS measurements may be inaccurate on calls to splits that intraflow to the attendant group.

## Interactions

---

None.

## Call Prompting

---

See the *DEFINITY Enterprise Communications Server Release 6 Call Vectoring/EAS Guide* for a detailed description of Call Prompting and its uses. The guide contains information that is critical to the effective and efficient use of this feature.

Call Prompting uses specialized vector commands to process incoming calls based on information collected from the caller or from an ISDN-PRI message. It can be used in various applications to better handle incoming calls. The following list gives a brief description of some Call Prompting applications.

- Automated Attendant — Allows the caller to enter the extension of the party that he or she would like to reach. The call is routed to that extension.
- Data In/Voice Answer (DIVA) Capability — Allows the caller to hear an announcement based on the digits that he or she enters, or to be directed to a hunt group or another system extension.
- Data Collection — Allows the caller to enter data that can be used by a host/adjunct to assist in call handling. This data, for example, may be the caller's account number.
- CINFO (Caller Information Forwarding) Routing — Allows a call to be routed based on digits supplied by the network in an ISDN-PRI message.
- Message Collection — Gives the caller the option of leaving a message or waiting in queue for an agent.

## How to administer Call Prompting

---

### Required forms

| Form                                  | Field  | Page                  |
|---------------------------------------|--|-----------------------|
| System Parameters<br>Customer-Options | ■ Vectoring (Prompting)  | <a href="#">5-277</a> |
|                                       | ■ Vectoring (CINFO)  |                       |
|                                       | ■ ISDN-PRI — for CINFO only  |                       |
|                                       | ■ This form describes other vectoring options that may be required depending upon the application. |                       |
| Feature-Related System<br>Parameters  | ■ Prompting Timeout  | <a href="#">5-123</a> |
| Vector Directory Number               | ■ All  | <a href="#">9-214</a> |

*Continued on next page*

**Required forms**

| Form                        | Field  | Page                  |
|-----------------------------|--|-----------------------|
| Announcements/Audio Sources | ■ Complete all fields for each extension that provides a Call Prompting announcement | <a href="#">5-26</a>  |
| Hunt Group                  | ■ Vector   | <a href="#">5-158</a> |
| Call Vector                 | ■ Complete a form for each Call Prompting vector                                     | <a href="#">9-207</a> |
| Station (multi-appearance)  | ■ Button/Feature Button Assignments - callr-info                                     | <a href="#">6-14</a>  |
| Attendant Console           | ■ Feature Button Assignments -callr-info   | <a href="#">5-35</a>  |

If Vectoring (Basic) is not enabled on the System-Parameters Customer-Options form, the Call Prompting feature cannot queue calls or make conditional checks based on queue or agent status, time of day, or day of week.

CINFO requires the AT&T Intelligent Call Processing (ICP) service, ISDN-PRI, and Vectoring (Prompting).

You can administer any display-equipped voice terminal or attendant console with a Caller Information CALLR-INFO button. The button displays digits collected for the last *collect digits* command.

You must have Call Vectoring software for CMS to use Call Prompting (with or without Call Vectoring) with CMS.

**Considerations**

Call prompting, with the exception of CINFO, competes with several features for ports on the call classifier - detector circuit pack or equivalent.

**Interactions**

The following interactions apply specifically to Call Prompting. For general Call Vectoring interactions that may affect Call Prompting applications see [“Call Vectoring” on page 9-63](#).

- Authorization Codes

If authorization codes are enabled, and a *route-to* command in a prompting vector accesses AAR or ARS, if the VDN's FRL does not have the permission to use the chosen routing preference, then the system does not prompt for an authorization code and the *route-to* command fails.

- CallVisor ASAI

ASAI-provided digits can be collected by the Call Vectoring feature via the *collect* vector command as dial-ahead digits. CINFO is passed to CallVisor ASAI.

- Hold

With the exception of CINFO, if a call is put on hold during the processing of a *collect* command, the command restarts, beginning with the announcement prompt, when the call is taken off hold. All dialed-ahead digits are lost. Similarly, if a call to a vector is put on hold, vector processing is suspended when a *collect* command is encountered. When the call becomes active, the *collect* command resumes.

- Inbound Call Management (ICM)

You can use Call Prompting to collect information that may later be used by an adjunct to handle a call.

- Transfer

If a call to a VDN is transferred during a *collect* command, the *collect* command restarts when the transfer is complete, and all dialed-ahead digits are lost. Similarly, if a call to a vector is transferred, vector processing is suspended when a *collect* command is encountered. When the transfer is complete, the *collect* command resumes. This is not true when a *collect* command collects CINFO digits. In this case vector processing is not suspended. Attendant extended calls do suspend vector processing in the same way as transferred calls.

## Call Vectoring

---

Call Vectoring processes incoming and internal calls according to a programmed set of commands. These commands, called vector commands, determine the type of processing that calls receive. For example, vector commands can direct calls to on-premise or off-premise destinations, to any hunt group, split, or skill, or to a specific call treatment such as an announcement, forced disconnect, forced busy, or delay. Vectors can queue or route calls based on a variety of different conditions.

There are many different applications for Call Vectoring. However, it primarily is used to handle the call activity of ACD splits/skills.

For more information about administering call vectoring, see [“Best Service Routing™” on page 9-44](#) and [“Look-Ahead Interflow” on page 9-98](#).

See the *DEFINITY Enterprise Communications Server Call Vectoring/EAS Guide* for a detailed description of Call Vectoring and its uses. The guide contains information that is critical to the effective and efficient use of this feature.

## How to administer Call Vectoring

---

### Required forms

| Form                                  | Field   | Page                  |
|---------------------------------------|---|-----------------------|
| System Parameters<br>Customer-Options | ■ Vectoring (Basic)   | <a href="#">5-277</a> |
|                                       | ■ Vectoring (G3V4 Enhanced)   |                       |
|                                       | ■ Vectoring (G3V4 Advanced Routing)   |                       |
|                                       | ■ Vectoring (ANI/II-Digits Routing)   |                       |
| Vector Directory Number               | ■ All   | <a href="#">9-214</a> |
| Announcements/Audio<br>Sources        | ■ Complete all fields for each extension that provides a vectoring announcement | <a href="#">5-26</a>  |
| Hunt Group                            | ■ Vector  | <a href="#">5-158</a> |
|                                       | ■ ACD   |                       |

**Required forms**

| Form                              | Field  | Page                  |
|-----------------------------------|--|-----------------------|
| Call Vector                       | <ul style="list-style-type: none"> <li>■ Complete a form for each vector</li> </ul>  | <a href="#">9-207</a> |
| Feature-Related System Parameters | <ul style="list-style-type: none"> <li>■ Vector Disconnect Timer</li> <li>■ Music/Tone on Hold</li> <li>■ Port</li> <li>■ Music (or Silence) on Transferred Trunk Calls</li> </ul> | <a href="#">5-123</a> |
| Vector Routing Table              | <ul style="list-style-type: none"> <li>■ All</li> </ul>  | <a href="#">9-219</a> |

Do not change a vector while it is processing calls since calls already in the vector could experience problems. Instead, add a new vector and change the VDN to point to the new vector.

You cannot enter a VDN extension in the fields listed in [Table 9-8](#).

**Table 9-8. VDN extension cannot be entered in these fields.**

| Form                        | Field  |
|-----------------------------|--|
| Announcements/Audio Sources | <ul style="list-style-type: none"> <li>■ Extension Number</li> </ul>   |
| Call Coverage Answer Group  | <ul style="list-style-type: none"> <li>■ Group Member Assignments</li> </ul>                                       |
| Call Coverage Paths         | <ul style="list-style-type: none"> <li>■ Coverage Point Assignments, other than the last coverage point</li> </ul> |

| Terminating Extension Group                | <ul style="list-style-type: none"> <li>■ Member Extensions</li> </ul>   |

You can enter a VDN extension in the following fields.

| Form                      | Field   |
|---------------------------|---|
| Abbreviated Dialing Lists |   |
| Call Coverage Paths       | <ul style="list-style-type: none"> <li>■ allow it as the last coverage point only</li> </ul>          |
| Hunt Group                | <ul style="list-style-type: none"> <li>■ Night Destination</li> </ul>                                 |
| Listed Directory Numbers  | <ul style="list-style-type: none"> <li>■ Night Destination</li> </ul>                                 |
| Trunk Groups              | <ul style="list-style-type: none"> <li>■ Night Destination</li> <li>■ Incoming Destination</li> </ul> |

You cannot enter a VDN extension as auxiliary data for the following buttons:

- Bridged Appearance (brdg-app)
- Data Call Setup (data-ext)

You can enter a VDN extension as auxiliary data for the following buttons:

- Remote Message Waiting Indicator (aut-msg-wt)
- Facility Busy Indication (busy-ind)
- Manual Message Waiting (man-msg-wt)
- Manual Signaling (signal)

## Interactions

---

- AP Demand Print
 

A VDN cannot be used as an argument to the feature access code for AP Demand Print.
- Attendant Control of Trunk Group Access
 

If a *route-to* step in a vector dials a controlled trunk group, vector processing continues at the next step.
- Attendant Recall
 

Attendant Recall to a VDN is blocked.
- AUDIX Interface
 

A *route-to* step in a vector may call the AUDIX extension. If a voice port can be seized to that adjunct, vector processing is terminated. The system sends a message to AUDIX requesting retrieval of messages for the originating extension (not the VDN).

AUDIX may also be accessed by the *queue-to main split* and *check-backup split* commands. Also, the messaging step may use an AUDIX hunt group in its operation.

- Authorization Codes

If authorization codes are enabled, and if a *route-to* command in a prompting vector accesses AAR or ARS and the VDN's FRL does not have the permission to utilize the chosen routing preference, then no authorization code is prompted for and the *route-to* command fails.
- Automatic Alternate Routing (AAR)/Automatic Route Selection (ARS)

Any *route-to* command in a vector can dial an AAR/ARS FAC followed by other digits. It cannot dial only the FAC.
- Automatic Callback

Automatic Callback cannot be used for calls placed to a VDN.
- Bridged Call Appearance

VDN extensions cannot be assigned to bridged appearance buttons. A *route-to* command to an extension with bridged appearances updates bridged appearance button lamps.
- Busy Verification of Terminals and Trunks

Busy verification of VDNs is denied and intercept tone is returned.
- Call Coverage

A VDN may be administered as the last point in a coverage path.
- Call Forwarding

Calls can be forwarded to a VDN. Calls placed by a *route-to* command to an extension that has call forwarding activated are forwarded.

An attendant or voice terminal with console permission cannot activation/deactivation call forwarding for a VDN.

An attendant or voice terminal with console permission cannot activation/deactivation call forwarding for a vector-controlled hunt group.
- Call Detail Recording

You can administer the Feature Related System Parameters form so that the VDN extension is used in place of the Hunt Group or Agent extension. This overrides the "Call to Hunt Group - Record" option of CDR for Call Vectoring calls.

If a vector interacts with an extension or group that has Call Forwarding All Calls active, normal Call Forwarding/CDR interactions apply.

For incoming calls to a VDN, the duration of the call is recorded from the time answer supervision is returned.

  - If answer supervision is returned by the vector, and the call never goes to another extension, then the VDN extension is recorded as the called number in the CDR record.

- If the call terminates to a hunt group, then the VDN, hunt group, or agent extension is recorded as the called number as per the administration described above.
- If the call terminates to a trunk, then the following two CDR records are generated:
  - An incoming record with the VDN as the called number and the duration from the time answer supervision was provided to the incoming trunk.
  - An outgoing record containing the incoming trunk information as the calling number and the dialed digits and the outgoing trunk information as the called number.

Outgoing vector calls generate ordinary outgoing CDR records with the originating extension as the calling number.

No Ineffective Call Attempt records are generated for Call Vectoring *route-to* commands that are unsuccessful.

- Call Detail Recording — Account Code Dialing

If a *route-to number* command in a vector specifies an CDR account code, vector processing continues at the next step.

- Call Park

Calls cannot be parked on a VDN.

- Call Waiting Termination

If an extension is busy and has call waiting termination administered, the *route-to with cov n* operation is considered unsuccessful and vector processing continues at the next step. *Route-to with cov y* is successful (call will wait) and vector processing terminates.

- Class of Restriction

Each VDN in the system has a COR associated with it. This VDN COR is used to determine the calling permissions/restrictions, the AAR/ARS PGN, and the priority queuing associated with a vector.

- Code Calling Access

A VDN cannot be used as the argument to the code calling access feature access code.

If a *route-to number* command in a vector specifies the code calling feature access code, vector processing continues at the next step.

- Conference

A call to a VDN can be included as a party in a conference call only after vector processing terminates for that call.

- Data Restriction

Music will play on calls from data restricted extensions when the call receives music as the result of a wait-time vector step.

- Facilities Restriction Level

If a *route-to* command dials an external number via AAR/ARS, the FRL associated with the VDN COR is used to determine the accessibility of a routing preference in an AAR/ARS pattern.
- Facility Busy Indication

The facility busy lamp indication for a VDN is always off. A facility busy button may be used to call a VDN.
- Facility Test Calls

If a *route-to number* command in a vector specifies a Facility Test Call, vector processing continues at the next step.
- Forced Entry of Account Codes

If a COR requiring entry of account codes is assigned to a VDN, the *route-to number* commands executed by the associated vector are unsuccessful and vector processing continues at the next step.
- Individual Attendant Access

A call sent to an attendant by a *route-to number* command can wait in the attendant priority queue. The call is removed from vector processing.
- Integrated Directory

VDN names and extensions are not available in the Integrated Directory feature.
- Intercept Treatment

A VDN cannot be used for Intercept Treatment.
- Inter-PBX Attendant Calls

A *route-to number* command in a vector can dial the Inter-PBX Attendant. If the call attempts to access a controlled trunk group, vector processing continues at the next step.
- Intraflow and Interflow

The functionality of intraflow and interflow may be obtained using the *check-backup split* and *goto* Call Vectoring commands.

Calls may intraflow from an ACD split which is not vector-controlled into one that is vector-controlled.
- Leave Word Calling

LWC messages cannot be stored, canceled, or retrieved for a VDN.
- Night Service

A VDN can be administered as a night service destination.

*Route-to* commands that route to destinations with night service activated redirect to the night service destinations.
- Priority Calling

A VDN cannot be used with the priority calling access code. Intercept tone is supplied to the user. If a *route-to number* in a vector specifies the priority calling access code, vector processing continues at the next step.

- Property Management System Interface

VDNs cannot be used with the following features and functions: Message Waiting Notification, Check-In, Check-Out, Room Status, and Automatic Wakeup.

- Recorded Announcement

The first announcement extension, second announcement extension, first announcement delay, second announcement delay, and recurring second announcement do not exist for a vector-controlled hunt group.

- Redirection on No Answer

If an ACD split/skill or Direct Agent call is not answered after an administered number of rings, RONA can redirect that call to a VDN for alternate treatment.

- Ringback Queuing

External call attempts made via *route-to* commands with coverage no are not queue via Ringback Queuing when all trunks are busy. External call attempts made via *route-to* commands with coverage yes are.

- Send All Calls

If the destination of a *route-to with coverage no* command has the Send All Calls feature active, calls are not redirected. If there is an idle appearance, the call terminates and vector processing stops. If not, vector processing continues at the next step.

If the Send All Calls button is pressed after a vector call is terminated, button activation is denied.

- Time of Day Routing

Since a *route-to number* command in a vector can specify the AAR or ARS access codes, the TOD routing algorithm can be used to route the call.

- Timed After Call Work (ACW)

A Timed ACW interval can be assigned to a VDN.

- Timed Reminder

The attendant Timed Reminder is not available for calls placed, transferred, or extended to a VDN. Vectoring causes all other timers to be ignored.

- Transfer

Calls can be transferred to a VDN.

- Traveling Class Mark

A TCM is sent when a *route-to* command dials a seven-digit ETN or 10-digit DDD number via AAR/ARS. This TCM is the FRL associated with the VDN COR.

## Expert Agent Selection

---

See the *DEFINITY Enterprise Communications Server Release 6 Call Vectoring/EAS Guide* for a detailed description of Expert Agent Selection. The guide contains information that is critical to the effective and efficient use of this feature.

Use Expert Agent Selection (EAS) to route incoming Automatic Call Distribution (ACD) calls to the agent who is best qualified to handle the call, that is, the agent with the specialized skills or experience required to best meet the caller's needs.

In addition, EAS provides the following capabilities:

- You assign all agent functions to the agent login ID and not to a physical voice terminal. Therefore, EAS agents can login to and work at any voice terminal in the system.
- Using the agent login ID, a caller places a call directly to a specific agent. These calls can be treated and reported as ACD calls.

EAS ensures the best possible service to the caller.

## How to administer EAS

---

### Required forms

| Form                                  | Field                                   | Page                  |

*Continued on next page*

**Required forms — Continued**

| Form                              | Field   | Page                  |
|-----------------------------------|---|-----------------------|
| CDR System Parameters             | <ul style="list-style-type: none"> <li>■ Record Called Agent Login ID Instead of Group or Member</li> </ul>   | <a href="#">5-63</a>  |
| Call Vector                       | <ul style="list-style-type: none"> <li>■ All</li> </ul>   | <a href="#">9-207</a> |
| Feature-Related System Parameters | <ul style="list-style-type: none"> <li>■ Expert Agent Selection (EAS) Enabled</li> <li>■ Minimum Agent-LoginId Password Length</li> <li>■ Direct Agent Announcement Extension/Delay</li> <li>■ Message Waiting Lamp Indicates Status For</li> </ul> | <a href="#">5-123</a> |

- 
1. If the Message Center field is set to AUDIX on the Hunt Group form, the Skill and ACD fields must be set to y, but the Vector field can be set to either y or n.
- 

EAS must be both optioned on the System Parameters Customer-Options form, and enabled on the Feature-Related System Parameters form. Once EAS is optioned, you can complete most of the EAS-related administration prior to enabling the feature.

When EAS is optioned on the System-Parameters Customer-Options form, Skill Hunt Groups replace splits. In addition, help messages, error messages and field titles change from "Split" to "Skill" on various forms.

Any EAS agent Login ID must be part of the station numbering plan.

Physical aspects of the voice terminal, such as the set type and button layout, are associated with the voice terminal and not the Login ID. On the Station form with the EAS featured optioned, when a work-mode button is selected, no "Gp" information can be entered. The assist and queue status buttons require that "Group" be entered.

**How to administer Direct Agent Announcement**

Direct Agent Announcement (DAA) enhances Direct Agent Calling capabilities for CallVisor Adjunct-Switch Application Interface (ASAI) and Expert Agent Selection (EAS). It plays an announcement to Direct Agent callers waiting in a queue. The following forms should be administered for DAA.

You must also have enabled either Expert Agent Selection (EAS) or ASAI Adjunct Routing (or both).

### Required forms

| Form                                  | Field                                 | Page                  |

### Detailed administration for EAS

In general, EAS uses vectors to route calls to agents with the required skills. To administer EAS you must:

- Assign skills to VDNs on the Vector Directory Number form.
- Create vectors that will route a call to the correct skill.
- Assign skills with priority levels to agents on the Agent Login ID form.

### VDN administration

You can administer up to three VDN skill preferences on the Vector Directory Number form in the 1st Skill, 2nd Skill and 3rd Skill fields. These fields indicate the skills that are required to handle calls to this VDN. All of the VDN skills on the VDN form are optional. For example, only the first and third, or only the second and third VDN skills might be assigned. Vector steps can then refer back to these fields to route calls. For example, *queue-to main skill 1st* routes calls the skill administered as 1st on the VDN form.

### Vector administration

When a call routes to a VDN, the VDN directs the call to the vector that is specified on the Vector Directory number form. The vector then queues the call to the skill specified in a vector step. You can write vectors that route calls either to specific skill numbers or to the skill preferences administered on the Vector Directory Number form.

## Agent administration

Assign skills to each agent. In addition, assign a skill level to each skill for the agent. When a vector routes incoming calls to a skill, the call is delivered to an available agent with the skill assigned. If no agents are available, the call is queued until it can be answered by an agent who has the skill required to handle the call.

## Detailed description

### Call distribution

The call distribution method and Call Handling Preference administration determine which agent will receive an incoming call.

#### Call Distribution Method

EAS can use either Uniform Call Distribution (UCD) or Expert Agent Distribution (EAD) routing as the call distribution method. Both methods use the Most-Idle Agent (MIA) algorithm to route calls. The MIA algorithm creates a queue of agents who are available to receive calls. With UCD routing, the queue is a single list of all available agents. When an agent becomes available, he or she is added to the bottom of the list. With EAD routing, the MIA queue is maintained by agent skill level. When an agent becomes available he or she is added to the bottom of the list of agents who have this skill assigned at the same level. Thus when a new call arrives, it is delivered to an available agent at the highest level (most expert).

#### Call Handling Preference administration

Call Handling Preference administration on the Agent Login ID form can route calls based either on greatest need or on agent skill level.

[Table 9-9](#) summarizes how a call is routed based on greatest need or agent skill level administration with either UCD or EAD distribution.

**Table 9-9. Call Handling Preference Call Distribution**

|  | EAD with Skill Level  | EAD with Greatest Need  | UCD with Skill Level  | UCD with Greatest Need  |
|--|---|---|---|---|
| Agents are available. When a new call arrives it is delivered to:                                  | Most-idle agent with the highest skill level for the calls' skill.                        | Most-idle agent with the highest skill level for the call's skill.  | Most-idle agent with the call's skill.  | Most-idle agent with the call's skill.                              |
| Agents are not available, calls are in queue. When an agent becomes available, he or she receives: | Highest priority oldest call waiting for agent's highest level skill with calls in queue. | Highest priority oldest call waiting for any of the agent's skills. | Highest priority oldest call waiting for the agent's highest level skill with calls in queue. | Highest priority oldest call waiting for any of the agent's skills. |

### MIA Across Splits/Skills

In addition, both UCD and EAD can be used in conjunction the MIA Across Splits/Skills option. With MIA Across Splits/Skills, when an agent answers a call from any skill, the agent is removed from the MIA queue for all the skills he or she is logged into.

See, [“Automatic Call Distribution” on page 9-25](#) for more information about UCD, EAD, and MIA Across Splits/Skills.

### Additional Agent Login ID Capabilities

The following capabilities are also associated with agents' login IDs.

- Auto-Answer — When EAS is optioned, auto answer settings can be assigned to agents on the Agent LoginID form. An agent's auto answer setting will apply to the station where the agent logs in. If the auto answer setting for that station is different, the agent's setting overrides the station's.
- Calls — to call an EAS Agent, the caller dials the Login ID extension. The call is extended to the physical extension where the agent with that Login ID is logged in. Calls to the Login ID reach the agent independent of the voice terminal the agent is currently using. For example, when agents use multiple phones because they have multiple offices or rotate desks, login IDs allow these agents to be reached independent of their current location.

- Name — calls to the Login ID display the name associated with the Login ID and not the name associated with the voice terminal. This is also true for calls made from a voice terminal with an agent logged in.
- Coverage — when the agent is logged out, or when calls go to coverage because the agent is busy, or does not answer, calls to the Login ID go to the coverage path associated with the agent and not the voice terminal. When an agent is logged out, calls go to the agent's busy coverage destination.
- Restrictions — calls to the Login ID or from the agent use the restrictions associated with the agent and not the voice terminal.

Voice terminals are fully functional when an agent is not logged in. The restrictions, coverage, and name revert to the voice terminal administration when the agent logs out.

## Direct Agent Calling

Calls to an agent's Login ID are treated as Direct Agent calls if the caller and the agent have the "Direct Agent Calling" class of restriction. Direct Agent calls can be originated by stations or trunks. If the caller or agent does not have the proper COR, the call is treated as a normal non-ACD (personal) call.

Direct Agent Calls are treated as ACD calls. For example they receive zip tone answer, queuing, after call work and are measured by BCMS and CMS.

Any of the agent's skills can be his or her Direct Agent skill. When greatest need is optioned as the Call Handling Preference, the agent will always get Direct Agent calls before any skill calls. This is because Direct Agent calls have a higher priority than skills calls. However, when skill level is optioned as the Call Handling Preference, the agent will get direct agent calls first only if the direct agent skill has the agent's highest skill level. Otherwise calls from a skill with a higher level will be distributed before Direct Agent calls. If the Direct Agent skill and another skill are the same skill level, the agent will always receive Direct Agent calls before the other skill calls because Direct Agent calls have a higher priority.

A *route-to* vector command with an EAS Login ID as the destination is treated as a Direct Agent call if the VDN and agent have the COR and the Direct Agent field is set to "y".

## Considerations

---

Station User records cannot be shared between TTI ports and EAS LoginID extensions. This causes a reduction in the number of possible EAS LoginID extensions allowed by the System depending on the number of administered TTI ports. For example, if 2,000 TTI ports are administered, the maximum number of allowable EAS LoginIDs is reduced by 2,000.

EAS agent Login IDs are also tracked for personal calls. CMS uses the first skill an EAS Agent is logged into to track personal calls. If the first logged-into skill is unmeasured, CMS credits the agent Login ID with the personal call, but no skill hunt group is credited with the personal call.

The system can have either splits or skill hunt groups but not both simultaneously. Non-ACD hunt groups can exist with either splits or skill hunt groups. Skill hunt groups are required when using EAS.

## Interactions

---

Unless otherwise specified, the feature interactions for skill hunt groups are the same as for vector-controlled splits.

- Abbreviated Dialing  
Abbreviated dialing can be used to log in/out EAS agents. Abbreviated dialing lists/buttons can only be administered for stations.
- Add/Remove Skills  
In the EAS environment, agents have the ability to add and remove skills during a login session by dialing a FAC. Other voice terminal users with console permissions can add or remove an agent's skill on behalf of the agent. (Note that the ability to add and remove skills depends on whether a user has a class of restriction (COR) that allows adding and removing skills.)
- Administration Without Hardware  
EAS Login ID extensions are extensions without hardware. Login ID extensions require space in the dial plan.
- Agent Work Mode States  
With EAS, agents can only be in a single work mode at any one time for all their skills.
- Assist  
The Assist feature can be used with a skill hunt group (for example, where there is one supervisor per skill hunt group). When assist is selected, a call is placed to the supervisor associated with the skill for the active call.
- AUDIX  
Calls to the EAS agent Login ID can cover to AUDIX.
- Auto-Available Splits  
If a skill hunt group is administered as an Auto-Available Skill (AAS) the EAS Login IDs assigned to this skill must also be administered as Auto-Available. When the switch reinitializes, these Login IDs are automatically logged in with the Auto-In work-mode. If any switch features attempt to change the work-mode to anything except to Auto-In, this attempt is denied. This feature is not intended for human agents.

- Automatic Answering with Zip Tone

The Automatic Answer option can only be administered for a physical extension.
- Call Forwarding

Skill hunt groups (since they are vector-controlled) cannot be call forwarded. EAS agent Login IDs cannot be forwarded, but the physical extension where the EAS agent is logged in can be forwarded.
- Call Park

Calls cannot be parked on the skill hunt group extension.
- Call Pickup

Skill hunt group extensions and EAS Login ID extensions cannot be members of a call pickup group.
- Class of Restriction (COR)

Skill hunt groups do have a class of restriction. This is used if the skill hunt group extension is called directly.

The COR for an EAS agent Login ID overrides the physical extension's COR of the voice terminal an EAS agent logs into.
- Class of Service (COS)

EAS agents do not have a COS associated with their Login ID. Therefore, the COS of the voice terminal is not affected when an EAS agent logs into that terminal.
- Directed Call Pickup

An EAS agent can use the Directed Call Pickup feature to pick up a call and/or have his or her calls picked up by another terminal user. The Class of Restriction of the agent will override the Class of Restriction of the station where the agent is logged in.

If both the station's COR and the logged-in agent's COR allow the call to be picked up using Directed Call Pickup, the user picking up the call can use either the station's extension or the agent's loginID.
- Displays - Voice Terminal

When an EAS agent logs in, the display for originators who call the Login ID shows the Login ID and agent name (as administered via the Agent Login ID form). Calls that the agent originates show the Agent Login ID and agent name at the receiving terminal's display. However, the user can display the name of the physical terminal where the EAS agent is logged in. To do this, the user must be active on a call with the agent, and must have a terminal with an alphanumeric display and an inspect button. When the inspect button is pressed during a call to or from the EAS agent, the physical terminal name of the agent is displayed.

Calls to the physical extension show the physical extension's number and name on the originator's display.

- Leave Word Calling

EAS agents can retrieve LWC messages left for the Login ID of the agent using the message retrieval button.
- Look Ahead Interflow

VDN skills are not sent to another ACD/PBX when a call interflows using Look Ahead Interflow. If skills have the same meaning on both ACDs, then a Look Ahead Interflow command to a VDN with the same skills assigned can provide a mapping of the skills.
- Message Waiting Lamp

The Message Waiting Lamp by default tracks the status of messages waiting for the logged in EAS agent LoginID rather than messages for the physical terminal. The operation of the Message Waiting Lamp can be changed so that it tracks the status of messages waiting for the physical terminal where the agent is logged in. See [“Feature-Related System Parameters” on page 5-123](#) for more information.
- Queue Status Indications

Physical extensions can be administered with Queue Status Indicator buttons and lamps for skill hunt groups. Queue Status Indicators can be administered for all skills needed by agents using that physical extension, given that enough buttons are available.
- Service Observing

The Service Observing feature is activated in the EAS environment by dialing either the physical extension of the terminal where an EAS agent is logged in or the Login ID of the agent.
- VuStats

VuStats displays can show an agent’s skill assignments and can show some measurements by skill.

## **Inbound Call Management**

---

Inbound Call Management (ICM) allows you to integrate DEFINITY features with host-application processing and routing, and automate delivery of caller information to agents' displays. You can create a sophisticated system to handle inbound calls for applications such as telemarketing and claims processing.

To implement ICM, you integrate DEFINITY features such as Automatic Call Distribution (ACD), Expert Agent Selection (EAS) Call Vectoring, Direct Agent Calling, and Call Prompting with an application on a host processor. The host application, or adjunct, can be a CallVisor/PC, CONVERSANT voice system, Telephony Services Server serving a local-area network, or a vendor application using the CallVisor Adjunct/Switch Applications Interface (ASAI). A CallVisor ASAI link between the switch and adjunct allows the adjunct to control incoming call processing and routing.

In addition, you can automate ACD agent terminal displays and associate them with new and transferred calls, and assist calls to a supervisor. You can display incoming call information such as Calling Party Number (CPN), Billing Number (BN), and Dialed Number Identification Service (DNIS). Or, you can set up the adjunct to retrieve caller information from a database and display it on a particular agent's screen, based on the service dialed.

See ["Detailed description" on page 9-83](#) for more information on applications. See *DEFINITY Communications System Generic 3 CallVisor ASAI Planning* for information on vendor application partners.

### **How to administer ICM**

---

Display the System-Parameters Customer-Options and ensure that the ACD option is enabled. If you are using CallVisor ASAI or Call Vectoring, ensure appropriate ASAI Capability Groups options or the Vectoring (Basic) and/or Vectoring (Prompting) options are enabled.

### Required forms

| Form                                  | Field                             | Page                  |
|---------------------------------------|-----------------------------------|-----------------------|
| System-Parameters<br>Customer-Options | ■ ACD                             | <a href="#">5-277</a> |
|                                       | ■ Vectoring (Basic)               |                       |
|                                       | ■ Vectoring (Prompting)           |                       |
|                                       | ■ ASAI Capability Groups          |                       |
| Trunk Group (ISDN-PRI)                | ■ Per Call CPN/BN                 | <a href="#">7-219</a> |
| Hunt Groups                           | ■ Group Type                      | <a href="#">5-158</a> |
|                                       | ■ ACD                             |                       |
|                                       | ■ Queue                           |                       |
|                                       | ■ Vector                          |                       |
|                                       | ■ Measured                        |                       |
|                                       | ■ Supervisor Extension            |                       |
|                                       | ■ Controlling Adjunct             |                       |
|                                       | ■ Queue Length                    |                       |
|                                       | ■ Calls Warning Threshold         |                       |
|                                       | ■ Calls Warning Port              |                       |
| ■ Time Warning Threshold              |                                   |                       |
| ■ Time Warning Port                   |                                   |                       |
| Class of Restriction                  | ■ Direct Agent Calling (optional) | <a href="#">5-72</a>  |
| Call Vector                           | ■ All                             | <a href="#">9-207</a> |
| Station (agent stations)              | ■ All                             | <a href="#">6-28</a>  |
| Agent LoginID (EAS only)              | ■ All                             | <a href="#">9-193</a> |

- **Trunk Group form** — Administer the Per Call CPN/BN field for the appropriate ISDN-PRI trunk group. The corresponding information is sent with a call-offered event report to the adjunct.
- **Hunt Group form** — Complete a Hunt Group form for each split that the ICM adjunct will monitor.

- **Call Vector** form — If you are using Call Vectoring, an ASAI link interface extension number is required for **adjunct routing** vector commands. This extension is the same as the one you enter on the Station form.

See [“Automatic Call Distribution” on page 9-25](#), [“Call Vectoring” on page 9-63](#), [“Call Prompting” on page 9-60](#) and [“CallVisor Adjunct-Switch Application Interface” on page 4-250](#) and any other features you are implementing for ICM for additional administration requirements.

## Detailed description

### Applications

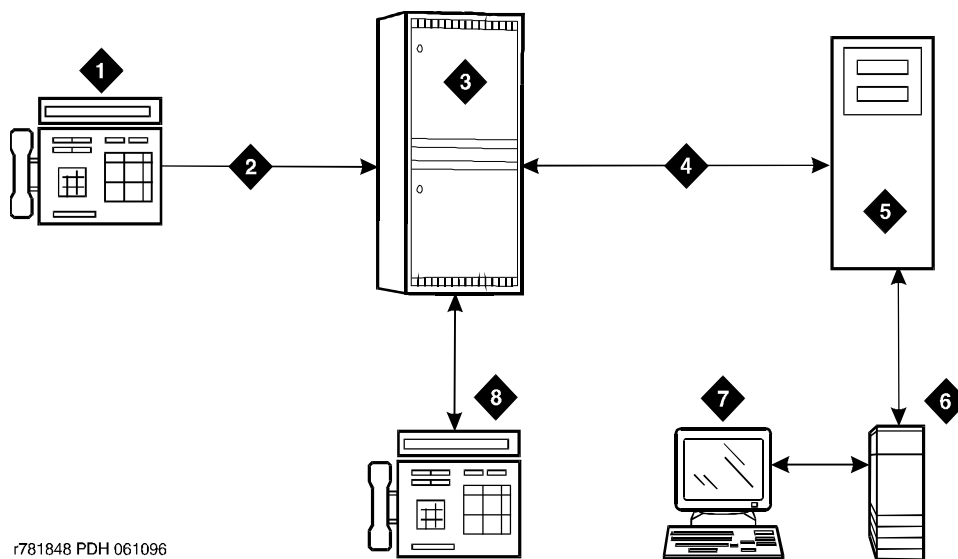

The following are some typical ICM applications:

- The system passes calling party/billing number (CPN/BN) information and the call is routed to an adjunct application for screen pop and supervisory transfers, with screen duplication.
- The system sends to the adjunct application both caller and prompter information about all incoming calls to a particular number. According to caller information in a database, the application directs the switch to route the call. For example, the call could be routed to a preferred agent, to best customer treatment, or to accounts receivable.
- The system uses Call Prompting to obtain a customer account number and then passes this information to the adjunct for call routing or screen pop.
- The system connects the caller to a voice response unit (VRU), along with caller CPN/BN and DNIS information. The caller then interacts with the VRU to direct how the call is handled. The system can verify a caller's identity and provide access to database information such as claims status or account balance.
- With Direct Agent Calling, an adjunct application can transfer a call to a specific ACD agent and have the call treated as an ACD call and tracked on Call Management System (CMS).
- An adjunct application can attach information used by another application to an ICM call using User-to-User Information fields. The adjunct transfers the call, along with the application-specific information, over primary rate interface (PRI) trunk to a CallVisor ASAI application at another switch. For example, an application at one switch can determine a caller's account or claim number and pass this information to a special list on another switch, where an application will transfer the call.

See *DEFINITY Communications System Generic 3 CallVisor ASAI Technical Reference* for additional application scenarios.

### Agent data screen delivery applications

You can use the CONVERSANT voice system to deliver appropriate display data about callers to agents. You can pass information such as CPN/BN, DNIS, and Lookahead Interflow information, digits collected from Call Prompting, and which agent is selected to a CONVERSANT voice system. CONVERSANT delivers the appropriate data screen to the agent who takes the voice call. CONVERSANT can transfer or duplicate data screens for transferred or conferenced calls. A simplified configuration of this type of application is shown in [Figure 9-2](#). CONVERSANT VIS is used as an example — other adjunct processors have similar capabilities but should be verified for a particular application. If the host supports ASAI, CONVERSANT is not needed.

r781848 PDH 061096

#### Figure Notes

- |                   |                         |
|-------------------|-------------------------|
| 1. Voice terminal | 5. CONVERSANT           |
| 2. ISDN-PRI       | 6. Host                 |
| 3. DEFINITY ECS   | 7. Agent data terminal  |
| 4. ASAI           | 8. Agent voice terminal |

Figure 9-2. Simplified ICM Configuration for Data Screen Delivery

General processing for this type of application occurs as follows.

1. The CONVERSANT voice system or host requests notification for events such as call offered, call ended, call connected, call dropped, call transfer, and alerting.
2. The switch notifies CONVERSANT with event reports when the call arrives, when the agent answers, when the call drops, and so on.
3. CONVERSANT sends information to the host application so that it can send a data screen to the agent's data terminal.

CONVERSANT can determine when a call drops before being answered and can track abandoned calls or use CPN/BN information for callbacks.

### **Integration with speech processing adjuncts**

ICM can be used to provide integration with VRUs. The advantages of using ICM with CallVisor ASAI in addition to tip/ring interfaces are as follows:

- Data-screen integration is provided on transferred calls.
- Answer notification is provided on internal calls (CallVisor ASAI capabilities let you know what happens with the call).
- ISDN network information such as CPN/BN and DNIS is delivered to agents (call prompting for this information is not necessary).

A simplified configuration of this application is shown in [Figure 9-3](#).

r781849 PDH 061096

### Figure Notes

- |                   |                         |
|-------------------|-------------------------|
| 1. Voice terminal | 5. Speech processor     |
| 2. ISDN-PRI       | 6. Tip/ring lines       |
| 3. DEFINITY ECS   | 7. Agent voice terminal |
| 4. ASAI           | 8. Agent data terminal  |
|                   | 9. Host                 |

Figure 9-3. Simplified ICM Configuration for Speech Processor Integration

General processing for this type of application occurs as follows

1. The switch uses CallVisor ASAI link to pass incoming call information to the CONVERSANT voice system.
2. The ACD split or EAS skill on the switch distributes the call to an available voice line.
3. After digits are collected via a DTMF keypad, CONVERSANT transfers the call back to an ACD split or specific agent on the switch via CallVisor ASAI.
4. If the call is transferred to a split agent, the switch uses CallVisor ASAI link to pass an event report on which agent receives the call.
5. CONVERSANT forwards the agent ID to the host application, which delivers a data screen to the agent.

6. Agents can display collected digits on their data terminals. Except for the dialed number, information from a CONVERSANT voice system cannot be carried with the call and displayed on a voice terminal. For example, digits collected in a CONVERSANT voice system adjunct cannot be passed to the switch for display.
7. If the collected digits are the extension where the call is being routed, these routing digits are passed to the switch as the destination in the CallVisor ASAI third-party make-call request. CONVERSANT uses the request to set up various types of calls.

## Host/adjunct call routing

The host or CONVERSANT adjunct uses incoming call information to route the call to a split, vector, particular agent, or location off the switch. CONVERSANT can also direct the system to handle the call as a priority call. Routing can be based on the caller's area code or country code, digits collected via Call Prompting, dialed number or service, agent availability, or information in a customer database.

To implement this type of call routing, make sure that calls come into a vector that contains an *adjunct routing* vector command. This command causes the switch to initiate the route CallVisor ASAI capability. Vector processing occurs while the caller waits. A default split or answering position can also be specified in the vector, in case CONVERSANT does not respond in the administered amount of time (determined by the announcement/wait steps). Announcement and wait steps are needed to give the host time to respond.

For adjunct routing, if the call queues to a split or leaves vector processing, a route-end request is sent to CONVERSANT.

## Considerations

---

Administrators and planners must consider:

- ICM traffic
- Rated switch capacity
- CallVisor ASAI interface traffic
- Rated capacity of the adjunct application processor

Lucent Technologies Technical Design Center can provide planning assistance.

In addition, you must consider the following:

- CallVisor ASAI and BX.25 CPN/BN-ANI are not supported simultaneously.
- Direct Agent Calls (DACs) are allowed only if the caller and the receiving agent have a Class of Restriction (COR) that allows Direct Agent Calling.

- DACs cannot go through vectors.
- DACs cannot be made over a DCS link. If the receiving agent is not an internal extension, the call is denied.

## Interactions

---

- Call Prompting  
Digits collected by Call Prompting are passed with current call information to a CONVERSANT adjunct.
- Direct Agent Calling  
Direct Agent Calling allows an adjunct to direct a call to a particular ACD agent and have the call treated as an ACD call. Calls that enter the switch as ACD calls and are routed to a particular agent via adjunct routing, or are transferred via a third-party make-call request, are treated as ACD calls for the duration of the call. See [“Automatic Call Distribution” on page 9-25](#) for more information on Direct Agent Calls.
- Priority Calling  
CallVisor ASAI allows both Priority Calling and Direct Agent Calling for the same call.

## Information Forwarding

---

Whenever DEFINITY ECS interflows a call over ISDN trunk facilities (for example, PRI or BRI) by means of a *route-to* (with Lookahead Interflow active), *queue-to best*, or *check best* command, the following information is sent with the call via user-to-user information transport (via UUI IE or QSIG MSI) and can be used by adjuncts or displayed at the receiving switch:

- ASAI user information
- the name of the active VDN (LAI DNIS)
- other LAI information (a time stamp showing when the call entered the current queue, the call's priority level in its current queue, and the type of interflow)
- any collected digits (this does not include dial-ahead digits). These digits are available for processing at remote vectors and/or displaying to the agent.
- the number of seconds that the call has already spent in vector processing (called "in-VDN time")
- Universal Call ID (UCID)

### NOTE:

Sending of information depends on priority settings and activated features.

Forwarding of the last three items, collected digits, in-VDN time, and UCID is new in DEFINITY ECS G3V6.3.

## Interactions

---

- Best Service Routing  
Best Service Routing-related data is sent in addition to the associated ASAI user data and UCID. For more information, see *Call Vectoring/Expert Agent Selection* (555-230-521).

## User-to-User Information Transport

---

In the past, lookahead interflow transported the LAI Information Element (IE) in codeset 6 or 7, which functioned over non-QSIG private networks, but only over certain public networks.

Now, call centers can transport application information (including the LAI information) over many more public ISDN networks because of using User to User Signaling (UUS) Supplementary Services that incorporate user-to-user information (codeset 0 UUI). Information passes over QSIG private networks using manufacturer specific information (MSI—codeset 0 Facility IE) in various messages.

This feature

- enables multiple DEFINITY applications to share the contents of the UUI IE or MSI
- allows for backwards compatibility with pre-R6.3 DEFINITY software.

For more information about how to administer user-to-user information transport, see the Information Forwarding chapter in the *Call Vectoring/Expert Agent Selection (EAS)* guide, 555-230-521.

## Support of new features

Information transport supports these call center features:

- Enhanced Look-Ahead Interflow—routes calls from busy call centers to centers that are less busy.

### NOTE:

Look-Ahead Interflow information can be forwarded using information transport or the traditional codeset 6/7 LAI IE.

- Best Service Routing—routes calls to the best available agents wherever they are.
- Universal Call ID—provides a means to collect and trace call data from multiple call centers.

For information about enhanced lookahead interflow, see [Look-Ahead Interflow on 9-98](#). For information about Best Service Routing, see [Best Service Routing™ on 9-44](#). For information about Universal Call ID, see [Universal Call ID on 9-130](#).

## Administering User-to-User Information Transport

---

This section outlines the procedure to administer your incoming and outgoing trunk groups to send user data over your network. Before administering the trunk group, review these guidelines:

- If you are using shared UUI (any Supplementary Service other than **b**), then you must administer the UUI *Treatment* for the trunk groups (both outgoing and incoming at the remote end) as **shared**. Use this option when you want to forward information to R6.3 or later DEFINITY switches in non-QSIG networks.
- With QSIG (Supplementary Service **b**), you need to administer Shared UUI to include ASAI user information with MSI transport. If UUI *Treatment* is the default **service-provider**, DEFINITY forwards the ASAI user data (if provided) in a non-shared codeset 0 UUI IE while forwarding the other data as MSI.

 **NOTE:**

You do not need to complete this procedure if you do not intend to send user data over the network.

[Table 9-10](#) lists the form and fields needed to administer information transport on trunk groups.

**Table 9-10. Forms needed to administer information transport**

| Form needed                   | Fields needed                      | Why is this field needed?  | Is field optional?   | Page   |
|-------------------------------|------------------------------------|--|--|--|
| ISDN Trunk Group (BRI or PRI) | UUI IE Treatment                   | Set field to either <ul style="list-style-type: none"> <li>■ <b>shared</b> (for trunk groups connected to DEFINITY R6.3 or later if you want shared data).</li> <li>■ <b>service-provider</b> (for trunk groups connected to pre-DEFINITY R6.3 switches or if you want service provider functionality).</li> </ul> | Y<br><br>However, this field cannot be blank.  | for BRI <a href="#">7-208</a><br><br>for PRI <a href="#">7-233</a> |
|                               |                                    | Maximum Size of UUI IE Contents  | Set according to what the network supports. 128 (default) is recommended for private networking. | Y<br><br><a href="#">7-208</a><br><a href="#">7-233</a>            |
|                               | Shared UUI Feature Priority fields | Set the priority for each type of user data (such as UCID, ASAI, and other application information). Only needed for non-QSIG trunk groups.  | Y<br><br>If blank, info not sent.  | <a href="#">7-211</a><br><a href="#">7-236</a>                     |

To administer Shared UUI information transport:

1. In the command line, enter **change trunk-group n** and press RETURN.  
The Trunk Group administration form comes up. *n* is the number of the trunk group you want to administer.
2. Go to page 2 of the form.
3. In the UUI Treatment field, enter **shared** and press RETURN.

 **CAUTION:**

*If the trunk group is connected to a pre-DEFINITY 6.3 switch or if you want service provider functionality, do not enter **shared**. Instead, leave the default **service-provider** in this field. You cannot use*

*Shared UUI unless the trunk group is connected to a DEFINITY 6.3 (or later) switch.*

The `Maximum Size of UUI IE Contents` field appears.

If you enter **shared** and the `Send Codeset 6/7 LAI trunk group` option is on, you send the LAI information twice (unless the LAI Name and Other LAI data items' priorities are blank with non-QSIG—with QSIG, both are always sent), and you may exceed the maximum ISDN message size.

4. If you want to change the default size of 128 in the `Maximum Size of UUI IE Contents` field, then enter the number for the maximum UUI size. If you want to keep the default size, go to Step 5.

You must administer the trunk groups to send the appropriate amount of user information over the connected network. For example, if the public network only supports 32 bytes of user information, and you enter a number larger than 32, the network may reject the entire UUI IE.

DEFINITY accepts a range from 32 to 128.

5. Go to page 4 (the `Shared UUI Feature Priorities` page which comes up only when the `UUI Treatment` field is set to **shared**).

Notice that all feature names (whether enabled or not) appear on this page. The default values were assigned when Shared UUI was enabled.

6. Either leave the default settings, or reassign numbers from 1 to 6 (1 is the highest priority) to each feature. For more information about user needs, see *Determining User Information Needs* in the next section.

 **NOTE:**

If you leave a feature field blank, that feature will not transport in the UUI IE. If the public network supports less than 82 bytes, you need to choose what feature information you want to send, and give that feature field a higher priority.

7. Press **ENTER** to save your changes.

## Determining User Information Needs

The network byte limit on user information contents (the user data part of the UUI IE) must be large enough to carry the data needed for the customer application.

If you want to forward information over a network that does not support at least 82 bytes of user data, you must determine the space required for the application and adjust priorities accordingly. For more information, see “Determining User Information Needs” in the Information Forwarding chapter of the *Call Vectoring/Expert Agent Selection (EAS)* guide, 555-230-521.

## Considerations

---

- Enhanced information forwarding has been tested with several major carriers. To find out if these capabilities work with your carrier, check with your account team for the most current information. If testing has not been done to verify operation over the public networks involved with the preferred specific configuration, use of private ISDN trunking between the nodes should be assumed until successful testing has been completed.
- Any switch that acts as tandem node *must* have priorities assigned to the Shared UUI features for non-QSIG trunk groups. Even if this switch does not create anything, the priorities must be set correctly to pass the information along. For more information, see the Troubleshooting section.
- The `Send codeset 6/7 LAI` trunk group option operates independently of the `UUI IE Treatment` trunk group option. However, if you turn both of these options on, you'll send the same information twice and possibly exceed the maximum ISDN message size. DEFINITY provides a warning message when both options are administered. There are two ways to correct when the user data exceeds the maximum message size, either:
  - put a blank in the priority fields for `VDN Name` and `Other LAI Information` on the Shared UUI Feature Priorities form, or
  - disable the `Send codeset 6/7 LAI` option.
- For non-QSIG or QSIG trunk groups to DEFINITY R6.3 (or later) switches that require information forwarding, the `UUI IE Treatment` should be **shared** and the `Send Codeset 6/7 LAI IE` should be **n**. For more information, see the *DEFINITY ECS Call Vectoring/Expert Agent Selection (EAS)* guide, 555-230-521.
- Information transported via the Shared UUI is DEFINITY-proprietary; the information will not work with non-DEFINITY switches unless these switches adhere to the proprietary encoding.

## Troubleshooting

---

The following troubleshooting hints should be reviewed when information is not forwarded, even though you received no error messages while administering the Shared UUI feature, and all software and connections meet the minimum requirements:

- If DCS is used, make sure *all* ISDN trunks between DEFINITY switches used for DCS or remote AUDIX are configured in the D-channel mode.
- For each ISDN trunk administered with the Shared UUI option, make sure the UUI size does not exceed the UUI IE size that the network can support.
- For all non-QSIG ISDN trunks, make sure the `UUI IE Treatment` field is set to **shared**.

- Make sure trunk group options are set correctly for the application and configuration.
- Applications may fail on networks supporting limited UUI transport. Administration determines which application's UUI will be transported in these cases. If a given application is failing, first check the administration to determine if the application in question has the highest priority. This applies to tandem nodes as well as originating nodes.

Applications that originate UUI on tandem nodes can request that assigned priorities at the tandem node be applied to the resulting UUI. Therefore, it is possible for a tandem node to erase UUI information received from the originator.

In other words, passing UUI through a tandem node transparently as required for UUS Service 1, does not apply to DEFINITY's proprietary shared UUI procedures.

## Intraflow and Interflow

---

Intraflow and Interflow allow you to redirect ACD calls from one split to another split when the splits are not vector-controlled. Intraflow redirects calls to other splits within the system using Call Coverage or Call Forwarding All Calls. Interflow redirects calls to an external split or location using Call Forwarding All Calls.

### Intraflow

---

Use Call Coverage with Intraflow to redirect ACD calls from one split to another *conditionally*, according to the coverage path's redirection criteria. For example, you can define a split's coverage path to automatically redirect incoming ACD calls to another split when a terminal is busy or unanswered. You can redirect calls to less busy splits, for more efficient call handling.

Use Call Forwarding with Intraflow to *unconditionally* forward a split's calls.

### Interflow

---

Interflow allows you to redirect ACD calls from a split on one switch to a split on another switch or external location. Use Call Forwarding All Calls with Interflow to *unconditionally* forward calls directed to a split extension to an off-premises location. Calls can be forwarded to destinations off the PBX (that is, phone numbers on the public telephone network). You cannot use Call Coverage with Interflow. If a coverage point station or split is forwarded/interflowed, it is taken out of the coverage path.

For details on how to forward calls to an external extension, see [“Call Forwarding” on page 4-224](#). See [“Call Vectoring” on page 9-63](#) and [“Look-Ahead Interflow” on page 9-98](#) for information on advanced Interflow capabilities. See [“Call Coverage” on page 4-146](#) for information on Call Coverage redirection criteria.

## How to administer Intraflow and Interflow

### Required forms

| Form                              | Field  | Page                  |
|-----------------------------------|--|-----------------------|
| Feature-Related System Parameters | <ul style="list-style-type: none"> <li>■ Coverage — Don't Answer Interval for Subsequent Redirection</li> </ul>        | <a href="#">5-123</a> |
| Feature Access Code (FAC)         | <ul style="list-style-type: none"> <li>■ Call Forwarding Activation</li> <li>■ Call Forwarding Deactivation</li> </ul> | <a href="#">5-113</a> |
| Hunt Group                        | <ul style="list-style-type: none"> <li>■ Inflow Threshold</li> <li>■ Priority on Intraflow</li> </ul>                  | <a href="#">5-158</a> |
| Coverage Paths                    | <ul style="list-style-type: none"> <li>■ Don't Answer</li> <li>■ Busy</li> <li>■ Number of Rings</li> </ul>            | <a href="#">5-94</a>  |

### Detailed description

Assign an inflow threshold for each split receiving Intraflow and Interflow calls. This threshold prevents a split from receiving new ACD calls if the oldest call in the queue has been there longer than the threshold. If an ACD call is forwarded or redirected through Call Coverage, but cannot be routed to another split or coverage path point, it remains in queue at the original split even though coverage tone may be heard.

For a split with Intraflow and Call Coverage assigned, you can also assign Priority on Intraflow. When an ACD call intraflowing from a split with Priority on Intraflow to a covering split enters the split's queue, that call is placed ahead of nonpriority calls but behind other priority calls already in the queue. All priority calls are answered before any nonpriority calls.

Calls intraflowed via Call Coverage to a covering split are never connected to the first delay announcement at the covering split. Calls redirected via Call Forwarding receive the delay first announcement at the forwarded-to split, but never receive a forced first announcement.

As an illustration of how Intraflow works, assume the following:

- A call is intraflowed from split 1 to split 2 via Call Coverage.
- Split 1 is assigned priority on intraflow.
- Split 2 has a queue with three priority calls and four nonpriority calls.
- Split 2 has an inflow threshold of 90 seconds and the oldest call in queue at split 2 has been in queue for 60 seconds.

- Split 2 has been assigned a second delay announcement and has a second delay announcement interval of 45 seconds.
- Music-on-Hold is provided.

When the call is intraflowed from split 1 to split 2, the call is placed in the split 2 queue as the fourth priority call, ahead of the four nonpriority calls. The call stays in the queue for 45 seconds and is still not answered. Then the call is connected to the second delay announcement for split 2. After the announcement, the caller hears music until an agent answers the call.

You can assign a Coverage ICI button to an agent's multiappearance voice terminal. The agents use the button to identify a call that is intraflowed from another split. When an agent receives such a call, the button lamp lights.

## Considerations

---

The same coverage path can be used for as many splits as desired. You should administer redirection criteria for a split's coverage path so that calls are redirected under Busy or Don't Answer conditions. Do not use All or Send All Calls as redirection criteria.

## Interactions

---

- Call Coverage

All splits with the same coverage path are automatically assigned the same Don't Answer Interval. The default Don't Answer Interval is 2.

If Intraflow via Coverage is active, the Coverage Don't Answer Interval associated with Call Coverage begins when a call enters the split queue.

If the Coverage Don't Answer interval expires before either of the two delay-announcement intervals expires, a call is redirected to coverage. If either of the delay-announcement intervals expires before the Coverage Don't Answer interval, the call is connected to a delay announcement, if available.

If no coverage point is available to handle a call, a call remains in queue and may then be connected to a delay announcement.
- Temporary Bridged Appearance

If an ACD call is routed to a split agent but is intraflowed to another split before being answered, the Temporary Bridged Appearance at the agent's terminal or console is no longer maintained.

## Look-Ahead Interflow

---

Use Look-Ahead Interflow to balance the load of ACD calls across multiple locations. With Look-Ahead Interflow, you can optionally route a call to a backup location based on your system's ability to handle the call within parameters defined in a vector. In turn, the backup system can accept or deny the call also based on parameters defined in a vector.

DEFINITY 6.3 release includes an enhanced Look-Ahead Interflow that

- results in First in First Out (FIFO) or near FIFO call routing via a new conditional
- uses less computer processing resources during Look-Ahead Interflow than pre-DEFINITY 6.3 software.
- provides enhanced, globally-supported information forwarding over public or private ISDN (for example, PRI and BRI) networks using non-QSIG or QSIG protocols. For more information, see [Information Forwarding](#) on [9-89](#).

### NOTE:

The rest of this section assumes you will read the *DEFINITY Enterprise Communications Server Call Vectoring/EAS Guide (555-230-521)* for a detailed description of Look-Ahead Interflow and its uses. The guide contains information that is critical to the effective and efficient use of this feature.

## How to administer Look-Ahead Interflow

### Required forms

| Form                                  | Field  | Page                  |
|---------------------------------------|--|-----------------------|
| System Parameters<br>Customer-Options | ■ Vectoring (Basic)                                    | <a href="#">5-277</a> |
|                                       | ■ ISDN-PRI   |                       |
|                                       | ■ Lookahead Interflow                                  |                       |
| Trunk Group (ISDN)                    | ■ Outgoing Display                                     | <a href="#">7-219</a> |
|                                       | ■ Codeset to Send TCM, Lookahead                       |                       |
|                                       | ■ Supplementary Service Protocol                       |                       |
|                                       | ■ UII Treatment  |                       |
| Feature-Related<br>System Parameters  | ■ Interflow-Qpos EWT Threshold                         | <a href="#">5-141</a> |
| ISDN Numbering -<br>Public/Unknown    | ■ Ext Len  | <a href="#">7-95</a>  |
|                                       | ■ Ext Code   |                       |
|                                       | ■ CPN Prefix   |                       |
| Call Vector                           | ■ Complete a form for each Look-Ahead Interflow vector | <a href="#">9-207</a> |

See [“Call Vectoring” on page 9-63](#) for associated Call Vectoring administration.

- System-Parameters Customer-Options — For full functionality, options must be enabled at both the sending and receiving switches. If Look-Ahead Interflow is not optioned on the receiving switch, interflow still results on a look-ahead basis. However, the forwarded Dialed Number Identification Service (DNIS) (sending switch VDN name) information is ignored and tandem Look-Ahead Interflow is not provided.
- Trunk Group Form (ISDN) — If you do not want the call originator’s display to update on each Look-Ahead Interflow call attempt, look-ahead calls should be routed over trunk groups with the `Outgoing Display` field set to `n`.
- Feature-Related System Parameters Form — Administer the `Interflow-Qpos EWT Threshold` field when working with enhanced Look-Ahead Interflow. Any calls that will be answered before this threshold will not be interflowed (therefore saving CPU resources).
- ISDN Numbering - Public/Unknown Form — Administer a CPN Prefix for each Vector Directory Number (VDN) that maps to a vector used to place Look-Ahead Interflow calls. If you do not, a Look-Ahead Interflow DNIS of all blanks displays on the answering agent’s voice terminal.

For private network non-QSIG connectivity with direct facilities between DEFINITY systems, administer Look-Ahead Interflow DS1/E1 circuit packs with Country Protocol Option 1 independent of the country where the system is located.

## Considerations

---

- LAI has been tested with several major carriers. To find out if these capabilities work with your carrier, check with your account team for the most current information. If testing has not been done to verify operation over the public networks involved with the preferred specific configuration, use of private ISDN trunking between the nodes should be assumed until successful testing has been completed.
- All calls routed over ISDN facilities by a **route-to number with cov n** or **route-to digits with cov n** vector command on a switch where Look-Ahead Interflow is enabled are treated as Look-Ahead Interflow call attempts.

A vector may route a call over an ISDN facility to a destination that is not a VDN. The sending switch processes this call as a Look-Ahead Interflow call even though it is not. ISDN processing at the receiving switch causes the call to always be accepted. However, the DNIS and any other information in the Look-Ahead Interflow information forwarded with the call are ignored.

- Until the lookahead attempt is accepted by the receiving switch, the caller continues to hear any feedback applied by the sending switch vector and will remain in any split/skill queues.
- **Route-to number with coverage y** or **route-to digits with coverage y** commands never result in a Look-Ahead Interflow call attempt. The sending end assumes the call is always going to be accepted. This command always completes the call. Moreover, the command should not be used if the vector at the receiving switch might deny the call, since the caller in this case would be given a busy signal or would be disconnected. Use this command with coverage y only when you want unconditional interflow (with Look-Ahead Interflow active) and the terminating switch is set up accordingly.
- Audible feedback may be provided to the caller before interflow is attempted. Therefore, another audible feedback from the receiving switch may confuse the caller. For example, a caller hearing ringback on the sending switch may be confused if music is applied suddenly when the call interflows to the receiving switch.

## Interactions

---

- AAR/ARS

ISDN facilities used to provide Look-Ahead Interflow to a VDN on another switch in a private network can use the AAR feature if private facilities are to be used for call routing.

- Agent Terminal Display

If collected digits are forwarded with an interflowed call, the forwarded digits are displayed to the answering agent (unless they're overridden with newly collected digits).

- Attendant Control of Trunk Group Access

Calls will not route over a trunk with Attendant Control of Trunk Group Access set.

- Authorization Codes

Authorization Codes must not be required for interflow routing. Assign a high enough FRL to the VDN so that the route desired for routing interflow calls can be used without requiring an Authorization Code entry. If a route choice is encountered that requires a higher FRL, the interflow is considered an invalid destination (rejected for Look-Ahead Interflow or not available for standard interflow) without the application of recall dial tone.

- BCMS

BCMS does not log LAI attempts, nor does it report accumulated in-VDN time.

- Call Detail Recording — Sending Switch

No Ineffective Call Attempt or Outgoing Call CDR records are generated for vector *route-to* commands that are unsuccessful including denied Look-Ahead Interflow attempts.

If a local (on-switch) call to a VDN generates a Look-Ahead Interflow call attempt that is accepted, and answer supervision is returned from the receiving switch, then one Outgoing Call CDR record is generated with the originating extension as the calling number.

If an incoming (off-switch) call to a VDN generates a Look-Ahead Interflow call attempt that is accepted, and no answer supervision is returned from the receiving switch, then one incoming CDR record is generated. The VDN is the called number, and the duration is from the time answer supervision was provided to the incoming trunk.

If an incoming (off-switch) call to a VDN generates a Look-Ahead Interflow call attempt that is accepted, and answer supervision is returned from the receiving switch, then two incoming CDR records are generated:

- An incoming record with the VDN as the called number and the duration as the time since answer supervision was provided to the incoming trunk. This is generated if the call is initially answered in the sending switch before interflow takes place.

— An outgoing record containing the incoming trunk information as the calling number and the dialed digits and the outgoing trunk information as the called number.

■ Call Detail Recording — Receiving Switch

On the receiving switch, an incoming Look-Ahead Interflow call is treated like any other incoming vector call.

If answer supervision is returned by the vector, and the call is never terminated to another destination, then the VDN extension is recorded as the called number in the CDR record.

If the call terminates to a hunt group, then the VDN, hunt group, or agent extension is recorded as the called number. If the `Record VDN in Record` field of the Feature Related System Parameters is `y`, then the VDN extension overrides the `Call to Hunt Group - Record` administration option for vector calls.

■ Call Prompting

Digits collected at the sending switch, no matter how they are collected (caller-entered, ASAI provided, CINFO provided, etc.) are forwarded with interflowed calls and available at the remote switch via information forwarding. For more information, see [Information Forwarding](#).

**NOTE:**

Dial-ahead digits are not forwarded with the call. There is a maximum of 16 forwarded digits.

■ Centralized Attendant Service

A centralized attendant can be a Look-Ahead Interflow destination.

■ Display - 27 Character

The VDN name (part of the LAI information forwarded with calls) can be up to 15 characters long. Any characters over this limit will be dropped.

■ Facilities Restriction Level and Traveling Class Marks

The FRL for interflow over ARS/AAR route choices is assigned to the original VDN used for the incoming call.

■ Incoming Call Management

The adjunct routing capabilities of vectoring can be used at the sending switch to determine if a call should be interflowed. Adjunct routing at the receiving switch can be used to tandem the call to a far-end switch.

If the call terminates to a trunk (tandem), then two CDR records are generated:

— An incoming record with the VDN as the called number and the duration as the time since answer supervision was provided to the incoming trunk.

- An outgoing record containing the incoming trunk information as the calling number and the dialed digits and the outgoing trunk information as the called number.
- Lucent Distributed Networking - Manufacturers Specific Information (MSI)  
LAI (whether enhanced or not) may not function with systems from other vendors (unless that vendor develops a corresponding capability that works with DEFINITY ECS).
- Network Access  
LAI operates over public, private, or virtual private (for example, SDN) ISDN-BRI and -PRI networks that meet minimum network requirements.  
The sending of a Look-Ahead Interflow codeset 6/7 information element is counted toward Message Associated User-to-User Information (MA-UUI) counts.
- QSIG  
LAI and information forwarding function over QSIG trunk facilities if the remote locations are DEFINITY systems. You may get LAI call control functionality with other vendors if DEFINITY is the starting point.
- Redirect on No Answer (RONA)  
Calls redirected to a VDN by RONA can be subsequently processed and routed by LAI applications.
- Service Observing  
You can observe a call in LAI processing via VDN observing throughout the life of the call (as long as the call is still connected through the local DEFINITY ECS). All current restrictions on Service Observing still apply. Incoming calls can be service observed at the remote switch.
- Trunk-to-Trunk Transfer  
Interflowed calls may be transferred by a receiving switch to another trunk connection.
- VDN Override  
The name of the active VDN for a call is displayed at the remote answering agent.

## Multiple Call Handling

---

Multiple Call Handling (MCH) allows agents to receive an ACD call while other types of calls are alerting, active, or on hold.

### How to administer MCH

---

#### Required forms

---

| Form       | Field                    | Page                  |
|------------|--------------------------|-----------------------|
| Hunt Group | ■ ACD                    | <a href="#">5-158</a> |
|            | ■ Multiple Call Handling |                       |

The MCH column on the List Hunt Group form contains the value that you enter in Multiple Call Handling.

### Detailed description

---

#### Applications

Use Multiple Call Handling in applications where you want agents to take additional calls without dropping the active call. Examples of applications include:

- An agent and a caller may need to wait on a call for information. MCH allows the agent to put the call on hold and handle other ACD calls until information is available.
- ACD calls may be more important to your business than non-ACD calls. Use MCH to interrupt agents on non-ACD calls with an ACD call.
- In an EAS environment, calls from one skill may be more important than calls from another skill. Use MCH to interrupt an agent who has a call from the less-important skill with a call from the more-important skill.

You can use MCH in an Expert Agent Selection (EAS) or non-EAS environment.

- With EAS, you can administer any combination of MCH and non-MCH skills for an agent. If an EAS agent is a member of both MCH and non-MCH skills, he or she can handle multiple simultaneous ACD or Direct Agent Calls only in the MCH skills.
- Without EAS, agents can be logged into only one split if it is an MCH split. Similarly, a non-EAS agent logged in to a non-MCH split cannot log into an MCH split.

## MCH example

In this example, an agent is logged into 4 skills, each with a different MCH option. [Table 9-11](#) shows how calls are delivered when an unrestricted-line appearance is available and the agent is in Auto-In or Manual-In work mode (AUX work mode is not pending).

**Table 9-11. MCH Call Delivery Example**

| Condition  | Calls Delivered?                |                                 |                                     |                                      |
|--|---------------------------------|---------------------------------|-------------------------------------|--------------------------------------|
|  | Skill 1<br>(MCH=<br>on-request) | Skill 2<br>(MCH=<br>one-forced) | Skill 3<br>(MCH=one<br>- per-skill) | Skill 4<br>(MCH=<br>many-<br>forced) |
| No calls on set                                  | yes                             | yes                             | yes                                 | yes                                  |
| One active extn call                             | no                              | yes                             | yes                                 | yes                                  |
| Skill 1 call active                              | no                              | yes                             | yes                                 | yes                                  |
| Skill 2 or 4 call active                         | no                              | no                              | yes                                 | yes                                  |
| Skill 3 call active                              | no                              | no                              | no                                  | yes                                  |
| Extn call held, no other action                  | no                              | yes                             | yes                                 | yes                                  |
| Skill 1, 2, or 4 call held, no other action      | no                              | no                              | yes                                 | yes                                  |

Agents and supervisors in on-request MCH splits or skills can use Queue Status, VuStats, and BCMS/CMS reports to determine if a call is waiting that must be answered immediately.

## MCH settings

### On request

In on-request splits or skills, the following is true.

- If an agent goes into Auto-In or Manual-In work mode, but there are no calls in the queue, the agent is placed at the bottom of the MIA queue or at the bottom of their skill level in the EAD queue, or is made available in the DDC queue.

- Agents must select Auto-In or Manual-In work mode for each new ACD call they take while a call is on hold.
- The agent can take additional ACD calls as long as there is an available line appearance.

Use on-request MCH in conjunction with a feature such as VuStats, which agents can use to see when the split queue is getting full and take additional calls.

### One forced

An agent who is idle or active on a non-ACD call is automatically interrupted with an ACD call from this split or skill when no other ACD call for any of the agent's splits or skills are alerting, active, or held. In addition, the following must also be true:

- The agent is in Manual-In or Auto-In work mode.
- The agent is the most idle or next available.
- An unrestricted line appearance is available.
- AUX work or Move from CMS are not pending.

As long as an ACD call is active or held, the agent does not automatically receive an additional call from the one-forced split or skill. An agent in a one-forced split/skill in Auto-In or Manual-In work mode is unavailable for that split/skill from the time that an ACD call rings until all ACD calls are abandoned, redirected, or dropped. However, the agent can request another ACD call from a one-forced split or skill by placing the active call on hold and selecting Manual-In or Auto-In work mode.

If an agent with multiple skills is active on an ACD call for a group with one-forced MCH, the agent could be forced to take an ACD call for one of his or her other skills, depending on that skill's MCH settings.

Because one-forced MCH forces an ACD call to alert an agent who is not on an ACD call, use it when you want ACD calls to take precedence over other calls.

### One per skill

You must have EAS to use one-per-skill MCH. An agent with no ACD calls for this skill is automatically interrupted with a single ACD call from this skill under the same conditions listed for one-forced.

If a one-per-skill call is active or held, the agent does not automatically receive additional calls from that skill. However, the agent can request another ACD call from a one-per-skill in the usual way.

If an agent with multiple skills is active on an ACD call for a one-per-skill group, the agent could be forced an ACD call for one of his or her other skills if those skills are many-forced or one-per-skill MCH.

Use one-per-skill MCH when calls from one skill are of higher priority than other ACD calls.

### **Many forced**

Agents are automatically interrupted with an ACD call under the same conditions listed for one-forced. As soon as an agent answers an alerting ACD call, the agent immediately becomes available to receive another ACD call from a many-forced split or skill.

Agents in many-forced groups in Auto-In or Manual-In work mode are unavailable only when an ACD call is ringing.

Use many-forced MCH when agents must answer important or urgent calls, even when they must put equally important calls on hold. It can also be used to force Direct Agent calls to an agent.

## **Considerations**

---

- Agents can receive multiple calls only when in Auto-In or Manual-In work mode. All forced MCH calls are delivered with ringing at the agent's station, not with zip tone. Requested MCH calls are delivered with ringing or zip tone.
- Agents can toggle between Auto-In and Manual-In work mode.
- If an agent selects ACW or AUX work mode with calls on hold, the work mode is pending until all calls complete or until a Manual-In call completes. New ACD calls are not delivered when AUX work is pending. When an ACD or Direct Agent call with pending ACW completes, the agent enters ACW. When an agent is active on a non-ACD call with ACW pending, the agent can receive forced MCH calls.
- If an agent is either in Auto-In work mode and active on an ACD or Direct Agent call, or in Auto-In or Manual-In work mode and active on a non-ACD call and a Manual-In ACD or Direct Agent call abandons from hold, the agent is pending for ACW work mode and the after-call button lamp flashes.
- If an agent reconnects to an ACD or Direct Agent call on hold, his or her work mode changes to the call's work mode (Auto-In or Manual-In).
- Do not use forced MCH with DDC distribution because the first agent continues to receive calls until all line appearances are busy.

## Interactions

---

- Automatic Hold

To answer a ringing ACD call, an agent in a many-forced, one-forced, or one-per-skill split/skill pushes the line-appearance button. If automatic hold is administered, the active call is automatically placed on hold. Otherwise, the agent must first push hold.

- Call Work Codes and Stroke Counts

Agents handle multiple ACD calls simultaneously with MCH can enter CWCs and Stroke Counts. When an agent does so with multiple calls on the station, the code/count is associated with the last call the agent handled. If an agent enters a code/count during an active call with calls on hold, the code/count is associated with the active call.

If an agent with on-request MCH is active on a call that requires forced entry of CWC or stroke counts and places the call on hold without entering a code/count, he or she cannot request another call.

If agents with many-forced MCH are in a split/skill with forced entry of CWC or stroke counts, they are forced to handle an ACD call even if they have not entered a code/count.

- Direct Agent Calling

Agents can handle multiple Direct Agent calls if their direct agent skills have MCH. The queue-status indicator is not lit when a Direct Agent call queues to a split/skill. Agents are notified that calls are waiting with a ringing and a flashing current-work-mode lamp.

- Move Agent While Staffed

An agent with a move pending can place a call on hold and request another ACD call. All calls and ACW must complete before the pending move occurs.

- Non-ACD calls

If an agent activates Auto-In or Manual-In work mode with calls on hold, he or she can answer or originate a non-ACD call. With on-request MCH, the agent is temporarily unavailable for ACD or Direct Agent calls. With forced MCH, a call can be delivered. If an agent in ACW reconnects to an AUXIN/AUXOUT call, the agent remains in ACW.

- Queueing

When an agent is available, the agent is placed at the end of the queue for Uniform Call Distribution (UCD) hunt groups or at the bottom of the skill type for Expert Agent Distribution (EAD) hunt groups, or is made available for Direct Department Calling (DDC) hunt groups. When the agent becomes the most available according to group type (UCD, EAD, or DDC), he or she receives a queued ACD or Direct Agent call.

If the last agent on a forced MCH split is pending for AUX work mode in a nonvector-controlled split, the agent must empty the queue before going to AUX work mode. The agent continues receiving ACD calls until the queue is emptied.

- Redirection on No Answer

If an agent has a call active or on hold and the RONA timer expires for another ringing ACD call, RONA redirects the alerting call back to the split/skill or administered VDN. The agent is not taken out of service when the call redirects, but is placed at the bottom of the Most Idle Agent (MIA) or Expert Agent Distribution (EAD) queue.

- Restricted line appearance

If you administer last-available line appearance as Restricted Last Appearance for an agent's terminal, the agent does not receive additional ACD calls because the appearance is reserved for making conference or transfer calls.

## Queue Status Indications

---

Queue Status Indications allows you to assign queue-status indicators for Automatic Call Distribution (ACD) calls based on the number of calls queued and time in queue. You can assign these indications to lamps on agent, supervisor, or attendant terminals or consoles to help users monitor queue activity.

In addition, you can define auxiliary queue warning lamps to track queue status. On voice terminals and consoles with displays, you can display the number of calls queued and time in queue of a split's oldest call.

### How to administer Queue Status Indications

---

---

## Detailed description

---

There are two types of Queue Status Indications:

- Number of queued calls (NQC)  
The system report the total number of calls, excluding direct agent calls (DACs), in queue at a hunt group.
- Oldest queued time (OQT)  
The system reports the time in queue of the oldest call in a split queue.

You can also use auxiliary queue warning lamps to provide both types of indications. Install the lamps at any location convenient to split agents.

If a queue status threshold is reached, the lamp next to the associated button flashes. If calls are queued but the threshold is not reached, the lamp lights steadily. If no calls are queued, the lamp goes dark.

If agents at voice terminals and consoles with displays press either the OQT or NQC button, the following information is briefly displayed:

- Split name (or extension, if name is not assigned)
- Oldest queued time
- Number of queued calls

You can use Queue Status Indications to provide status information for attendant groups or other hunt group types (DDC and UCD). With attendant groups, the button names (AQT and AQC) are different than for split queues, the display shows OPERATOR instead of split name or extension, and all status information applies to the attendant group queue.

If you need to know how many queue status buttons you've administered, or how many your system will allow you to administer, check page 5 of the System Capacity form.

## Interactions

---

- Attendant and Voice Terminal Displays Timer  
The timer and the queue status information can be displayed at the same time. On 1-line displays, the timer is displayed in the last eight display positions and the number of queued calls is not displayed. On 2-line displays, the timer is displayed on the first line and the queue status information is displayed on the second line.
- CMS  
When you use CMS to move an agent from one split to another, all buttons associated with the first split, including NQC and OQT buttons, become associated with the second split.

## Reason Codes

---

Reason Codes allows agents to enter a numeric code that describes their reason for entering Auxiliary (AUX) work mode or for logging out of the system. Reason codes give call center managers detailed information about how agents spend their time. Use this data to develop more precise staffing forecasting models or use it with schedule-adherence packages to ensure that agents are performing scheduled activities at the scheduled time.

You can administer the codes so that entry is forced or optional. Ten reason codes are available, including a default code. You can assign two system-wide names to each code — one for entering AUX work mode and one for logging out.

You can use VuStats to display the reason code name or number. Use VuStats or CMS to gather historical and real-time reason-codes statistics.

You must have Expert Agent Selection (EAS) enabled to use reason codes.

### How to administer Reason Codes

## Detailed description

### Forced reason codes

If you have administered forced reason codes, agents cannot enter AUX work mode or log out until they enter a code. Agents can enter codes 1 — 9, but not default code 0.

If an agent enters an invalid code or fails to enter a code within the administered timeout interval, the change is denied and the agent remains in the current work mode. If the agent dialed a FAC, the agent hears an intercept tone. If the agent pressed the AUX button, the AUX lamp flutters and then goes dark (or lights steadily if the agent was already in AUX with a different reason code).

### Requested reason codes

If you have administered requested reason codes, agents need not enter a code to enter AUX work mode or log out. Agents can enter the codes 0 — 9. If an agent enters an invalid code or fails to enter a code within the timeout interval, the agent enters AUX work mode or logs out with default code 0.

### Entering AUX work mode

An agent can enter an AUX reason code in one of three ways:

- Pressing an AUX work button with an assigned code
- Pressing an AUX work button with no assigned code and responding to the prompt for a reason code
- Dialing an AUX work FAC and responding to the dialtone prompt for a reason code

If there are no calls ringing, active, or held at the voice terminal, agents enter AUX work mode immediately and the AUX lamp lights steadily. Otherwise, the AUX lamp blinks until the agent completes all calls at the terminal.

If a button for AUX work is associated with the reason code that the agent entered, the button lamp lights. If no such AUX button exists, the system lights the first AUX button lamp with no administered reason code.

You can assign an AUX button without a reason code to an agent's voice terminal. This allows agents with a limited number of buttons to use all 10 reason codes.

### Logging out

To log out with a reason code, the agent dials the logout FAC, hears a second dial tone and enters a reason code. The agent hears confirmation tone and is logged out.

## Default code

Default code 0 is used when the system puts an agent into AUX work mode or logs the agent out without the involvement of the agent. For example:

- When an agent logs in and is put into AUX mode
- When an agent makes or receives a non-ACD call from the available state
- When a call is redirected as a result of Redirection on No Answer (RONA) and the agent is logged out or put into AUX mode
- When agent skill assignments are changed while an agent is staffed (the system automatically logs the agent out and back in)
- When an agent forces a logout without entering a code (for example, by pulling the headset)
- When an agent who is requested to enter a reason code fails to enter a valid code within the 10-second timeout period
- When an agent with requested reason codes enters # or \*

## Considerations

---

- If an agent in Auto-In or Manual-In work mode dials the logout FAC but fails to enter a reason code and logout reason codes are forced, the agent is returned to the available state. ACD calls are delivered even if the agent has left the voice terminal. To prevent this, be certain that agents enter AUX or ACW work mode before logging out.
- When an agent changes to AUX work mode and the AUX Work Reason Code Type is set to none, the agent is put into AUX work mode with the default reason code even if you have administered a different reason code for the AUX button. Setting AUX Work Reason Code in this way allows you to complete button administration before activating the feature.
- Do not administer AUX buttons without a reason code for hybrid station sets.
- When an agent in AUX work mode is active on a non-ACD call, the agent cannot immediately change the reason code. A change is pending until the call drops.
- There is a limit to the number of agents who can simultaneously be entering either a reason code or a Call Work Code. See the *DEFINITY Enterprise Communications Server Release 6 System Description Pocket Reference* for this limit.

## Interactions

---

- **Abbreviated Dialing**

You can program FACs for AUX work mode or logout with or without an associated Reason Code on automatic-dial buttons or in abbreviated-dial lists. At the reason code prompt, when an agent selects an abbreviated-dial or automatic-dial button, the first digit of the button is taken as the reason code.
- **Agents in Multiple Skills**

When an agent who is assigned to multiple skills enters AUX work mode with a reason code, the agent enters AUX work for all of his or her skills with the same reason code.
- **ASAI**

ASAI allows a host to log an agent out and place an agent in AUX work mode with a reason code. The host can query the agent's current work mode and receive the reason code associated with the AUX work mode.
- **Auto-Available Split**

The system logs AAS agents out for Redirection on No Answer with the default reason code.
- **Basic Call Management System**

Statistics about AUX work mode by reason code are not available in BCMS reports.
- **CMS**

CMS tracks time in AUX work mode by reason code and displays reason codes for agents currently in that mode. When an agent is moved from CMS while the agent is staffed, the system logs the agent out using the default code, and then logs the agent back in again. If an agent is in AUX work mode when moved, the agent is returned to AUX work mode with the same reason code when the move is completed.
- **Direct Agent Calling**

When a Direct Agent call is queued for an agent in AUX work mode with a reason code, the appropriate AUX button lamp flutters to alert the agent to the queued call. If there is no AUX button lamp, agents receive an audible alert (ring-ping or call-waiting tone). If there is an AUX button with no assigned reason code administered, then that lamp flutters.
- **Redirection on No Answer**

When a call is redirected via RONA, an agent is placed into AUX work mode with the default code or is logged out with the default code if the agent is in an auto-available skill.

## Redirection on No Answer

---

Redirection on No Answer (RONA) redirects a ringing ACD split or skill call or Direct Agent Call after an administered number of rings. RONA prevents an unanswered call from ringing indefinitely. The call can redirect either to the split or skill to be answered by another agent or to a VDN for alternative call handling. Direct Agent Calls route to the agent's coverage path, or to a VDN if no coverage path is administered.

You must have ACD enabled to use RONA. Administer RONA for each ACD split hunt group as required. RONA can be used in Auto-Available Splits (AAS), or in splits and skills with agents operating in Manual-In work mode. You can administer RONA for vector-controlled or nonvector-controlled splits or skills.

Do not administer RONA for splits controlled by adjuncts or AUDIX or for auto-answer agents assigned splits or skills because calls must ring at a terminal to be redirected.

### How to administer RONA

---

#### Required forms

| Form                    | Field                                | Page                  |

| Station (multifunction) | ■ Button Assignments<br>— noans-alrt | <a href="#">6-14</a>  |

You must set Controlling Adjunct to **none**.

### Detailed description

---

When RONA is invoked for a call, the system:

- Places an agent in AUX work mode, and thus unavailable to receive calls from other splits or skills. In an AAS, the agent is logged out.

- Redirects split or skill calls back to the split or skill or administered VDN.  
Redirected calls are queued at the highest priority so that they are distributed before any other split or skill calls. See [“RONA Routing Sequences” on page 9-118](#) for more information about call redirection.
- Sends a message to CMS.  
When a RONA timeout occurs, the Noans-alm lamp for the split/skill lights steadily. The supervisor presses the Noans-alm button to display the login ID or the extension and name of the last agent timed out with RONA.
- Records the redirection in BCMS or CMS. See [“Using BCMS/CMS reports with RONA” on page 9-119](#) for additional information.

## Application examples

### VRU applications

Typically, RONA is used with VRU applications in AAS configurations. RONA detects VRU failures and provides alternate operation. For example, an adjunct port failure is not detected by ACD call processing. RONA detects the failure, takes the port out of service, and provides notification of the failure.

Use Call Vectoring for flexible call handling in case of a VRU failure. Assign RONA a converse split connected to the Conversant or to equivalent VRU ports. Whenever RONA times out on a ringing call delivered via the *converse-on* command to a VRU port, the agent is logged out and the call is redirected back to the converse split.<sup>1</sup> With a complete VRU failure, all VRU ports are eventually logged out and vector processing for the *converse-on* command bypasses that step for new calls.

The [Screen 9-1](#) vector shows how to provide automatic backup for a complete VRU failure.

```
CALL VECTOR
01 wait-time 0 secs hearing ringback
02 converse-on split... (VRU returns the digit "1" as a return code
    followed by additional digits for the application)
03 collect 1 digits after announcement none
04 goto step 6 if digits = "1"
05 goto vector xxx (for backup when the VRU fails)
06 collect 2 digits after announcement none
07 ...
```

### Screen 9-1. Call Vector

---

1. RONA can't redirect a call to an administered VDN from a *converse* step.

In [Screen 9-1](#), the application works as expected as long as the VRU returns the digit string, which includes a return code of 1. In this case, the condition in Step 4 is satisfied and the program branches to Step 6, which provides normal application processing.

On the other hand, if all VRU ports in an AAS split are logged out by a RONA timeout, the *converse-on* command step (Step 2) is skipped, and no digits are collected by Step 3 (after the 10-second timeout). The condition in Step 4 is not satisfied and vector processing proceeds to Step 5, which branches to vector xxx to connect the call to an agent.

### Other applications

You can use RONA for applications that involve human agents with manual answering and other adjunct applications, such as Home Agent. For example, a call may not be answered because an agent left without entering AUX work mode or logging out. You can use RONA to make the nonanswering agent unavailable and redirect calls to another agent or to the RONA VDN.

## RONA Routing Sequences

[Table 9-12](#) and [Table 9-13](#) describe how RONA redirects split or skill calls and Direct Agent calls.

**Table 9-12. RONA Routing Sequence for Direct Agent Calls**

| Redirection Destination | Explanation   |
|-------------------------|---|
| Coverage path           | Direct Agent calls redirect to a coverage path, if one exists. Priority calls do not route to coverage.   |
| RONA VDN                | If no coverage path exists but a VDN is administered for RONA, Direct Agent calls redirect to the VDN.  |
| VDN return destination  | For external calls, if neither a coverage path nor a RONA VDN are administered, then Direct Agent calls redirect to the VDN Return Destination extension. |
| None                    | Calls continue ringing.   |

**Table 9-13. RONA Routing Sequence for Split/Skill Calls**

| Redirection Destination | Explanation  |
|-------------------------|--|
| RONA VDN                | If a RONA VDN is administered, calls redirect to the VDN.  |
| Requeue to split/skill  | If a RONA VDN is not administered, calls redirect to the split or skill.   |
| Coverage path           | In nonvector-controlled splits, if calls cannot requeue to the split, they redirect to the split's coverage path if one is administered.                         |
| VDN return destination  | For external calls, if a split coverage path or a RONA VDN is not administered and calls can not requeue, they redirect to the VDN Return Destination extension. |

### Using BCMS/CMS reports with RONA

You can use BCMS and CMS reports to determine which agents had RONA timeouts and how calls were redirected.

With R3V2 and later releases of CMS, the exception report lists agents who were timed out and made unavailable. With BCMS and earlier releases of CMS, you can determine which agents were in AUX work mode or logged-out with AAS.

With R3 CMS, you can use the real-time "Split Status" report to see which agents are in AUX work mode, but you need a custom report to see logged-out agents.

With BCMS, use SAT to create a list of unstaffed agents for the split to see which agents are logged out (for AAS applications). With EAS, list agent-loginid specifying unstaffed and AAS = yes.

With BCMS, agents' changes to AUX work mode appears in the BCMS Split (AGENT) Status report. In an AAS split, agents log out, so they do not appear in the Split Status report. When the call is requeued, the System Status report shows only the AVG ANSW SPEED time and AVG ABAND TIME time for the requeued call. The Historical Split and System reports show both a FLOWOUT (primary split) and FLOWIN (redirected split) for requeued calls, while the VDN report shows only a FLOWOUT.

Direct Agent calls are recorded as ACD split calls but the flowout is recorded only if an agent's coverage path requeues the call to a split.

Since BCMS does not report exceptions, RONA events are not reported. If you have BCMS, use the RONA split lamp indicator for RONA event indication.

## Returning AAS agents to service

When RONA redirects a call that was directed to an AAS, the agent is logged out. To return an AAS agent to service, readminister the agent as a member of the AAS split to be logged in again in one of the following ways:

- For ACD splits, remove the agent from the split and then resubmit the split Hunt Group form with the agent added to it. Alternatively, administer the agent in a different location in the split members list on the Hunt Group form. Use the *list unstaffed-agents* command to get a list of all AAS agents that have been logged out, not just AAS agents that were logged out because of a RONA timeout.
- For EAS skills, readminister the Agent LoginID form so that the AAS agent is automatically logged in. To determine which EAS agents are logged out, use the *list agent-loginid* command.
- For ACD splits and for EAS skills, you can busy-out the AAS agent station with the *G3-MT busyout station* command and release it with the *release station* command. Releasing the AAS agent station automatically logs the agent in. If all AAS agent ports on the circuit pack had a RONA timeout, busy-out and release the entire circuit pack.
- Use CMS Move Agents to move up to 32 agents at a time into a dedicated unused split/skill and then move the agents back into the AAS split/skill. You can set this up using the timetable on a manual-scheduled basis to activate when the VRU has been restored to service after a failure.
- Use ASAI to log the logged-out agents back in via ASAI login request messages.

## Considerations

---

- RONA can timeout while an agent is actually at the terminal if the agent does not answer soon enough or has selected another work mode while a call is ringing. RONA handles the call as usual, making the agent unavailable. With ACD splits, agents at multifunction terminals know that they have been made unavailable when they see the AUX-Work lamp lit. They press the Auto-In or Manual-In button to become available.
- Specify a coverage path or VDN for redirection for nonvector-controlled splits or for Logical Agent IDs with EAS Direct Agent Calls to ensure that calls are always redirected.

## Interactions

---

- AAS

Use AAS with RONA for VRU ACD non-ASAI adjunct-controlled split applications. Assign AAS only to ACD hunt groups. When all lines in a vector-controlled AAS split are logged out, the split is considered unavailable, and vector processing skips the step in the vector for new calls.

If RONA occurs on the last VRU port in an AAS split, the call is not requeued to the converse split, but is processed by the next vector step.

Any calls queued to a split that has been taken out of service may be left at this split. When the system reinitializes, all busied-out ports are automatically logged back into the AAS splits. New calls cause a RONA timeout if the adjunct or agent still does not answer after the system reinitializes.

- Abandoned Call Search

Abandoned Call Search, if defined for a trunk, is reapplied to call on that trunk that RONA requeued whenever the calls are routed to another agent.

- Agents in multiple splits

When a RONA timeout occurs, an ACD split agent is placed in AUX work mode with notification to CMS for all splits that the agent is logged into. The agent is responsible for becoming available in each split. In an AAS, agents are logged out of all splits that they are logged into. You must log agents back into the AAS splits.

- Agent logout

An agent can log out from a multifunction set while an ACD call subject to RONA is ringing the set. However, if the agent logs out before RONA times out, RONA timing is canceled, and RONA redirection and notification occur immediately.

- Agent work modes

If an agent presses the ACW button with an ACD call ringing, the change request is pending. If the agent has a pending change to ACW before a RONA timeout occurs on a ringing ACD call, RONA timing continues. At timeout, the call is redirected, CMS is notified, and the agent is placed in AUX work (overriding the pending ACW request).

If an agent presses the AUX-Work button with an ACD call ringing, the change request is pending. With ACD splits, since the RONA time-out changes the state to AUX-Work, there is no conflict with the pending AUX-Work change request. With AAS splits, an agent-initiated AUX-Work change is denied per existing operation.

- ASAI

RONA applies to vector-processed calls that are routed by an adjunct to an ACD split or agent as a Direct Agent Call.

You can assign RONA to ASAI adjunct-monitored splits and adjunct-monitored calls. An event report is not sent to the ASAI adjunct when a RONA timeout puts an agent into AUX work mode.

The adjunct makes an agent query (as part of the value query capability group) to determine the agent's state. Once the call is queued to the split, the adjunct receives a call-queued event report if event reporting is active for the domain (VDN or nonvector-controlled split).

An adjunct-monitored split can be assigned as an auto-available split. The logout event for an AAS split is sent to the adjunct when RONA timeout logs an agent out.

You cannot assign RONA to an adjunct-controlled split. An adjunct-controlled split cannot be an AAS.

ASAI CONVERSANT VRU applications are configured with nonvector-controlled splits using manual-answer operation on analog lines to CONVERSANT ports. The ASAI link provides event notification for the ACD split for enhanced services. In addition, you can log in and log out the ports as required. (AAS splits are not used for this application because the ASAI link controls the login or logout).

You can assign RONA to these splits to detect failure conditions in the same manner as non-ASAI VRU applications. RONA does not notify CONVERSANT of AUX work mode changes. ASAI CONVERSANT cannot query to determine the states of its ports. You must restore ports manually after a failure via CONVERSANT management screens. Complete failure is automatically restored when CONVERSANT reinitializes. [Table 9-14](#) describes ASAI events that the switch sends the adjunct for various stages of the RONA call. Also included are the ASAI associations (assuming that they are active) for which the events are provided. For the split to have Notification association active, the split must not be vector-controlled or adjunct-controlled.

Table 9-14. RONA/ASAI Events

| Stage of Call                                  | ASAI Event   | ASAI Associations  |
|--|--|--|
| 1. RONA timeout                                | Logout (for AAS)   | Domain (agent) control   |
| 2. Call redirected to split                    | Call redirected  | Domain (station) control (for agent ext call is leaving)                                       |
|  | Call queued (only if the call queues)  | Domain (station) control, (for new agent & for internal originator) call control, notification |
| 3. Call redirected to VDN processing           | Call redirected  | Domain (station) control (for agent ext that call is leaving)                                  |
|  | Call redirected (only if call is redirected to a VDN with Notification active) | Notification   |
|  | Call offered to Domain   | Notification (VDN)   |
| 4. Call delivered to agent                     | Alerting   | Domain (station) control, (for new agent & for internal originator) call control, notification |
| 5. Call routed to split's coverage path        | Call redirected followed by existing operation of ASAI Events                  | Domain (station) control (for agent ext that call is leaving)                                  |
| 6. Infinite feedback to caller                 | Call redirected  | Domain (station) control (for agent ext that call is leaving)                                  |
| 7. Continue vector processing                  | Call redirected followed by existing ASAI events                               | Domain (station) control (for agent ext that call is leaving redirecting to VDN)               |
| 8. Call routed to direct agent's coverage path | Call redirected followed by existing operation of ASAI events                  | Domain (station) control (for agent ext that call is leaving)                                  |

When a call is redirected via ASAI Redirect Call, the RONA timer is canceled.

- Attendant return call

If an attendant extends a call to an ACD split or VDN for which the return call timer is not activated, the call does not interact with RONA. The Attendant Return Call Timer is not set if an attendant extends the call to another attendant.

- AUDIX Transfer

RONA applies to a call transferred by AUDIX to an ACD split.

A redirected call to AUDIX does not go to split or agent coverage after it is transferred out of AUDIX. If RONA times out on this type of call, the call cannot be redirected.

- Automatic answering

If an agent with automatic answering receives a call with zip tone instead of ringing, RONA timing is canceled.

- Call Coverage

Direct Agent calls are redirected to the agent's coverage path if a path is administered. A temporary bridged call appearance is not maintained for a call directed to an ACD hunt group or VDN, or for a Direct Agent call.

When a call is redirected to an ACD split or direct agent logical ID as a point in the coverage path via Expert Agent Selection (EAS), the Coverage Subsequent Redirection/CFWD No Answer timer is started on the call.

Covered calls go to the next point in the split's coverage path.

If no other point is available to accept the call, the call remains queued or continues to ring the current coverage point. When RONA times out at the coverage point, the following occurs:

- RONA does not reset the Subsequent Redirection/CFWD No Answer timer. The timer that expires first controls the call.
- If the coverage point for a covered call is a direct agent logical agent ID whose split has RONA, and if RONA times out first, the call is sent to the next point in the split's coverage path, not to the agent's coverage path. The Subsequent Redirection/CFWD No Answer timer is reset when the call is redirected to the next coverage point.
- If RONA was applied to an ACD call that was a previously redirected coverage call (that is, the RONA split was a point in the coverage path), RONA is used to requeue the call as specified for a noncovered call. However, the call is not designed to go to split coverage or forwarding. The Subsequent Redirection/CFWD No Answer timer is reset if RONA requeues the call to the RONA split. Both the RONA timer and Subsequent Redirection/CFWD No Answer timer are reapplied.
- If RONA applies to an ACD call that was a previously-redrafted coverage call (for example, the RONA split was the second point in the coverage path), the call is redirected to the next coverage point in the principal's coverage path if the call cannot be requeued to the RONA split. The Subsequent Redirection/CFWD No Answer timer is reset.

- If no other point in the coverage path exists or other points are unavailable, the split-covered call that cannot be requeued or the direct-agent-covered call receives call-cannot-be-redirection handling.

- Call Detail Recording (CDR)

When an agent is assigned to be recorded on the CDR record as the called number, the RONA redirected-to answering destination is recorded as the final called number. You can administer CDR to record the VDN, the hunt group, or the answering agent as the called number.

- Call Forwarding All

If an adjunct Direct Agent call is made to an agent's extension that has Call Forwarding All assigned and it is redirected by RONA, the call follows the agent's coverage path.

A call forwarded via Call Forwarding to a split or logical agent ID with RONA is sent to the principal's coverage path instead of going to the split's coverage path (if the call cannot be requeued) or to the agent's coverage path (for a Direct Agent call) on RONA redirection.

- Call Pickup

A member of an agent's pickup group can pick up an ACD call that is being timed for RONA. RONA is cancelled.

- Call Vectoring

RONA applies to vector-controlled ACD splits when calls are queued via the *queue-to main split*, or *converse-on split*, or *check-backup split* commands. Also, RONA applies to nonvector-controlled and vector-controlled ACD splits when calls are routed to the split via a *route-to* or a *messaging split* command. Basic Call Vectoring handles an AAS with all agents logged out as unavailable and skips the relevant step, just as it does for a split with all queue slots busy. With an *adjunct routing* or *route-to with coverage* step that routes to a vector-controlled split with all agents logged out, the call is given a busy tone just as when the call cannot queue to a nonvector controlled split according to the existing operation.

Vector events are generated for a RONA timeout when *converse-on* processes a call or results in a RONA redirection failure, and when a vector step is skipped because all AAS agents are logged out.

Do not assign vector-controlled splits coverage, forwarding, or night service, because Call Vectoring provides these functions. These functions do not apply to RONA-redirection calls involving vector-controlled splits.

- Calling/Called Number Display

A call to a split that RONA redirects is similar to a direct call to the split. If the call goes to coverage, the destination display looks like it does for a normal covered call.

9 Call Center

*Redirection on No Answer*

Page 9-126

An internal or DCS caller to an ACD hunt group or VDN sees displayed the hunt-group or VDN name and extension. This display remains when the call rings an agent. A Direct Agent call (with EAS) initiated at a voice terminal displays the agent name and logical ID when the call rings the agent's terminal. If the ACD-split or Direct Agent call goes to coverage, the name remains, but the extension or logical ID portion changes to "cover." This also happens when RONA redirects a call.

- Delay announcements

Delay announcements assigned to non-vector-controlled splits are applied to requeued RONA calls as usual for redirected calls.

- Direct Agent Calling

RONA applies to Direct Agent calls from splits with RONA assigned. RONA timing applies when a Direct Agent call (from an adjunct or voice terminal) is delivered to and rings an agent with manual answering. Agents are placed in AUX work mode or logged out even if they are the last agent in the split and ACD split calls are queued. Direct agent calls that are queued for an agent remain queued and are not delivered because the agent is unavailable. Don't-answer (DA) coverage continues for the queued calls.

If an agent with a coverage path is made unavailable by a RONA time-out on a non-covered Direct Agent call, the call follows the agent's coverage path. With EAS, the agent's logical extension coverage path for Direct Agent calls is used. If the agent has no coverage path or if the path is unavailable, the call cannot be redirected and the caller hears previously-provided feedback.

If Direct Agent call comes from a split that has forwarding or night service, the call is forwarded, precluding RONA timing. If the agent has forwarding or Send-All-Calls, the Direct Agent call is forwarded (ACD calls only) or goes to coverage, precluding RONA timing.

- Direct Department Calling

RONA applies to DDC-type hunt-group ACD calls.

- Home Agent

RONA applies to Home Agent lines that terminate on the CONVERSANT Home Agent system as a means to detect port failures. Home Agent lines use Manual Answer and are not present in AAS. Once RONA notification is made, you can correct the failure and restore service manually on CONVERSANT.

- Inbound Call Management (ICM)

RONA applies to ICM-managed calls that ring an agent in an ACD split with RONA assigned.

- Message Center/Server Service

You can assign RONA to Message Center/Server ACD splits.

- Multiple Call Handling (MCH)

If an MCH agent has a call active or on hold and the Redirection on No Answer timer expires for another ringing ACD call, the ringing call is redirected to the split/skill or administered VDN. When the call redirects, the agent is not made unavailable, but is placed in the Most Idle Agent (MIA) queue.

- Music-on-Hold access — Music on Transferred trunk call

Trunk callers who are transferred to another destination continue to hear administered music (or silence), not ringback, while the call rings. This applies while the transferred call queues to a split.

If the trunk call (an ACD call or Direct Agent call) is transferred to a split with RONA, timeout applies to the call, but the caller continues to hear the previous feedback instead of ringback.

- Night Service

When Night Service is activated, calls (including RONA calls) for the hunt group redirect to the night station extension. If the night service split has RONA assigned, RONA timing is reapplied to the redirected call.

- Queue status indications

Calls that RONA requeues are counted in the queued calls total. When a RONA call is queued, the call's call-wait time is reset, so RONA does not affect the oldest call waiting (OCW) time.

- Queuing

When redirected to a split, RONA timed-out ACD calls in a nonvector-controlled split are queued at the highest priority. These calls are distributed before any other calls, except Direct Agent calls.

- Stations

RONA applies to ACD split or direct agent ACD calls that ring at multifunction or hybrid stations with Manual Answering in an ACD hunt group.

RONA applies to Off-Premises Station (OPS) lines in an ACD split.

- Voice Response Integration (VRI)

You can assign RONA to converse splits. RONA timing applies to calls that a *converse-on* command queues and delivers. RONA timing is canceled if a call is delivered to an agent in another split to whom the system previously tried to queue a call.

RONA interacts with a converse split that is an AAS like any other AAS.

If RONA must redirect a call to an agent port in a converse split and the queue is full or all AAS agents are logged out, the call is processed by the next vector step while the caller continues to hear the previous vector feedback.

## Interactions with other ringing call timers

Several features time the ringing when an ACD call is delivered to an agent. You can use RONA's timer in conjunction with other timers.

### NOTE:

The timer that expires first applies to the call. RONA is canceled if any of the other timers expires first, except in the case of coverage timers.

When a coverage timer expires, RONA timing is canceled only when the call goes to coverage. If RONA times out first, the other timers continue timing or are stopped and may later be reset. The timers that may interact with RONA are listed in [Table 9-15](#) and [Table 9-16](#). [Table 9-16](#) indicates what happens to the timer if RONA times out first

**Table 9-15. Timer Description**

| Timer       | Description   |
|-------------|---|
| Split DA    | Split Call Coverage Don't Answer (nonvector-controlled) |
| Covering DA | Covering Point DA - Subsequent Redirection No Answer    |
| Agent DA    | Agent DA Coverage (Direct Agent Calls)                  |
| NATO        | DID/CO Trk No Answer Timeout                            |
| WAST        | Wait Answer Supervision Timer                           |

**Table 9-16. RONA/Timer Interaction**

| Timer       | RONA Timeout | Restarted After Redirection?                     |
|-------------|--------------|--|
| Split DA    | Stopped      | If queued or delivered to another agent          |
| Covering DA | Stopped      | If redirects to covering point                   |
| Agent DA    | Stopped      | If covers to Direct Agent with coverage          |
| NATO        | Continues    | N/A  |
| WAST        | Stopped      | If ringing destination or RONA redirection fails |

If you want RONA notification and redirection, set the number of rings (or equivalent time) for a RONA timeout to shorter than other timeout periods. DA timers start when a call is placed in queue and continue when the call rings the

station. Since RONA starts only when the call is ringing, the RONA interval is usually set to two or three rings, while the DA interval is set to 10 or more rings.

Since queue time is variable, assign a coverage timeout period that is greater than the longest expected queue time plus three or four rings (the time the call could ring the agent).

The NATO timer starts when the call seizes the incoming trunk. The timer could thus be timing before the call is queued by vector processing. Therefore, set the NATO timer to greater than the longest expected time before the call rings the agent (including time before and after being queued) plus three or four rings.

The WAST timer starts when the call rings the agent. Set the RONA timer to a slightly shorter interval (fewer than 10 rings) than the WAST 50-second interval.

## Universal Call ID

---

Universal Call ID (UCID) is a unique tag assigned to a call.

In simple call scenarios, the tag stays with that call within a DEFINITY-based network connected by ISDN lines. In complex call scenarios, the tag often merges with other tags.

### ⇒ NOTE:

The UCID data element is “universal” because it does not just identify a call on one particular DEFINITY switch; a UCID uniquely identifies a call across a network of DEFINITY switches.

## What is UCID’s purpose?

---

The purpose of UCID is to tag a call with a unique identifier.

UCID provides a way to track calls across multiple DEFINITY switches and Voice Response Units (INTUITY CONVERSANT for DEFINITY R6.3).

Call centers can use UCID to track call history. Because UCID can uniquely identify every call in a network of any size, it is possible to track call-related data from multiple sources (DEFINITY and INTUITY CONVERSANT) and multiple sites. For example, you can combine data from many locations and print reports that enable you to track a call throughout its lifecycle. For information about such reports, refer to the CentreVu<sup>®</sup> Call Management System R3V6 Reports manual 585-215-851.

### ⇒ NOTE:

Although UCID is intended for call centers, a DEFINITY ECS configured to create UCIDs will assign one to *every* call—not just to Automatic Call Distribution (ACD) calls.

In the near future, a client tool will use UCIDs to present a unified call record.

## What does UCID look like?

---

The Universal Call ID is an 8-byte data element that displays as a 20-character number. It looks something like this:

01035051001071518260

## How Does UCID Work?

---

For every new call that comes into or is originated by a DEFINITY or CONVERSANT product, the product creates a UCID. Depending on the call scenario, the UCID will either remain unique to that call or merge with other UCIDs.

## What creates UCIDs?

Both DEFINITY ECS and CONVERSANT can create UCIDs once the capability has been enabled. In other words, neither product automatically creates UCIDs until the feature is enabled.

## When are UCIDs created?

Once DEFINITY ECS or CONVERSANT is administered to create UCIDs, these products assign a UCID to each call. For incoming calls over ISDN trunks, DEFINITY ECS determines whether or not the call already has a UCID. If so, the switch preserves the existing UCID and does not create a new one. If the call does not have a UCID, the switch creates one when call processing begins. For incoming calls over non-ISDN trunks, DEFINITY ECS creates a UCID for the call because non-ISDN trunks do not support the transmission of UCID.

For outgoing calls, DEFINITY ECS creates a UCID when the caller goes off-hook.

## How are UCIDs transmitted?

How DEFINITY ECS transmits UCIDs depends on the sending and receiving equipment. See [Table 9-17](#) for an overview.

**Table 9-17. UCID Transmission**

| Sender             | Receiver           | Connection   | UCID contained in  |
|--------------------|--------------------|--|--|
| DEFINITY ECS       | DEFINITY ECS       | ISDN (BRI or PRI) trunks using QSIG service protocol       | codeset 0 Facility IE as manufacturer specific information (MSI) IE <sup>1</sup> |
| DEFINITY ECS       | DEFINITY ECS       | ISDN (BRI or PRI) trunks using Shared UUI service protocol | codeset 0 shared user-to-user information (UUI) IE <sup>1</sup>                  |
| DEFINITY ECS       | INTUITY CONVERSANT | ASAI   | various ASAI messages  |
| INTUITY CONVERSANT | DEFINITY ECS       | ISDN-PRI   | codeset 0 shared UUI IE <sup>1</sup>   |
| DEFINITY ECS       | CentreVu CMS       | BX.25  | SETUP5 CMS message   |
| DEFINITY ECS       | CTI adjunct        | ASAI   | various ASAI messages  |

1. Refer to [Information Forwarding](#) section.

## How are UCIDs tracked?

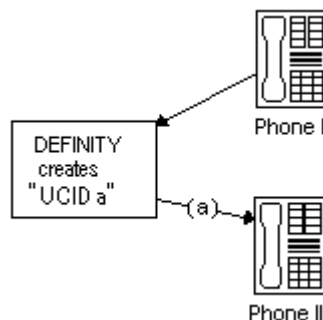

---

The way a network maintains and tracks a UCID depends on the call path. To illustrate UCID transport throughout a call's life cycle, this section describes several call scenarios:

- Station-to-station Calls
- Incoming Trunk Calls
- Outgoing Trunk Calls
- Simple Transfer or Conference
- Complex Transfer *and* Conference

### Station-to-Station Calls

This scenario describes what happens when Phone I calls Phone II (both phones are on the same switch).

DEFINITY creates a new UCID (such as UCID "a") for any call originated by an internal station user.

## Incoming Trunk Calls

UCID is assigned to an incoming call.

DEFINITY either

- receives UCID “x” information from an incoming call over an ISDN trunk.
- creates UCID “y” for incoming calls that do not already have a UCID.

There is one CMS call history record for each incoming call.

## Outgoing Trunk Calls

UCID is associated with the outgoing trunk call from Phone I.

DEFINITY creates a UCID (such as UCID “x”) for an outgoing trunk call and then sends it over an outgoing shared UUI or QSIG ISDN trunk.

DEFINITY creates a UCID (such as UCID “x”) for an outgoing trunk call even if the trunk (such as a non-ISDN trunk) does not support the transmission of a UCID.

## Simple Transfer or Conference

This scenario describes a simple transfer or conference call scenario.

When an incoming trunk or station call is received by the station user at Phone I and transferred to or conferenced with another station user or outside party:

1. DEFINITY creates a UCID for the incoming call if it needs one.

2. DEFINITY creates a new UCID for the temporary conference or transfer portion of the call.

3. DEFINITY merges the temporary portion of the call with the original call when the conference or transfer is completed within the DEFINITY switch. This is when the overriding UCID (such as UCID "a"), becomes the UCID for all parties within the DEFINITY.

**⇒ NOTE:**

If the outgoing trunk does not support the sending of UCIDs, then the UCID of the outgoing call at the receiving switch will be "null".

If the call is transferred to another switch, only the UCID for the transfer (UCID "b") gets passed on. This is because the DEFINITY cannot merge UCIDs if the call is not completed within the switch.

**⇒ NOTE:**

If, during the conference or transfer, the incoming call drops before the operation is complete, the two UCIDs will not appear to be associated because no merge of the two parts of the call was done.

### Complex Conference

The following complex call scenario illustrates when a station user adds an incoming call to an existing conference.

In this scenario,

1. Phones I, II, and III are in the same conference call with UCID "x".
2. The person at Phone III receives an incoming call from Phone IV (this call has UCID "y" associated with it).

3. The person at Phone III puts the conference call on hold and answers the incoming call from Phone IV.
4. The person at Phone III decides to add Phone IV into the conference call.
5. The person at Phone III
  - a. presses the Conference button
  - b. presses the call appearance button to return to the conference call
  - c. presses the Conference button again.

This brings the conference call into the call between Phones III and IV.

6. UCID "y" overrides UCID "x" because the DEFINITY views Phone IV as the primary party in the conference initiated by step 5.

7. The UCIDs associated with each segment of the complex conference are sent to CMS if the parties in the call are measured (for this example, if the parties are ACD agents in a measured split/skill).

## DEFINITY before INTUITY CONVERSANT

The following scenarios describe what happens to UCID information when a call comes in to DEFINITY before it goes to INTUITY CONVERSANT. In this configuration, the INTUITY CONVERSANT serves as a Voice-Response Unit (VRU) that controls the routing of incoming ACD calls.

### ⇒ NOTE:

This configuration is more common than a call coming in to INTUITY CONVERSANT before reaching DEFINITY.

This section describes two scenarios:

- Simple call tracking
- CONVERSANT transfers a call

### Simple call tracking

The following call scenario describes when a call comes in to DEFINITY before INTUITY CONVERSANT.

When DEFINITY is before INTUITY CONVERSANT:

1. DEFINITY ECS receives an incoming call over an ISDN trunk.
2. DEFINITY does one of two things:
  - If the incoming call has a UCID (such as UCID “x”), then DEFINITY passes it along.
  - If the incoming call does not have an associated UCID, DEFINITY creates a new one (such as UCID “y”).
3. DEFINITY passes the UCID to INTUITY CONVERSANT through an ASAI connection (via the activation of split/skill or VDN “event notification” by the INTUITY CONVERSANT).
4. UCID information is sent to CMS if trunk, VDN(s), and/or split/skill(s) involved in the call are measured.

### INTUITY CONVERSANT Transfers a Call

The following call scenario involves a CONVERSANT behind DEFINITY configuration when CONVERSANT initiates a call transfer after the call is answered by a port on the INTUITY CONVERSANT that serves as an ACD agent.

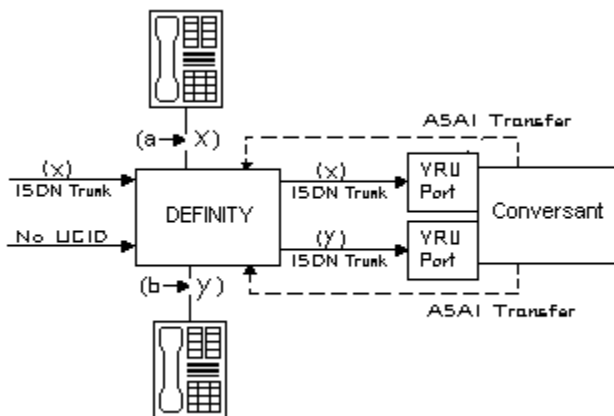

1. Call is directed to INTUITY CONVERSANT VRU port (typically by call vectoring) with UCID information (UCID "x" or UCID "y").

2. INTUITY CONVERSANT determines the call's destination and transfers the call (via an ASAI "third-party transfer" operation).

3. DEFINITY ECS temporarily creates a new UCID (such as UCID "a" or UCID "b") for the transfer portion of the call (the original UCID is quickly merged into the call).

4. The UCIDs of the transfer segment and merged call are returned to INTUITY CONVERSANT in ASAI acknowledgment messages.

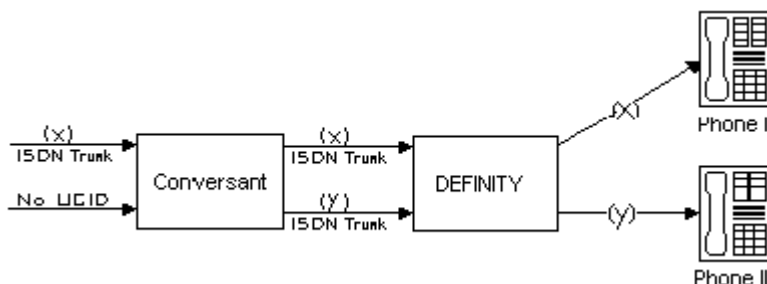

- DEFINITY sends UCID information to CMS if trunk, VDN(s), and/or split/skill(s) involved in the call are measured.

### INTUITY CONVERSANT before DEFINITY

This scenario illustrates a system configuration where a call comes in to INTUITY CONVERSANT before reaching DEFINITY. In this configuration, INTUITY CONVERSANT provides voice response services and/or call screening so that the number of incoming calls to the DEFINITY ECS is reduced.

**⇒ NOTE:**

This configuration is less common than the DEFINITY before INTUITY CONVERSANT configuration.

### When INTUITY CONVERSANT is before DEFINITY

- INTUITY CONVERSANT receives an incoming call with UCID "x".

or

INTUITY CONVERSANT creates a new UCID "y" and associates it with the incoming call (if the call has no UCID already associated with it).

**⇒ NOTE:**

For INTUITY CONVERSANT to recognize an incoming UCID (such as UCID "x") from an ISDN trunk, special INTUITY CONVERSANT scripting is required. When INTUITY CONVERSANT receives a call from the public network, it automatically creates a new UCID because it cannot recognize whether or not the call already has a UCID.

- INTUITY CONVERSANT sends UCID to DEFINITY ECS over an ISDN-PRI trunk.
- DEFINITY receives UCID and reuses it for the incoming call.
- DEFINITY reports UCID to CMS if the trunks, VDNs, and/or splits/skills associated with the call are measured.

## Interactions

---

- Distributed Communications System (DCS)
 

If DCS is used in a network of DEFINITY switches where UCIDs are tracked, the DCS feature must be configured with ISDN trunks having the Shared UUI service protocol. Otherwise, calls that are handled through one of the many DCS features (such as DCS Coverage) will not retain the UCID initially assigned to the call.
- Remote AUDIX
 

For remote AUDIX over DCS, the DCS trunk(s) used to accomplish the remote AUDIX operation must be configured (as described previously in “Distributed Communications System”) to retain the UCID associated with a call.
- Tandem Calls
 

When a call is tandemed through a DEFINITY ECS switch, the UCID information may be blocked or passed through the tandem switch. To pass a UCID through a tandem switch, both the incoming and outgoing trunks at the tandem switch must be configured to handle UCIDs. See [“Information Forwarding” on page 9-89](#) for proper private and public network information forwarding administration.

## Before You Start

---

Before you start to administer the UCID feature, be aware that UCIDs are successfully transmitted *only* when all DEFINITY network components meet the requirements (software and connections) specified below.

Some requirements vary, depending on how you want to use UCID. [Table 9-18](#) shows the requirements for different applications of UCID.

**Table 9-18. Requirements for UCID Applications**

| What do you want to do?                     | Your system must meet the following <b>software</b> requirements... | Your system must have the following <b>connections</b> ...     |
|---|---|--|
| Have DEFINITY create UCIDs                  | DEFINITY R6.3 or later  |  |
| Have DEFINITY send UCID to another DEFINITY | DEFINITY R6.3 or later  | ISDN (BRI/PRI) trunks with Shared UUI or QSIG service protocol |
| Have DEFINITY send UCID to CONVERSANT       | DEFINITY R6.3 or later<br>CONVERSANT 7.0 or later                   | ASA link to CONVERSANT   |

**Table 9-18. Requirements for UCID Applications**

| What do you want to do?                       | Your system must meet the following <b>software</b> requirements...   | Your system must have the following <b>connections</b> ...          |
|---|---|---|
| Have DEFINITY receive UCID from CONVERSANT    | DEFINITY R6.3 or later<br>CONVERSANT 7.0 or later   | ISDN-PRI connection (with shared UUI) between switch and CONVERSANT |
| Have DEFINITY send UCIDs to CMS               | DEFINITY R6.3 or later<br>CMS R3V6 or later   | BX.25 connection from switch to CMS                                 |
| Have DEFINITY send UCIDs to a CTI Application | DEFINITY R6.3 or later<br>T-Server R3.1.0 or later<br>DEFINITY PBX Driver (G3PD)- R3.1.0 or later<br>CallVisor PC V6 or later | ASAI link to adjunct  |

 **NOTE:**

You can check your software version numbers by typing **list config software** at the SAT terminal. Because “V6” (version 6) includes 6.1 through 6.3, you may have to check that your network has the separate 6.3 upgrade (this is the earliest DEFINITY version to support UCID).

To maximize the benefits of UCID, it is recommended that all switches be configured with DEFINITY R6.3 (or later) software. However, because upgrading a network is often a gradual process, there may be a switch that cannot yet support UCIDs. In this environment, disallow the UCID transmission for any trunk group connected to a pre-DEFINITY R6.3 switch. For information about enabling or disabling UCID transmission on a trunk group, see “How to Administer Universal Call ID” later in this chapter.

In the case of a DEFINITY network component that cannot support UCIDs, it is recommended that the component (ISDN trunk group, ASAI connection, or CMS software) be administered to disallow the sending or receiving of UCID. For example, if a DEFINITY R6.3 is connected to a non-Lucent Technologies PBX, then the connecting ISDN trunk must be administered to not send UCID over that trunk for outgoing calls.

**How to Administer Universal Call ID**

These instructions assume you’re using the SAT (Subscriber Access Terminal) screen or a terminal emulator to access the DEFINITY software.

There are three tasks involved in administering UCID on DEFINITY ECS. Complete these tasks in the following order:

- Task a. Check ASAI Interface before enabling UCID
- Task b. Set DEFINITY ECS to create and send UCIDs
- Task c. Enable UCID Transmission on Trunk Groups

### Task a: Check ASAI Interface before enabling UCID

If this procedure is not performed, you may encounter the “ASAI Interface feature not assigned” error message in later steps.

**Table 9-19. Form Needed to Check ASAI Interface**

| Form needed       | Field needed?  | Why is this field needed?            | Is field optional? | Page                  |
|-------------------|----------------|--------------------------------------|--------------------|-----------------------|
| Optional Features | ASAI Interface | Global setting to send UCIDs to ASAI | Y                  | <a href="#">5-277</a> |

To check the ASAI interface:

1. In the command line, enter **change system-parameters customer-options** and press RETURN.
2. On page 1, enter **y** in the *ASAI Interface* field.
3. Log out and log back in if this and any other fields in this form have changed.

## Task b: Set DEFINITY ECS to create and send UCIDs

You must administer each DEFINITY switch that you want to create UCIDs. If you do not administer a switch, it will pass along an already-created UCID, but it won't create one if a call comes to it first.

**Table 9-20. Forms Needed for DEFINITY to Create and Send UCID**

| Form needed                       | Fields needed                    | Why is this field needed?                        | Is field optional? | Page                  |
|-----------------------------------|----------------------------------|--|--------------------|-----------------------|
| Feature-Related System Parameters | Create Universal Call ID (UCID)? | To generate a UCID for each call when necessary. | N                  | <a href="#">5-133</a> |
|                                   | UCID Network Node ID             | Important component of the UCID tag.             | N                  | <a href="#">5-133</a> |
|                                   | Send UCID to ASAI?               | So that ASAI receives UCIDs.                     | Y                  | <a href="#">5-141</a> |
|                                   | Adjunct CMS Release              | So that CMS receives UCIDs.                      | Y                  | <a href="#">5-145</a> |

For DEFINITY to create and send UCIDs:

1. If your network includes CMS and you want CMS to track UCIDs, then enter **busyout mis** in the command line. If not, go to step 2.
2. In the command line, enter **change system-parameters feature** and press RETURN.  
The Feature-Related System Parameters form comes up.
3. Go to page 4 of the form.
4. In the Create Universal Call ID (UCID)? field, enter **y**.
5. In the UCID Network Node ID field, enter the node ID number.

Valid numbers are from 1 to 32,767.

### CAUTION:

*The UCID Network Node ID **must** be unique for every DEFINITY and CONVERSANT in the system. If it is not unique, the integrity of the UCID is compromised.*

6. If your network includes ASAI, go to page 7 of the form. If not, go to step 8.
7. In the Send UCID to ASAI? field, enter **y**.

8. If you have performed the **busyout mis** command, go to step 9. If not, you are done with this task (Task b), so press **(ENTER)** to save your work and go to Task c.
9. Go to page 8 of the form.
10. In the `Adjunct CMS Release` field, enter **R3V6**.
11. Press **(ENTER)** to save your work.
12. In the command line, enter **release mis**.

### Task c: Enable UCID Transmission on Trunk Groups

When you send UCIDs over ISDN trunks, it is administered on a trunk group basis. [Table 9-21](#) provides the form and field information that you need to perform this task.

**Table 9-21. Enabling UCID transmission on trunk groups**

| Form needed | Fields needed                  | Why is this field needed?  | Is field optional? | Page                  |
|-------------|--------------------------------|--|--------------------|-----------------------|
| Trunk Group | Group Type                     | To specify correct trunk type: ISDN is the only type that supports UCID. | N                  | <a href="#">7-202</a> |
|             | Supplementary Service Protocol | Specify correct service type. <b>b</b> is for QSIG, others are for UUI.  | N                  | <a href="#">7-202</a> |
|             | Send UCID?                     | Allows or blocks UCID transmission.                                      | N                  | <a href="#">7-208</a> |

To enable UCID transmission on a trunk group:

1. In the command line, enter **change trunk-group n** and press RETURN.  
The Trunk Group administration form comes up. *n* is the number of the trunk group you want to administer.
2. On page 1, enter **ISDN** in the Group Type field.
3. In the `Supplementary Service Protocol` field, enter the letter of the service protocol you want for this trunk group.  
**b** is for QSIG, other protocols are for UUI.
4. Go to page 2 of the form.
5. In the `Send UCID?` field, enter **y**.
6. Press **(ENTER)** to save your changes.

You also need to administer your trunk groups to send user data over your private and public networks. To administer the trunk groups, see [“Information Forwarding” on page 9-89](#).

## Considerations

---

- UCID has been tested with several major carriers. To find out if these capabilities work with your carrier, check with your account team for the most current information. If testing has not been done to verify operation over the public networks involved with the preferred specific configuration, use of private ISDN trunking between the nodes should be assumed until successful testing has been completed.

## Troubleshooting

---

The following troubleshooting hints should be reviewed when UCIDs are not transmitted, even though you received no error messages while administering the UCID feature, and all software and connections meet the minimum requirements:

- A tandem switch has the `Send UCID?` option set to **y** for all trunk groups that AAR/ARS or station users may use to tandem an incoming call.
- If DCS is used, make sure *all* ISDN trunks between DEFINITY switches used for DCS or remote AUDIX are configured in the D-channel mode.
- For CMS tracking purposes, make sure all trunks, VDN, and split/skills that handle calls for which UCIDs are tracked are administered as “measured” (either “both” or “external”).

## VDN in a Coverage Path

---

VDN in a Coverage Path (VICP) enhances Call Coverage and Call Vectoring to allow you to assign Vector Directory Numbers (VDNs) as the last point in coverage paths. Calls that go to coverage can be processed by vectoring/prompting to extend Call Coverage treatments.

### How to administer VICP

---

#### Required Forms

---

| Form                    | Field | Page                  |
|-------------------------|-------|-----------------------|
| Coverage Paths          | ■ All | <a href="#">5-94</a>  |
| Call Vector             | ■ All | <a href="#">9-207</a> |
| Vector Directory Number | ■ All | <a href="#">9-214</a> |

- Call Coverage Path form — Set one of the following to the extension of the VDN to be used as a coverage point: Point 1, Point 2, Point 3, Point 4, Point 5, Point 6.

### Considerations

---

A VDN is not allowed as a member of a coverage answer group. A vector cannot route a covered call to a coverage answer group — a coverage answer group can only be a point in a coverage path.

Removing a VDN from the system with the *remove vdn <extension>* command automatically removes the VDN from any coverage paths.

### Interactions

---

None

## VDN of Origin Announcement

---

VDN of Origin Announcement (VOA) provides agents with a short message about a caller's city of origin or requested service based on the VDN used to process the call.

Use VOA messages to help agents to respond appropriately to callers. For example, if you have two 800 numbers, one for placing orders and one for technical support, you can administer two VDNs to route calls to the same set of agents. When an incoming call is routed to a VDN with a VOA assigned (for example, "new order" or "tech help"), the VDN routes the call to a vector, which can place the call in an agent queue. When an agent answers the call, he or she hears the VOA message and can respond appropriately to the caller's request.

### How to administer VOA

---

#### Required forms

| Form                              | Field   | Page                  |
|-----------------------------------|---|-----------------------|
| Attendant Console                 | <ul style="list-style-type: none"> <li>■ Feature Button Assignments — VOA Repeat</li> </ul> | <a href="#">5-35</a>  |
| Class of Restriction (COR)        | <ul style="list-style-type: none"> <li>■ VDN of Origin Announcements</li> </ul>             | <a href="#">5-72</a>  |
| Feature-Related System Parameters | <ul style="list-style-type: none"> <li>■ Hear Zip Tone Following VOA?</li> </ul>            | <a href="#">5-123</a> |
| Announcements/Audio Sources       | <ul style="list-style-type: none"> <li>■ All</li> </ul>                                     | <a href="#">5-26</a>  |
| Vector Directory Number           | <ul style="list-style-type: none"> <li>■ VDN of Origin Annc. Extension</li> </ul>           | <a href="#">9-214</a> |
| Voice Terminals                   | <ul style="list-style-type: none"> <li>■ Feature Button Assignments — VOA Repeat</li> </ul> | <a href="#">6-4</a>   |

- Announcements/Audio Sources — Assign each VOA you want to use. You can administer aux-trunk types with queue, without queue, and with barge-in. You can administer integrated types with queue and without queue. Do not administer analog and integrated repeating announcement types as VOAs.

The VDN for which you are administering a VOA must be in a vector command line.

### Detailed description

---

The agent cannot hear the caller while the VOA message is playing. The caller is not connected to the agent until after the message completes and cannot hear the message or the agent during the message. The caller hears ringback while the agent is listening to the VOA.

Agents logged in at multiline terminals see the call-appearance button for an incoming call flash until after the VOA completes. An agent can press the flashing call-appearance button to stop the VOA.

To repeat the VOA, an agent presses the VOA Repeat button. The VOA Repeat button lamp lights during the VOA. The VOA Repeat button lamp remains lit if the repeat request is queued. If an agent presses the VOA Repeat button while the lamp is lit, the VOA is stopped. If an agent presses the VOA Repeat button but there is no VOA or the system cannot play the VOA within three seconds, the lamp flutters.

You assign VOAs for each VDN. However, the VOA applies to a COR, so you must administer a COR for agents who will receive VOAs.

You can set up VOAs in four ways:

- Agents can hear a unique announcement based on the dialed number identification service (DNIS) received from the service office or carrier switch. Assign each DNIS as the VDN of a vector. Set up the VOA to announce the services associated with the DNIS.

 **NOTE:**

The announcement associated with the current VDN only plays if the VDN Override for the previous VDN is set to y. If VDN Override for the previous VDN is set to n, the VOA associated with that VDN plays.

- Use vector steps, an integrated prompting, or *converse-on* step to route calls to a VDN. Set up the VOA to announce the service the caller requested or to announce a condition that caused the call to *route-to* the VDN.
- You can route calls to a voice response system, directly or through a vector. Use voice prompting to direct the caller to enter a touchtone response, and route the call to a specific VDN based on the caller's response. Set up the VOA to indicate the service the caller selected.
- If agents require a caller's city of origin, assign the trunk group to a particular VDN. Set up the VOA to provide the location of the origin of the trunk group. Subsequent VDNs can be used to handle the call, or multiple VDNs can be assigned to a single vector.

 **NOTE:**

VDN Override applies to VOA in the same way that VDN Override applies to display information. If a VDN with a VOA has VDN Override enabled, the system overrides the original VOA with VOAs in subsequent VDNs to which the call is routed.

## Considerations

---

- Because callers are kept waiting while a VOA plays, messages should be kept very brief — no more than 1.5 seconds in length. Agents should use a speakerphone or headset, so they do not miss the VOA while they are picking up the handset. If agents cannot use a speakerphone or headset, administer voice terminals with a VOA Repeat button.
- If you have multiple announcement boards, you should place shorter VOAs on one board and longer recorded announcements on the other to avoid delaying delivery of VOAs. If you have only one announcement board, place VOAs on the integrated board and consider installing an auxiliary announcement device for longer announcements.
- Agents must be on the same switch as the VOA.
- A VOA can be assigned to multiple VDNs, but a VDN can have only one VOA.
- If you use the TN750 circuit board for integrated announcements, the system maintains a separate logical queue for VOAs. If the VOA cannot be delivered to the agent within 1 second because of traffic or inoperative equipment, the system does not provide the announcement. VOAs are higher priority than other announcements on the TN750. A burst of VOAs can delay other announcements. Therefore, record non-VDN of Origin Announcements as auxiliary or analog.
- Auxiliary announcements are connected for a duration of 1 to 2 seconds on a barge-in basis, immediately after the agent answers (or is assigned the call for auto-answer) and the incoming call is extended to the agent. Integrated and non-barge-in auxiliary announcements are connected for the duration of the announcement. The switch does not ensure that the integrated announcement is shorter than the allowed playback time.
- VOA supports Auxiliary Trunks (aux-trunk) with barge-in, queue, or without queue. For aux-trunk with or without queue, when the trunk is idle, a VDN call seizes the trunk to start the VOA and the system plays the entire announcement (not just 1 to 2 seconds). However, if the announcement is busy and if aux-trunk has barge-in, the call does not queue but bridges onto the announcement for 1 to 2 seconds. When the VOA completes, the trunk is released along with the listeners, and the next call requiring the VOA starts the process over again. For this reason, your aux-trunk announcements should consist of one short announcement that repeats during the full announcement time. For example, you might want to record “New Order” as many times as possible, so that when a call bridges to the announcement, the agent hears “New Order” no matter where the agent bridges into the announcement.
- If you use aux-trunk or integrated announcement without queue and a port is busy when a VDN call comes in, the system cannot play an announcement. If you use aux-trunk or integrated announcement with queue, the system plays the current announcement for an agent and then connects the next agent in the queue.

## Interactions

---

- Agent Call Handling (Answering Options)
  - Automatic Answer

ACD agents at voice terminals in Auto Answer mode hear a zip tone, then the VOA. You can also administer a zip tone after the VOA completes, to alert agents that an announcement is complete and a caller is connected.

Non-ACD agents can receive a VOA if a call is routed to them via vector processing. When non-ACD agents at voice terminals in Automatic Answer mode receive calls, they hear a call ID tone then the VOA. Agents hear a second zip tone after the VOA indicating connection to the caller.
  - Manual Answer

When non-ACD agents at voice terminals in Manual Answer mode receive calls they hear ringing, answer the call, and hear the VOA.
- ASAI Adjunct Routing

If a vector step includes Adjunct Routing, the VOA is played for the agent to whom the call is routed.
- Auto-Available Split (AAS)

AAS is intended to be used for splits containing only nonhuman adjuncts such as AUDIX or Conversant; however, VOAs can be directed to Auto-Available splits.
- Call Forwarding

VOAs apply to forwarded calls, including those forwarded to a hunt group. The answering station must be on the same switch. If a VOA is forwarded, the message is played only if the destination extension is administered with a COR that allows VOA.
- Call Pickup

Call Pickup allows an agent to pick up a ringing call on another extension. If the pick-up extension has COR permissions for VOA, the agent can receive a VOA.
- Conference

If an agent receives a call and then conferences in additional stations, any station on the connection can use VOA Repeat button to replay the VOA. Only the person using the button can hear the VOA unless the call is being service observed.

- Converse-on split

A converse-on split is one used in a *converse-on* vector step. When a *converse-on* vector step is executed, a VOA is not applied. After returning to the vector, the call can be routed to a station or VDN where the answering agent receives the VOA (as if the *converse-on* step had not been processed).

- Coverage

VOA applies to coverage paths.

- Data Restriction

Data Restriction prevents tones from being applied to line or trunk circuits during a data call. VOAs are not played for data-restricted calls.

- Direct Agent Calling

Direct Agent Calling allows a vector to route a call to particular ACD agent and have the call treated as an ACD call. The VOA only applies to direct agent calls if the calls reach an agent through vector processing. Direct agent calls from a voice terminal on a switch are not vector-processed and cannot cause a VOA to be played.

- Enhanced Automatic Wake-up

If you are using enhancements to Automatic Wake-up with integrated announcements, there can be contention for integrated announcement ports. VOAs have priority over Automatic Wake-Up announcements.

- Expert Agent Selection (EAS)

When you are using EAS, the logical agent COR definition determines the assignment of VOAs for each extension. EAS uses the COR of the logical agent instead of the COR for the terminal being used by the agent.

- Hold

Agents cannot use the VOA Repeat button if their calls are all on hold. The VOA Repeat button only applies to active calls.

- Home Agent

You can assign an initial VOA to a home-agent port on the switch. However, home agents cannot use a VOA Repeat button because home agents need a dial access code (DAC) to reach features and VOA replay does not use a DAC.

- Hunt Groups

VOAs apply to calls routed to a hunt group. The COR for the answering station's extension determines whether the station can receive a VOA.

- Lookahead Interflow

VOAs apply only to the switch where the VDN is defined. If a call interflows to another switch, the VOA is lost. You can have the interflow to another switch access a VDN with the same VOA message as on the original switch.
- Redirection on No Answer (RONA)

If a call re-queues to a split or skill because the RONA timer expired, the VOA applies to the call when an agent answers the call.
- Service Observing

The system handles Service Observing calls as conference connections. If the observer presses the VOA Repeat button only he or she hears the announcement. However, if another party on the call presses the VOA Repeat button, the user and the observer hear the VOA.
- Supervisor Assist

If an agent requests supervisor assistance and conferences the supervisor into a call, either the agent or the supervisor can use their VOA Repeat button to replay the VOA, but only the person who presses the button hears the VOA.
- Transfers

If an agent receives a VDN call and transfers the call, the answering party can use the VOA Repeat button to replay the message.
- VOA distribution

If you use long VOAs or multiple VOAs, there may be a delay between the zip tone and the announcement. The system provides multiple announcement circuit packs to help prevent announcement delays. Contact your Lucent representative for more information.

## Voice Response Integration

---

Voice Response Integration (VRI) integrates Call Vectoring with the capabilities of voice response units (VRUs) such as the Lucent Technologies CONVERSANT Voice Information System (CVIS). With VRI, you can:

- Run a VRU script while retaining control of a call in vector processing
- Run a VRU script while a call is queued, retaining its position in the queue
- Pool CONVERSANT ports for multiple applications
- Use a VRU as a flexible external-announcement device
- Pass data between the system and a VRU
- Tandem VRU data through a switch to an ASAI host

The *converse-on* command, which is part of Basic Call Vectoring, provides these capabilities. Use a *converse-on* call-vector step to integrate a VRU with Automatic Call Distribution (ACD). VRI allows you to use VRU capabilities while controlling a call in ACD.

Include VRUs with vector processing to take advantage of the following:

- Access to local and host databases
- Validation of caller information
- Text-to-speech capabilities
- Speech recognition
- Increased recorded announcement capacity
- Audiotex applications
- Interactive voice-response (IVR) applications
- Transaction-processing applications

VRI allows users to make productive use of queuing time. For example, while a call is queued, a caller can listen to product information via an audiotex application or can complete an interactive voice-response transaction. It may be possible to resolve the caller's questions while the call is queued, which helps reduce queuing time for other callers during peak times.

For more information on VRI and the *converse-on* command, see the *DEFINITY Enterprise Communications Server Release 6 Call Vectoring/Expert Agent Selection (EAS)*.

## How to administer VRI

---

Enable Call Prompting to allow the system to collect digits from the caller and CONVERSANT to return data. You must have Call Prompting to administer the Converse Data Return Code and use the digits keyword for the <data\_1> or <data\_2> fields on the *converse-on* command.

### Required forms

| Form                                  | Field   | Page                  |
|---------------------------------------|---|-----------------------|
| System Parameters<br>Customer-Options | ■ Call Prompting  | <a href="#">5-277</a> |
| Feature Access Code (FAC)             | ■ Converse Data Return Code                                     | <a href="#">5-113</a> |
| Feature-Related System<br>Parameters  | ■ Converse Delay Data1/Data2<br>■ Converse Signaling Tone/Pause | <a href="#">5-123</a> |
| Call Vector                           | ■ All   | <a href="#">9-207</a> |

## Detailed description

---

A call queued to an ACD split retains position in the queue while a VRU script is being run. When an agent becomes available, the line to the VRU is dropped and the caller connects to the agent.

The *converse-on* command delivers a call to a predetermined converse split (skill). A converse split is administered and operates exactly like other splits. Nonconverse splits are ACD splits accessed by *queue-to main* and *check-backup* vector steps.

Members of a converse split are the ports connected to the VRU. If all VRU ports are busy, a call queues to the converse split with the administered priority. After the VRU answers the call, the *converse-on* command may pass up to 2 data items to the VRU, depending on command parameters specified. You can pass data required by a VRU script or data that selects the VRU script to be run.

Whether or not you pass data, a caller is connected to the VRU, which runs the VRU script. Audible feedback provided by the vector is not heard and no further vector steps are run until the VRU script completes. The VRU may return data to the system and then drops the line to the system. Vector processing continues at the step following the *converse-on* command.

If the call was queued to a nonconverse split before the *converse-on* command was run, the call retains its queue position. If an agent becomes available while the VRU script runs, the system drops the line to the VRU and connects the caller to the agent. The VRU detects the disconnect and terminates the VRU script. For *converse-on* command syntax, see *DEFINITY Enterprise Communications Server Release 6 Call Vectoring/Expert Agent Selection (EAS)*.

Call Prompting allows you to collect and use digits that the VRU returns. These digits are handled as dial-ahead digits. Rules for collecting and processing VRU digits are the same as for Call Prompting.

You can use digits returned from the VRU in the following ways:

- To display for the answering agent's (automatically for 2-line displays or with the CALLR-INFO button for other displays)
- As an extension in a *route-to digits* vector step. For example:

```
converse-on split . . . (VRU returns 4 digits)
collect 4 digits after announcement none
route-to digits coverage y
```

- For vector-conditional branching in an *if digits equals* vector step. For example:

```
converse-on split . . . (VRU returns 1 digit)
collect 1 digit after announcement none
goto vector 101 if digits = 1
goto vector 102 if digits = 2
goto vector 103 if unconditionally
```

- Tandemed to an ASAI host

Collected digits are passed to ASAI hosts in Call Offered to Domain Event reports and in *route request* messages, thus caller digits or database information returned from the VRU can be tandemed through the system to ASAI hosts. For example:

```
converse-on split ... (VRU returns 9 digits)
collect 9 digits after announcement none
adjunct route link Y
```

In this vector, the digits returned from the VRU are forwarded to the ASAI host in the adjunct routing *route request* message.

### SECURITY ALERT:

*When you use a VRU application that returns data for a collect-digits step, the opportunity for toll fraud exists when the VRU application does not return any data. Take the following precautions:*

- If the collected digits are used to route calls internally, ensure that the Class of Restriction (COR) for the vector directory number (VDN) does not allow calls to route externally.

- If the collected digits are used to route calls externally, use a password to verify that the collected digits have been passed by the VRU application. For example, in the following vector, the VRU application returns a 3-digit password followed by the 8-digit external number. The vector routes calls without the correct password to a vector 23.

```
converse-on split 10 pri m passing none and none (VRU returns  
11 digits)  
collect 3 digits after announcement none  
goto vector 23 if digits <> 234  
collect 8 digits after announcement none  
route-to digits with coverage n
```

## Interactions

---

Converse splits interact like other vector-controlled splits unless noted here.

- Adjunct Switch Applications Interface (ASAI)

When a *converse-on* vector step places a call to an ASAI-monitored domain, ASAI event messages are sent over the ASAI link. When a *converse-on* step places an ASAI-monitored call, the ALERT message sent to the ASAI adjunct includes a cause IE, Coding Standard 3 value 23 (CS3/23), which informs the adjunct that the call has not been dequeued from any nonconverse splits.

If a *converse-on* step is run while an adjunct routing request is outstanding, the request is canceled.

ASAI cannot transfer or conference calls, but can direct the system to do this.

- Agents

Although not recommended, you can use a *converse-on* step to deliver a call to a group of human agents. To agents, the call looks like an ACD call, except they cannot use certain features, such as Transfer, Conference, and Supervisor Assist.

The agent can return data to vector processing by pushing the transfer button (or flash hook on analog) and dialing the converse-on data return code and required digits.

- Answer supervision

Answer supervision is returned only once during a call. If a call is answered because of a *converse-on* step, answer supervision is sent if it hasn't previously been sent. If digits are passed to the VRU, answer supervision is sent after digits are sent.

- INTUITY AUDIX

If a *converse-on* step calls AUDIX, the call is handled as a direct call to AUDIX. The caller hears the AUDIX welcome message and can retrieve messages as usual.

If a call is forwarded to a VDN and then delivered to an AUDIX hunt group by a *converse-on* step, the call to AUDIX is treated as a redirected call, and the caller may leave a message.

- Auto-Available Split (AAS)

A *converse-on* vector step can place a call to an AAS. Use auto-available converse splits for VRI except when ASAI controls the converse split.

- Automatic answering

When you administer CONVERSANT ports as agents of a converse split, do not administer agents as automatic answer. The system-provided zip tone may interfere with the interaction between CONVERSANT and the calling party.

- BCMS/CMS

BCMS tracks calls that a *converse-on* step places to a BCMS-measured hunt group. CMS tracks calls that a *converse-on* step places to a CMS-measured hunt group, split, or skill.

The VDN tracks such calls as waiting in the vector. A call is considered answered when answered by a nonconverse split agent, not when answered by a converse split agent. The converse split tracks this as a separate “answered” call when the VRU answers. Though trunk and split totals may no longer match, VDN and trunk totals match.

- Call Detail Recording

The duration of a call to a VDN is recorded from when answer supervision is returned after a successful *converse-on* step. Unsuccessful *converse-on* steps do not generate ineffective call-attempt records. *Converse-on* steps cannot place calls; these steps simply direct a call to a hunt group.

- Call Park

Calls that a *converse-on* step placed cannot be parked.

- Call Pickup

Do not use Call Pickup with *converse-on* steps.

- Class of Restriction

The system does not check CORs when a *converse-on* vector step routes a call to a split.

- Conference

You cannot conference a call routed by a *converse-on* step.

- Direct Department Calling

You can administer a converse split as a DDC split.
- Distributed Communications System

If an incoming DCS call is placed to a vector with a *converse-on split x pri m passing ani...* step, the caller's DCS extension is sent to the VRU.
- Expert Agent Selection

*Converse-on* steps can place calls to a skill hunt group.
- Hold

An agent answering a converse call can put the call on hold, but the caller does not hear music on hold. If a call is queued to a backup split before it was sent to the VRU and a nonconverse split agent answers the call on hold, the agent who placed the call on hold is dropped, and the caller connects to the answering agent.
- Hold — Automatic

Automatic hold applies to converse-on calls.
- Hunt Groups

A *converse-on* step can deliver a call to a vector-controlled or AUDIX hunt group, ACD split, agent skill, or message center.
- ISDN

You can administer a *converse-on* step to send a caller's calling party/billing number (CPN/BN) to CONVERSANT using the caller keyword.
- Intraswitch CDR

If a converse-on call is answered and either the caller or the VDN associated with the call is administered for intraswitch recording, timing for the call is started and the CDR record shows "calling party to VDN" as the originating and answering parties.
- Line-side T1 connectivity

T1 connectivity between the DEFINITY ECS and CONVERSANT is supported for VRI. The DS1 board must be a TN767E (or later) or TN464F (or later). Administer all converse agents as DS1FD-type stations. Operation of the converse step using Line-side T1 is identical to that over a tip/ring line. In particular, delay-timing and output speed is the same as for analog lines. T1 connectivity to CONVERSANT is supported only in the United States and Canada.
- Look-Ahead Interflow

If an incoming call or a call routed by a *converse-on* vector step is answered by a VRU, or is queued to the converse split while a Look-Ahead Interflow call attempt is outstanding, the attempt is accepted.

- Message Center

*Converse-on* steps can deliver calls to message hunt groups. Such calls are handled as direct calls to the message hunt group.

If a call is forwarded to a VDN and a *converse-on* step delivers it to a message split, it is handled as a redirected call.

A *converse-on* step can queue a call to three different skills and then to a converse skill group or split.

- Music-on-Hold

During the data return phase of a *converse-on* step, the caller is placed on hold, but does not hear music.

- Nonvector-controlled splits

A *converse-on* step cannot route a call to a nonvector-controlled split.

- Queuing

*Converse-on* calls queue when they are delivered to busy hunt groups. Call Vectoring audible feedback is not disconnected while a *converse-on* call is queued.

If a *converse-on* step is run while a call is queued to a non-converse split, the call remains in queue, even after being answered by the VRU.

*Converse-on* steps can queue calls at one of four priority levels: low, medium, high or top. You administer the queue priority of a call on the *converse-on* step.

- R2-MFC Signaling

R2-MFC signaling trunks can send ANI to VRUs via the ani data item on the *converse-on* step.

- Recorded announcement

Use VRI to increase the system's recorded announcement capacity by offloading some recorded announcements to a VRU, such as CONVERSANT. Using the *converse-on* step, redirect callers to a group of VRU ports by passing the number of the announcement to be played. CONVERSANT can play any announcement on any port.

Although only one caller can be connected to each port, up to 48 callers can be connected simultaneously to CONVERSANT. The maximum number of callers that can be connected to a VRU simultaneously varies with each VRU.

- Redirection on No Answer (RONA)

If a *converse-on* step calls a hunt group with "no answer timeout" administered, and the call rings an agent/port for longer than the timeout interval, the call redirects and the agent/port is put into AUX work mode (or logged out if the agent is an AAS member).

With RONA, the call is requeued to the split. The call cannot requeue to the split if it is an AAS with all agents logged out or if the queue is full. If the call cannot be requeued, the *converse-on* step fails, a vector event is logged, and processing restarts at the next vector step.

- Service Observing

Calls delivered by a *converse-on* step can be observed. To prevent the observer from hearing tones associated with data being sent to the VRU, the observer is not connected to the call until after data is passed. If the VRU returns data, the observer is put in service-observing-pending mode and the caller is put on hold while the data is sent. When the *converse-on* session ends and the VRU drops the line, the observer remains in service-observing-pending mode and waits for the next call.

In addition, the observer observing a VDN does not hear data being sent. After data is sent, the observer rejoins the call.

Do not administer a service observing warning tone because the warning tone may interfere with the interaction between CONVERSANT and the caller.

- System measurements

System measurements track *converse-on* calls to hunt groups.

- Touch-tone dialing

A caller can use touch-tone dialing while digits are passed in a *converse-on* session. The data is not corrupted. The system does not collect the dialed numbers as dial-ahead digits.

After the system sends digits to CONVERSANT, a caller can enter touch-tone digits at a CONVERSANT prompt. After CONVERSANT has returned data to the system and an additional *collect <#> digits* vector step is run, a caller can enter a touch-tone response to a system prompt.

- Transfer

A call delivered by a *converse-on* step cannot be transferred.

If an attempt to transfer a *converse-on* call is made, a vector event is logged, the line to CONVERSANT is dropped, and processing restarts at the next vector step.

If a human agent tries to transfer a call, the transfer fails and the agent reconnects to the call.

- Transfer out of AUDIX

If a *converse-on* step delivers a call to an AUDIX hunt group and the caller tries to transfer out of AUDIX, the transfer fails and processing continues at the next vector step.

- Uniform Call Distribution (UCD)

You can administer a *converse* split as a UCD split.

- VDN display override

If a call that accesses multiple VDNs encounters a *converse-on* step that passes vdn, normal display override rules determine which VDN number is sent to the VRU.

- Vector-controlled splits

*Converse-on* steps can deliver calls only to skills or vector-controlled splits.

## VuStats

---

VuStats presents Basic Call Management System (BCMS) statistics on voice terminal displays. Agents, supervisors, call center managers, and other users can press a button and view statistics for agents, splits or skills, VDNs, and trunk groups.

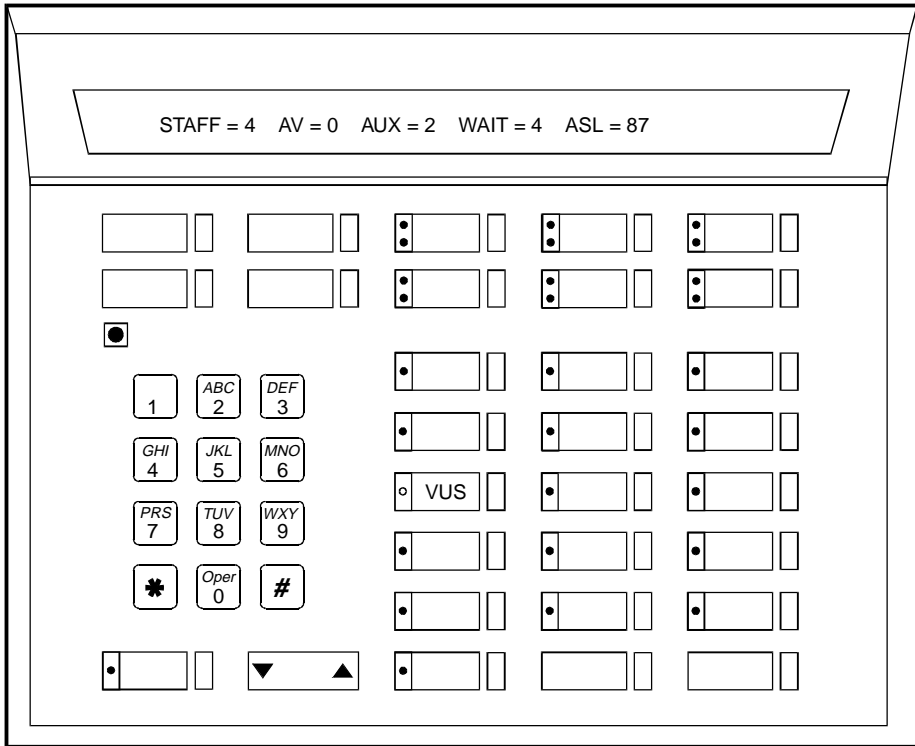

These statistics reflect information collected during the current BCMS interval, information collected since the agent logged in or since the day began, or historical data accumulated over an administered number of intervals. The information is limited to 40 characters displayed at a time. VuStats can display on demand or update periodically.

With VuStats, any digital-display voice-terminal user can view BCMS statistics otherwise available only on BCMS reports or management terminals. These statistics can help agents monitor their own performance or can be used to manage splits or small call centers.

### NOTE:

Although VuStats can run with either BCMS or CMS enabled, neither is required.

Figure 9-4 illustrates a CallMaster terminal with a VuStats display.

callmstr CJL 061896

Figure 9-4. CallMaster Terminal with VuStats Display

## How to administer VuStats

**Table 9-22. System-Parameter Customer-Options form**

| Form                              | Field                                | Page                  |
|-----------------------------------|--------------------------------------|-----------------------|
| System Parameter Customer-Options | ■ ACD                                | <a href="#">5-277</a> |
|                                   | ■ BCMS/VuStats Login ID              |                       |
|                                   | ■ BCMS/VuStats Service Level         |                       |
|                                   | ■ VuStats or VuStats (G3V4 Enhanced) |                       |

Display the System-Parameter Customer-Options form and ensure that ACD, BCMS/VuStats Login IDs, BCMS/VuStats Service Level, and VuStats or VuStats (G3V4 Enhanced) are set to **yes**.

### Required forms

| Form                              | Field                               | Page                  |

| VuStats                           | ■ All                               | <a href="#">9-161</a> |

- Feature-Related System-Parameters form
  - **ACD Login Identification Length** — If you are not using EAS, enter a number (1–9) that identifies the length of Agent Login IDs used by BCMS/VuStats. If you are not using BCMS/VuStats Login IDs, accept the default 0. This field defines the ACD login ID length and the BCMS login ID length, so you must coordinate with the BCMS administrator before changing this field.
  - **BCMS/VuStats Measurement Interval** — This interval determines how frequently BCMS polls and records data for BCMS reports and VuStats displays. Set this field to **half-hour** or **hour**.

If you specify **hour**, an entire day of traffic information is available for BCMS history reports. Otherwise, only half a day is available. There is a maximum of 25 measurement intervals, including the current interval.
  - **BCMS/VuStats Abandon Call Timer** — Set this field to 1–10, or leave blank. This value is the number of seconds a call can last and still be recorded as an abandoned call. For example, if you set this field to 5, a call could last up to 5 seconds and be recorded as abandoned. Thus, very short calls are not included as ACD calls in BCMS and VuStats statistics. Abandoned time is measured from the time the call is answered until the agent hangs up. Any time an agent is on a call that is within the abandon call timer value is recorded as total AUX time with the default reason code. Use this timer if your central office does not provide disconnect supervision.
  - **Validate BCMS/VuStats Login IDs** — Set to **n** to allow entry of any ACD login of the proper length. Set to **y** to allow entry only of login-IDs that have been entered on the BCMS/VuStats Login-ID form.
  - **Clear VuStats Shift Data**. Set to **on-login** or **at-midnight** to specify when shift data for an agent is cleared.
- Agent Login ID form — Administer Agent Login IDs for EAS. With EAS, VuStats accesses agent and agent-extension object type information based on agent login ID. Agents logging in agent IDs (administered on this form or BCMS/VuStats Login ID form) can view their own statistics on any VuStats voice terminal they are using. If agent IDs are not administered, VuStats displays only statistics collected for the agent's extension.
- Trunk Group form — For each trunk group that will have VuStat display statistics, set Measured to **internal** or **both**. Specify **internal** to record statistics for BCMS/VuStats. Specify **both** to record statistics for BCMS/VuStats and CMS.

- Attendant Console form — Administer a VuStats feature button (vu-display) to allow an attendant to display VuStats statistics. There is no limit to the number of VuStats buttons that can be administered.
  - **Fmt** — When you assign VuStats feature buttons, an Fmt field appears. You can associate a VuStats feature button with a particular display format. The Fmt value identifies the VuStats format used to display the information. Specify 1 — 50 in the Fmt (1 is the default format). See "Format Number" in this section for additional information.
  - **ID number** — Optionally administer an ID number for each vu-display button. Use the ID number to define the agent, split, trunk group, or VDN that the VuStats display will describe. The ID can be an agent login ID or extension number, a split or trunk group number, or a VDN extension. For example, a vu-display button administered with split ID 6 is used to view statistics for split number 6.

Do not administer IDs for VuStats displays with the agent object type. Agent object type displays are limited to statistics for the logged-in agent.

IDs allow supervisors and agents to bypass entering an agent extension, split, or VDN number when viewing statistics. IDs can also be used to limit access to certain statistics to designated voice terminals.

- BCMS/VuStats Login ID form — Administer Agent Login IDs if you do not have EAS. BCMS/VuStats Login IDs can be used to track statistics by specific agent rather than extension number. Specify any character, except a space, to be used as a placeholder for data in Format Description text. \$ is the default. Each character holds a place for one character of data. See "Data Field Character" in this section for more information.
- Hunt Group form
  - **ACD** — Set this field to **y**.
  - **Acceptable Service Level** — Specify the number of seconds within which calls to this hunt group are answered. Calls answered within this time are considered acceptable. BCMS and VuStats use this value to determine the percentage of calls that meet the acceptable service level.
  - **Measured** — Set this field to **internal** or **both**. Specify **internal** to record statistics for BCMS/VuStats. Specify **both** to record statistics for BCMS/VuStats and CMS.
  - **Objective** — Specify an objective, or goal, for the split. Examples include an agent objective of a number of ACD calls to be handled, an average talk time, or a percent of calls to be answered within the acceptable service level.

- Voice Terminal (Station) form — Administer a VuStats feature button (vu-display) to allow agents to display VuStats statistics. See “Attendant Console form” above for more information.
- Vector Directory Number form

For each VDN that has statistics displayed by VuStats, administer the following fields:

- **Acceptable Service Level** — Specify the number of seconds within which calls to this VDN are answered. Calls answered within this time are considered acceptable. BCMS and VuStats use this value to determine the percentage of calls that meet the acceptable service level.
- **Measured** — Set this field to **internal** or **both**. Specify **internal** to record statistics for BCMS/VuStats. Specify **both** to record statistics for BCMS/VuStats and CMS.
- VuStats Display Format form
  - **Format Number** — The system generates a format number automatically when it creates a VuStats display. You cannot change this number. You can create 50 different display formats. Format Number 1 is a predefined sample format that you can modify. See “Attendant Console form” in this section for more information.
  - **Next Format Number** — Specify the number of the display to be shown after the current display when a user presses the “next” button. To link displays, administer a next button Attendant Console or Station form. In general, you only link displays with the same object type.
  - **Number of Intervals** — Specify the number of BCMS intervals used to collect data when you have specified **interval** as the period for a historical Data Type. For example, if the BCMS interval is 1 hour and you specify 8 in this field, historical data with a period of interval is based on the previous 8 hours. See “Period” in this section for more information.
- **Object Type** — Set this field to one of five object types: **agent**, **agent-extension**, **split**, **trunk-group**, and **VDN**. Each object type displays specific types of data.
  - **Agent** — Provides agents with their own statistics, or statistics about the splits/skills they log into.
  - **Agent-extension** — Provides supervisors with statistics about agents or the splits/skills the agents log into. VuStats can automatically display statistics for a specific agent (if you administer agent login ID or BCMS/Vustats Login ID). Or, supervisors can enter the ID of any agent they want to review.
  - **Split** — Displays statistics about a specific split/skill. You must administer the split as Measured (internal or both) on the Hunt Group form.

- **Trunk-group** — Displays statistics about a specific trunk group. You must administer the trunk group as Measured (internal or both) on the Trunk Group form.
- **VDN** — Displays statistics about a specific VDN. You must administer the VDN as Measured (internal or both) on the Vector Directory Number form.

See [“What information is displayed” on page 9-170](#) in this section for a description of data that is displayed for each object type.

- **Data Type** — Specify data types to define what data is displayed for each object type. You can specify up to 10 data types for each display. See [Table 9-173](#) for a description of data types associated with each object type.
- **Period** — Set the amount of time to be used to collect the historical data for display. Set this field to **day**, **interval**, or leave blank. Day displays all data collected for a Data Type since midnight. Interval displays all data collected for a Data Type during the number of intervals specified in Number of Intervals ending with the current interval. Leaving the field blank displays only the data collected for the current interval.
- **Threshold** — Specify the conditions under which the VuStats button lamp flashes, alerting agents when there is a problem. Set both a comparator and a threshold value. For example, if you want to alert agents when the percent of calls within acceptable service level drops below 90%, specify the split-percent-in-service-level data type with a Threshold comparator of  $\leq$  and a threshold value of 90.
- **Split Reference** — Some data types associated with agent and agent-extension object types display statistics about the split/skill an agent is logged into. These data types usually begin with the word split. For example, the data type “split-agents-available” displays how many agents are available on a specific split or all splits the agent is logged into.
- Specify a reference number with the data type to define which split the displayed data is for. The reference number also describes the order in which an agent logged into the split. For example, specifying reference number 1 for the data type “split-agents-available” displays the number of agents available on the first split the agent is logged into.

Specify **Top** to display the first-administered highest-level skill for EAS agents, or the first split logged into for non-EAS agents. Specifying **All** displays data for all splits the agent is logged into and is valid only for acd-calls, average-acd-talk-time, shift-acd-calls, and shift-average-acd-talk-time data types.

- **Data Field Character** — Specify any character, except a space, to be used as a placeholder for data in the Format Description. \$ is the default. For example, in the entry “AUX=\$\$” the dollar signs each hold a place for one character of data.
- **Format Description** — Specify the text to be displayed with a data type, followed by Data Field Characters needed as placeholders for data-type data. List data types in the Data Type fields in the same order that the data type text appears in Format Description.

For example, in [Screen 9-2](#), STAFF, AV, AUX, WAIT, and ASL are all text labels for data types. STAFF is associated with the first data type, split-agents-staffed, AV is associated with the second data type, split-agents-available, and so on.

```

                                VUSTATS DISPLAY FORMAT
Format Number: 1                      Object Type: agent
Next Format Number: 2                  Update Interval: 30      On Change? n
Data Field Character: $
Number of Intervals:

Format Description: STAFF=$$ AV=$$ AUX=$$ WAIT=$$$$$$ ASL=$$$

Data Type                               Format   Period   Threshold   Ref
1: split-agents-staffed
2: split-agents-available
3: split-agents-in-aux-all
4: split-oldest-call-waiting           m:ss
5: split-acceptable-service-level      m:ss
.
.
    
```

Screen 9-2. Format Description Example

If the data for a field is too large for the number of data field characters entered, VuStats displays asterisks. If name database items are too large for the number of data field characters, VuStats truncates the data. VuStats also displays Split Objective (assigned on the Hunt Group form) as asterisks if the information exceeds the data field size.

- **Format** — Specify the format of data that has a time value. Format is required for time-value data types such as “split-oldest-call-waiting”. Specify one of the following:
  - **ccs** -- Hundred-call seconds (CCS) rounded to the nearest CCS
  - **h** -- Hours rounded to the nearest hour
  - **h:mm** -- Hours and minutes rounded to the nearest minute
  - **h:mm:ss** -- Hours, minutes, and seconds

- **m** -- Minutes rounded to the nearest minute
  - **m:ss** -- Minutes and seconds
  - **s** -- Seconds
- **Update Interval** — Set the interval at which the VuStats display data is updated to one of the following:
- **no-update** — The display does not update and appears only for the interval specified in the Display Interval field.
  - **polled** — The display updates every hour or half-hour depending upon the value in BCMS/ VuStats Measurement Interval on the Feature-Related System-Parameters form.  
  
Specifying polled may impact system performance at the time of the measurement interval.
  - **10, 20, 30, 60, 120** — The display updates every 10, 20, 30, 60, or 120 seconds.
- **On Change** — Specify whether the display will update whenever the agent changes work state. Set this field to **y** or **n**. If set to **y**, the display updates when the agent changes state and updates according to the Update Interval.
- **Display Interval** — Administer only if you specified a no update Update Interval. Specify one of the following:
- **not-cleared** — The display does not clear. The display remains until it is overwritten by another feature or the user presses the normal button.
  - **5, 10, 15, 30** — The display clears after 5, 10, 15, or 30 seconds.

## Detailed description

---

### What information is displayed

The following forms and fields determine information that VuStats displays.

---

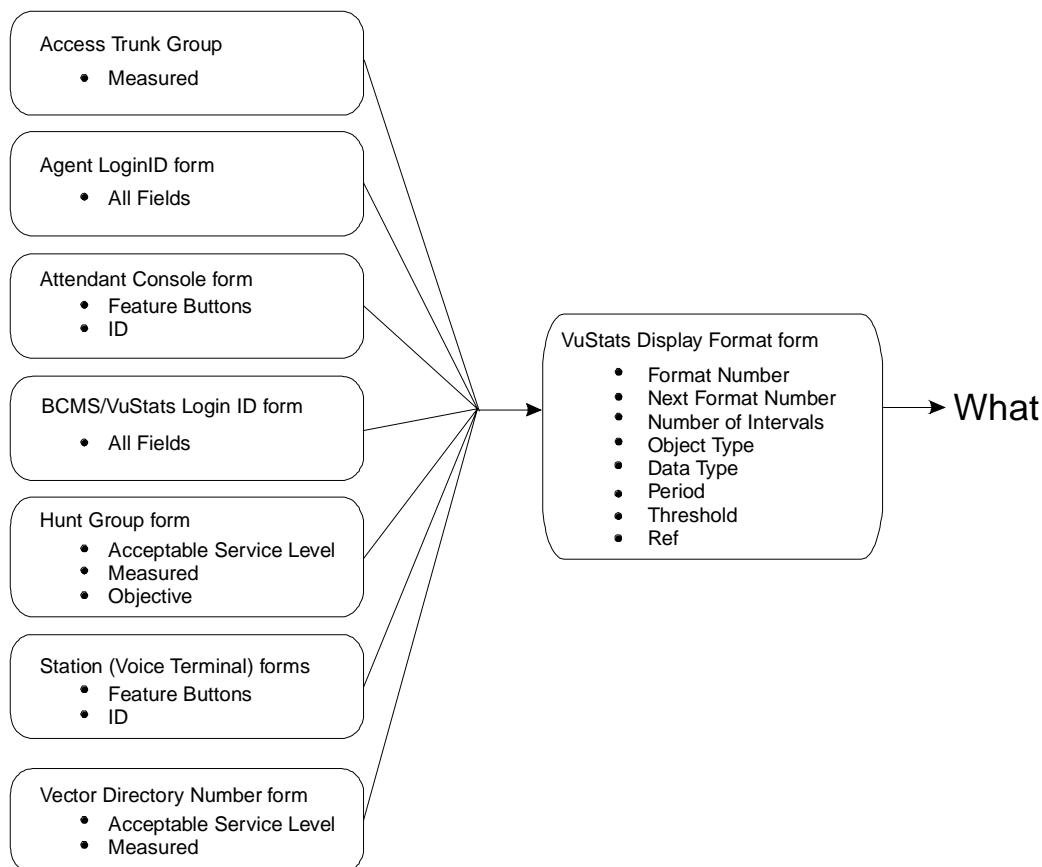

Figure 9-5. Forms that Determine What Information Appears on the VuStats Display

### Data Type

Data type defines what data is displayed for an object type. For example, for an agent object type, VuStats can display information agents are interested in, such as the total number of calls the agent has answered since login, the average time the agent has spent on ACD calls, the number of agents available to receive calls for a split, and the percent of calls within the acceptable service level.

For split object types, VuStats can display split description and performance information, such as average speed of answer, number of calls waiting, and agent work states. VuStats can also display an objective, acceptable service level, or percent of calls answered within the acceptable service level for a split.

See [Table 9-182](#) and [Table 9-186](#) for more information on data types.

## Period

VuStats can show statistics that have accumulated for the day, or for an administered number of intervals. For example, if you administer VuStats to display the number of ACD calls for the past 4 completed intervals, it displays the number of ACD calls received in the past 2 hours (1/2-hour intervals) or 4 hours (1-hour intervals) plus those completed during the current interval. Using historical data can affect processor occupancy, depending upon the number of active users, their update rates, and the number of historical data types.

With agent or agent-extension object types, shift data is available for the number of ACD calls answered, the average ACD talk time, and AUX work mode time by Reason Code for an agent. You can clear shift data at midnight or the next time an agent logs in.

## Threshold

Many data types can be administered with a threshold comparator and value. When the condition defined by the threshold is true, and the data type is shown on the display, the VuStats button lamp flashes. For example, suppose a format is created in which the oldest call waiting data type is administered with a threshold of  $\geq$  (greater than or equal to) five minutes. Whenever that VuStats format is displayed, if the oldest call in queue has been waiting for five minutes or longer, the VuStats lamp flashes on the voice terminal. Each time the display updates, the threshold is checked for each data type being displayed.

## Format description

Use Format Description to create labels on the display to identify data. For example, in [Figure 9-4](#) "AUX=" identifies the data type "split-agents-in-aux-all" (that is, the number of agents currently in AUX work mode for a specified split). Text appears on the display exactly as you enter it in the field. Text is optional.

Because of the 40-character limit, use abbreviations when possible. For example, use "S=" to indicate "split number".

## Display linking

Link display formats to increase the amount of information users can view. For example, link a display of information for an agent's first split to a display of information for the agent's second split. Or, link a display of information about the work states of all agents on a split linked to another display of information about calls waiting, number of calls abandoned, or oldest call waiting for the split.

If you use display linking, assign a Next button on agent terminals.

## How the information looks

The following fields on the VuStats Display form determine how information looks on the VuStats display.

---

**Figure 9-6. Fields that Determine What Information Appears on the VuStats Display**

VuStats statistics appear on the second line of 2-line DCP terminal displays or on the first line of 1-line DCP terminals and all BRI terminals. On voice terminals with 2 x 24 displays, the display automatically wraps to the second line of the display. When VuStats is activated, it overwrites and cancels any display feature on the second line of a 2-line display and on the first line of a 1-line display.

You define the following format information on the VuStats Display Format form:

- Labels for data types and the amount of space reserved for data
- Order in which data types appear on the display
- Format for time-related data types
- Display links

## When the information updates

The following forms and fields determine when VuStats displays update.

---

**Figure 9-7. Fields that Determine When Information Updates on the VuStats Display**

Most display features that use the second line of a 2-line display or the first line of a 1-line display overwrite and cancel VuStats. Reason Codes and Call Work Codes only suspend VuStats; when the prompt is removed, the VuStats display reappears.

User press the normal button to clear the VuStats display.

Administer VuStats to display information until agents press the normal button or another operation overwrites the VuStats display. Or, administer VuStats to display for an interval of 5, 10, 15, or 30 seconds.

You can also administer VuStats to update displayed statistics every 10, 20, 30, 60 or 120 seconds or every time an agent changes work mode or a BCMS Measurement Interval is completed, or not update at all.

## Tables of Data Types

[Table 9-23](#), [Table 9-24](#), [Table 9-25](#) and [Table 9-26](#) describe the data types you can define for each object type.

**Table 9-23. Agent and Agent-Extension Data Types**

| VuStats Data Type     | Description  | BCMS Report: Field Name/Column Heading                |
|-----------------------|--|---|
| acd-calls             | Split/skill calls and direct agent calls answered by an agent  | Split status/VDN Status/Agent Report: ACD CALLS       |
| agent-extension       | The extension for a specific agent; if either BCMS/VuStats Login IDs or EAS is optioned, then this shows the agent's login ID. | Split Status: Login ID or EXT                         |
| agent-name            | The administered name for a specific agent.  | Split Status/Agent Report/Agent Summary Report: Agent |
| agent-state           | The agent's current work state   | Split Status: STATE                                   |
| average-acd-call-time | The average of hold-time plus talk-time.   | None  |

*Continued on next page*

Table 9-23. Agent and Agent-Extension Data Types — *Continued*

| VuStats Data Type        | Description  | BCMS Report: Field Name/Column Heading           |
|--------------------------|--|--|
| average-acd-talk-time    | The average time a specific agent has spent talking on completed ACD calls during a specified time period for all internally-measured splits/skills that the agent was logged into. This does not include the time a call was ringing or was on hold at an agent's terminal. | Agent Report/Agent Summary Report: AVG TALK TIME |
| average-extension-time   | The average amount of time an agent spent on non-ACD calls while logged into at least one split/skill during the reported interval. This average does not include time when the agent was holding the EXTN call.   | Agent Report/Agent Summary Report: AVG EXTN TIME |
| call-rate                | The current rate of ACD calls handled per agent per hour for all split/skills.   | None   |
| current-reason-code      | The number of the Reason Code associated with the agent's current AUX work mode, or with the agent's logout.   | None   |
| current-reason-code-name | The name of the Reason Code associated with the agent's current AUX work mode or with the agent's logout.  | None   |
| elapsed-time-in-state    | The amount of time an agent has been in the current state.   | None   |
| extension-calls          | The number of incoming and outgoing non-ACD calls that an agent completed while logged into at least one split/skill.  | Agent Report: EXTN CALLS                         |
| extension-incoming-calls | The number of non-ACD calls that an agent receives while logged into at least one split/skill.   | Split Report: EXT IN CALLS                       |
| extension-outgoing-calls | The number of non-ACD calls that an agent places while logged into at least one split/skill.   | Split Report: EXT OUT CALLS                      |

*Continued on next page*

Table 9-23. Agent and Agent-Extension Data Types — *Continued*

| VuStats Data Type  | Description   | BCMS Report: Field Name/Column Heading |
|--------------------|---|--|
| shift-acd-calls    | The number of ACD calls answered by an agent during the administered period.                                | None                                   |
| shift-aux-time-1   | The amount of time an agent has spent in AUX work mode for Reason Code 1 during the administered period.    | None                                   |
| shift-aux-time-2   | The amount of time an agent has spent in AUX work mode for Reason Code 2 during the administered period.    | None                                   |
| shift-aux-time-3   | The amount of time an agent has spent in AUX work mode for Reason Code 3 during the administered period.    | None                                   |
| shift-aux-time-4   | The amount of time an agent has spent in AUX work mode for Reason Code 4 during the administered period.    | None                                   |
| shift-aux-time-5   | The amount of time an agent has spent in AUX work mode for Reason Code 5 during the administered period.    | None                                   |
| shift-aux-time-6   | The amount of time an agent has spent in AUX work mode for Reason Code 6 during the administered period.    | None                                   |
| shift-aux-time-7   | The amount of time an agent has spent in AUX work mode for Reason Code 7 during the administered period.    | None                                   |
| shift-aux-time-8   | The amount of time an agent has spent in AUX work mode for Reason Code 8 during the administered period.    | None                                   |
| shift-aux-time-9   | The amount of time an agent has spent in AUX work mode for Reason Code 9 during the administered period.    | None                                   |
| shift-aux-time-all | The amount of time an agent has spent in AUX work mode for all Reason Codes during the administered period. | None                                   |

*Continued on next page*

Table 9-23. Agent and Agent-Extension Data Types — Continued

| VuStats Data Type              | Description   | BCMS Report: Field Name/Column Heading                     |
|--------------------------------|---|--|
| shift-aux-time-default         | The amount of time an agent has spent in AUX work mode for the default Reason Code (code 0) during the administered period.   | None   |
| shift-aux-time-non-default     | The amount of time an agent has spent in AUX work mode for Reason Codes 1 through 9 during the administered period.   | None   |
| shift-aux-time-reason-code     | The amount of time an agent has spent in AUX work mode for the agent's current Reason Code during the administered period.  | None   |
| shift-average-acd-talk-time    | The average talk time for ACD calls for a specific agent during the administered period.  | None   |
| skill-level                    | The skill level at which the skill was assigned to the agent.   | None   |
| split-acceptable-service-level | The number of seconds within which calls must be answered to be considered acceptable. Identified on a per-hunt group basis. Timing begins when the call enters the hunt group queue. | Split Status: Acceptable Service Level                     |
| split-acd-calls                | Split/skill calls and direct agent calls answered by an agent.  | System Status/Split Report/Split Summary Report: ACD CALLS |
| split-after-call-sessions      | The number of times all agents have entered After Call Work (ACW) for a specific split/skill.   | None   |
| split-agents-available         | The number of agents currently available to receive ACD calls for a specific split. This includes agents in Auto-In or Manual-In work mode.   | Split Status: Avail  |
| split-agents-in-after-call     | For a specific split, the number of agents currently in ACW.  | Split Status: ACW  |

| VuStats Data Type           | Description  | BCMS Report: Field Name/Column Heading |
|-----------------------------|--|--|
| split-agents-in-aux-1       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 1.                          | None                                   |
| split-agents-in-aux-2       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 2.                          | None                                   |
| split-agents-in-aux-3       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 3.                          | None                                   |
| split-agents-in-aux-4       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 4.                          | None                                   |
| split-agents-in-aux-5       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 5.                          | None                                   |
| split-agents-in-aux-6       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 6.                          | None                                   |
| split-agents-in-aux-7       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 7.                          | None                                   |
| split-agents-in-aux-8       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 8.                          | None                                   |
| split-agents-in-aux-9       | For a specific skill, the number of agents currently in Aux work mode with Reason Code 9.                          | None                                   |
| split-agents-in-aux- all    | For a specific split/skill, the total number of agents currently in Aux work mode for all Reason Codes.            | Split Status: AUX                      |
| split-agents-in-aux-default | For a specific split/skill, the number of agents currently in Aux work mode with the default Reason Code (code 0). | None                                   |

*Continued on next page*

Table 9-23. Agent and Agent-Extension Data Types — Continued

| VuStats Data Type               | Description  | BCMS Report: Field Name/Column Heading                         |
|---------------------------------|--|--|
| split-agents-in-aux-non-default | For a specific skill, the number of agents currently in Aux work mode with Reason Codes 1 through 9.   | None   |
| split-agents-in-other           | The number of agents currently who: are on a call for another split, are in ACW work mode for another split, have a call on hold but are not in another state, or have a call ringing at their terminals, or are dialing a number while in AI/MI.  | Split Status: Other  |
| split-agents-on-acd-calls       | The number of agents currently on split/skill or direct agent ACD calls for a specific split.  | Split Status: ACD  |
| split-agents-on-extension-calls | The number of agents in a specific split who are currently on non-ACD calls.   | Split Status: Extn   |
| split-agents-staffed            | The number of agents currently logged into a split.  | Split Status: Staffed  |
| split-average-acd-talk-time     | The average talk time for ACD calls during a specific period/day for a specified split.  | System Status/Split Report/Split Summary Report: AVG TALK TIME |
| split-average-after-call-time   | The average time for call-related ACW completed by agents for this split (the same as average-after-call-time, but only available for agent and agent-extension object types). Call-related ACW time is recorded when an agent leaves the ACW state. If an agent is in call-related ACW when an interval completes, all of the ACW time will be recorded for the interval in which the agent leaves ACW. | System Status: AVG AFTER CALL                                  |
| split-average-speed-of-answer   | The average speed for answering split and direct agent ACD calls that have completed for a specified split/skill.  | System Status/Split Report/Split Summary Report: AVG SPEED ANS |

Table 9-23. Agent and Agent-Extension Data Types — Continued

| VuStats Data Type              | Description   | BCMS Report: Field Name/Column Heading                                  |
|--------------------------------|---|---|
| split-oldest-call-waiting      | The time the oldest call has been waiting for a specific split/skill.   | System Status:<br>OLDEST CALL   |
| split-percent-in-service-level | For a specific split/skill, the percentage of calls answered within the administered service level on the hunt group form.  | System Status/Split Report/Split Summary Report: % WITHIN SERVICE LEVEL |
| split-total-acd-talk-time      | For a specified split/skill, the total time agents spent talking on split/skill calls and direct agent calls for this split.  | None  |
| split-total-after-call-time    | The total time an agent spent in call-related ACW for this split/skill and non-call-related ACW for any split/skill during a specific time period, excluding time spent on incoming or outgoing extension calls while in ACW.   | Split Report/Split Summary Report:<br>TOTAL AFTER CALL                  |
| split-total-aux-time           | The total time an agent spent in AUX mode for this split/skill.   | Split Report/Split Summary Report:<br>TOTAL AUX/OTHER                   |
| total-acd-call-time            | The total talk time plus the total hold time for split/skill and Direct Agent ACD calls.  | None  |
| total-acd-talk-time            | The total time agents spent talking on split/skill calls and direct agent calls.  | None  |
| total-after-call-time          | The total time an agent spent in call-related or non-call-related ACW for any split during a specific time period, excluding time spent on incoming or outgoing extension calls while in ACW. (With EAS, all non-call related ACW time is associated with the first skill logged into.) | Agent Report/Agent Summary Report:<br>TOTAL AFTER CALL                  |

Table 9-23. Agent and Agent-Extension Data Types — *Continued*

| VuStats Data Type    | Description  | BCMS Report: Field Name/Column Heading                |
|----------------------|--|---|
| total-aux-time       | The total time an agent spent in AUX work for all splits/skills (simultaneously) that the agent was logged into. If an agent entered AUX in one interval, but ended AUX in another, each of the intervals will reflect the appropriate amount of time spent in the interval (agent reports also include OTHER time). | Agent Report/Agent Summary Report:<br>TOTAL AUX/OTHER |
| total-available-time | The time an agent was available in at least one split/skill.   | Agent Report:<br>TOTAL AVAIL TIME                     |
| total-hold-time      | The total amount of time ACD calls were on hold at a specific agent's voice terminal. This time is the "caller's hold time" and is independent of the agent's state. This time does not include hold time for non-ACD calls on hold.   | Agent Report:<br>TOTAL HOLD TIME                      |
| total-staffed-time   | The total amount of time an agent was logged into one or more splits/skills during a specific period/day. An agent is clocked for staff time as long as he or she is logged into any split.  | Agent Report:<br>TOTAL TIME STAFFED                   |

Table 9-24. Split Data Types

| VuStats Data Type        | Description   | BCMS Report: Field Name/Column Heading              |
|--------------------------|---|---|
| acceptable-service-level | The number of seconds within which calls must be answered to be considered acceptable. Identified on a per-hunt group basis. Timing begins when the call enters the hunt group queue. | Split Status/Split Report: Acceptable Service Level |
| acd-calls                | Split calls and direct agent calls answered by an agent   | Split status/VDN Status/Agent Report: ACD CALLS     |
| after-call sessions      | The number of times all agents have entered After Call Work (ACW).  | None  |
| agents-available         | The number of agents currently available to receive ACD calls. This includes agents in Auto-In or Manual-In work mode.  | Split Status: Avail                                 |
| agents-in-after-call     | The number of agents currently in ACW mode.   | Split Status: ACW                                   |
| agents-in-aux-1          | The number of agents currently in Aux work mode for Reason Code 1 for the referenced skill.   | None  |
| agents-in-aux-2          | The number of agents currently in Aux work mode for Reason Code 2 for the referenced skill.   | None  |
| agents-in-aux-3          | The number of agents currently in Aux work mode for Reason Code 3 for the referenced skill.   | None  |
| agents-in-aux-4          | The number of agents currently in Aux work mode for Reason Code 4 for the referenced skill.   | None  |
| agents-in-aux-5          | The number of agents currently in Aux work mode for Reason Code 5 for the referenced skill.   | None  |
| agents-in-aux-6          | The number of agents currently in Aux work mode for Reason Code 6 for the referenced skill.   | None  |

Table 9-24. Split Data Types — *Continued*

| VuStats Data Type         | Description   | BCMS Report: Field Name/Column Heading |
|---------------------------|---|--|
| agents-in-aux-7           | The number of agents currently in Aux work mode for Reason Code 7 for the referenced skill.   | None                                   |
| agents-in-aux-8           | The number of agents currently in Aux work mode for Reason Code 8 for the referenced skill.   | None                                   |
| agents-in-aux-9           | The number of agents currently in Aux work mode for Reason Code 9 for the referenced skill.   | None                                   |
| agents-in-aux-all         | The number of agents currently in Aux work mode for all Reason Codes for the referenced split/skill.  | Split Status: AUX                      |
| agents-in-aux-default     | The number of agents currently in Aux work mode for the default Reason Code (code 0) for the referenced split/skill.  | None                                   |
| agents-in-aux-non-default | The number of agents currently in Aux work mode for Reason Codes 1 through 9 for the referenced skill.  | None                                   |
| agents-in-other           | The number of agents who currently: are on a call for another split, are in ACW work mode for another split, have a call on hold but are not in another state, or have a call ringing at their terminal, or are dialing a number from AI/MI mode. | Split Status: Other                    |
| agents-on-acd-calls       | The number of agents currently on split/skill or direct agent ACD calls for a specific split.   | Split Status: ACD                      |
| agents-on-extension-calls | The number of agents in a specific split who are currently on non-ACD calls.  | Split Status: Extn                     |
| agents-staffed            | The number of agents currently logged into the specified split.   | Split Status: Staffed                  |

Table 9-24. Split Data Types — *Continued*

| VuStats Data Type       | Description  | BCMS Report: Field Name/Column Heading     |
|-------------------------|--|--|
| average-acd-talk-time   | The average talk time for ACD calls during a specific period/day for a specified split.  | System Status/Split Report: AVG TALK TIME  |
| average-after-call-time | The average time for call-related ACW completed by agents in this split. Call-related ACW time is recorded when an agent leaves the ACW state. If an agent is in call-related ACW when an interval completes, all of the ACW time will be recorded for the interval in which the agent leaves ACW.         | System Status: AVG AFTER CALL              |
| average-speed-of-answer | The average speed for answering split/skill and direct agent ACD calls that have completed for a specified split/skill during a specified time. This includes queue time and ringing time for this split.  | System Status/Split Report: AVG SPEED ANS  |
| average-time-to-abandon | The average time calls waited before abandoning.   | System Status/Split Report: AVG ABAND TIME |
| call-rate               | The current rate of ACD calls handled per agent per hour for all split/skills.   | none                                       |
| calls-abandoned         | The number of calls that abandoned.  | System Status/Split Report: ABAND CALLS    |
| calls-flowed-in         | The total number of calls for a specific split that were received as a coverage point (intraflowed) from another internally-measured split, or were call-forwarded (interflowed) to the split. This does not include calls that were interflowed from a remote switch by the Look Ahead Interflow feature. | Split Report/Split Summary Report: FLOW IN |

| VuStats Data Type | Description                                       | BCMS Report: Field Name/Column Heading  |
|-------------------|---|---|
| vdn-extension     | The extension of a vector directory number (VDN). | VDN Status/VDN Report: VDN EXT          |
| vdn-name          | The name of a vector directory number (VDN).      | VDN Status/VDN Summary Report: VDN NAME |

Table 9-26. Trunk Group Data Types

| VuStats Data Type          | Description  | BCMS Report: Field Name/Column Heading |
|----------------------------|--|--|
| average-incoming-call-time | Average holding time for incoming trunk calls.                                       | Trunk Group: INCOMING TIME             |
| average-outgoing-call-time | Average holding time for outgoing trunk calls.                                       | Trunk Group: OUTGOING TIME             |
| incoming-abandoned-calls   | Incoming calls abandoned during a specified time period for a specified trunk group. | Trunk Group: INCOMING ABAND            |
| incoming-calls             | Incoming calls carried by a specified trunk group.                                   | Trunk Group: INCOMING CALLS            |
| incoming-usage             | The total trunk holding time for incoming calls in hundred call seconds.             | Trunk Group: INCOMING CCS              |
| number-of-trunks           | The number of trunks in a specified trunk group.                                     | Trunk Group: Number of Trunks          |
| outgoing-calls             | The number of outgoing calls carried by a specified trunk group.                     | Trunk Group: OUTGOING CALLS            |
| outgoing-completed-calls   | The number of outgoing calls that received answer supervision or answer timeout.     | Trunk Group: OUTGOING COMP             |
| outgoing-usage             | The total trunk holding time for outgoing calls in hundred call seconds.             | Trunk Group: OUTGOING CCS              |

Continued on next page

Table 9-26. Trunk Group Data Types — *Continued*

| VuStats Data Type         | Description  | BCMS Report: Field Name/Column Heading |
|---------------------------|--|--|
| percent-all-trunks-busy   | The percent of time all the trunks in a specified trunk group were busy during a specified period/day. Timing for a call begins when the last trunk is seized. | Trunk Group: % ALL BUSY                |
| percent-trunks-maint-busy | The percent of time trunks were busied out for maintenance during a specified period/day.  | Trunk Group: % TIME MAINT              |
| trunk-group-name          | The name administered for a specific trunk group.  | Trunk Group: Trunk Group Name          |
| trunk-group-number        | The number administered for a specific trunk group.  | Trunk Group: Trunk Group Number        |
| trunks-in-use             | The number of trunks currently in use (not idle).  | None                                   |
| trunks-maint-busy         | The number of trunks currently busied out for maintenance.   | None                                   |

## Considerations

Some VuStats data is accumulated for an agent's login session. This shift data clears either at midnight or the next time the agent logs in depending upon how the system is administered. If the data clears at login and agents log out to go to lunch, the system clears their accumulated data when they log back in after lunch.

To accumulate a full day's statistics, you can require agents and supervisors to keep a running total of all their login sessions, or, to avoid this, use historical data, require agents to use AUX work mode when temporarily unavailable, or administer the system to clear shift data at midnight.

## Interactions

---

- **BCMS**

You must have BCMS activated to receive BCMS reports. VuStats displays data collected by BCMS, but BCMS need not be enabled for you to use VuStats.
- **Call Prompting**

When Call Prompting digits are displayed, VuStats is canceled. When an agent reactivates VuStats, the VuStats display overwrites the Call Prompting display.
- **Call Work Codes (CWC)**

The CWC-display prompt suspends VuStats, so when the CWC prompt is removed, the VuStats display reappears.

If VuStats is activated while a CWC is being entered (that is, the pound (#) sign is not yet dialed), the CWC display is overwritten. The CWC must be reentered.
- **Change skills**

An agent changing skills automatically cancels VuStats. Display of the new skills overwrites the VuStats display. When the agent reactivates VuStats, the VuStats display overwrites the new skills display.
- **CMS**

Moving an agent from one split or skill to another does not affect the ID assigned to the vu-display button.

If an agent is moved from one split or skill to another, the system does not associate VuStat buttons from the agent's previous split or skill to the new split or skill. Therefore if you must frequently move agents between splits or skills, do not associate agents' VuStats buttons with a specific split or skill. Instead, associate the VuStats button with the agent format (without an ID) on each agent's voice terminal and use a split reference to view the agent's split/skill.
- **EAS-PHD**

When you have EAS-PHD enabled, VuStats can provide statistical data for all twenty skills. However, agent statistics by skill (agent or agent-extension object types) are available only for the current interval or for the "shift-acd-calls" and "shift-average-acd-talk-time" data types.
- **Integrated Directory**

If an agent activates Integrated Directory, VuStats is automatically cancelled. The Integrated Directory display overwrites the VuStats display and the VuStats button extinguishes. When VuStats is reactivated, the VuStats display overwrites the Integrated Directory display.

- Queue-Status Indications

The queue-status button display automatically cancels VuStats. When VuStats is reactivated, the VuStats display overwrites the queue-status display.

- Reason Codes

Using certain VuStats data types, you can report real-time and historical AUX work mode time by Reason Code or AUX work mode time summed for each Reason Code.

The Reason Codes display prompt suspends VuStats; when the Reason Codes prompt is removed, the VuStats display reappears.

- Service Observing

On terminals with a 1-line display, the Service Observing button display automatically cancels VuStats. When VuStats is reactivated, the VuStats display overwrites the Service Observing display.

# Call Center Forms

## Agent LoginID

---

This form is used to administer Agent LoginIDs for the Expert Agent Selection feature.

### Administration Commands

---

Use the following administration commands to administer the Agent LoginID form.

| Action  | Object        | Qualifier <sup>1</sup>                         |
|---------|---------------|--|
| add     | agent-loginid | xxxxx (extension) or "next"                    |
| change  | agent-loginid | xxxxx (extension)                              |
| display | agent-loginid | xxxxx (extension) ['print' or 'schedule']      |
| remove  | agent-loginid | xxxxx (extension)                              |
| list    | agent-loginid | ['staffed'  'unstaffed' ['name' x]['aas' y/n]] |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.

### Form Instructions

---

Make assignments as required for the following fields on the form:

- **Login ID** — Display-only field. Contains the identifier for the Logical Agent as entered on the command line.
- **Name** — Enter up to a 27-character string naming the agent. Any alpha-numeric character is valid. Default is blank.
- **TN** — Enter the Tenant Partition number. Default is "1."
- **COR** — Enter the Class of Restriction (from 0 to 95) for the agent. Default is 1.
- **Coverage Path** — Enter the number of the Coverage Path used by calls to the LoginID or leave blank (default). This is used when the agent is logged out, busy, or does not answer.
- **Security Code** — Enter the 4-digit security code (password) for the Demand Print messages feature. This field may be blank (default).
- **Direct Agent Skill** — Enter the number of the skill that is used to handle Direct Agent calls.
- **Call Handling Preference** — Choices are **skill-level**, **greatest-need**, and **percent-allocation**. When calls are in queue and an agent becomes available, "skill-level" delivers the oldest, highest priority call waiting for

the agent's highest level skill. "Greatest-need" delivers the oldest, highest priority call waiting for any of the agent's skills. "Percent-allocation" is a new call selection method available only with Lucent's CentreVu<sup>®</sup> Advocate software. For more information, please see the *CentreVu<sup>®</sup> Advocate User Guide* (585-215-855).

- **Service Objective** — This field is displayed only when the call handling preference is **greatest-need** or **skill-level**. Service Objective is a new feature that is part of Lucent's CentreVu<sup>®</sup> Advocate software. For more information, please see the *CentreVu<sup>®</sup> Advocate User Guide* (585-215-855).
- **Direct Agent Calls First** (not shown) — This field replaces the *Service Objective* field when **percent-allocation** is entered in the *Call Handling Preference* field. Percent allocation is only available with Lucent's CentreVu<sup>®</sup> Advocate software. For more information, please see the *CentreVu<sup>®</sup> Advocate User Guide* (585-215-855).
- **AAS** — Enter "y" if this extension will be used as a port for an Auto Available Split/Skill. Default is "n."

**WARNING:**

*Entering "y" in the AAS field clears the password and requires execution of the "remove agent-loginid" command. To set AAS to "n", this logical agent must be removed then re-added.*

**WARNING:**

*This option is intended for switch adjunct equipment ports only, not human agents.*

- **AUDIX** — Enter "y" if this extension will be used as a port for an AUDIX. Default is "n."

**NOTE:**

The AAS and AUDIX fields cannot both be "y".

- **LWC Reception** — Enter where LWC messages will be stored for this Agent LoginID. For R5r configurations, valid entries are "audix", "msa" "spe" (default), and "none". For R5si configurations, valid entries are "audix", "msa-spe" (default), and "none."
- **Port Extension** (not shown) — Only displayed if either the AAS or AUDIX field is "y". Enter the assigned extension for the AAS or AUDIX port. This extension cannot be a VDN or an Agent LoginID.
- **AUDIX Name for Messaging** — Only applicable to R5r configurations. Enter the name of the AUDIX used for LWC Reception and/or the name of the AUDIX that provides coverage for this Agent LoginID or leave blank (default).

- **Messaging Server Name for Messaging** — Only applicable to R5r configurations. Enter the name of the Messaging Server used for LWC Reception and/or the name of the Messaging Server that provides coverage for this Agent LoginID or leave blank (default).
- **LoginID for ISDN Display** — Enter “y” if the Agent LoginID CPN and Name field is to be included in ISDN messaging over network facilities. In this case, the physical station extension CPN and Name is sent. Default is “n.”
- **Password** — Only displayed if both the AAS and AUDIX fields are “n”. Enter up to nine digits as the password the Agent must enter upon login. Valid entries are the digits 0 through 9. The minimum number of digits that must be entered in this field is specified in the Minimum Agent-LoginID Password Length field on the Feature-Related System Parameters form.

**NOTE:**

Values entered into this field will not be echoed to the screen.

- **Password (enter again)** — Only displayed if both the AAS and AUDIX fields are “n.” Reenter the same password exactly as it was entered in the Password field.

**NOTE:**

Values entered into this field will not be echoed to the screen.

- **Auto Answer** — Valid entries are **all**, **acd**, **none**, and **station**. When Expert Agent Selection is optioned, the agent’s auto answer setting will apply to the station where the agent logs in. If the auto answer setting for that station is different, the agent’s setting will override the station’s.

The entries **all**, **acd**, and **none** have the same effect as the corresponding entries on the Station form. Enter **all** to allow all calls (ACD and non-ACD) terminated to the agent to be cut through immediately. Enter **acd** to allow only ACD split /skill calls and direct agent calls to auto answer. If this field is **acd**, Non-ACD calls terminated to the agent ring audibly. Enter **none** (default) to cause all calls terminated to this agent to receive an audible ringing treatment. Enter **station** if you want auto answer for the agent to be controlled by the auto answer field on the Station form.

- **SN (Skill Number)** — Enter the Skill Hunt Group(s) that this agent handles. The same skill may not be entered twice. If EAS-PHD is not optioned, up to 4 skills can be entered. If EAS-PHD is optioned, up to 20 skills can be entered.
- **RL (Reserve Level)** — Enter the reserve level (if any) assigned to this agent with the Service Level Supervisor feature. Service Level Supervisor is available as part of Lucent’s CentreVu<sup>®</sup> Advocate software. For more information, please see the *CentreVu<sup>®</sup> Advocate User Guide* (585-215-855).

- **SL (Skill Level)** — Enter the priority level that each skill has for this particular agent. If EAS-PHD is not optioned, 2 priority levels are available. If EAS-PHD is optioned, 16 priority levels are available. In releases prior to R3V5, level 1 was the primary skill and level 2 was the secondary skill.
- **PA (Percent Allocation)** — This field is displayed only when the call handling preference is **percent-allocation**. Percent Allocation is available as part of Lucent's CentreVu<sup>®</sup> Advocate software. For more information, please see the *CentreVu<sup>®</sup> Advocate User Guide* (585-215-855).

```

add agent-loginID 9011                                     Page 1 of 1

```

Screen 9-1. Agent LoginID Form

### Implementation Notes

The Port Extension field is only displayed if either the AAS or AUDIX field is "y".

The AUDIX Name for Messaging and Messaging Server Name for Messaging fields are only displayed for R5r configurations.

The Password and Password (enter again) fields are only displayed when both the AAS and AUDIX fields are "n".

## Best Service Routing (BSR) Application Plan

---

Use this form to identify the remote locations used in each BSR application.

**NOTE:**

For an explanation of BSR application plans see [“Best Service Routing™” on page 9-44.](#)

### Administration Commands

---

Use the following administration commands to administer the BCMS/VuStats Login ID form. Valid application numbers are 1–255.

| Action            | Object               | Qualifier <sup>1</sup>             |
|-------------------|----------------------|------------------------------------|
| add               | best-service-routing | xxx (application number) or 'next' |
| change            | best-service-routing | xxx (application number)           |
| display           | best-service-routing | xxx (application number)           |
| remove            | best-service-routing | xxx (application number)           |
| list <sup>2</sup> | best-service-routing |                                    |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.
2. The command “list best-service-routing” displays the List Best Services Routing Applications form. This is a display-only form and is shown below.

### Form Instructions

---

Make assignments as required for the following fields on the form:

- **Application Number**—This display-only field shows the identifying number of the plan you’re working with. Numbered from 1 to 255.
- **Application Name**—Give the application plan a name with up to 15 characters.
- **Location Number**—One plan may have 1–255 locations. Location numbers are identifiers, and therefore need not be in sequential order. For example, you could assign locations with the identifiers 1, 3, 14 and 89 to one application plan.

```
list best-service-routing
      BEST SERVICE ROUTING APPLICATIONS

      Number           Name
      xxx             International
      xxx             Tech Support
      xxx             Sales
```

**Screen 9-3. List Best Service Routing Applications Form**

## BCMS/VuStats Login ID

---

If you want to monitor call activity by agent login IDs, and if the "BCMS/VuStats Login ID" field on the System-Parameters Customer-Options form is set to "y" but the EAS feature is not optioned, the administrator uses this form to administer valid logins.

You do not have to enter names. If you do not use names with the login IDs, the data you receive from BCMS and/or VuStats defaults to "ID xxxxxxxx" where "xxxxxxx" is the login ID.

### NOTE:

Only agents using one of the administered login IDs can successfully log in to a split measured by BCMS.

## Administration Commands

---

Use the following administration commands to administer the BCMS/VuStats Login ID form.

| Action  | Object                 | Qualifier <sup>1</sup> |
|---------|------------------------|------------------------|
| add     | bcms/vustats login IDs |                        |
| change  | bcms/vustats login IDs | [login ID]             |
| display | bcms/vustats login IDs | [login ID]             |
| list    | bcms/vustats login IDs | [login ID] count X     |

---

1. Brackets [ ] indicate the qualifier is optional.

## Form Instructions

---

Make assignments as required for the following fields on the form:

- **Login ID** — A number up to nine digits that an agent must enter to be measured in a split by BCMS. The login IDs are restricted to up to five digits if you are using EAS. The system validates each login ID. If you enter a duplicate login ID, the system displays an error message and places the cursor at the duplicate field. Also, the login ID must be the same length as the number in the "ACD Login Identification Length" field on the Feature-Related System-Parameters form. If the login ID you enter does not match the length specified in the "ACD Login Identification Length" field, the system displays an error message and places the cursor at the field that is incorrect.

**NOTE:**

The administered login length may change to another value, but doing so changes the allowed length for all IDs entered on this form. Before agents with logins that do not match the administered login length can log on, you must readminister either the ACD login identification length to fit the existing logins or change the logins to match the ACD login identification length.

- **Name** — A name associated with the login ID (optional).

```
change bcms/vu-stats login IDs                                     Page 1 of x
                                                                    BCMS/VU-STATS LOGIN IDS

```

Screen 9-4. BCMS/VuStats Login IDs Form

### Implementation Notes

The form appears only two pages (64 IDs) at a time. If you are adding login IDs, you can fill two pages and then reissue the command to fill an additional two pages, and so on. If you are changing or displaying login IDs, the system displays two pages of login IDs beginning with the ID you specified; if you did not specify a login ID when you issued the command, the display begins with the first login ID. The **list** command lists all login IDs and may run to 63 pages.

## Call Center System Parameters

Call Center System Parameters are listed on pages 7 and 8 of the Feature-Related System Parameters form. They are duplicated here for your convenience.

### Page 7 of the form

```
CALL CENTER SYSTEM PARAMETERS                                     Page 7 of 8

  Minimum Agent-LoginID Password Length:
  Direct Agent Announcement Extension: _____ Delay: ____
  Message Waiting Lamp Indicates Status For: station

VECTORIZING
  Converse First Data Delay: 0           Second Data Delay: 2
  Converse Signaling Tone (msec): 100    Pause (msec): 70_
  Prompting Timeout (secs): 10
  Interflow-qpos EWT Threshold: 2

SERVICE OBSERVING
  Service Observing Warning Tone? n

ASAI
  Call Classification After Answer Supervision? n   Send UCID to ASAI? n
```

### Screen 9-5. Feature-Related System Parameters form (page 7 of 8)

EAS parameters:

- **Expert Agent Selection (EAS) Enabled** — Only displays if `Expert Agent Selection (EAS)` on the System-Parameters Customer-Options form is `y`. Enter `y` to enable Expert Agent Selection. To enable this field, either no ACD or vectoring hunt groups may exist or, existing ACD or vectoring hunt groups must be "skilled." Default is `n`.
- **Minimum Agent-LoginID Password Length** — Only displays if `Expert Agent Selection (EAS)` on the System-Parameters Customer-Options form is `y`. Enter the minimum number of digits that must be administered as an EAS Agent's LoginID password. Valid entries are `0` through `9` or blank. Entering a `0` or blank indicates no password is required. Default is blank.
- **Direct Agent Announcement Extension** — Only displays if `Expert Agent Selection (EAS)` or `ASAI` on the System-Parameters Customer-Options form is `y`. Enter a valid announcement extension (consistent with the dial plan).

- **Direct Agent Announcement Delay** — Only displays if `Expert Agent Selection (EAS)` or `ASAI` on the `System-Parameters Customer-Options` form is **y**. Enter the number of seconds (**0** to **99**) the caller will hear ringback before the Direct Agent Announcement is heard by the calling party.
- **Message Waiting Lamp Indicates Status For** — Only displays if `Expert Agent Selection (EAS)` on the `System-Parameters Customer-Options` form is **y**. If `Expert Agent Selection (EAS) Enabled` is **y**, you can enter either **station** or **loginID**, otherwise you can only enter **station**.

Vectoring parameters:

- **Converse First Data Delay/Second Data Delay** — Only displays if `Vectoring (Basic)` on the `System-Parameters Customer-Options` form is **y**. The `First Data Delay` prevents data from being outpulsed (as a result of a converse vector step) from the system to a voice response unit (VRU) before the unit is ready. The delay commences when the VRU port answers the call. Enter the number of seconds (**0** to **9**) for the delay. Default is **0**. The `Second Data Delay` is used when two groups of digits are being outpulsed (as a result of a converse vector step) from the system to the VRU. The `Second Data Delay` prevents the second set from being outpulsed before the VRU is ready. The delay commences when the first group of digits has been outpulsed. Enter the number of seconds (**0** to **9**) for the delay. Default is **2**.
- **Converse Signaling Tone/Pause** — Only displays if `Vectoring (Basic)` and `DTMF` on the `System-Parameters Customer-Options` form are **y**. In the `Signaling Tone` field, enter the length in milliseconds of the digit tone for digits being passed to a voice response unit (VRU). In the `Pause` field, enter the length in milliseconds of the delay between digits being passed. The optimum timers for the VRU are a 100 msec tone and 70 msec pause.

Values entered in the `Tone/Pause` fields are rounded up or down depending upon the type of circuit pack used to outpulse the digits.

- **TN742B or later suffix analog board** — Tone and pause round up or down to the nearest 25 msecs. For example a 130 msec tone rounds down to 125 msecs, a 70 msec pause rounds up to 75 msec for a total of 200 msecs per tone.
- **TN464F, TN767E or later suffix DS1 boards** — Tone and pause round up to the nearest 20 msecs. For example a 130 msec tone rounds up to 140 msecs, a 70 msec pause rounds up to 80 msecs for a total of 220 msecs per tone.

If a circuit pack has been used for end-to-end signalling to the VRU, and has then been used to send digits to a different destination, the VRU timers may stay in effect. To reset your timers to the system default, pull and reseat the circuit pack.

- **Prompting Timeout (secs)** — Only displays if `Vectoring (Prompting)` on the System-Parameters Customer-Options form is **y**. Enter the number of seconds, from **4** to **10** (default), before the Collect Digits command times out for callers using rotary dialing.
- **Interflow-qpos EWT Threshold** — Part of enhanced Look-Ahead Interflow. Any calls predicted to be answered before this threshold will not be interflowed (therefore saving CPU resources). Enter the number of seconds for this threshold. The default is 2 seconds.

Service Observing parameters:

- **Service Observing Warning Tone** — `Service Observing (Basic)` on the System-Parameters Customer-Options form must be **y** before this field may be administered. Enter **y** to assign a warning tone to be given to voice terminal users and calling parties whenever their calls are being monitored using the Service Observing feature. Default is **n**.

**NOTE:**

The use of Service Observing features may be subject to federal, state, or local laws, rules or regulations or require the consent of one or both of the parties to the conversation. Customers should familiarize themselves and comply with all applicable laws, rules, and regulations before using these features.

ASAI parameters

- **Call Classification After Answer Supervision?** — For use with ASAI Outbound Call Management (OCM). Enter **y** to force the switch to rely on the network to provide answer/busy/drop classification to the switch. After the call has been answered, a call classifier can be added to perform answering machine, modem and voice answering detection. Enter **n** for standard operation.
- **Send UCID to ASAI?** — Enter **y** to enables transmission of Universal Call ID (UCID) information to ASAI. Enter **n** (default) to prevent transmission of UCID information to ASAI.

## Page 8 of the form

### Screen 9-6. Feature-Related System Parameters form (page 8 of 8)

#### Agent and Call Selection Parameters:

- **MIA Across Splits or Skills?** — Enter **y** to remove an agent from the MIA queue for all the splits/skills/hunt groups that he or she is available in when the agent answers a call from any of his or her splits/skills/hunt groups. The default is **n**.
- **ACW Agents Considered Idle?** — Enter **y** (default) to have agents who are in After Call Work included in the Most-Idle Agent queue. Enter **n** to exclude ACW agents from the queue.
- **Call Selection Measurement** — Valid entries are **current-wait-time** (default) and **predicted-wait-time**. This field determines how DEFINITY ECS selects a call for an agent when the agent becomes available and there are calls in queue. Current Wait Time selects the oldest call waiting for any of the agent's skills. Predicted Wait Time is a feature of CentreVu<sup>®</sup> Advocate. For more information, please see the *CentreVu<sup>®</sup> Advocate User Guide* (585-215-855).

#### Reason Codes Parameters:

- **Aux Work Reason Code Type** — Enter **none** if you do not want an agent to enter a Reason Code when entering AUX work. Enter **requested** if you want an agent to enter a Reason Code when entering AUX mode but do not want to force the agent to do so. Enter **forced** to force an agent to enter a Reason Code when entering AUX mode. To enter **requested** or **forced**, the Reason Codes and EAS on the System-Parameters Customer-Option form must be **y**.

- **Logout Reason Code Type** — Enter **none** if you do not want an agent to enter a Reason Code when logging out. Enter **requested** if you want an agent to enter a Reason Code when logging out but do not want to force the agent to do so. Enter **forced** to force an agent to enter a Reason Code when logging out. Enter **forced** to force an agent to enter a Reason Code when entering AUX mode. To enter **requested** or **forced**, the `Reason Codes` and `EAS` on the System-Parameters Customer-Option form must be **y**.

Call Management System Parameters:

- **Adjunct CMS Release** — Specifies the release of the CMS adjunct used with the system. For CMS, this field cannot be blank. Default is blank.
- **ACD Login Identification Length** — Enter the number of digits (**0** through **9**) for an ACD Agent Login ID if `Expert Agent Selection (EAS)` on the System-Parameters Customer-Options form is **n**. Default is **0**. If `BCMS/VuStats Login IDs` is **y**, the ACD Login ID length must be greater than 0. This field identifies an ACD agent to CMS. The number you enter in this field must equal the number of characters in the agent's login ID. For CMS, this field cannot be 0.
- **BCMS/VuStats Measurement Interval** — You can enter **half-hour** or **hour** (default) for polling and reporting measurement data if the `BCMS (Basic)` and/or the `VuStats` on the System-Parameters Customer-Options form is **y**. If neither of these features is optioned, and if you enter a value in the `BCMS Measurement Interval` field, the system displays the following error message:

**<value> cannot be used; assign either BCMS or VuStats first**

If you receive this message, see your Lucent Technologies representative to turn on `BCMS (Basic)` and/or `VuStats` on the System-Parameters Customer-Options form.

There are a maximum of 25 time slots available for measurement intervals. If **hour** is specified, an entire day of traffic information will be available for history reports; otherwise, only half a day will be available. This does not affect daily summaries as they always reflect traffic information for the entire day. The interval may be changed at any time, but will not go into effect until the current interval completes.

- **BCMS/VuStats Abandon Call Timer (seconds)** — Enter **none** or **1–10** to specify the number of seconds for calls to be considered abandoned. Calls with talk time that is less than this number (and that are not held) are tracked by BCMS and displayed by VuStats as ABAND calls.
- **Validate BCMS/VuStats Login IDs** — Enter **n** to allow entry of any ACD login of the proper length. Enter **y** to allow entry only of login-IDs that have been entered on the BCMS Login-ID form.
- **Clear VuStats Shift Data** — Enter **on-login** to clear shift data for an agent when the agent logs in. Enter **at-midnight** to clear shift data for all agents at midnight.

## Call Vector

This form programs a series of commands that specify how to handle calls directed to a Vector Directory Number (VDN). Refer to *DEFINITY Enterprise Communications Server Release 5 Call Vectoring/EAS Guide* for additional information.

### Administration Commands

Use the following commands to administer the Call Vector form.

| Action              | Object | Qualifier <sup>1</sup>                        |
|---------------------|--------|---|
| change <sup>2</sup> | vector | 1-MAX   |
| display             | vector | 1-MAX ['print' or 'schedule']                 |
| list                | vector | 1-MAX ['count' 1-MAX] ['print' or 'schedule'] |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.
2. Do not change a call vector while it is processing a call. It is recommended to add a new vector with the Call Vector form, and then use the Vector Directory Number form to point an existing VDN to the new vector.

Screen 9-9. Call Vector Form (Page 3 of X)

Make assignments as required for the following fields on the form:

- **Number** — Display-only field when the form is accessed using a **change** or **display** administration command. Enter a vector number when completing a paper form.
- **Name** — Enter up to 27 alphanumeric characters to represent the vector name. This is an optional field. Default is blank.
- **Multimedia** — Indicates whether the vector should receive early answer treatment for multimedia calls. This only applies if Multimedia Call Handling is enabled. If you expect this vector to receive multimedia calls, set this field to **y**. Valid values are **y** or **n**. If this value is **y**, the call is considered to be answered at the start of vector processing, and billing for the call starts at that time. See [“Multimedia Call Handling” on page 11-30](#) for more information.

- **Lock**—This field controls access to the vector from Lucent CentreVu<sup>®</sup> products. Enter **n** to give CentreVu<sup>®</sup> CMS and CentreVu<sup>®</sup> Control Center users the ability to administer this vector from these client programs. Enter **y** if you do not want this vector to be accessible to these client programs. Locked vectors can only be displayed and administered through the SAT or a terminal emulator.

 **NOTE:**

Always lock vectors that contain secure information (for example, access codes).

- **Basic** — Display-only field. Indicates whether the `Vectoring (Basic)` option is enabled on the System-Parameters Customer-Options form. Valid values are **y** or **n**.
- **EAS** — Display-only field. Indicates whether the `Expert Agent Selection (EAS)` option is enabled on the System-Parameters Customer-Options form. Valid values are **y** or **n**.

 **NOTE:**

When `Expert Agent Selection (EAS)` is enabled, the help messages and error messages associated with this form will reflect a terminology change from "Split" to "Skill". In addition, the vector commands entered also will be affected by this terminology change (for example, *check backup split* becomes *check backup skill* when EAS is enabled).

- **G3V4 Enhanced** — Display-only field. Indicates whether you can use G3V4 Enhanced Vector Routing commands and features.
- **ANI/II-Digits** — Display-only field. Indicates whether you can use ANI and II-Digits Vector Routing Commands. ANI/II-Digits Routing requires that `G3V4 Enhanced` be set to **y**.
- **ASAI Routing** — Display-only field. Indicates whether or not the `CallVisor Adjunct/Switch Applications Interface (ASAI) Routing` option is enabled on the System-Parameters Customer-Options form. Valid values are **y** or **n**.
- **Prompting** — Display-only field. Indicates whether the `Vectoring (Prompting)` option is enabled on the System-Parameters Customer-Options form. Valid values are **y** or **n**.
- **LAI** — Display-only field. Indicates whether Look-Ahead Interflow is enabled.
- **G3V4 Adv Route** — Display-only field. Indicates whether you can use the G3V4 Advanced Vector Routing commands.
- **CINFO** — Display-only field. Indicates whether the `Vectoring (CINFO)` option is enabled on the System-Parameters Customer-Options form. Valid values are **y** or **n**.

- **BSR**—A **y** in this display-only field indicates that the Vectoring (Best Service Routing) option is enabled on the System-Parameters Customer-Options form. Thus, you can use BSR commands and command elements in your vectors. An **n** indicates that the BSR option is not enabled.
- **01 through XX** — Enter vector commands as required (up to the maximum allowed in your configuration).

## Reason Code Names

---

Use the Reason Code Names form to assign names to Reason Codes. You can assign a different name to each Reason Code for Aux Work and for Logout.

### Administration Commands

---

Use the following administration commands to access the Reason Code Names form.

| Action  | Object            |
|---------|-------------------|
| display | reason-code-names |
| change  | reason-code-names |

### Form Instructions

---

Make assignments as required for the following fields on the form.

- **Aux Work** — For each Reason Code enter the name to be associated with this Reason Code when the agent uses this Reason Code to enter Aux Work mode. Names can be up to ten characters long.
- **Logout** — For each Reason Code enter the name to be associated with this Reason Code when the agent uses this Reason Code to log out. Names can be up to ten characters long.

REASON CODE NAMES

|                      | Aux Work | Logout |
|----------------------|----------|--------|
| Reason Code 1:       | _____    | _____  |
| Reason Code 2:       | _____    | _____  |
| Reason Code 3:       | _____    | _____  |
| Reason Code 4:       | _____    | _____  |
| Reason Code 5:       | _____    | _____  |
| Reason Code 6:       | _____    | _____  |
| Reason Code 7:       | _____    | _____  |
| Reason Code 8:       | _____    | _____  |
| Reason Code 9:       | _____    | _____  |
| Default Reason Code: | _____    | _____  |

## SIT Treatment for Call Classification

---

This form is used to provide the capability of specifying the treatment of Special Information Tones (SITs) used for Outbound Call Management type calls with USA tone characteristics. The TN744 Call Classifier circuit pack ports are used to detect SITs. The TN744 is capable of detecting the following six SITs:

- SIT Ineffective Other
- SIT Intercept
- SIT No Circuit
- SIT Reorder
- SIT Vacant Code
- SIT Unknown
- AMD Treatment

### Administration Commands

---

Use the following administration commands to administer the SIT Treatment For Call Classification form. In some cases, just the most commonly used commands are shown. Refer to [Appendix B, "Administration Commands"](#), for a complete listing of all administration commands, the command structure, and the use of abbreviated command words when entering a command.

| Action  | Object        | Qualifier <sup>1</sup>  |
|---------|---------------|-------------------------|
| change  | sit-treatment | —                       |
| display | sit-treatment | ['print' or 'schedule'] |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word can be entered.

### Form Instructions

---

Make assignments as required for the following fields on the form:

In the field following each type of SIT, enter "answered" to specify that the call is classified as answered, and is therefore sent to an agent; or enter "dropped" to specify that the call is classified as not answered, and is therefore not sent to an agent.

- **SIT Ineffective Other** — Sample announcement following this SIT — "You are not required to dial a "1" when calling this number." Valid entries are "answered" and "dropped." Default is "dropped."

9 Call Center Forms

SIT Treatment for Call Classification

- **SIT Intercept** — Sample announcement following this SIT — “XXX-XXXX has been changed to YYY-YYYY, please make a note of it.” Valid entries are “answered” and “dropped.” Default is “answered.”
- **SIT No Circuit** — Sample announcement following this SIT — “All circuits are busy, please try to call again later.” Valid entries are “answered” and “dropped.” Default is “dropped.”
- **SIT Reorder** — Sample announcement following this SIT — “Your call did not go through, please hang up and dial again.” Valid entries are “answered” and “dropped.” Default is “dropped.”
- **SIT Vacant Code** — Sample announcement following this SIT — “Your call cannot be completed as dialed, please check the number and dial again.” Valid entries are “answered” and “dropped.” Default is “dropped.”
- **SIT Unknown** — A situation or condition that is unknown to the network is encountered. Valid entries are “answered” and “dropped.” Default is “dropped.”
- **AMD (Answering Machine Detected)** — An ASA1 adjunct can request AMD for a switch-classified call. If Answering Machine is detected, one of two treatments is specified. Valid entries are “dropped” and “connected.” Default is “dropped.”

AMD Treatment has two separately administrable subfields. Talk Duration is for full seconds and Pause Duration is for fractions of a second, separated by a display-only decimal point. Talk Duration defaults to 2.0 seconds and allows a range from 0.1 seconds to 5.0 seconds in increments of 0.1 seconds. Pause duration defaults to 0.5 seconds and allows a range from 0.1 seconds to 2.0 seconds in increments of 0.1 seconds.

```
SIT TREATMENT FOR CALL CLASSIFICATION
SIT Ineffective Other:  dropped
SIT Intercept:         answered
SIT No Circuit:       dropped
SIT Reorder:          dropped
SIT Vacant Code:     dropped
SIT Unknown:         dropped
AMD Treatment:        dropped
Pause Duration (seconds): 0.5
Talk Duration (seconds): 2.0
```

Screen 9-11. SIT Treatment For Call Classification Form

## Vector Directory Number

---

This form is used to define vector directory numbers (VDNs) for the Call Vectoring feature. A VDN is an extension number used to access a call vector. Each VDN is mapped to one call vector.

VDNs are software extension numbers (that is, not assigned to physical equipment). A VDN is accessed via direct dial CO trunks mapped to the VDN (incoming destination or night service extension), DID trunks, and LDN calls. The VDN may be Night Destination for LDN.

For more information, refer to the *DEFINITY Enterprise Communications Server Release 5 Call Vectoring/EAS Guide*.

### Administration Commands

---

Use the following administration commands to administer the Vector Directory Number form

| Action  | Object | Qualifier <sup>1</sup>   |
|---------|--------|--|
| add     | vdn    | xxxxx (extension number of VDN to be added) or 'next'                                |
| change  | vdn    | xxxxx (extension number of VDN to be changed)  |
| display | vdn    | xxxxx (extension number of VDN to be displayed) ['print' or 'schedule']              |
| list    | vdn    | xxxxx (extension number of VDN to be listed) ('count' 1-MAX) ['print' or 'schedule'] |
|         | vdn    | bsr xxx (number of a BSR application plan)   |
| remove  | vdn    | xxxxx (extension number of VDN to be removed)  |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word can be entered. MAX is the maximum number available in your system configuration. Refer to *DEFINITY ECS Release 5 — System Description Pocket Reference*.

### Form Instructions

---

Make assignment as required for the following fields on the form:

- **Extension** — Enter the extension associated with the VDN when completing a paper form. The extension is a 1- to 5-digit number that starts with a valid first digit and length as defined by the System's dial plan. This is a display-only field when using an administration command such as add or change to access the form.

- **Name** — Enter up to a 27-character alphanumeric name that identifies the VDN. This is an optional field that need not contain any data. The name may be truncated on agents' displays depending on the application. When information is forwarded with an interflowed call, only the first 15 characters are sent.
- **Allow VDN Override?** — This entry affects the operation of an agent's display and certain options/data assigned to the VDN when a call is routed through several VDNs. If it is set to **n**, the name of this VDN appears on the agent's display and the VDN's AUDIX mail is accessed. If any subsequent VDNs are used to process this call, their names will not appear on the terminating display and the AUDIX mail for the original VDN is accessed. If the field is set to **y**, the name of the VDN appearing on the terminating display will depend on the administration and chaining of the subsequent VDNs and the AUDIX mail for the last VDN is accessed. Default is "n."

For Expert Agent Selection (EAS), if this field is **y** on the original VDN, the Skills of the new VDN will be used. If this field is **n** on the original VDN, the Skills of the original VDN will be used.

For Best Service Routing (BSR), if this field is **y** on the original VDN, the BSR Application and Available Agent Strategy of the new VDN will be used. If this field is **n** on the original VDN, the BSR Application and Available Agent Strategy of the original VDN will be used.

- **COR** — Enter a 1- to 2-digit number that specifies the class of restriction (COR) to be assigned the VDN. The default value is "1." The field cannot be blank and must have an entry in the range from 0 through 95.
- **TN** — Enter the Tenant Partition number. The default value is "1".
- **Vector Number** — Enter a 1- to 3-digit vector number that specifies a particular call vector that is accessed through the VDN. Valid entries are in the range from 1 through the maximum number allowed in your system configuration. The field cannot be blank.
- **AUDIX Name** — Only displayed for R5r and later configurations. If this VDN is associated with the AUDIX vector, enter the name of the AUDIX machine as it appears in the Adjunct Names form.
- **Messaging Server Name** — Only displayed for R5r configurations. If this VDN is associated with MSA, enter the name of the server as it appears in the Adjunct names form.
- **Measured** — Used to collect measurement data for this VDN. Valid entries are "internal," "external," "both," or "none." Data may be collected for reporting by BCMS or CMS. Default is "none."

 **NOTE:**

The BCMS feature must be enabled on the System-Parameters Customer-Options form for the Measured field to be set to "internal" or "both." In addition, the appropriate CMS release must be

administered on the Feature-Related System Parameters form if the field is being changed to “external” or “both.”

- **Acceptable Service Level (sec)** — Only displayed when the BCMS/VuStats Service Level option is enabled on the System-Parameters Customer-Options form and the Measured field is “internal” or “both.” Enter the number of seconds within which calls to this VDN should be answered. This will allow BCMS to print out a percentage of calls that were answered within the specified time. Valid entries are 0 through 9999 seconds. Default is blank.

The following field appears only if VDN of Origin Announcements is enabled on the System-Parameters Customer-Options form.

- **VDN of Origin Ann. Extension** — Enter the extension number of the VDN of Origin announcement. Default is none.
- **1st/2nd/3rd Skill** — Only displayed when Expert Agent Selection is enabled on the System-Parameters Customer-Options form. Enter the desired Skill numbers (or leave blank) in each field.
- **Return Destination** — The VDN extension number to which an incoming trunk call will be routed if it returns to vector processing after the agent drops the call.
- **VDN Timed ACW Interval** — When a value is entered in this field, an agent in auto-in work mode who receives a call from this VDN is automatically placed into After Call Work (ACW) when the call drops. Enter the number of seconds the agent should remain in ACW following the call. When the administered time is over, the agent automatically becomes available. This field has priority over the “Timed ACW Interval” field on the Hunt Group form.
- **BSR Application** — To use multi-site Best Service Routing with this VDN, enter a 1- to 3-digit number to specify an application plan for the VDN. This field only appears if Lookahead Interflow (LAI) and Vectoring (Best Service Routing) are enabled on the System Parameters Customer-Options form.
- **BSR Available Agent Strategy** — The available agent strategy determines how Best Service Routing identifies the “best” split or skill to service a call in an agent surplus situation. To use Best Service Routing with this VDN, enter an agent selection strategy in this field. Acceptable entries are 1st-found, UCD-LOA, UCD-MIA, EAD-LOA, and EAD-MIA.

This field only appears if Vectoring (Best Service Routing) is enabled on the System Parameters Customer-Options form.

**Screen 9-13. Vector Directory Numbers — List Form**

**Implementation Notes**

AUDIX Name and Messaging Server Name are only displayed for a R5r configuration.

The BCMS feature must have been optioned if the Measured field is set to "internal" or "both." In addition, the appropriate CMS release must be administered on the Feature-Related System Parameters form if the field is being changed to "external" or "both."

The 1st/2nd/3rd Skill fields are only displayed when Expert Agent Selection is enabled on the System-Parameters Customer-Options form.

The BCMS Acceptable Service Level (sec) field is only displayed if the BCMS Acceptable Service Level option is enabled on the System-Parameters Customer-Options form and the Measured field is "internal" or "both."

Data for the Orig Annc column appears only when VDN of Origin Announcement is enabled on the System-Parameters Customer-Options form.

To list all VDNs using the same BSR Application Plan, type the administration command **list VDN BSR xxx** (xxx is the number of the BSR Application Plan used by one or more VDNs).

## Vector Routing Table

---

This form is used to store “ani” or “digits” that you refer to in your “goto” vector steps. It is available to you only if the Vectoring (G3V4 Enhanced) field on the System-Parameters Customer-Options form is set to yes.

For more information, refer to [“Call Vectoring” on page 9-63](#) or to *DEFINITY Enterprise Communications Server Release 5 Call Vectoring /EAS Guide*.

### Administration Commands

---

You can use the commands listed in the table below to administer Vector Routing Tables. In addition, you can use the “List Usage” command to see the vectors and digit fields used by a Vector Routing Table.

| Action  | Object | Qualifier                              |
|---------|--------|--|
| add     | vrt    | 1 through x, or next                   |
| change  | vrt    | 1 through x, or next                   |
| display | vrt    | 1 through x, or next                   |
| remove  | vrt    | 1 through x, or next                   |
| list    | vrt    | none - all Routing Tables will display |

### Form Instructions

---

Make assignment as required for the following fields on the form:

- **Number** — This is the table number that you entered on the command line. It is a display only field.
- **Name** — Enter a 1 to 15-character alphanumeric table name. You may leave this field blank.
- **Sort?** — Enter “y” if you want the digit fields to be sorted. Default is “n.” If you elect not to sort the numbers, they will remain in the order that you entered them. If you elect to sort the number fields, they will be sorted as described below. Remember that leading zeros are significant. That means that 02 will sort ahead of a 2 followed by a space.
  - Any Plus signs (+) will sort first.
  - Any question marks (?) will sort second.
  - All numbers (0–9) will sort last.

- **Number (1-32)** — Enter a number. Entries in this field also can include the “+” and/or “?” wildcard. The “+” represents a group of digits. The “?” represents a single digit. The field is limited to 16 characters and these characters are restricted as follows:
  - You may enter only a plus sign (+), a question mark (?), or the numbers 0 through 9. No other entries are valid.
  - You may enter one plus sign (+) as either the first or last character in the number field. However, you cannot use this character as the sixteenth character of the number field.
  - You may use as many question marks (?) as you wish, anywhere in the number field.
  - You may not embed blanks in the number field.
  - You may leave the field entirely blank. If you leave the field blank DEFINITY ECS will store the entry as a null value.

Screen 9-14. Vector Routing Table Form (1 of 3)

## VuStats Display Format

---

Use the VuStats Display Format form to define the content and layout of information on VuStats voice terminal displays. The system has 50 different display formats; the first display is a predefined example format, which can be changed; displays 2 through 50 are blank. Each display format can contain up to ten data items. However, the amount of data to be displayed is limited to 40 characters, due to the physical limitations on display voice terminals.

### Administration Commands

---

Use the following administration commands to access the VuStats Display Format form.

| Action  | Object                 | Qualifier <sup>1</sup> |
|---------|------------------------|------------------------|
| change  | vustats-display-format | 1-50                   |
| display | vustats-display-format | 1-50                   |
| list    | vustats-display-format | 1-50 count ##          |

1. Specify a number from 1 to 50 to indicate the number of the display format to be to changed or displayed. "Count ##" is the number of display formats to list.

### Form Instructions

---

Enter the data as required for the following fields on the form:

- **Format Number** — This is the display format number you entered on the command line. It is a display only field and cannot be modified.
- **Next Format Number** — To link this display to another display, enter the number of the display format that should appear when a VuStats user presses the next button, or enter "none."
- **Data Field Character** — The character that will be used in the Format Description field to identify the position and length of each data field (see the Format Description field description below). The default is "\$." Enter another character if the "\$" is needed for fixed text in the Format Description field. Any character is valid except a space.
- **Number of Intervals** — If you intend to display interval-based historical data, specify the number of measurement intervals in this field. You can enter a number between 1 and 24. If you enter 24, and the BCMS measurement interval on the Feature-Related System Parameters form is set to 1 hour, you will receive information on the previous 24 hours. If the

BCMS measurement interval is set to half-hour, you will receive information on the previous 12 hours. You can also leave this field blank. If you do, you will receive information on the current interval.

- **Object Type** — The type of object for which data will be displayed. Enter one of the following values: “agent” (for staffed agents to view their own statistics), “agent-extension” (for other users to view agent statistics), “split” (default), “trunk-group,” or “vdn.”
- **Update Interval** — The interval, in seconds, between display updates. Enter one of the following values:

| Valid Input | Description  |
|-------------|--|
| no-update   | The display is not updated, and appears only for the interval specified in the Display Interval field                          |
| polled      | Updates the display hourly or half-hourly, based on the value in "BCMS Measurement Interval" (System-Parameters Features form) |
| 10          | Updates every 10 seconds   |
| 20          | Updates every 20 seconds   |
| 30          | Updates every 30 seconds, default value  |
| 60          | Updates every 1 minute   |
| 120         | Updates every 2 minutes  |

- **On Change** — Enter “y” to update the display whenever the agent’s state changes. The update on agent state change is in addition to the update as a result of the value entered in the Update Interval field. If “n” is entered, an update will only occur based on the Update Interval and not on the agent state change.
- **Display Interval** — The interval, in seconds, for which data is displayed if “no update” is entered in the Update Interval field. Enter one of the following values:

| Valid Input | Description  |
|-------------|--|
| Body        |  |
| 5           | Display clears after 5 seconds   |
| 10          | Display clears after 10 seconds, default value   |
| 15          | Display clears after 15 seconds  |
| 30          | Display clears after 30 seconds  |
| not-cleared | The display does not clear, and the data appears until the display is used for another operation or until you press the Normal button. |

- **Format Description** — The definition of the layout for the 40-character display. Specify the starting position and the length of the data items by entering, for each data field, an optional label for the field followed the appropriate number of data field characters (such as \$s). Each "\$" represents one character in the display. For example, if the data will be a maximum of five characters long (for example, to display 5-digit agent extensions), enter "\$\$\$\$\$."

 **NOTE:**

Some data types have preset maximum field length limits based on switch administration. For example, the data type "acceptable-service-level" is taken from the BCMS Acceptable Service Level field on the Hunt Group and Vector Directory Number forms; on this form, the field allows a maximum number of four characters. Therefore, for the acceptable-service-level, you should not create a VuStats display field that consists of more than four characters (that is, "\$\$\$\$"). Other data types have similar limits.

Field lengths for data items that appear as time must match the value in the Format field, which is discussed below. Remember to account for possible colons when the display will be in a time format.

Format descriptions can be all text (such as a message of the day) or they can be all data fields, in which case users will have to memorize the labels or use customer-provided overlays above or below the display.

 **NOTE:**

If the numeric data for a field is too large for the number of data field characters entered, the VuStats display will show asterisks instead of data. If name database items are too large for the number of data field characters, the VuStats display will truncate the data to fit the data field size. The split objective, as entered on the Hunt Group form, will display as asterisks if the information exceeds the data field size.

### Data Item Fields

On lines 1 through 10, beneath the Data Type field label enter data items for the display format. These data items are associated with the sets of data field characters in the Format Description field. Each data item is defined by one or more of the following fields: Data Type, Format, Period, Threshold, and Split Reference. Input for these fields is described in more detail below.

Enter each data item in the same order as data fields are defined in the Format Description field. For example, Line 1 of the Data Type field must contain the data item for the first data field (that is, the first set of \$s).

- **Data Type** — The data item to be included in the current display format. For a complete list of data types available for each object type, see "Tables of Data Types" on page 3-540.

- **Format** — The format for displaying the data type. The format is required only for a data type with a time value. Enter one of the following Format values.

| Valid Input | Description   | Minimum Input Length |
|-------------|---|----------------------|
| ccs         | Hundred call seconds (CCS) rounded to the nearest CCS | 1                    |
| h           | Hours rounded to the nearest hour                     | 1                    |
| h:mm        | Hours and minutes rounded to the nearest minute       | 4                    |
| h:mm:ss     | Hours, minutes, and seconds                           | 7                    |
| m           | Minutes rounded to the nearest minute                 | 1                    |
| m:ss        | Minutes and seconds                                   | 4                    |
| s           | Seconds   | 1                    |

- **Period** — Enter the measurement period for the data type. If the data type is historical data, you cannot leave this field blank. Valid entries are “day” (midnight to the current time), “interval” (the time specified in the “Number of Intervals” field), or blank. Refer to [“Tables of Required and Allowed Fields” on page 9-227](#) to determine if a measurement period is required for a particular Data Type.
- **Threshold** — The threshold field is always an optional field. It contains two subfields, the threshold comparator and the threshold value. The threshold value is used with the threshold comparator to determine if a threshold warning should be generated. A threshold warning is generated if the specified condition is met for one or more of the data items. If the specified condition is not met for any of the data items, then no threshold warning is generated. The threshold value can be any numeric value from 0 to 999. Valid threshold comparators are:
  - = (equal to)
  - <> (not equal to)
  - < (less than)
  - <= (less than or equal to)
  - > (greater than)
  - >= (greater than or equal to)

- **Ref** — A reference to a split/skill; this field does not appear unless the Object Type is either “agent” or “agent-extension.” This field is required only if the data type is an agent-related data type collected on a per-split basis or a split-related data type for one of the agent’s logged-in splits. Enter one of the following values:

- “Top” references the first-administered, highest-level skill for EAS agents, or the first split logged into for non-EAS agents.

 **NOTE:**

With EAS, the “top” skill for VuStats is the first administered, highest level skill measured “internally” or “both.” For CMS it is the first-administered, highest-level skill measured “externally” or “both.” Therefore, it is possible for the top skill to be a different number skill for CMS than it is for VuStats. To avoid this, measure all skills as “both.”

- “All” displays the combined data for all splits the agent is logged into.
- Any number from 1-20. The number represents a split to which the agent has logged in. For example, if the Ref field contains “1,” VuStats displays the data for the first split the agent logged into, if the Ref field contains “2,” VuStats displays the data for the second split the agent logged into, and so on.

VUSTATS DISPLAY FORMAT

**Screen 9-16. VuStats Display Format — Example Change/Display Form**

**List VuStats Display Format Screen**

A second VuStats Display Format screen is available with the **list** command. The purpose of this screen is to present the format of all, or a selected number, of VuStats displays. The List VuStats Display Format screen displays the Format Number, Next Format Number, Number of Intervals, Object Type, Update Interval, and Format Description fields, and all designated data items, including the Data Type, Format, Threshold, and Ref (split reference).

Use this screen to compare VuStats displays to each other. This “list” presentation is most helpful when trying to see how displays are linked to each other. The screen includes the Next field, which contains the number of the next display (if any) to which a display is linked.

[Screen 9-17](#) shows an example of the List VuStats Display Format screen. The fields for this screen are described below. Refer to the previous field descriptions in this section for more information.

**No** — Number. The unique identifying number of each display format.

**Next** — The number of the next display if the current display is linked to (followed by) another display format, or “none” if the current display format is not linked to another display format.

**Int** — Number of Intervals. The number of measurement intervals.

**Object Type** — The type of object for which data will be displayed.

**Update** — Update Interval. The time between display updates.

**Format Description** — The definition of the display's layout. The first line of the Format Description contains the text that precedes the data on a display plus the length of each data field (indicated by \$s). The succeeding lines of the Format Description identify the data items, in the order they are to appear. The data items are the actual measurements and other information that tell how agents, splits, vector directory numbers (VDNs), trunk groups, and the call center are performing. The data items are followed by the format (if any), which identifies how the data is to appear in the display, the period and threshold (if any), and the split reference (if any).

## Hospitality

# 10

---

This section contains the following DEFINITY ECS Hospitality features. Hospitality forms are located at the end of this chapter. Note that in this section, the term “guest” refers to a guest or a patient.

| <b>Feature</b>                       | <b>Page</b>           |

## Attendant Room Status

---

Attendant Room Status allows the attendant to see whether a room is vacant or occupied and each room's housekeeping status.

### NOTE:

This feature is available only if you have Enhanced Hospitality enabled on the System-Parameters Customer-Options form. (See your Lucent Technologies support representative for assistance with this form.)

## How to administer Attendant Room Status

---

## Detailed description

---

### Check In/Check Out Status

The attendant determines check in/check out status by pressing the OCC-ROOMS (occupied rooms) button on the attendant console.

This activates check in/checkout mode. The DXS lamps light for all occupied rooms. The console displays a message indicating that it is in check in/check out mode.

Occupancy status normally updates as guests check in and out.

### Maid Status

The attendant determines maid status by pressing the MAID-STAT button on the attendant console. This activates Maid-Status mode. The attendant is prompted to enter a status number (1 through 6). The display shows the state corresponding to that number and lights the DXS lamps for all rooms currently in that state.

While the console is in Maid-Status mode, the attendant can enter another status number. The console display shows the new status and lights the DXS lamps for all rooms in that state.

The status of a room updates when a maid or inspector dials from the room and changes the status.

The messages that appear on the console identify each of six states and are user-defined. (For example, you could define state 1 as clean, ready to use and state 2 as occupied, needs cleaning). As with other display messages, administer the prompts and status messages for a specific language.

## Considerations

---

- The feature is not available for attendants connected to the switch by a distributed communications system (DCS). Attendant consoles are the only terminals that can access this feature

## Interactions

---

- **Outgoing Calls**

When Check in/Check out mode is active, the attendant can make outgoing calls via the keypad. The attendant can return to normal mode or any other mode by pressing the appropriate button on the console. Check in/Check out mode does not affect other attendant operations.

When Maid Status mode is active, the attendant cannot make outgoing calls via the keypad. However, the attendant can make calls via the DXS module or the feature buttons. Attendant can return to normal mode or any other mode by pressing the appropriate button on the console.

## Automatic Wakeup

---

Automatic Wakeup allows attendants, front desk users, and guests to place an automatic wakeup call to a certain extension at a later time.

If the Dual Wakeup enhancement is activated, each extension is allowed two wakeup call requests within one 24-hour time period. If the Room Activated Wakeup with Tones enhancement is activated, wakeup calls can be activated via tones that prompt users for the time they wish to waken. These enhancements are activated on the change system-parameters hospitality form by entering **y** in the Dual Wakeup and Room Activated Wakeup with Tones fields. These options default to **y** and can only be changed by Lucent Technologies personnel.

### How to administer Automatic Wakeup

---

**Detailed description**

Wakeup requests may be placed from 5 minutes to 23 hours and 55 minutes in advance of a wakeup call.

When a user answers a wakeup call, the system can provide a recorded announcement, a speech-synthesis announcement, music, or silence depending on the administration of Automatic Wakeup.

All wakeup times entered into the system round to the nearest five minutes. For example, a requested time of 6:58 am stores in the system as 7:00 am. The switch bases time-validity checks on the rounded figure.

Wakeup calls are placed within two and one-half minutes of the requested time, and never reroute, forward, or go to coverage. Before placing the wakeup call, the system overrides Do Not Disturb for the extension.

If a wakeup-call attempt is not answered or if the extension is busy, the system tries two more times at 5-minute intervals. If the call does not complete after three attempts, the switch leaves a LWC message for a designated extension (usually assigned to a button on the attendant console or backup voice terminal). The system maintains a complete record of all wakeup-call activity for the past 24 hours.

Users with touch-tone dialing can enter a wakeup request (if they have a speech synthesizer board and no display set) or can have the attendant set a wakeup time. Users with rotary-dial terminals call the attendant to request a wakeup call.

Activate Automatic Wakeup either by dialing the FAC or by pressing the automatic wakeup entry button. If the system has a speech synthesizer board, the system provides voice prompting. If the user has a display set, the system provides display prompting.

- Voice Prompting with Room Activated with Tones Off

A guest enters his or her own wakeup-call request. The request is entered only for the extension where the call originates.

After the user dials the Automatic Wakeup FAC, the system generates voice prompts (the system must have a voice synthesizer). These prompts tell the user when to enter information and what information is needed. Use touch-tone buttons to enter the information. The system accepts military or standard time. The user dials the automatic wakeup FAC again to change or delete a wakeup request.

If the user makes invalid entries, a standard message generates that notifies the user of the error. The system then repeats the original prompt for input. If invalid entries occur on the second try, the system informs the user to dial the attendant for assistance.

- Voice Prompting with Room Activated with Tones On

A guest enters his or her own wakeup-call request. The request is entered only for the extension where the call originates.

After the user dials the Automatic Wakeup FAC, the system generates recall dial tone (the system does not need a voice synthesizer). This dial tone prompts the user to enter the time in a 24-hour, 4-digit format. Confirmation tone means that the wakeup request is successful.

- Display Prompting with Dual Wakeup Off

Display prompting is provided to attendants, front-desk users, and to other users with display-equipped voice terminals. Administer front-desk users (or any other voice terminals you want to grant permissions to) with a console permission class of service (COS) to perform the same actions as the attendant. Other users can enter a wakeup request only for the extension where the call originates.

The attendant presses the automatic wakeup entry button to activate the feature. If the attendant is on an active call with a system user, the user's extension displays as the default extension after pressing the pound sign

(#). If the displayed extension is not the extension of the user requesting the wakeup call, the attendant can change it. Display prompting continues until the attendant enters all necessary information and the request for the wakeup call is confirmed.

If a condition exists that does not allow the system to accept the wakeup request, the system displays the reason for denial. Wakeup requests are denied for one of the following reasons:

- Too Soon — Indicates that the requested wakeup time is within the current five-minute wakeup interval
- System Full — Indicates that the maximum number of wakeup calls is reached
- Interval Full — Indicates that the maximum number of wakeup calls in any 15-minute interval is reached

The attendant can change or cancel a wakeup call request at any time.

■ Display Prompting with Dual Wakeup On

Display prompting with Dual Wakeup works the same as Display Prompting with Dual Wakeup off (described in the previous text), except that after the first wakeup request is entered, the user is prompted for the second wakeup request.

When the system places a wakeup call, one of the following occurs:

- Extension Is Busy — The wakeup call is placed again later.
- No Answer — The extension rings for 30 seconds. If the call is not answered, the system tries again later.
- Ringing Blockage — If four or more ports on the same analog-circuit pack are already ringing, the system waits 16 seconds and tries again. If the second attempt is blocked, the call has failed and the system waits five minutes before trying again.
- Call Is Answered — The guest answers the wakeup call and hears either music, a recorded announcement, the speech-synthesizer announcement, or silence.
- System Reset — indicates that a system reset level 1 or system reset level 2 occurred while the system attempted to place the wakeup call. Calls affected by these conditions are treated as other wakeup attempts.

If a wakeup call is incomplete because of a busy, no answer, ringing blockage, or system reset, the system attempts to place the call two more times at five-minute intervals. If the call is not completed after three attempts, the system leaves an LWC message.

A special extension, called the Wakeup Messages Extension, is administered exclusively for receiving failed wakeup-call LWC messages. When a failed

message is retrieved, the display shows the date, time, and extension for the failed wakeup-call attempt.

Assign an automatic-message waiting (AMW) button and associated lamp to attendant consoles or front-desk terminals. The number associated with the button can be the wakeup-messages extension. The AMW lamp lights when a failed wakeup message is waiting. The user retrieves the message by invoking coverage-message retrieval on the wakeup-message extension. The user presses the AMW button to place the console or terminal in coverage-retrieval mode. The user then retrieves the failed wakeup-call attempt messages. Only attendants and specified voice-terminal users can retrieve and delete failed wakeup messages.

The system maintains an audit-trail record of wakeup-call activity for the past 24 hours. The wakeup-call buffer can only hold a number of records equal to the maximum number of stations administrable on the switch. For example, if a maximum of 200 stations is administrable, only 200 automatic-wakeup records are stored.

You can display wakeup events at the management terminal, or print to a designated printer. If the system has a journal printer, wakeup events print as they occur.

The audit trail record contains the following information:

- Type of event:
  - Request — A new wakeup-call request is made.
  - Change — The time is changed on an existing wakeup-call request.
  - Cancel — A wakeup request is canceled.
  - Move To — The wakeup request for this room moves to another room.
  - Move From — The wakeup request for another room moves from the old room to the new room.
  - Move-Cancel — A wakeup request from another room replaces the request for this room.
  - Swap — A room swap occurs and at least one of the rooms has a wakeup request. Wakeup calls swap when a room swap is performed. A journal entry is made for each room. If the room receives a wakeup call as the result of the swap, the time of the call is provided in the entry. If the room loses a wakeup call as the result of the swap (and has not received another), the time is not present in the entry.
  - Completed — The wakeup call completes successfully.
  - Not Completed — The wakeup call failed.

— Skip — The wakeup call is skipped. This event occurs if the system time advances past the requested time of a wakeup call.

- Time of the event
- Extension number receiving the call
- Time of the wakeup request
- Extension (or 0 for the attendant) where the event took place
- Number of call attempts that were placed
- An indication of why a wakeup-call attempt failed

In addition, all wakeup-time changes are recorded. This record shows the original time requested and the changed time. The audit-trail record is not backed up and all wakeup data is lost if a system failure occurs.

Schedule the following reports for printing on a daily basis:

- Wakeup Activity report – summarizes wakeup activity for each extension that had any wakeup activity over the past 24 hours.
- Wakeup Summary report — gives an hour-by-hour summary of the number of scheduled wakeup calls, the number of wakeup calls completed, and a list of extensions. The report covers all automatic-wakeup events for each hour over a 24-hour period.

With VDNs and multiple announcements, you can choose as the announcement extension a VDN that reaches one announcement if the system clock is less than 12:00 and another if the system clock is greater than 12:00. The hotel guest hears “good morning” before noon and “good evening” after noon. Or, a business customer can choose as the announcement extension a VDN that points to an extension assigned to a quorum bridge, with the wakeup time as a scheduled teleconference time. When the wakeup call is completed, the customer automatically connects to the teleconference bridge.

You can administer a multiple announcement to repeat. To enable repeating announcements, enter announcement type *integ-rep* on the Recorded Announcement form. With repeating integrated-message functionality, the announcement keeps repeating from when the first guest (of a group of guests receiving the same wakeup announcement at the same time) goes off-hook until the last guest goes on-hook.

If the announcement type is either an externally-recorded announcement or is integrated-repeating, you can administer the wakeup-call queue for barge-in. Barge-in means that the guest receiving the wakeup call hears the announcement as soon as he or she is off-hook, even if the announcement is not at the beginning. This provides the capability of many users being bridged onto the same announcement port, eliminating the need for a separate port for each wakeup call. For additional information, see Recorded Announcement.

## Considerations

---

- Up to 10 attendant consoles and/or front desk terminals may be in the wakeup display mode at any one time.
- Wakeup call attempts are not rerouted, forwarded, or sent to coverage.

## Interactions

---

- Attendant or Voice Terminal Display

If the console or terminal is in automatic-wakeup mode and the user presses another display-mode button, wakeup mode aborts and the wakeup request is not entered, changed, or deleted.
- Do Not Disturb

If Do Not Disturb is active at a voice terminal, Automatic Wakeup deactivates Do Not Disturb for that terminal, and the system places the wakeup call.
- PMS Interface

A Check-Out request cancels an active-wakeup call request for the guest room. Room Change/Room Swap requests through PMS cause a wakeup request to change or swap.
- Voice Synthesis Board

Auto Wakeup competes with the following features for use of the speech-synthesizer board.

  - Do Not Disturb
  - Leave Word Calling Message Retrieval
  - Visually Impaired Attendant Service

## Do Not Disturb

---

Do Not Disturb allows guests, attendants, and authorized front-desk voice-terminal users (those with console permission) to request that no calls, other than priority calls, terminate at a particular extension until a specified time. At the specified time, the system automatically deactivates the feature and allows calls to terminate normally at the extension.

### How to administer Do Not Disturb

### Detailed description

---

Do Not Disturb is a form of termination restriction associated with an automatic deactivate time. When Do Not Disturb is active, the user receives only those calls associated with Automatic Callback, Automatic Wakeup, and Priority Calling, and those calls that are redirected to that extension via the Call Coverage and Call Forwarding All Calls. All other calls redirect to a recorded announcement, an attendant, or intercept tone.

Voice-terminal users with touch-tone dialing can activate this feature themselves or ask the front desk to do it for them. Users with rotary-dial terminals must call the attendant or front-desk user to request Do Not Disturb.

## Activation by Voice Terminal Users

Voice-terminal users can activate Do Not Disturb by dial access or by button access. If users have a speech-synthesizer board, they can activate Do Not Disturb themselves, without attendant assistance.

- Dial Access

When a user dials a Do Not Disturb feature access code (FAC), the system prompts the user to enter a deactivate time. The user may later change or delete the request by dialing the Do Not Disturb FAC again and entering the required information.

If the user makes invalid entries or if system conditions prevent entry of the request, the system informs the user to dial the attendant or front desk for assistance, if the user has a speech-synthesizer board.

- Button Access

If a voice terminal has a Do Not Disturb button, the user can press the button to activate the feature. The handset may be on-hook or off-hook. The user presses the button a second time to deactivate the feature.

The lamp associated with the Do Not Disturb button lights until the feature is deactivated with the button. An automatic-deactivate time is not provided.

## Activation by Attendant

The attendant can activate the feature for a user or a group of users. (The assigned COR determines which users are in the group.) The attendant presses the Do Not Disturb — Extension button followed by the extension, or the Do Not Disturb — Group button. The extension followed by the appropriate COR number.

The attendant can cancel a Do Not Disturb request by activating the feature, entering the desired extension or group COR number, and pressing the delete button.

## Activation via a PMS

The system provides an interface to a Property Management System (PMS). This interface allows activation and deactivation of controlled restrictions. Activation of Do Not Disturb through a PMS is similar to activation of termination restriction. A scheduled deactivate time cannot be specified.

## Audit Trail Reports

The system keeps a record of all voice terminals that are in Do Not Disturb mode. You can display or print this information.

Administer the following reports for printing on a daily basis:

- Do Not Disturb Status Report — This report lists all extensions with Do Not Disturb active and the specified deactivate time for each.
- Do Not Disturb Plus COR Status Report — This report lists all extensions, plus those whose controlled-restriction level is termination restriction. (The attendant activates termination restriction for a specific extension or COR. A deactivate time is not associated with termination restriction.)

Records do not include Do Not Disturb information for extensions that are both termination and outward restricted.

## Considerations

---

- Do Not Disturb lessens the attendant's workload when voice-terminal users with speech-synthesizer boards activate the feature themselves.
- A front-desk user must have a console-permission COS to activate this feature.
- The number of available speech-synthesis ports is the only limit on the number of users receiving voice prompting.

## Interactions

---

- Automatic Callback  
Do Not Disturb does not block an Automatic Callback call. Return calls terminate at a voice terminal in the normal way.
- Automatic Wakeup  
An Automatic Wakeup call deactivates Do Not Disturb and alerts the guest at the specified time.
- Call Coverage  
If a point in a coverage path has Do Not Disturb active, calls covering to that extension alert the extension unless the extension has controlled-restriction termination active. When Do Not Disturb is active and a terminal does not have a coverage path, calls are routed to the attendant.
- Call Forwarding All Calls  
If Do Not Disturb is active at the forwarding extension, the caller receives intercept treatment. If Do Not Disturb is active at the forwarded-to extension, the call alerts the forwarded-to extension.

- Controlled Restriction

When a terminal has total-controlled restriction, it cannot receive or place any calls. However, it can receive a call if another station has an auto-icom button pointing to the controlled-restriction station.

- Internal Automatic Answer (IAA)

Activation of Do Not Disturb at the called voice terminal preempts IAA.

- PC Console

You cannot implement Do Not Disturb at a PC Console.

- PMS Interface

Checkout from either a PMS or the switch automatically deactivates Do Not Disturb for the specified extension.

## Hospitality Services

---

A system with Hospitality enabled and Hospitality Parameter Reduction disabled provides all system capabilities and supports all types of customers. A system with both Hospitality and Hospitality Parameter Reduction enabled provides reduced system parameters that have a major impact on essential system features used by non-lodging customers. The Hospitality features set (Auto Wakeup, Do Not Disturb, PMS) is the same on both packages.

|                   | — check-out                      |                       |
|                   | — dn-dst                         |                       |
|                   | — ext-dn-dst                     |                       |
|                   | — mwn-act                        |                       |
|                   | — mwn-deact                      |                       |
|                   | — crss-alert                     |                       |

---

### Detailed description

---

Parameters reduced when Hospitality Parameter Reduction is enabled are listed in *DEFINITY Enterprise Communication System Release 6 System Description Pocket Reference*.

The following parameters are affected:

- Trunks
- Hunt groups
- Pickup groups
- Call coverage paths

## **Interactions**

---

None

## Names Registration

---

Names Registration automatically sends a guest's name and room extension from the PMS to the switch at checkin, and automatically removes this information at checkout.

### How to administer Names Registration

---

Refer to "[Property Management System Interface](#)" on [page 10-21](#) for information on the PMS interface and associated administration guidelines.

#### Required forms

---

| Form        | Field  | Page                  |
|-------------|--|-----------------------|
| Hospitality | ■ PMS Protocol Mode<br>— transparent or ASCII            | <a href="#">10-30</a> |
|             | ■ Default Coverage Path for Client Rooms<br>— default    |                       |
|             | ■ Milliseconds Before PMS Link Acknowledgment<br>Timeout |                       |

---

### Detailed description

---

The information provided by Names Registration displays on any attendant console or display-equipped voice terminal (as might be used for example, by Room Service, Security, and others). The information allows hotel personnel to provide personalized greetings to calling guests. For example, if John Smith calls room service, personnel with a display-equipped voice terminal, see John's name and room extension and can answer with a personalized greeting.

The name of the calling or called party can display on display-equipped voice terminals. To maintain necessary guest security, hotels do not divulge guests' room numbers to other guests or callers. For this reason, do not assign display-equipped voice terminals to guest rooms.

### Check In

The switch performs the following procedures at check in:

1. Information about the guest is obtained and stored in the hotel's PMS.
2. The PMS sends a checkin message to the switch.
3. The switch stores the guest's name and coverage path.

4. The switch removes the outward restriction on the telephone in the guest room. The switch removes all LWC messages.
5. The switch changes the status of the room from unoccupied to occupied.

At checkin, update the PBX names internal table and the call-coverage path for the guest phone. Name Registration automatically sends a guest's name, extension (room), and preferred call-coverage path to the switch.

## Check Out

1. The switch clears any previous wakeup calls.
2. The switch clears message-waiting lamp indications.
3. The switch activates controlled outward restriction, removes the guest's name, and identifies any unopened messages.

At checkout, Name Registration automatically changes the call-coverage path to the administered Default Coverage Path for Client Rooms.

## Guest Information Input/Change

Use Guest Information Input/Change to change the guest name associated with an extension, input a guest name after checkin, or change a call-coverage path. For example, hotel may checkin airline personnel before their arrival to guarantee their reservation. However, hotel personnel may be unaware of the guests' names and so wait until their arrival to update the names.

## Name Registration Information Format

For both Name Registration and Guest Information Input/Change, a guest name may consist of as many as 15 characters, including spaces and commas. Do not use periods. See ["Interactions" on page 10-19](#) for more information.

The name may be in all upper case letters, all lower case letters, or a mixture of upper case and lower case letters. To use Integrated Directory, enter the name using one of the following methods.

- Last name, comma, first name (for example, Jones, Fred)
- Last name, comma, first name, space, title/middle initial/name (for example, Jones, Fred Mr)
- Last name only (for example, Jones)
- First name, space, middle name, space, last name (for example, Fred A Jones)

## Call Coverage

Both Names Registration and Guest Information Input/Change messages contain call-coverage path numbers. These numbers do not display but are used to configure the appropriate call-coverage arrangements for guest extensions. Arrangements can be for voice mail, text messages, any available coverage point, or no coverage at all.

Administer call-coverage paths on the switch, and use the associated path numbers to establish coverage arrangements at checkin. For suites, administer paths to allow one room in the suite to be the coverage point for the other. To make customized arrangements at time of checkin (such as coverage from one guest room to another), manually administer the path attributes at the switch.

## Considerations

---

- Call-coverage path numbers sent by PMS to the switch for automatic reconfiguration are limited to those administered in the switch and stored in PMS.
- A guest room extension can have a maximum of five digits.
- An input in PMS of the name displayed on display-equipped voice terminals updates the switch.

## Interactions

---

- Call Coverage

Call-coverage arrangements are not limited to automatic update during checkin messages sent from PMS. Hotel personnel require coverage points other than those designated for guests. Call-coverage paths can be manually administered at the switch via the management terminal.
- COS

If an extension has a client room COS, the save translation operation clears the station name and sets the coverage path to the default coverage path for client room when stored on tape. This does not affect the existing information in memory. However, if the translations are read in, it affects existing extensions until a database swap synchronizes the switch and PMS.
- Interface

During a Room Change/Room Swap, the name originally associated with the first terminal is changed or swapped to the second terminal along with call-coverage path, automatic wake-up entries, message-waiting status, and controlled restrictions.

- **Name Character Length**

The switch supports 27-character names, but the PMS interface supports only 15-character names.

## Property Management System Interface

---

Property Management System (PMS) Interface provides a communications link between the switch and a customer-owned PMS. The PMS allows a customer to control certain features in a hospital and hotel/motel environments. Refer to *DEFINITY ECS GuestWorks Server and System 75 Property Management Interface Specifications*.

### How to administer PMS Interface

---

#### Required forms

---

| Form  | Field   | Page                  |

## Detailed description

The following table summarizes how the hospitality features are activated when you use only the switch and when you use the PMS.

### **PMS/Switch links**

| <b>Feature</b>                                      | <b>Switch Only</b>   | <b>With PMS</b>   |
|---|--|---|
| Automatic Wakeup                                    | Activated via console button                                   | N/A   |
| Call Coverage                                       | Activated via administration with TERRANOVA ECS Administration | Activated via PMS terminal — Transparent or ASCII mode          |
| Check-In/Check-out                                  | Activated via console button                                   | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Controlled Restriction                              | Activated via console button                                   | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Do Not Disturb                                      | Activated via console button                                   | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Emergency Access to Attendant                       | Activated by guest action                                      | N/A   |
| Housekeeping Status                                 | Activated via console button                                   | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Message Waiting Notification                        | Activated via console button                                   | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Names Registration                                  | Activated via administration with TERRANOVA ECS Administration | Activated via PMS terminal — Transparent or ASCII mode          |
| Room Change/Swap and Guest Information Input/Change | Activated via administration with TERRANOVA ECS Administration | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Room Occupancy                                      | Activated via console button                                   | Activated via PMS terminal — Normal, Transparent, or ASCII mode |

The PMS Interface provides the following:

- A communications protocol for controlling message exchange between the switch and a PMS
- An application module for controlling the operation of PMS features
- Status data on all guest/patient rooms for selected features

The protocol is full-duplex asynchronous and provides the mechanisms for setting up a data session with PMS, message-exchange control, error identification, and recovery. The interface supports standard data rates.

Two protocol modes are provided: the normal-protocol mode as described above, and transparent-protocol mode. Transparent-protocol mode supports ASCII-character transmission.

The application module of the PMS Interface implements requested features and provides backup if the PMS link is down. Whether or not the link is down, the switch always maintains the following data for each room:

- Whether the room is vacant or occupied
- Whether the voice terminal's message lamp is on or off
- Whether a controlled restriction is active at the voice terminal and, if so, which one
- The guest's name and coverage path

When the PMS link is down, the switch automatically activates Check-In/Check-Out for the attendant console and front-desk terminal with display capability, and continues to support PMS features activated from guest/patient-room voice terminals.

When the PMS link is up again, the switch sends one of the following messages to PMS:

- No room-status changes occurred during loss of communications.
- Room-status changes did occur during loss of communications; therefore, a data exchange is needed to synchronize the switch and the PMS databases.
- The system failed momentarily, destroying its record of room status; therefore, a data exchange is needed to synchronize the switch and the PMS databases.

When the PMS link is down or not used, the switch maintains an audit-trail report of all events that are normally sent to the PMS. The audit-trail report (accessed via the management terminal) is a sequential listing of all PMS transactions executed by the switch when the PMS link is down. Included are error events that occur when the link is up or down.

If you have a PMS printer and the PMS link is down, the following status changes print as changes occur:

- Room number
- FAC dialed
- Any additional information digits that were dialed
- Reason for the entry (error message)
- Time that the error occurred

Additional reports print to the PMS Journal/Schedule printer. These include Automatic Wakeup activity, Emergency Access to the Attendant activity, and scheduled reports.

A supporting function called Room Data Image synchronizes the switch and PMS databases after a PMS link goes down and comes back up. Information exchanged includes:

- Room extension
- Whether the room is occupied or vacant
- Message Waiting lamp status
- Controlled Restriction status
- Guest's name
- Call Coverage path

### Message Waiting Notification

Message Waiting Notification requests originate from attendant consoles, front-desk terminals, or PMS terminals. When a request is entered, PMS sends a message to the switch to change the state of the Message Waiting lamp. If the lamp is activated by AUDIX, INTUITY Lodging, or Leave Word Calling (LWC), the PMS cannot deactivate the lamp. PMS cannot turn LWC or AUDIX messages on or off; these are controlled by the switch.

Assign a console permissions COS to any console or terminal as part of the "System Wide Retrieval Stations" to retrieve requests for another station. Assign a client room COS to the extensions for which Message Notification is to be made.

### Controlled Restriction

When Controlled Restriction is activated through the PMS, the PMS sends a message to the switch to assign one of the following restrictions to the voice terminal in a guest/patient room:

- No restriction
- Outward restriction
- Total restriction

- Station-to-station restriction
- Termination restriction
- Combined outward and termination restriction
- Combined outward and station-to-station restriction
- Combined termination and station-to-station restriction

The attendant can still set Controlled Restriction for a voice terminal whether the PMS link is up or down.

## PMS-Down Log

The pms-down log records only those User Controller Restriction events that are for stations having a Class of Service (COS) where:

- the Client Room is **y**
- the Controlled Restriction Configuration is **act-pms**
- the pms link is not up
- the pms log extension is valid

## Housekeeping Status

Your housekeeping staff enters status information from voice terminals in guest/patient rooms or from designated terminals. You can assign up to 10 Housekeeping Status access codes within two different types:

- Room Voice-Terminal access code type  
Staff members dial up to six access codes that represent room status plus up to six additional digits for items such as maid identification.
- Designated Voice-Terminal access code type  
Staff members dial up to four access codes that represent room status plus the room extension and then up to six additional digits for items such as maid identification.

The switch notifies PMS when Housekeeping Status information is entered. If the PMS is unavailable, the switch writes this information to a log. The log is accessible at the switch terminal, and is sent to the log printer, if administered.

## Check In/Check Out

A Check-In request deactivates the outward-controlled restriction on the terminal in a guest/patient room. A Check-Out request deactivates any controlled restrictions and changes the controlled-restriction level to outward restriction, checks for any messages, clears the wakeup request, and deactivates Do Not Disturb.

## 10 Hospitality

### Property Management System Interface

Page 10-26

If you do not use PMS or if the PMS link is down, the attendant can activate Check-In and Check-Out from an attendant console or a front-desk terminal with display capability and console permission. This requires two buttons, Check-In and Check-Out. Pressing either button places the display in the respective mode and allows use of the touch-tone or DTMF buttons for entering data (rather than for placing calls).

The attendant exits Check-In or Check-Out mode by pressing any other button associated with the display (for example, the Normal Mode button). This restores the display and the touch-tone or DTMF buttons to normal operation.

A Check-In/Check-Out request sends information for Names Registration to the switch. This information includes the guest's name, room extension, and call-coverage path. If the PMS link is down and checkin is done from an attendant console or display-equipped front-desk terminal, the guest's name and coverage-path information is not automatically updated.

If a guest/patient room has both a voice and a data extension, the checkout request applies only to the voice extension. See [“Names Registration” on page 10-17](#) for more information on Check-In and Check-Out.

### Room Change/Room Swap

Room Change/Room Swap is provided only through PMS and activated from a PMS terminal. With Room Change, data pertaining to the old room — including a pending wakeup request, the guest's name (transparent/ASCII mode), and the guest's call-coverage path (transparent/ASCII mode) — moves to the new room. With Room Swap, data pertaining to the two rooms swap. With either feature, if the occupancy status is inconsistent, the system sends an error message to PMS.

### Names Registration

Names Registration automatically sends a guest's name and room extension from PMS to the switch at checkin, and removes this information at checkout. The guest's call-coverage path is sent to the switch during checkin and set to the administered Default Call Coverage Path for Client Rooms at checkout.

### Guest Information Input/Change

Guest Information Input/Change allows the attendant to enter or alter guest information (name or coverage path). Information changed at the PMS is automatically sent to the switch.

## PMS/INTUITY Message Tandeming

PMS/INTUITY Message Tandeming allows the following PMS administrative messages to tandem through the switch to an INTUITY Lodging adjunct. This eliminates the need for the INTUITY-to-PMS voice messaging link. This does not remove the need for the INTUITY-to-PMS call accounting link.

- Check-in
- Check-out
- Room-data-image
- Guest-information
- Message-waiting status
- Room-swap

When the Data Communication Interface Unit (DCIU) (DEFINITY/INTUITY interface) link is down and the PMS/DEFINITY link is up, The switch buffer holds up to 100 PMS messages. The switch updates the INTUITY Lodging adjunct once the DCIU link is up. If the buffer overflows before the link is up, the database resync among PMS/DEFINITY/INTUITY initiates by demand or by a routine database update from PMS.

Note that in GuestWorks, this feature is called "Server/INTUITY/PMS Link Integration".

## Considerations

- You can use LWC or Integrated Message Center Service for the hospital or hotel/motel staff and Message Waiting Notification for guests/patients. However, if you do not use Message Waiting Notification, Integrated Message Center Service is used for both.
- Do not remove an extension while the PMS link is active.
- Normal-protocol mode allows extensions of up to four digits. Transparent/ASCII-protocol mode allows extensions of up to five digits.
- When save translations is done when transparent/ASCII-protocol mode is active, station names with client-room COS save as blank and coverage paths save as the default coverage path for client rooms.
- The PMS link may not work correctly when multiple p-extensions have the same leading digit and adjacent lengths. For example, 3 and 4 p-extensions with the same leading digit may cause problems. The same applies to 4 and 5, and 5 and 6.
- A room extension may begin with 0 only if the PMS sends a prefix digit or a fixed number of digits.

## Interactions

---

- Attendant Console or Front Desk Terminal  
Activate Controlled Restriction, Check-In/Check-Out, and Message Waiting Notification at an attendant console or a front-desk terminal with console permission. The attendant console receives visual notification of the status of the PMS link between the system and the PMS.
- AUDIX Interface  
Message lamps activated by this feature cannot deactivate with feature buttons or with feature messages from the PMS.
- Automatic Wakeup  
Set or cancel an Automatic Wakeup request for a guest room as a result of Room Change/Room Swap or Check-Out.
- Do Not Disturb  
Set or cancel a Do Not Disturb request for a guest room as a result of a different Controlled Restriction, Room Change/Room Swap, or Check-Out.
- Leave Word Calling (LWC)  
Message lamps activated by this feature cannot deactivate with Manual Message Waiting feature buttons.  
If Room Change is active, LWC messages for the old room do not move to the new room. If Room Swap is active, LWC messages for the two rooms do not swap. Therefore, do not encourage use of LWC in guest rooms.
- Restriction — Controlled  
Controlled Restriction for a group of user extensions, when activated from the switch, is not conveyed to the PMS. The PMS is not able to add or remove such restrictions by sending feature messages.

# Hospitality Forms

## Hospitality

---

This form is used to implement the system parameters associated with the hospitality features. To use and administer the Hospitality-related features, Hospitality must be enabled on the System-Parameters Customer-Options form. Contact your Lucent Technologies support representative for assistance.

### Administration Commands

---

Use the following administration commands to administer the Hospitality form.

| Action  | Object                        | Qualifier <sup>1</sup>  |
|---------|-------------------------------|-------------------------|
| change  | system-parameters hospitality | —                       |
| display | system-parameters hospitality | ['print' or 'schedule'] |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word can be entered.

### Form Instructions

---

Make assignments as required for the following fields on each page of the form:

#### Page 1 of the Form

- **Message Waiting Configuration** — This indicates whether message waiting notification requests and changes are being exchanged between the server and the PMS. Allowable entries are **act-nopms**<sup>1</sup> or **act-pms**. The option **act-nopms** indicates that message waiting is operational on the server but message waiting information is not being transmitted between the PMS and server. The option **act-pms** indicates that message waiting is active on the server and information between the PMS and server is being transmitted. The default is **act-nopms**.
- **Controlled Restrictions Configuration** — This indicates whether controlled restriction information is being exchanged between the server and the PMS. If active (**act-pms**), the server and the PMS exchange and accept controlled restriction information. Allowable entries are **act-nopms**<sup>1</sup> and **act-pms**. The default is **act-nopms**.

---

1. If **act-nopms**, the message is acknowledged (MESSAGE ACK), but no action is taken.

- **Housekeeper Information Configuration** — This indicates whether housekeeper information is being exchanged between the server and the PMS. If active (**act-pms**), the server and PMS exchange and accept housekeeper information. Allowable entries are **act-nopms**<sup>1</sup> or **act-pms**. The default is **act-nopms**.
- **Number of Housekeeper ID Digits** — This is the number of digits (0 to 6) that the housekeeper must dial for identification. The default is 0.
- **Extension of PMS Log Printer** — This is a valid data extension number (cannot be a VDN extension) that is assigned to the data module connected to the PMS/Log printer. This extension is dialed by the server to send housekeeping and PMS events to the printer.
- **Extension of Journal/Schedule Printer** — This is a valid data extension number (cannot be a VDN extension) that is assigned to the data module connected to the Journal/Schedule printer. This extension can be the same as the PMS/Log printer and both sets of reports may be printed on the same printer. This extension is dialed by the server to send journal information or schedule reports to the printer.
- **Client Room Coverage Path Configuration** — This indicates whether the server and the PMS exchange coverage path information for guest stations. If active (**act-pms**), the server and PMS exchange and accept coverage path information. Allowable entries are **act-nopms**<sup>2</sup> or **act-pms**. This field does not apply to normal mode. When upgrading from a release that does not support this feature, the field is set to **act-pms** if the PMS protocol mode is administered for transparent or ASCII mode. The default is **act-nopms**.
- **Default Coverage Path for Client Rooms** — This indicates the coverage path assigned when the server receives a check-out message for a valid extension or a new check-in. This applies only to stations with a “client room” class of service in the “occupied” mode. This field does not apply to normal mode; it is used only for transparent or ASCII mode. The value in this field is also used during a translation save as the coverage path for each station with “client room” class of service.
- **Forward PMS Message to INTUITY Lodging** — This indicates whether the PMS-to-INTUITY messages will be sent through the server (y) or directly to the Lucent INTUITY Lodging system (n). This field does not apply to normal mode; it is used only in ASCII mode.
- **Extension of PMS** — This indicates the data extension number (cannot be a VDN extension) the server must dial to access PMS. When this extension is entered and PMS is ready, the server brings up the link.
- **PMS Protocol Mode** — This indicates the message protocol mode used between the server and PMS. Allowable entries are **normal** and **transparent**. The default is **normal**.

---

2. If **act-nopms**, the message is acknowledged (MESSAGE ACK), but no action is taken.

- **ASCII mode** — This indicates whether the ASCII-only mode is being used for the PMS message set. The PMS Protocol Mode field must be set to **transparent**. This field does not apply to normal mode. The default is **n**.
- **Seconds Before PMS Link Idle Timeout** — This indicates the idle time in seconds (**5 to 20**) that the server waits for an acknowledgment from the PMS before the server enters link failure mode from the PMS transmission link. The default is **10**.
- **Milliseconds Before PMS Link Acknowledgment Timeout** — Enter the time in milliseconds (100 to 1500) the system waits for an acknowledgment from the PMS indicating it correctly received a message. Default is **150**. The possible values are:
  - 100 - 300 ms (normal mode)
  - 100 - 1500 ms (transparent or ASCII mode)
- **PMS Link Maximum Retransmissions** — This indicates the number of times (**1 to 5**) that the server will retransmit a message to the PMS in response to a negative acknowledgment or send an inquiry for acknowledgment from the PMS before giving up on the message. The default is **3**.
- **PMS Link Maximum Retransmission Requests** — This indicates the number of times (**1 to 5**) that the server will allow the PMS to request acknowledgment for a message that it sent. The default is **3**.
- **Take Down Link for Lost Messages** — This indicates whether the link will be taken down if messages are being lost. Enter **y** to cause the PMS link to come down; enter **n** to keep the link operating. Careful monitoring of the PMS error log is recommended when using this option. The default is **y**.

## Page 2 of the Form

- **Dual Wakeup** — Enter **y** if each extension can request two wakeup calls within one 24-hour time period.
- **Room Activated Wakeup with Tones** — Enter **y** if wakeup calls can be activated via tones that prompt users for the time they wish to waken. (This allows room activated wakeup calls without the use of a speech synthesizer or a display telephone.)
- **Time of Scheduled Wakeup Activity Report** — This indicates the time of day that the Wakeup Activity Report will be printed on the Journal/Schedule Printer. This report summarizes the wakeup activity for each extension that had wakeup activity for the past 24 hours. Enter the time **hh:mm:am/pm** where hh=hour, mm=minute, am/pm=A.M. or P.M.
- **Time of Scheduled Wakeup Summary Report** — This indicates the time of day that the Wakeup Summary Report will be printed on the Journal/Schedule printer. This report gives an hour-by-hour summary of the number of scheduled wakeup calls and a list of extensions to which

wakeup calls were attempted but did not complete during the hour. Enter the time **hh:mm:am/pm** where hh=hour, mm=minute, am/pm=A.M. or P.M.

- **Time of Scheduled Emergency Access Summary Report** — This indicates the time of day that the Emergency Access Summary Report will be printed on the Journal/Schedule printer. The time is represented by **hh:mm:am/pm** where hh=hour, mm=minute, and am/pm=A.M. or P.M.
- **Announcement Type** — This indicates the type of automatic wakeup announcement the hotel guest will receive. Allowable entries are as follows:
  - external (applicable when using an announcement adjunct)

If **external** is used, complete the **Auxiliary Board for Announcement** field.
  - integrated (applicable when using the TN750B or TN750C announcement circuit pack)

If **integrated** is used, complete the **Integrated Announcement Extension** field. The extension you enter must be a valid integrated announcement extension (administered on the Recorded Announcements form) or a VDN. If you enter an invalid extension, the server displays an error message.
  - mult-integ (multi-integrated; applicable when using the TN750B or TN750C announcement circuit pack)

If **mult-integ** is used, complete the **Default Announcement Extension** field. The extension you enter must be a valid integrated announcement extension (administered on the Recorded Announcements form) or a VDN. If you enter an invalid extension, the server displays an error message.
  - voice-synthesis

If **voice-synthesis** is used, complete the **Announcement Ports** field.
  - music-on-hold

If **music-on-hold** is used, no other field appears.
  - silence (default)

If **silence** is used, no other field appears.

 **NOTE:**

One of the following four fields appears depending on what data is entered in the Announcement Type field.

- **Auxiliary Board for Announcement** — This field displays only when the **external** announcement type is used. This indicates the equipment location of an auxiliary trunk circuit that connects to the external announcement equipment. Enter a 4- or 5-character circuit pack number.

- **Integrated Announcement Extension** — This field displays only when the **integrated** announcement type is used. This indicates the wakeup announcement extension when using the integrated announcement circuit pack. Enter the extension (5-digits or less) of the announcement you want to use for wakeup calls.
- **Default Announcement Extension** — This field displays only when the **mult-integ** announcement type is used. This indicates the default wakeup announcement extension when using the integrated announcement circuit pack. Enter the extension (5-digits or less) of the announcement you want to use for default wakeup calls.
- **Announcement Ports** — This field displays only when the **voice-synthesis** announcement type is used. For the **voice-synthesis** announcement type, this indicates the equipment location of two ports on the voice synthesizer circuit pack (TN725B). Any two of the four ports can be assigned.
- **Length of Time to Remain Connected to Announcement** — Enter the length of time in seconds (**0** to **300**) that a hotel guest will be connected to an announcement. This applies only after the guest has heard the announcement completely one time, but continues to listen for a second time. The default is **30**.
- **Extension to Receive Failed Wakeup LWC Messages** — This indicates where unsuccessful wakeup LWC messages will be stored. This is usually administered to an unassigned extension (cannot be a VDN extension) or to the attendant (attd). In addition, a LWC lamp for that extension is usually assigned to the attendant console as an indication of failed wakeup calls. The default is blank.
- **Routing Extension on Unavailable Voice Synthesis** — This indicates where a wakeup call will go to if both wakeup announcements on the Speech Synthesizer circuit pack are not available. This is usually administered to an unassigned extension (cannot be a VDN extension) or to the attendant (attd). The default is blank.
- **Display Room Information in Call Display** — This indicates the type of guest room information displayed on voice terminal displays. If this field is set to **n**, the voice terminals will display the name and extension number. If this field is set to **y**, the voice terminals will display the name and room number. The extension number and room number are not always the same number. The default is **n**.
- **Number of Digits from PMS** — This indicates the number of digits being sent from the PMS to the server to identify room numbers. If using mixed numbering in the server, leave this field blank. When using normal mode, digits **1** through **4** are valid. When using transparent or ASCII mode, digits **1** through **5** are valid. The default is blank.

**NOTE:**

If the **Number of Digits from PMS** field is blank and the **PMS Sends Prefix** field is set to **n**, the server will not support an extension that starts with 0.

- **PMS Sends Prefix** — This indicates if the PMS sends a prefix digit to the server as part of the room numbering plan. This field can be set to **y** or **n**. The default is **n**.

**NOTE:**

If the **PMS Sends Prefix** field is set to **n** and the **Number of Digits from PMS** field is blank, the server will not support an extension that starts with 0.

- **Number of Digits in PMS Coverage Path** — This indicates whether the coverage paths are **3** or **4** digits long. In Release 5, there can be up to 7500 coverage paths.
- **Digit to Insert/Delete** — Enter the leading digit that may be deleted and inserted back as described in the following text. The current PMS message set uses the extension number as the room identifier. In many customer configurations, the leading digit of the extension number is dropped to form the room number. In order to accommodate PMS devices that are based on room number and not extension, this leading digit may be deleted on messages from the PBX to the PMS, and then inserted back on messages from the PMS.

**NOTE:**

The PMS interface supports 3-, 4-, or 5-digit extensions, but prefixed extensions do not send the entire number across the interface. Only the assigned extension number is sent. Therefore, you should not use prefixed extensions for numbers that are also going to use the Digit to Insert/Delete function.

## Page 3 of the Form

- **Definition for Rooms in State 1 - 6** — The default is the Rooms in State number. You can enter up to 30 characters.

## Implementation Notes

---

One of four fields can appear after the **Announcement Type** field, depending on the data that is entered in the field. See the **Announcement Type** field description under “Page 2 of the Form.”

**CAUTION:**

*Do not set the time for the following reports to coincide when the server does its scheduled maintenance tests (usually at 1 a.m.). See the change*

*system-parameters maintenance screen to verify the time and coordinate this administration so the times do not overlap.*

The definitions for room states (page 3 of the form), are for Attendant Room Status only. If you are not using Attendant Room Status, you do not need to complete these fields.

## Multimedia

# 11

---

This chapter contains multimedia features available on DEFINITY ECS. The multimedia administration forms are located at the end of each section.

## Multimedia Applications Server Interface

---

The Multimedia Applications Server Interface (MASI) defines a protocol and a set of operations that are used to extend DEFINITY feature functionality to a Multimedia Communications Exchange (MMCX) system. MASI architecture fits the client/server model, where the DEFINITY functions as a server for MMCX clients. Examples of DEFINITY features supported by MASI include Call Detail Recording (CDR), AUDIX/INTUITY voice mail integration, and AAR/ARS.

MMCX can make use of both MASI features, and MMCX autonomous features. Autonomous features are those that MMCX provides, even if MASI is not enabled. This document does not discuss them unless there is a consideration for MASI administration.

Some autonomous MMCX features:

- Basic Call (Place/Drop)
- Call Coverage
- Conference
- Transfer

DEFINITY/MASI features:

- Basic Call (Place/Drop) — DEFINITY tracks the status of all calls placed to or from a MASI terminal.
- Call Detail Recording — DEFINITY tracks calls to and from MASI terminals and can produce call records that indicate if a call uses MASI.
- Call Coverage — DEFINITY tracks MMCX calls that are sent to coverage. A DEFINITY coverage path can contain both MASI terminals and DEFINITY stations.
- Conference — DEFINITY tracks conference calls that involve MASI terminals, if a DEFINITY station originates the conference. Conferences that involve MASI terminals and DEFINITY stations are voice-only. If the DEFINITY station originates the call, the caller can use the consultative form of conference or transfer.
- World Class Routing (AAR or ARS) — Calls from MASI terminals can take advantage of DEFINITY ECS World Class Routing capabilities.
- Voice messaging access to AUDIX/INTUITY — MMCX users can take advantage of AUDIX voice messaging, and receive message waiting indication.
- MMCX trunking — By assigning DEFINITY trunk access codes to interfaces from the MMCX to other MMCXs or the PSTN, DEFINITY ECS can monitor traffic over those interfaces.

## Before you start

---

### CAUTION:

*DEFINITY ECS offers a wide range of features, and MMCX users may want to take advantage of this. In some cases, these features will operate as expected. However, some features are not supported for use over the MASI link, and their behavior is unpredictable. You may cause harm to your system by attempting to use these features. The Interactions section contains a list of features, and lists those features that are absolutely not supported for use with MASI. If you administer features on the DO NOT ADMINISTER list, Lucent Technologies cannot be responsible for the result.*

For purposes of administration, there are feature buttons and groups of users that you must not administer with MASI terminal extensions. There are also features that you simply cannot administer for a MASI terminal, because the software does not allow it.

## About this document

---

The following document describes the Multimedia Applications Server Interface, and provides instructions on how to set it up, including administration and monitoring. It also includes a section on troubleshooting.

You need to use both the DEFINITY system administration terminal (SAT) and the MMCX administration terminal to administer MASI. This document describes what you need to do at the DEFINITY SAT. It also occasionally mentions administration that you must do at the MMCX administration terminal. For more detailed MMCX information, see the *MMCX Technical Reference*.

## List of terms

---

This is a list of terms that are specific to MASI, or that have meanings in the context of MASI that are not standard.

- **chgmasi** — The command you use to administer MASI at the MMCX administration terminal.
- **Interserver** — Connections between MMCX terminals on different MMCX servers/nodes.
- **MASI domain** — A MASI domain consists of a DEFINITY and one or more MASI nodes that share the same dial plan. That is, the extension numbers on the MMCX are known to the DEFINITY, and fit in the DEFINITY dial plan.
- **MASI interworking** — MASI interworking refers to the completion of a voice connection within DEFINITY, involving at least one MASI terminal and a MASI path.
- **MASI link** — The connection between the MMCX and the DEFINITY ECS.

- **MASI node** — A single MMCX server. You may connect more than one MASI node to a DEFINITY. Each node has a separate number. This node number needs to be consistent whenever referring to a specific MMCX server.
- **MASI non-interworking** — MASI non-interworking refers to the completion of a call by MMCX, not involving a MASI path.
- **MASI path** — The ISDN B-channels between MMCX and DEFINITY in a MASI environment. Paths are used for voice and data connections between DEFINITY and MMCX.
- **MASI signaling link** — ISDN D-channel used to transport a new ISO protocol called the MASI protocol between the DEFINITY ECS and the MMCX.
- **MASI terminal** — The DEFINITY representation of MMCX terminals in a MASI environment.
- **MMCX interface** — PRI interface for connecting an MMCX server to other public, private or WAN switching systems or equipment that is part of the public network. Similar to a DEFINITY trunk group. These may include non-MASI trunks connecting the DEFINITY ECS and the MMCX.
- **MMCX trunk** — The DEFINITY representation of trunk or network facilities terminating on MMCX. For purposes of MASI, they are called “interfaces.”

## Planning for MASI

---

Before you start to administer MASI, you should make a plan for how to do it. Among the configurations on the following pages, there is probably one that matches the configuration of your system fairly closely. You might want to either write on these pages, or draw up your own configuration. It may help you if you have already determined trunk group and signaling group numbers, unused extensions, and so on. The following are things you need to consider:

- Establish the dial plan on the MMCX to agree with that of the DEFINITY ECS. If you use Universal Dial Plan and MMCX, you may need to make adjustments for the MMCX dial plan.
- Find unused extensions and trunk group numbers. You need:
  - one trunk group number for each ISDN-PRI connection to the MMCX
  - one signaling group number for each MASI node and an unused DEFINITY extension for the signaling group
  - one unused DEFINITY extension for the Near-End Path Termination number for all MASI Paths to this ECS. You can use the same number for all MASI nodes in the domain.
  - two unused MMCX extensions for the nearpath and tscnum arguments to the **chgmasi** command. This is the command you use to administer MASI on the MMCX.

## MASI configurations

There are several ways to set up combinations of MASI nodes and DEFINITY servers. The following figures depict several possible configurations.

**Figure 11-1. MASI domain of one DEFINITY ECS and one MMCX**

The parts of this drawing, for MASI, are as follows:

- Trunk 1 — This is any type of trunk connection to the public network.
- Trunk 2 — This is the link between the DEFINITY ECS and the MMCX, and requires a TN464C or later DS1 circuit pack. You administer this link as an ISDN-PRI trunk group, a MASI path and an NCA-TSC.
- I1 and I2 — These are MMCX interfaces to destinations other than DEFINITY. Administer as MASI trunks.
- E1 and E2 — Endpoints (terminals) belonging to the MMCX. Administer as MASI terminals.
- MMCX — Determine a node number for each MMCX server. This can be any number from 1–15. Once established, DEFINITY informs the MMCX of its node number.

- S1 — DEFINITY station.

Figure 11-2. MASI domain of one DEFINITY and two (or more) MMCXs

Figure 11-3. Two separate MASI domains

Figure 11-4. One MASI domain, and one non-MASI MMCX

The MASI node must be directly connected to the DEFINITY ECS for MASI features to work. In this configuration, terminals that belong to MMCX 2 (E3 and E4), do not take advantage of MASI capabilities.

## How to administer MASI

This section discusses the administration required to make MASI work. You perform most of this administration from the DEFINITY SAT. However, there are a few things you must do at the MMCX administration terminal. This section sometimes refers to the **chgmasi** command. This is the command you use to administer MASI parameters on the MMCX. For more information about using the chgmasi command, refer to your *MMCX Technical Reference*.

### Step 1 — Establish customer options (Lucent Technologies)

A Lucent Technologies representative must activate MASI using the System-Parameters Customer-Options form. The representative should also verify that ISDN-PRI (R6r and later configurations) or ISDN-PRI over PACCON (R6vs/si/csi and later configurations), and AAR/ARS are enabled. The value of the G3 Version field must be V5 or higher. The actual software load must be R6.1 or higher.

On the MMCX, MASI must be enabled using the **chgmasi** command.

### Step 2 — Establish maintenance parameters and alarming options (Lucent Technologies)

Ensure that the Maintenance-Related System Parameters form, Packet Bus Activated field = y.

Using the **set options** command (Lucent Technologies init or inads logins only), set MASI alarming options. For more information, see *DEFINITY ECS Maintenance* for the appropriate model.

### Step 3 — Establish the physical connection

Establish the physical connection between the DEFINITY ECS and the MMCX. For more information about installing the cables, see *Installation for Adjuncts and Peripherals*.

### Step 4 — Administer circuit pack

Using the DS1 Circuit Pack form, verify that the DS1 circuit pack you use to establish the MASI link is administered as follows:

- Bit Rate = 1.544
- Line Coding = b8zs
- Line Compensation = 1
- Signaling Mode = isdn-pri
- Interface = network

- Country Protocol = 1
- Protocol Version = a

### Step 5 — Administer a signaling group

For each MASI node, you need to establish a unique signaling group. Use the command **add signaling-group xxx** to access the Signaling Group form.

Page 1 of 5

SIGNALING GROUP

Group Number: \_      Associated Signaling? y      Max number of NCA TSC: \_\_

Primary D-Channel: \_\_\_\_\_      Max number of CA TSC: \_\_

Trunk Group for Channel Selection: \_\_      Trunk Group for NCA TSC: \_\_

#### Screen 11-1. Signaling Group Form (Page 1 of 5)

For each link, establish a Non-Call Associated Temporary Signaling Connection (NCA-TSC) with the following attributes:

- **Associated Signaling** — MASI requires Facility Associated Signaling, so this field must be set to y.
- **Primary D-channel** — Enter a 6- to 7-character port number associated with the DS1 Interface circuit pack port. The port address of the PRI that carries D-channel signaling.

The entry breaks down as follows:

| Characters | Meaning        | Value                                  |
|------------|----------------|--|
| 1-2        | Cabinet Number | 1 – 44 (R5r and later configurations)  |
|            |                | 1 – 3 (R5si and later configurationsi) |
|            |                | 1 (R5vs and later configurations)      |
| 3          | Carrier        | A – E                                  |
| 4-5        | Slot Number    | 01 – 20                                |
| 6-7        | Port           | 16 or 24                               |

The port number is used to assign the primary D-channel in the Signaling Group. For 24-channel facilities, the 24th port is assigned as the D-channel. For 32-channel facilities, the 16th port is assigned as the D-channel.

11 Multimedia

Multimedia Applications Server Interface

- **Max Number of NCA TSC** — For MASI, this must be 1.
- **Max number of CA TSC** — Leave the default of 0.
- **Trunk Group For NCA TSC** — This can be left blank.
- **Trunk Group for Channel Selection** — This can be left blank.

| ADMINISTERED NCA TSC ASSIGNMENT |            |         |  |              |       |          | Page 2 of 5 |

| 9:                              | _____      | -       | _____                                      | _____        | _____ | _____    |             |
| 10:                             | _____      | -       | _____                                      | _____        | _____ | _____    |             |
| 11:                             | _____      | -       | _____                                      | _____        | _____ | _____    |             |
| 12:                             | _____      | -       | _____                                      | _____        | _____ | _____    |             |
| 13:                             | _____      | -       | _____                                      | _____        | _____ | _____    |             |
| 14:                             | _____      | -       | _____                                      | _____        | _____ | _____    |             |
| 15:                             | _____      | -       | _____                                      | _____        | _____ | _____    |             |
| 16:                             | _____      | -       | _____                                      | _____        | _____ | _____    |             |

Screen 11-2. Administered NCA TSC Assignment page of the Signaling Group form

- **Service/Feature** — Leave blank.
- **As-needed Inactivity Time-out (min)** — This field only applies to as-needed NCA-TSCs. Since MASI requires a permanent connection, leave blank.
- **TSC Index** — This display-only field specifies the administered NCA-TSCs assigned.
- **Local Ext** — Enter a valid, unassigned DEFINITY ECS extension. This extension does not need a port assignment and does not need to correspond to any other administration.
- **Enabled** — Enter y to enable the administered NCA-TSC. You may want to wait to enable this link until all other administration is in place. If this is y, DEFINITY ECS attempts to establish the connection as soon as you submit the form. This may cause your system to alarm, if other administration is not finished.
- **Establish** — Used to indicate the strategy for establishing this administered NCA-TSC. Enter **permanent** for MASI.

- **Dest. Digits** — A valid MMCX extension. This must correspond to the value of the *tscnum* argument to the **chgmasi** command.

**NOTE:**

These digits are sent as entered to the destination MMCX; no routing or other digit manipulation is performed.

- **Appl.** — Specifies the application this administered NCA-TSC is going to be used for. Enter **masi**.
- **Machine ID** — Used to indicate the MASI node to which this administered NCA-TSC is connected. This number should be the same as the MASI node number found on other forms.

### How to list TSCs or determine status of the TSC

To determine which TSCs are designated for MASI, use the **list masi tsc** command.

| MASI TEMPORARY SIGNALING CONNECTIONS (TSC) |                |           |            |         |             |                      |          |
|--|----------------|-----------|------------|---------|-------------|----------------------|----------|
| Sig. Grp                                   | Primary D-Chan | TSC Index | Local Ext. | Enabled | Established | Dest. Digits         | Mach. ID |
| xxx  | xxxxxxxx       | xxx       | xxxxx      | x       | xxxxxxxx    | xxxxxxxxxxxxxxxxxxxx | xx       |
| xxx  | xxxxxxxx       | xxx       | xxxxx      | x       | xxxxxxxx    | xxxxxxxxxxxxxxxxxxxx | xx       |
| xxx  | xxxxxxxx       | xxx       | xxxxx      | x       | xxxxxxxx    | xxxxxxxxxxxxxxxxxxxx | xx       |

Screen 11-3. MASI Temporary Signaling Connections (TSC) Display

This command displays the following:

- **Sig Grp** — The number of the signaling group to which this TSC belongs
- **Primary D-Channel** — Port location of the Primary D-channel
- **TSC Index** — The number of the MASI TSC within the signaling group
- **Local Ext.** — DEFINITY extension associated with the TSC
- **Enabled** — Indicates the state of the connection - enabled (y/n)
- **Established** — Value of established flag (as-needed/permanent)
- **Dest. Digits** — The MMCX extension that indicates the TSC destination
- **Mach. ID** — MASI node number

Once you establish and enable the signaling group, you need to verify that it is active. Use the command **status signaling-group signaling-group#** or **status**

**tsc-administered signaling-group# [/tsc-index] [print]** to determine if the link is active.

### Step 6 — Administer ISDN-PRI trunk group

Use the command **add trunk-group xxx** to access the Trunk Groups form. For a more detailed description of the ISDN-PRI trunk group, see [“ISDN-PRI trunk group” on page 7-219](#).

Establish an ISDN-PRI trunk group with the following attributes:

#### Page 1

- Group Type = isdn-pri
- TAC = valid TAC that conforms to your existing dial plan
- Direction = two-way
- Service Type = tie
- CDR Reports = n

You must also administer the PRI link from the MMCX to the ECS, using the MMCX administration terminal. See the *MMCX Technical Reference* for information on the **addpri** command.

### Step 7 — Administer MASI Path Parameters

Use the **change masi path-parameters** command to access the MASI Path Parameters form.

MASI PATH PARAMETERS

Near-End Path Extension: \_\_\_\_\_

| MASI Node | Trunk Group | Far-End Path Termination Number |
|-----------|-------------|---------------------------------|
| 1         | —           | _____                           |
| 2         | —           | _____                           |
| 3         | —           | _____                           |
| 4         | —           | _____                           |
| 5         | —           | _____                           |
| 6         | —           | _____                           |
| 7         | —           | _____                           |
| 8         | —           | _____                           |
| 9         | —           | _____                           |
| 10        | —           | _____                           |
| 11        | —           | _____                           |
| 12        | —           | _____                           |
| 13        | —           | _____                           |
| 14        | —           | _____                           |
| 15        | —           | _____                           |

Screen 11-4. MASI Path Parameters form

Establish a MASI Path with the following attributes:

- **Near-End Path Extension** — An unassigned DEFINITY extension. When using the **chgmasi** command to administer the MMCX, this is the farpath extension. See the *MMCX Technical Reference* for more information.
- **MASI Node** — The node number for the MMCX. For each MMCX/MASI node, this number must be the same everywhere it occurs (signaling group, masi trunk group, and masi terminal forms).
- **Trunk Group** — This is the DEFINITY trunk group number for the ISDN-PRI trunk that will be used to establish call paths.
- **Far-End Path Termination Number** — This is an unassigned MMCX extension. When using the **chgmasi** command to administer the MMCX, this is the nearpath extension. See the *MMCX Technical Reference* for more information.

## Step 8 — Administer MASI trunk groups

You use the MASI trunk group form to define MMCX interfaces that interconnect MASI nodes, or that connect MMCX nodes to another private switch or central office. Examples of MMCX interfaces include:

- PRI trunks linking MMCX servers
- PRI trunks linking MMCX to the PSTN
- PRI trunks from MMCX to DEFINITY that are used for purposes other than MASI
- LAN interfaces linking MMCX servers

Use the command **add masi trunk-group xxx (or 'next')** to access the MASI Trunk Group form. The trunk group number must not be assigned, and you cannot exceed the maximum total trunks for your system. Valid values for xxx are unused DEFINITY trunk group numbers between 1–96 for R6vs/si/csi and later configurations, and 1–120 for R6r and later configurations.

```

MASI TRUNK GROUP
Group Number: 15
Group Name: INCOMING CALL_____ COR: 1_ TN: 1 CDR Reports? y TAC: 915_
MASI Node Number: _ Remote Group Number: _
```

### Screen 11-5. MASI Trunk Group Form

- **Group Number** — This field displays the MASI trunk group number. This is the number assigned when executing the **add masi trunk-group** command.
- **CDR Reports** — Valid entries are “y,” “n,” and “r.” Default is “y.”
  - If you enter “y,” CDR records will be generated by completed outgoing calls terminated on this trunk group. If incoming calls are being recorded (the Record Outgoing Calls Only field on the CDR System Parameters form is set to “n”), then a single CDR record will be generated for answered calls with the call duration.
  - If you enter “n,” no CDR records will be generated by calls originated by or terminated on this trunk group.
- **Group Name** — Enter a unique name that identifies the trunk group. Up to 27 characters can be used; default is “INCOMING CALL.”
- **COR** — Enter a class of restriction (COR) number (0–95) that reflects the desired restriction; default is “1.”
- **TN** — This field displays the Tenant Partition number. For R6 and later configurations, all MASI trunks are associated with Tenant 1.
- **TAC** — Enter the trunk access code (TAC) that identifies the trunk group on CDR reports. You must assign a different TAC to each MMCX interface. Valid entries conform to the dial plan (1–4 digits, \* and # are valid first digits).
- **MASI Node Number** — The node number assigned to this MMCX machine.
- **Remote Group Number** — This is the number of the remote trunk group. For ISDN-PRI interfaces, valid values are any number 1–8; for LAN or WAN calling interfaces, the value must be 9. The combination of MASI Node Number and Remote Group Number must be unique. Remote group number corresponds to the group number on the MASI node.

### How to view a list of all MASI trunk groups

To view a list of all the MASI trunks administered on the ECS, use the command **list masi trunk-group**.

```

                                     MASI TRUNK GROUP
Group Number  TAC  Group Name                               Node  Remote
Number       TAC  Group Name                               Number Grp No.  CDR  COR  TN
xxx         xxxx  xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx  xx    x        x   xx  xxx

```

Screen 11-6. List masi trunk-group output

### How to determine the status of MASI trunk groups

To determine the status of a specific MASI trunk, use the command **status masi trunk-group xxx**, where xxx is the trunk group number. This command provides descriptive information about the trunk, and the number of currently active trunk calls.

```

                                     MASI TRUNK GROUP STATUS
Group Number: xxx           Number of Active MMCX Trunk Calls: xxx
MASI Node Number: xx
Remote Group Number: xxx

```

Screen 11-7. Status masi trunk-group output

### Step 9 — Administer MASI terminals

Use the **add masi terminal xxxxx** or **next** command to administer each MASI terminal as a MASI terminal. You use available extensions on the ECS, so they need to conform to DEFINITY ECS dial plan. The extension must match the

DEFINITY dial plan, and for the add command, the extension must not already be in use. The extension of the MASI terminal must match the number of the MASI terminal.

DEFINITY users dial the MASI Terminal Extension to reach MMCX users.

 **NOTE:**

Anytime you add a terminal or other extension to the MMCX, you must administer a corresponding MASI terminal on DEFINITY. If you do not, you will not be able to dial this extension from DEFINITY.

```

                                MASI TERMINAL

Extension: 1000                                BCC: 0
                                                MASI Node Number:  TN: 1_
                                                COR: 1_

Name: _____

TERMINAL OPTIONS

Send Display Info? y
    
```

Screen 11-8. MASI Terminal Form — page 1

- **Extension** — This field displays the extension that you entered on the command line.
- **BCC** — This field displays the bearer capability class of the terminal, and identifies the type of traffic the terminal supports. For MASI, this is always 0, for voice or voice-grade data.
- **MASI Node Number** — The number of the node on which this terminal resides.
- **TN** — The tenant partition in which this terminal resides. At present, all MASI terminals must reside within tenant 1. This field is display-only, and always 1.
- **COR** — The class of restriction associated with this terminal.
- **Name** — The name associated with the terminal. This can be any alphanumeric string up to 27 characters.
- **Send Display Info** — Indicates whether DEFINITY should forward display information associated with a call. Set to y.

```

                                     MASI TERMINAL

FEATURE OPTIONS
  LWC Reception: none___

  CDR Privacy? n

                                     AUDIX Name: _____
```

Screen 11-9. MASI Terminal form — page 2

- **LWC Reception** — This field indicates whether the terminal can receive Leave Word Calling messages. Valid values are none, audix, and spe (for R6r and later configurations) or mas-spe (for R6vs/si/csi and later configurations). SPE-based LWC is not supported for MASI terminals. However, if DEFINITY AUDIX is used without a Data Control Link, you must administer MASI terminals to receive SPE-based LWC messages. For such cases, the LWC feature is used by AUDIX to activate and deactivate message waiting lamps on MASI terminals.
- **CDR Privacy** — Indicates whether CDR Privacy is supported for this terminal. See [“Call Detail Recording” on page 4-167](#) for more information.
- **AUDIX Name** — This field only appears on R6r and later configurations. This field contains the name of the AUDIX adjunct for LWC messages. If LWC reception field is set to audix, this field must contain a name. The name must match a machine name on the Adjunct Names form.

```

                                     MASI TERMINAL

SITE DATA
  Room: _____

  Cable: _____
  Floor: _____
  Building: _____

BUTTON ASSIGNMENTS
  1: call-appr
```

Screen 11-10. MASI Terminal Form — page 3

- **Room** — Enter up to 10 characters to identify the MASI terminal location. This field may be blank.
- **Jack** — Enter up to 5 characters to identify the location where the MASI terminal is connected. This field may be left blank.
- **Cable** — Enter up to 5 characters to identify the cable that connects the MASI terminal to the system. This field may be left blank.
- **Floor** — Enter up to 7 characters to identify the floor where the MASI terminal is located.
- **Building** — Enter up to 7 characters to identify the building where the MASI terminal is located. Valid entries are listed in the site table.
- **Button Assignments** — This field contains a call appearance button and is display only.

### Duplicate masi terminal

Once you have one MASI terminal administered to your liking, you can use the **duplicate masi terminal** command to administer other stations with the same characteristics.

| MASI TERMINAL |       |       |       |       |
|---------------|-------|-------|-------|-------|
| Ext           | Name  | Room  | Jack  | Cable |

Screen 11-14. List extension type

Step 10 — Administer features

**AAR/ARS**

1. AAR/ARS is an optional feature on DEFINITY, and you need to purchase this option to use it with MMCX. To verify that this feature is enabled, use the command **display system-parameters customer-options**. If it is not enabled, call your Lucent Technologies representative.
2. The MMCX dial plan must use the same feature access codes as the DEFINITY ECS. If this is not already the case, modify the MMCX dial plan using the **chgdp** command. See the *MMCX Technical Reference* for more information.
3. Include this feature access code in the **chgmasi** command.

**CDR**

1. To get call detail records for calls over MMCX interfaces, set CDR Reports = y on the MASI Trunk Group form.
2. To get call records for calls over the ISDN-PRI trunk group, set CDR Reports = y on the ISDN-PRI Trunk Group form.
3. To track calls between a MASI terminal and other MASI terminals or DEFINITY stations, enter the MASI terminal extension on the Intraswitch CDR form.
4. Enter n in the Record Non-Call Assoc TSC field on the CDR System Parameters form.

**⇒ NOTE:**

If you use the same PRI trunks for MASI and non-MASI calls, it is strongly recommended that you do not enable CDR for these calls. Establish a separate trunk group for non-MASI calls and set CDR Reports = n.

## Coverage

To establish coverage from a MASI terminal to AUDIX:

1. Use the MMCX user interface to enter the AUDIX hunt group extension as the coverage point. You cannot use DEFINITY coverage administration for MASI terminals.
2. If AUDIX ports are not administered on DEFINITY, do so.
3. Set up the MASI terminal as an AUDIX subscriber. Enter the MASI terminal extension in the extension field on the Subscriber Administration form.

To establish coverage from a MASI terminal to another MMCX terminal or DEFINITY station:

1. Use the MMCX user interface to enter the desired extension as the coverage point for the MASI terminal. You cannot use DEFINITY coverage administration for MASI terminals.

## Step 11 — Verify administration

Make test calls from DEFINITY to MMCX, ensure that you can indeed place and receive calls.

Call an unattended MASI terminal. Verify that the call goes to AUDX. Retrieve the call from the MASI terminal. Verify that all works as expected.

## MASI command permissions

If you are the super-user for your system, you can restrict other administrative logins from changing MASI administration. To do this, use the **change permissions (login-ID)** command. Enter y in the Additional Restrictions field, then move to the Restricted Object List page of the form.

You may restrict the following MASI-related objects:

- masi-path-parameters
- masi-terminal
- masi-trunk-group
- masi-tsc

## Detailed description of features

### AAR/ARS

MMCX can take advantage of advanced routing features for voice-only calls to the PSTN or a DEFINITY system private network. Users must enter the AAR/ARS access code before the rest of the dialed digits. MASI will route the call over the DEFINITY private network (AAR) or the public network (ARS), based on the digits supplied by the MMCX user.

Routing patterns must contain only trunk groups that actually terminate on the DEFINITY ECS. Calls from one MMCX to another do not use AAR/ARS. Authorization codes are not supported.

### Call Detail Recording

Using the MASI link, DEFINITY is able to track call detail information for calls made using MMCX terminals and interfaces. CDR records all calls originating from or terminating at a MASI terminal. MASI CDR does not record ineffective call attempts when all MASI paths are busy.

The Resource Flag value of 8 indicates a MASI call. This field appears in unformatted, int-isdn, expanded and customized CDR formats. For formats other than these, you can determine that a call involves a MASI terminal or trunk by the TAC, dialed number or calling number fields.

The following are the CDR capabilities of MASI. Administration information is under the heading [“How to administer MASI” on page 11-9](#).

- Incoming/Outgoing Trunk Call Splitting  
Call splitting does not produce separate records for MMCX calls that are transferred or conferenced.
- Intraswitch CDR  
You can administer intraswitch CDR to monitor MASI terminals. To do this, simply add the MASI terminal extension on the Intraswitch CDR form. DEFINITY then monitors calls from MASI terminals to other MASI terminals, and calls between MASI terminals and DEFINITY stations.
- CDR Privacy  
You can administer a MASI terminal for CDR Privacy.
- Account Code Dialing and Forced Entry of Account Codes  
This is not supported for MASI terminals. Therefore, make sure the COR you assign does not force entry of account codes.
- Trunk CDR  
You can get call detail records for all incoming and outgoing calls made over MMCX interfaces.

## Call redirection / Voice-messaging access

MMCX users can enter a DEFINITY extension, including an AUDIX hunt group, Callmaster agent, attendant console or voice terminal as their coverage point.

If AUDIX is established as the MASI terminal's coverage point, the MASI terminal receives message waiting indication, and dials the AUDIX hunt group extension to retrieve messages. Once connected to AUDIX, operation for the MMCX user is the same as for a DEFINITY station user, including use of # to identify the extension, if desired.

### NOTE:

It is not possible to determine the call coverage status of a MASI terminal.

DEFINITY tracks calls to MASI terminals that follow the autonomous coverage path from the MASI terminal. MMCX calls redirected to DEFINITY stations contain display information.

MASI terminals that dial AUDIX directly, or that place calls to MASI terminals that cover to AUDIX, do not receive ringback if all AUDIX ports are busy. Instead, these callers see a message that the called party is busy, and the call drops.

## Transfer

MASI terminals cannot transfer calls to DEFINITY stations, and cannot transfer a call to another MASI terminal if the call involves a DEFINITY station.

## Conferencing

Conferences can involve both MASI terminals and DEFINITY stations, and either one may initiate the conference. DEFINITY stations participate in such conferences in voice-only mode. If an MMCX user initiates a conference that involves DEFINITY stations, the conference will drop when the initiator drops from the call. If a DEFINITY station initiates the conference, that station may drop without affecting the other conferees.

## Status tracking - terminals and trunks

DEFINITY tracks the active/idle status of all MASI terminals, and monitors traffic over MMCX interfaces.

## Trunk groups

For MASI purposes, there are two kinds of trunk groups: the ISDN-PRI trunk groups that serve as paths for establishing calls between DEFINITY stations or trunks and MASI terminals or interfaces, and the remote trunks that are interfaces from the MMCX to other entities. Each MASI remote trunk group appears to DEFINITY as a single unit, with no concept of members within the group.

 **NOTE:**

You cannot test, busy out, or release MASI remote trunk groups, since you cannot dial a MASI remote trunk TAC from DEFINITY. The TAC merely identifies the trunk to DEFINITY for status and CDR.

You cannot administer MASI trunks as part of DEFINITY route patterns.

## Interactions & Unsupported Features

We can generalize feature interactions to some extent. For example, since there are no buttons available to a MASI terminal, any feature that requires a button is also not available. MASI cannot support features that require the user to dial a trunk access code for a MASI remote trunk, or a feature access code other than AAR/ARS. The MMCX dial plan may contain only those feature access codes that are supported.

 **CAUTION:**

*DO NOT ADMINISTER the following features! The following features are not supported for use over the MASI link, and Lucent Technologies cannot responsible for the results if you attempt to administer them.*

### Unsupported Call Center features

- ASAI — You must not administer a MASI terminal in an ASAI domain. MASI terminals and MMCX trunks are not monitored by ASAI. It may be possible for a MASI terminal to place a call to a DEFINITY station that is part of an ASAI domain. ASAI will not be blocked from controlling this call, but there may be unpredictable results. The same is true for calls originating from an ASAI domain terminating at MASI terminals, and for ASAI-monitored hunt groups that contain MASI terminals.
- Automatic Call Distribution — You must not include a MASI terminal extension as part of an ACD hunt group. You must not mix MASI administration with anything related to ACD, including Outbound Call Management and PASTE.
- Call Vectoring — You must not include MASI terminal extensions in any step of a vector.

### Unsupported Basic features

- Bridged Call Appearances — You must not administer a bridged appearance that involves a MASI terminal.
- Call Coverage — You must not administer a MASI terminal in a DEFINITY station's coverage path.
- Call Forwarding — You must not forward a DEFINITY station to a MASI terminal.

## 11 Multimedia

### Multimedia Applications Server Interface

Page 11-26

- Call Pickup — You must not administer a MASI terminal as part of a pickup group.
- Intercom — You must not administer MASI terminals as members of any type of intercom group.
- Manual Message Waiting — You must not administer a manual message waiting button (man-msg-wt) with a MASI terminal as the referenced extension.
- Manual Signaling — You must not administer a manual signaling button (signal) with a MASI terminal as the referenced extension.
- Night Service — You must not administer a MASI terminal as a night service destination.
- Pull transfer — MASI terminals cannot perform a pull transfer operation. You must not administer this feature on an ECS where MASI is active. This applies only in Italy.
- Station Hunting — You must not administer a MASI terminal as part of a station hunting path.
- Terminating Extension Groups — You must not administer a MASI terminal as part of a TEG.

### Other interactions

The following section describes feature behaviors that may not be as expected, but that are not likely to be destructive.

#### Attendant features

- Dial Access to the Attendant — MASI terminals will be able to dial the attendant access code, if it is administered in the MMCX dial plan.
- Attendant Direct Extension Selection — Attendants are able to access MASI terminals via DXS buttons and busy lamp indicates status of the MASI terminal.
- Emergency Access to the Attendant — MASI terminals have emergency access using the attendant access code, if it is administered in the MMCX dial plan. However, off-hook alerting is not administrable.
- Attendant Intrusion — Attendants are able to activate intrusion towards MASI terminals.
- Attendant Override — Attendants are not able to activate override towards MASI terminals.
- Attendant Recall — MASI terminals cannot activate attendant recall.
- Attendant Remote Trunk Group Select — Attendants cannot use this feature to select MASI remote trunks.
- Attendant Return Call — Operates normally if a MASI terminal is the called party.

- Attendant Serial Call — Serial calls are denied if the calling party is an MMCX interface.
- Attendant Straightforward Outward Completion — The attendant is able to complete calls to DEFINITY trunks for MASI terminals.
- Attendant Through Dialing — The attendant can use Through Dialing to pass dial tone to MASI terminals.
- Attendant Timers — Attendant timers work the same no matter what kind of terminal is involved.
- Attendant Trunk Group Busy/Warning Indicators — You cannot administer Busy/Warning indicators for MASI trunks because they are not standard DEFINITY trunks. However, you can administer these indicators for the trunk group administered for MASI paths.
- Attendant Trunk Identification — The attendant is not able to identify the trunk name via button pushes.

### Basic features

- Abbreviated Dialing — A DEFINITY station can enter an MMCX extension in an AD list. However, MASI terminals cannot use AD.
- Administered Connections — MASI terminals must not be the originator nor the destination of an administered connection.
- Automatic Callback — Automatic callback does not work towards a MASI terminal.
- Automatic Circuit Assurance — You must not administer a MASI terminal as an ACA referral destination. You cannot administer ACA for MASI remote trunks.
- Busy Verification of Terminals and Trunks — You cannot use Busy Verification for MASI terminals or remote trunks.
- Call Detail Recording — CDR Account Code Dialing and Forced Entry of Account Codes are not supported for MASI terminals. See Call Detail Recording in Detailed Description for more information.
- Call Park — The attendant can park calls at the extension of a MASI terminal, but users can only retrieve these calls from a DEFINITY station, since MASI terminals cannot dial the Answer Back FAC.
- Data Call Setup — DEFINITY users cannot place data calls to MASI terminals.
- Facility Busy Indication — You can use FBI to track the status of MASI terminals. The FBI button and indicator lamp must be on a DEFINITY station. You cannot use FBI to track MMCX interfaces.
- Facility Test Calls — DEFINITY users cannot make test calls to MMCX interfaces.
- Go to Cover — MASI terminals cannot activate this feature.

## 11 Multimedia

### *Multimedia Applications Server Interface*

Page 11-28

- Leave Word Calling — The only valid LWC destination for a MASI terminal is AUDIX. You cannot administer SPE-based LWC. MASI terminals cannot send LWC messages to DEFINITY stations or MASI terminals.
- Loudspeaker paging — You can administer a MASI terminal as a code calling extension.
- Malicious Call Trace — MASI terminals cannot initiate malicious call trace.
- Message Retrieval — MMCX users can only retrieve messages through AUDIX.
- Music on Hold — Music on hold will only be available if a DEFINITY station has placed the call on hold.
- Override — Executive override does not work towards MASI terminals.
- Priority Calling — Priority calling is not supported for calls to or from MASI terminals.
- Ringback Queueing — Ringback Queueing is not supported for MASI terminals.
- Send All Calls — MMCX has an autonomous SAC function. See Call Redirection for more information.
- Tenant Partitioning — All MASI terminals exist in tenant 1, and you cannot change the tenant number.
- Time of Day coverage — As with all coverage, DEFINITY does not control coverage of the MASI terminal.
- Transfer out of AUDIX — A MASI terminal cannot use \*T to transfer from AUDIX to another MASI terminal.

### **Hospitality features**

- Do Not Disturb — MASI terminals cannot activate Do Not Disturb.

### **Multimedia features**

- Multimedia Call Handling — DEFINITY MMCH users are not able to make H.320 calls to MASI terminals over the MASI link. Calls between MMCX terminals and MMCH terminals are voice only.

## Troubleshooting

---

Verify proper operation using the following commands and follow normal escalation procedures to resolve any failures detected by the demand test.

1. Verify the DS1 trunk using the **test board <board location> long** command.
2. Verify the ISDN Signaling Group using the **test signaling-group <group number>** command. Also verify proper administration.
3. Verify the temporary signaling connection using the **test tsc-administered <group number>** command. Also verify proper administration.

### Common error conditions

If the cable from the ECS to the MMCX becomes disconnected, you should see alarms raised against ISDN-SGRP and UDS1-BD. In particular, you should observe ISDN-SGRP errors such as 769, 1793, and 257. To resolve, reconnect the cable and follow normal test procedures.

If the far-end path termination number is incorrect, you should observe MASI-PTH error 513. To resolve, correct administration using the MASI Path Parameters form.

If the Layer 3 TSC is not administered properly or is out of service, you should observe errors (but no alarms) raised against TSC-ADM. Verify the signaling group administration and follow normal escalation procedures for TSC-ADM. *What do these errors look like? Is this meant for anyone other than techs?*

If the TSC fails to come up even through Layer 2 Signaling Group and below pass tests, you may run **test tsc-administered <group number>** to force a switch heartbeat test, or simply wait 5–10 minutes for the link to recover. This situation may happen if the switch is rebooted or if the MASI interface is administered before the MMCX is properly administered.

You may want to use busy port and release port commands to unlock things if features are not working.

## **Multimedia Call Handling**

---

### **Functional description of MMCH**

---

Multimedia Call Handling (MMCH) enables you to control voice, video, and data transmissions using your voice terminal and PC. You can conduct video conferences and route calls like a standard voice call. You can also share PC applications so that you and your colleagues can collaborate while working from remote sites. MMCH enhances your voice terminal's capabilities to place or receive multimedia calls by taking advantage of DEFINITY ECS's powerful call-handling and routing features.

### **Operations in Basic or Enhanced modes**

There are two distinct levels of functionality: Basic and Enhanced. The Basic mode of operation treats a standard-protocol H.320 multimedia call as a data call. If the call is redirected, it is converted to a voice call. As a voice call, certain features are enabled, such as coverage, voice mail, and multiparty video conferencing. The Enhanced mode of operation allows a multifunction voice terminal to control a multimedia call like a standard voice call. Spontaneous video conferencing, call forwarding, call coverage, hold, transfer and park, along with many routing features, are available to multimedia calls. Both modes of operation allow data collaboration between multiple parties using the T.120 standard protocol.

### **Definitions: MMCH features and components**

---

#### **Multimedia call**

A multimedia call, for MMCH, is one that conforms to the H.320 and T.120 suite of protocol standards. These standards allow video-conferencing packages from different vendors to communicate with one another. The capabilities of the individual multimedia-endpoint package can vary, however.

- An H.320 call can contain voice, video and data.
- The bandwidth for MMCH calls is limited to 2 B-channels.

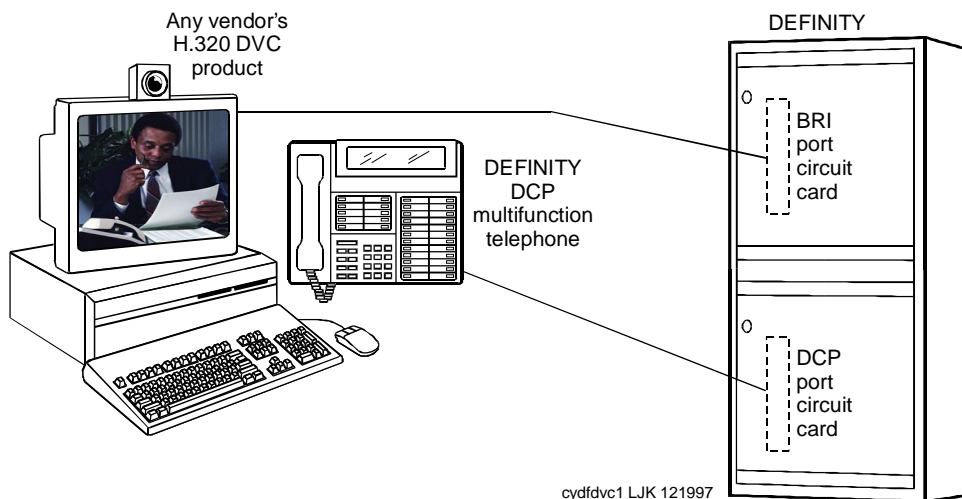

Figure 11-5. MMCH multimedia complex

### Basic multimedia complex

A Basic multimedia complex consists of a BRI-connected multimedia-equipped PC and a non-BRI-connected multifunction voice terminal administered in Basic mode. With a Basic multimedia complex, users place voice calls at the multifunction voice terminal and multimedia calls from the multimedia equipped PC. Voice calls will be answered at the multifunction voice terminal and multimedia calls will alert first at the PC and, if unanswered, will next alert at the voice station. A Basic multimedia complex provides a loose integration of the voice station and H.320 DVC system.

### Enhanced multimedia complex

An Enhanced multimedia complex consists of a BRI-connected multimedia-equipped PC and a non-BRI-connected multifunction voice terminal administered in Enhanced mode. The Enhanced multimedia complex acts as though the PC were directly connected to the multifunction voice terminal. Thus, voice call control, multimedia call control and call status are enabled at the voice terminal. An Enhanced multimedia complex provides a tight integration of the voice station and H.320 DVC system.

### Multimedia endpoint

The multimedia endpoint is a user's PC that has been equipped with an H.320 multimedia package. The PC is physically connected to the DEFINITY ECS with a BRI line.

Figure 11-6. Enhanced MMCH service link

### Enhanced mode service link

The service link is the combined hardware and software multimedia connection between the user's multimedia endpoint and the DEFINITY ECS which terminates the H.320 protocol. The service link provides video, data, and, optionally, voice streams to augment the capabilities of the voice terminal and PC. A service link only applies to an Enhanced multimedia complex, never to a Basic multimedia complex. The service link is administered on the station form and can be either "permanent" or "as-needed." For detailed information see [11-49](#).

### Feature Description

MMCH's two levels of functionality for a multimedia complex, Basic and Enhanced mode, are enabled either by switch administration (see "[System Level Administration](#)" on page 11-41) or by an mm-basic feature button or FAC (see [11-51](#)).

### Basic Mode Operation

#### In Basic Mode:

- All voice-only calls originate at the voice station.

## 11 Multimedia

### Multimedia Call Handling

Page 11-33

- All multimedia calls originate with the H.320 DVC system.
- All incoming voice calls attempt to alert at the voice station and receive all standard voice call treatment.
- All incoming H.320 multimedia calls attempt to alert on the H.320 DVC system initially. If answered, a 2-way video call will result. The Basic multimedia complex voice station will not be involved in the call in any way.

If the H.320 multimedia call is not answered at the H.320 DVC system and the Basic multimedia complex voice station has the H.320 field administered to "y", the call will:

- timeout at the DVC system
- alert at the associated voice station set as a voice-only call
- receive all standard voice call treatment.
- Call control depends on what type of call is being originated.
  - Video is received and controlled at the PC.
  - Voice is received and controlled at the telephone set.
- The voice station of a Basic multimedia complex must manually add their multimedia endpoint to a multimedia conference. There is limited support for multimedia feature interactions. A specific set of voice features work for multimedia calls.
- Service Links are not used by Basic mode complexes.
- A single number may be used to reach the Basic multimedia complex for voice or H.320 multimedia calls.

See ["Basic Mode MM complex" on page 11-59.](#)

## Enhanced Mode Operation

The Enhanced multimedia complex provides a much more tightly coupled integration of the complex voice station and H.320 DVC system. In Enhanced Mode:

- Both multimedia and voice calls must originate at the telephone set.
- Voice and multimedia calls can be controlled at the telephone set.
- Conferencing is spontaneous and established just like a voice-only conference call.
- There is extensive support for multimedia feature interaction. Most voice features work the same for multimedia calls.
- Service Links can be either "permanent" or "as-needed."

See ["Enhanced Mode MM complex" on page 11-73.](#)

## Physical Installation

---

The physical components necessary to utilize MMCH capabilities include:

- DEFINITY ECS software (see [“Administration commands” on page 11-41](#)).
- H.320 DVC systems that are BRI connected to the DEFINITY ECS.
- Non-BRI multifunction voice terminals.
- DEFINITY TN787 MultiMedia Interface (MMI) and TN788 Voice Conditioner (VC) boards.
- A T.120 Enhanced Services Module (ESM) server (necessary only if you plan to do T.210 data collaboration). Connectivity of the ESM requires an additional TN787 along with a TN2207 DS1 circuit pack.

## Dual Port Desktop

Both Basic and Enhanced multimedia complexes are dual-port desktops that consist of:

- a BRI-connected multimedia-equipped PC that supports the H.320 protocol
- a non-BRI-connected multifunction telephone set.

The PC and the multifunction voice terminal are individually wired to the DEFINITY ECS. These two pieces of equipment can be administratively associated to form a Basic or ENHANCED multimedia complex (see [“Planning & administration for MMCH” on page 11-37](#)).

MMCH works with any H.320 system that is fully H.320 compliant and operates at the 2B or 128K rate.

### NOTE:

If you intend to share applications among users or whiteboard capabilities, the endpoint software you choose must also support the T.120 protocol.

The following endpoint-software packages have been tested:

- PictureTel PCS 50 & PCS 100, Release 1.6T
- Proshare 2.0a, 2.1
- Zydacron Z250 Ver. 2.02, Z350 Ver. 1.2 (With Netmeeting 2.0)

## MMI & VC hardware

The MMCH feature requires the use of two additional circuit packs:

- Multi Media Interface (MMI) TN787J.
- Voice Conditioner (VC) TN788B.

The TN787 and TN788 are service circuit packs. The TN787 supports simultaneous operation of 16 2B H.320 calls. The TN788 supports the voice processing for 4 H.320 endpoints.

- These service circuit packs may be located in any Port Network.
- These packs do not require any translations as part of their implementation.
- The MMI and VC circuit packs are resource circuit packs akin to the Tone Detector circuit packs.
- These circuit packs require no switch administration and may be located in multiple port networks.
- Specific provisioning guidelines for the number and placement of these packs can be found by calling the Lucent Technical Support Center (TSC) at (303) 850 - 8187.

### **T.120 Data Collaboration Server**

The Expansion Services Module (ESM) provides T.120 data collaboration capability on a MMCH multipoint H.320 video conference.

- Each person in the conference who wants to participate in the data collaboration session, must have a personal computer with an H.320 video application that supports the T.120 protocol.
- The DEFINITY ECS must have an ESM installed.

## ESM Installation

### Figure Notes

1. Port B Y-cable connector to a TN787 multimedia interface (MMI) circuit pack
2. Port A Y-cable connector to a TN2207 PRI circuit pack
3. 25-pair Y-cable
4. 356A adapter
5. D8W cord connected to 356A adapter S/B port 8
6. Expansion service module (ESM)
7. Port B on compatible primary rate interface (PRI) card

### Figure 11-7. Typical Multimedia Call handling ESM Connections

Use the following procedure and [Figure 11-7](#) to connect to the ESM equipment:

1. Install the TN2207 primary rate interface (PRI) circuit pack and the TN787 multimedia interface (MMI) circuit pack in the DEFINITY System port carrier.

#### NOTE:

These two circuit packs should be co-located in the cabinet since they must be connected by a Y-cable on the back plane of the DEFINITY ECS.

2. Record the circuit pack locations.
3. Connect the ESM Y-cable as shown.
4. Administer the DS1 form and the signaling-group form for the ESM (see [“ESM T.120 Server Administration”](#) on page 11-53).
5. Configure the ESM adjunct.

## System Capacities

The following capacity information provides a starting point for understanding the current MMCH physical system limitations.

**Table 11-1. MMCH System Capacities**

|                                    | R6.3 si | R6.3 r |
|------------------------------------|---------|--------|
| TN787 MMI boards                   | 5       | 13     |
| TN788 VC boards                    | 20      | 52     |
| Max Simultaneous 3 MM pty calls    | 26      | 69     |
| Max Simultaneous Conversion calls  | 80      | 208    |
| Nominal Dual-Port Desktops         |         |        |
| ■ Basic mode office environment    | 675     | 2000   |
| ■ Enhanced mode office environment | 225     | 675    |
| ■ Enhanced mode Call Center        | 32      | 83     |

## Planning & administration for MMCH

The following are some of the tasks you perform in planning and administering MMCH.

### Planning the system

This is a list of questions to help you use DEFINITY ECS for multimedia.

- How many MMCH users are you going to have?
- How many multimedia calls do you expect to have at any given time?

With the information above you can determine how many Voice Conditioner (VC) and Multimedia Interface (MMI) circuit packs you need.

- Will users need data collaboration capabilities? If so, you need to install the Expansion Service Module (ESM).
- Which stations, hunt groups or vectors need early answer?
- Do you have ISDN-PRI trunks? It is possible to use separate DS1 trunks for data, but ISDN-PRI trunks are recommended.

## Installation checklist

1. Purchase MMCH right-to-use.
2. Lucent Technologies — enable MMCH on Customer-Options form.
3. Administer default multimedia outgoing trunk parameter selection on the System-Parameters Features form.
4. Administer MMCH related feature access code on the Feature Access Code form.
5. Install and administer hardware:
  - Install MMIs, VCs and ESM.
  - Administer ESM to ECS connection — DS1 Circuit Pack form, Signaling Group form.
  - Establish maintenance parameters — Maintenance Related System Parameters form.
6. Administer multimedia complexes:
  - Administer data modules — Data Module form
  - Administer stations as part of a multimedia complex, assign associated data module extension, multimedia mode, service link mode and appropriate multimedia buttons — Station forms
7. Administer early answer and H.320 flag for stations, the early answer flag for hunt groups, and the multimedia flag for vectors as appropriate.
8. Train end users.
9. Monitor traffic and performance.

## Multimedia Forms

---

## Administration commands

---

### System Level Administration

#### System-Parameters Customer-Options form:

To enable the MMCH release 6.3 feature, you must change the System-Parameters Customer-Options form. There are two MMCH related fields on page 2 of this form.

- The “Multimedia Call Handling (Basic)” field must be set to ‘y’ to allow MMCH Basic mode operation.
- The “Multimedia Call Handling (Enhanced)” field must be set to ‘y’ to allow MMCH Enhanced mode operations.

```
change system-parameters customer-options                               Page 2 of 4
                                OPTIONAL FEATURES
                                ISDN-BRI Trunks? n Restrict Call Forward Off Net? y
                                ISDN-PRI? y           Secondary Data Module? y
                                ISDN-PRI over PACCON? y           SoftLock? n
                                Malicious Call Trace? n           Station and Trunk MSP? n
                                Mode Code Interface? n           Tenant Partitioning? n
                                Multifrequency Signaling? y       Terminal Trans. Init. (TTI)? n
Multimedia Appl. Server Interface (MASI)? n           Time of Day Routing? n
                                Multimedia Call Handling (Basic)? y           Uniform Dialing Plan? y
                                Multimedia Call Handling (Enhanced)? y       Usage Allocation Enhancements? y
                                Personal Station Access (PSA)? n
                                                Wideband Switching? n
                                                Wireless? n
                                Processor and System MSP? n
                                Private Networking? y

(NOTE: You must logoff & login to effect the permission changes.)
```

Screen 11-15. System-Parameters Customer-Options Form (Page 2 of 4)

### System-Parameters Features form:

The default bandwidth for MMCH calls is defined on the System-Parameters Features form shown below.

 **NOTE:**

Originating a multimedia call with the mm-call button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form.

- This default parameter will be either 2x56 or 2x64.
- The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

```
change system-parameters features                               Page 2 of 8

                                FEATURE ACCESS CODE (FAC)
                                Multimedia Features

                                Basic Mode Activation: *01
                                Enhanced Mode Activation: *02
                                Multimedia Call Access Code: *03
Multimedia Data Conference Activation: *04 Deactivation: #04
                                Multimedia Multi-Address Access Code: *05
                                Multimedia Parameter Access Code: *06
    
```

### Screen 11-17. Feature-Access-Codes Form (Page 6 of 6)

- **Basic Mode Activation:** If you enter this FAC when your system is an Enhanced multimedia complex, it will revert to a Basic multimedia complex. If you enter this FAC when your system is a Basic mode station it will do nothing.
- **Enhanced Mode Activation:** If you enter this FAC when your system is a Basic multimedia complex, it will become an Enhanced multimedia complex. If you enter this FAC when your system is an Enhanced mode station it will do nothing.
- **Multimedia Call Access Code:** If you enter this FAC from any voice station, it indicates to the DEFINITY ECS that you are making an Enhanced multimedia mode call. If you originate a multimedia call with the multimedia call access code, it will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form.
- **Multimedia Data Conference Activation:** If you enter this FAC from any voice station that is participating in a multimedia call, it will alert the DEFINITY ECS that you want to enable data collaboration with the other parties on the call. If you enter this FAC a second time, it will give denial treatment (since a collaboration session is already active). This FAC only applies to voice stations on a DEFINITY ECS switch equipped with an ESM adjunct.

The Multimedia Data Conference Activation FAC must be entered after your system is active on a multimedia call. To enter the FAC:

1. Select TRANSFER
  2. Receive a dialtone
  3. Dial the Multimedia Data Conference Activation FAC
  4. Receive a confirmation tone
  5. Re-select the call appearance for the held-multimedia call.
- **Multimedia Data Conference Deactivation:** If you enter this FAC from the voice terminal that enabled data collaboration on a multimedia mode call, it will deactivate the data session and revert to a voice and video call. If you enter this deactivation FAC while participating in a data-collaboration multimedia call that *you did not initiate*, you will get denial treatment.

The Multimedia Data Conference Deactivation FAC must be entered after you are active on a multimedia call. To enter the FAC:

1. Select TRANSFER
  2. Receive a dialtone
  3. Dial the FAC
  4. Receive a confirmation tone
  5. Re-select the call appearance for the held multimedia call.
- **Multimedia Multi-Address Access Code:** The multimedia multi-address access code is similar to the multimedia call access code. It allows origination of a multimedia call from a voice station. It is used when the destination being dialed requires a different address for each of the 2 B-channels. For example, ISDN-BRI provided by a Central Office is provisioned with separate listed directory numbers for each B-channel. In order to make a 2B multimedia call to such a device, two sets of addresses must be entered.  
  
Originating a multimedia call with the multimedia multi-address access code will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form.
  - **Multimedia Parameter Access Code:** This FAC can be entered by any voice station to indicate to the DEFINITY ECS that you want to initiate a multimedia mode call with a specific bearer capability. This FAC would be followed by a 1 or 2 to indicate the following parameter selections respectively: 2x64 (unrestricted initial system default), 2x56 (restricted).

## Multimedia Complex/Station

Use the following administration commands to add, change, duplicate, or remove stations and data modules.

| Action    | Objects                | Qualifier  |
|-----------|------------------------|--|
| add       | station<br>data module | xxxxx (extension) or 'next'<br>xxxxx (extension) or 'next' |
| change    | station<br>data module | xxxxx (extension)<br>xxxxx (extension)                     |
| duplicate | station<br>data module | xxxxx (extension)<br>xxxxx (extension)                     |
| remove    | station<br>data module | xxxxx (extension)<br>xxxxx (extension)                     |

### Data module form

The H.320 DVC system should contain a BRI interface. You must connect this BRI interface to a port on a TN556 BRI circuit pack and administer it as a BRI data module.

- You may administer the data endpoint type as 7500 (recommended) or WCBRI.
- The fields for multimedia are the same on either form.
- The administration for a Basic mode and an Enhanced mode data module are exactly the same.

```

                                                                 Page 1 of 2

Screen 11-20. Data Module Form (Page 2 of 2)

- **Type** — Set the data module type to 7500 or WCBRI.
- **Multimedia** — This field appears on the data module form only if MM is set to yes on the System-Parameters Customer Options form. Enter Y to enable this data module to be multimedia compliant.

- **MM Complex Voice Ext:** (display only) — This field contains the number of the associated telephone in the complex. This is a display-only field, and is blank until you enter the data module extension in the Station form MM Complex Data Ext field. Once you have done that, these two extensions are associated as two parts of a multimedia complex.
- **XID and MIM Support** — These fields must be set to n.

### Station form

After you have administered the BRI data module, use the Station form to associate it with a voice station to form a multimedia complex. This is a one-to-one relationship: you can administer only one station and one data endpoint per multimedia complex. Neither the voice station, nor the data endpoint can be a member of another multimedia complex.

 **NOTE:**

A BRI station cannot be part of a multimedia complex.

### Station form, page 1

```

Screen 11-22. Station Form (Page 2 of 5)

- H.320 Conversion** — This field is optional for non-multimedia complex voice stations and for Basic multimedia complex voice stations. It is mandatory for Enhanced multimedia complex voice stations. Because the system can only handle a limited number of conversion calls, you may need to limit the number of telephones with H.320 conversion. Enhanced multimedia complexes must have this flag set to **y**.

For non-multimedia complex voice stations, setting this field to **y** allows H.320 calls to convert to voice and alert at the standalone voice station. If the call is unanswered at the voice station, the call will follow standard voice treatment. Any subsequent station that is reached in the routing of this call, that is, coverage points, forwarded destinations, call pickup members, and so forth, do not need to have the H.320 field enabled. The H.320 field is only needed at the *first* station that may receive the H.320 call.

For Basic multimedia complex voice stations, setting this field to **y** allows H.320 calls to convert to voice and alert at the Basic multimedia complex voice station *after* an attempt has been made to offer the call to the H.320 DVC system. If the call is unanswered at the H.320 DVC system, the call will alert at the voice station after 5 seconds or after the administered number of rings as specified in the voice station's coverage path. If the call is unanswered at the voice station, the call will follow standard voice treatment. Any subsequent station that is reached in the routing of this call, that is, coverage points, forwarded destinations, call pickup members, and so forth, do not need to have the H.320 field enabled. The H.320 field is only needed at the *first* station that may receive the H.320 call.

- **Service Link Mode** — The service link is the combined hardware and software multimedia connection between an Enhanced mode complex's H.320 DVC system and the DEFINITY ECS which terminates the H.320 protocol. A service link is never used by a Basic mode complex H.320 DVC system. Connecting a service link will take several seconds. When the service link is connected, it uses MMI, VC and system timeslot resources. When the service link is disconnected it does not tie up any resources. The Service Link Mode can be administered as either 'as-needed' or 'permanent' as described below:
  - As-Needed - Most non-call center multimedia users will be administered with this service link mode. The as-needed mode provides the Enhanced multimedia complex with a connected service link whenever a multimedia call is answered by the station and for a period of 10 seconds after the last multimedia call on the station has been disconnected. Having the service link stay connected for 10 seconds allows a user to disconnect a multimedia call and then make another multimedia call without having to wait for the service link to disconnect and re-establish.
  - Permanent - Multimedia call center agents and other users who are constantly making or receiving multimedia calls may want to be administered with this service link mode. The permanent mode service link will be connected during the station's first multimedia call and will remain in a connected state until the user disconnects from their PC's multimedia application or the DEFINITY ECS switch restarts. This provides a multimedia user with a much quicker video cut-through when answering a multimedia call from another permanent mode station or a multimedia call that has been early answered.
- **Multimedia Mode** — There are two multimedia modes, Basic and Enhanced, as described below:
  - Basic — A Basic multimedia complex consists of a BRI-connected multimedia-equipped PC and a non-BRI-connected multifunction telephone set. When in Basic mode, users place voice calls at the multifunction telephone and multimedia calls from the multimedia equipped PC. Voice calls will be answered at the multifunction telephone and multimedia calls will alert first at the PC and if unanswered will next alert at the voice station if it is administered with H.320 = y. A Basic mode complex has limited multimedia feature capability as described in ["Basic Mode Operation" on page 11-32](#).
  - Enhanced — An Enhanced multimedia complex consists of a BRI-connected multimedia-equipped PC and a non-BRI-connected multifunction telephone. The Enhanced mode station acts as though the PC were directly connected to the multifunction telephone; the service link provides the actual connection between DEFINITY ECS and the PC. Thus, voice and multimedia calls are originated and received at the telephone set. Voice and multimedia

call status are also displayed at the telephone set. An Enhanced mode station allows multimedia calls to take full advantage of most call control features as described in [“Enhanced Mode Operation” on page 11-33](#).

- **Multimedia Early Answer** — This field lets you set this phone for early answer of multimedia calls. The system will answer the incoming multimedia call on behalf of the station and proceed to establish the H.320 protocol. After audio path has been established to the caller, the call will then alert at the voice station. The station may then answer by going off-hook and will have immediate audio path. No hourglass tone will be heard by the answering party (see [“Hourglass Tone” on page 11-64](#)).

Example: An administrative assistant who does not have a multimedia PC, but may get multimedia mode calls from forwarding or coverage, may want to set the H.320 flag to **y** and the early answer flag to **y** on their voice station. This allows any multimedia call to be presented to the station with immediate voice path rather than hourglass tone. The answered call could then be transferred as voice to voice mail or transferred as multimedia to a user equipped with a multimedia endpoint.

## Multimedia Buttons

There are six new multimedia specific buttons that may be added to a voice station. Most of them may be placed on any voice station, whether it is part of a Basic multimedia complex, an Enhanced multimedia complex or not part of any multimedia complex. Two feature buttons, mm-basic and mm-pcaudio, may only be placed on stations which are part of an Enhanced multimedia complex.

All of the multimedia specific feature buttons have a corresponding feature access code except mm-pcaudio and mm-cfwd.

- The mm-pcaudio feature can only be used with a station form button.
- The mm-cfwd button may be replaced by the standard “*call forward*” FAC followed by the “*multimedia call*” FAC.

```

Screen 11-23. Station Form (Page 3 of 5)

- **mm-call** — This button may exist on any voice station. Most multimedia enabled users will want an mm-call button. This button (or it's corresponding FAC) must be used to indicate that the user is placing a multimedia mode call. To place a multimedia mode call the user would go off-hook, select an idle call appearance, and press the mm-call button followed by the destination extension digits. If the user has a speakerphone they can simply press the mm-call button, which preselects an idle call appearance, followed by the destination extension digits.

The mm-call button lamp lights when you press this button during call origination. The lamp also lights to indicate that the selected call appearance is a multimedia mode call.

- **mm-basic** — This button is only allowed on the voice station of a multimedia complex. The mm-basic button toggles your station between Basic and Enhanced modes. If you press the mm-basic button when you are an Enhanced multimedia complex, you will revert to a Basic multimedia complex and the button status lamp will be lit. If you press this button when you are a Basic mode station it will switch you to an Enhanced mode station and the button status lamp will not be lit. This button can NOT be used to change the station's multimedia mode when the station has an active multimedia call appearance.

Toggleing between Basic and Enhanced mode changes the station's administered Multimedia mode. When in Basic mode this field on the station form will show *basic*. When in Enhanced mode this field on the station form will show *enhanced*. The current station Multimedia mode will be saved to translation when a **save translation** command is executed.

- **mm-pcaudio** — This button only works for an Enhanced multimedia complex voice station. When originating or receiving a multimedia call, the audio path is connected to the voice station's handset or speakerphone device. The mm-pcaudio button allows a user to switch the audio portion of any call to their PC's audio input/output device (if available). To switch the audio path to the PC while active on a call, the user presses the mm-pcaudio button (if off-hook you may now hang up the handset). The mm-pcaudio button's status lamp will light up when the button is pushed to move the audio path to the PC and remain lit while the audio path is at the PC device.

**NOTE:**

If you are on a voice only call, the voice path will switch to the PC device but you will get muted or loopback video depending on the multimedia endpoint software.

A user may simply go off-hook on their voice station or press the speakerphone button to move the audio path of a multimedia call from the PC back to the voice station. Pressing the mm-pcaudio button while the status lamp is lit and the voice station's handset is on-hook will disconnect the user from the active call.

- **mm-datacnf** — Pressing the mm-datacnf button from any voice station that is participating in a multimedia call will light the status lamp and alert the DEFINITY ECS that you want to enable T.120 data collaboration with the other parties on the call. The button status lamp will also light for other participants in the multimedia call who have mm-datacnf buttons.

Pressing this button from the voice station that enabled data collaboration on a multimedia mode call will deactivate the data session and revert to a voice and video call. If you are participating on a multimedia call with data collaboration, but did not initiate the data collaboration, and you press this button, the status lamp led will flash momentarily and the T.120 data services will not be terminated, (only the station that activated the collaboration session can deactivate it). This button only works for stations connected to a DEFINITY ECS equipped with an ESM adjunct.

- **mm-cfwd** — The mm-cfwd button allows a user to indicate that multimedia mode calls will be forwarded off of the DEFINITY ECS switch as multimedia mode calls to a specific forwarded-to destination. If voice call forwarding is active and multimedia call forwarding is not active then multimedia calls going off of the DEFINITY ECS switch will be forwarded as voice only calls.

The mm-cfwd button status lamp will be lit to indicate that multimedia call forwarding is activated. Pressing the mm-cfwd button when the lamp is lit will deactivate multimedia call forwarding.

Note - pressing the mm-cfwd button is the same as dialing the regular call-fwd FAC followed by the mm-call button or FAC followed by the desired forwarded-to extension digits.

- **mm-multinbr** — The mm-multinbr call button is similar to the mm-call button. It allows origination of a multimedia call from any voice station. It is used when the destination being dialed requires a different address for each of the 2 B-channels. An example of this is Central Office provided ISDN-BRI. This type of BRI line is provisioned with separate listed directory numbers for each B-channel. In order to make a 2B multimedia call to such a device, two sets of address must be entered.

Originating a multimedia call with the mm-multinbr button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

## ESM T.120 Server Administration

```

### Screen 11-25. Signaling-Group Form (Page 1 of 5)

1. Enter **add signaling-group next** and the signaling-group form appears.
2. Change Associated Signaling: field to **y**.
3. Change Primary D-Channel Port: field to **xxxx16** (where xxx is the address of the TN2207 PRI circuit pack, for example: 1B0516).
4. The Max Number of NCA TSC: default is 0.
5. The Max Number of GA TSC: default is 0.
6. Trunk Group for NCA TSC: \_\_\_\_ (leave blank)
7. Trunk Group for Channel Selection: \_\_\_\_ (leave blank)
8. Logoff the terminal and then log back on the terminal to view your changes.

**Troubleshooting.** To determine ESM link status enter the following commands from the system administration terminal:

1. **Status esm**
2. **Status signaling-group**
3. **List MMI**

#### NOTE:

When you move ESM circuit packs, you **MUST** remove the DS1 and signaling group translations. You cannot use the **change circuit pack** command.

## Hunt Group Form

(See [11-69](#) for Hunting with Basic Complex or [11-71](#) for Hunting with Enhanced Mode Complex.)

```
change hunt-group 101                                     Page 1 of 3
                                                         HUNT GROUP

Queue Length: 5
Calls Warning Threshold: 2   Port:
Time Warning Threshold: 15  Port:
```

### Screen 11-26. Hunt Group Form (Page 1)

- **MM Early Answer** — This field is to be used when the hunt group will expect to receive H.320 multimedia calls and the members of the hunt group are voice extensions. The voice members of the hunt group should all have the H.320 field on each of their station forms set to “y”. The MM Early Answer field lets you set this hunt group for early answer of multimedia calls. The system will answer the incoming multimedia call on behalf of the agent and proceed to establish the H.320 protocol. After audio path has been established, the call will then alert at the agent’s voice station. The station may then answer by going off-hook and will have immediate audio path. No hourglass tone will be heard by the answering party. This is especially important for AUDIX hunt groups, because otherwise the caller may miss all or a portion of the AUDIX greeting.

The MM Early Answer field has no effect on voice calls.

The MM Early Answer field has no effect if the hunt group members are data extensions.

## Call Vector Form

```

change vector 10                                     Page 1 of 3
                                                    CALL VECTOR

```

### Screen 11-27. Call Vector Form (Page 1 of 3)

**Multimedia** — Very often, calls are routed to hunt groups or skills via a vector. The existing VDNs and vectors which exist for routing voice calls can be used to route multimedia calls.

In order to use a vector for multimedia calls that will terminate to voice stations, you must set the Multimedia field on the vector form to **y**. This field has no effect on voice calls routing through the vector. This field will cause multimedia calls routed through the vector to receive early answer treatment prior to processing the vector steps. This provides a talk path to the caller for announcements or immediate conversation with an agent.

**NOTE:**

Vectors which have the Multimedia field set to “y” must eventually route to hunt groups, skills or numbers which are voice extensions. A vector with the multimedia field set to “y” should never be set up to route to a hunt group or number which is a data extension.

When a vector is used to route video (56K/64K) calls to a hunt group comprised of data extensions, the vector *must* have the multimedia field set to **n**.

## Duplicating multimedia endpoints

Use the **duplicate station** command to enter groups of multimedia endpoints at one time. If the original station form had a data module page, the second page of this form appears.

| STATION |       |       |               |       |       |       |          |

Screen 11-29. Duplicate Station Form (Page 2)

Detailed feature operation descriptions follow.

## Basic Mode MM complex

---

**1-number access.** 1-number access permits originating users to make voice or multimedia calls to a Basic multimedia complex by dialing the same number for either type of call. The number may be the voice station extension or the data module extension. If the incoming call is a voice call, DEFINITY ECS directs it to the telephone. If the incoming call is 56K or 64K data call, DEFINITY ECS recognizes it as such and sends it to the multimedia endpoint. Likewise, if a voice call is addressed to the data extension, the system recognizes this and directs the call to the voice station.

Calls originating on the same switch as the Basic mode complex destination may always use 1-number access for voice or video. In order to take advantage of 1-number access for calls originating from a remote location, the incoming calls must arrive over ISDN-PRI trunks. If the system is setup with separate data non-PRI digital facilities multimedia calls must be made to the data extension.

AVD (Alternate voice/data) trunk groups cannot be used to provide 1-number access with MMCH. If the AVD trunk group has a BCC of 0, all calls arriving over the AVD trunk to the Basic mode complex will be assumed to be voice calls. If the AVD trunk group has a BCC of 1 or 4, all calls arriving over the AVD trunk to the Basic mode complex will be assumed to be multimedia calls.

**Originating voice calls.** All voice calls are originated at the voice station.

**Originating multimedia calls.** For a Basic mode complex, multimedia calls are normally originated at the user's multimedia equipped PC. These multimedia calls use the associated station's COR/COS.

The voice station of a Basic multimedia complex may also use the "mm-call" button or FAC, and the "mm-multinbr" button or FAC to originate multimedia calls. When these methods are used, a multimedia call is originated from the voice station. In order for the Basic multimedia complex to receive video, the user must make a call from the H.320 DVC system to the voice station of the complex or must make a multimedia call from the voice station to the H.320 DVC. This allows the station to spontaneously add themselves or other parties to a multimedia conference.

1. **H.320 DVC system GUI.** The normal way for a Basic multimedia complex endpoint to originate a multimedia call is through the vendor provided user interface. Generally, digits to dial are entered, speed is selected and the call originates from the DVC system. The voice station is not involved in such as origination.

Any voice station may use the following mechanisms to originate a multimedia call from the voice station. For stations that are not part of a multimedia complex, video cannot be provided. For voice stations that are part of a Basic multimedia complex, video is not provided until a multimedia call is made from the complex's H.320 DVC system to the

## 11 Multimedia

### Basic Mode MM complex

Page 11-60

voice station or a multimedia call is made from the voice station to the H.320 DVC system. Video is automatically included for Enhanced multimedia complexes (see [11-33](#)).

2. **mm-call (Multimedia Call) button.** If the station has an mm-call button administered, the user goes off-hook and selects the mm-call button. The user may select the mm-call button and then go off-hook. If the user has a speakerphone on the station, the user may originate the call simply by selecting the mm-call button. The speakerphone will automatically be placed off-hook and dialtone will be heard. Upon selection of the mm-call button, the mm-call status lamp (green led) should become solid.

The user now dials the destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, station busy indicators, etc. Originating a multimedia call with the mm-call button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

For calls with a bandwidth of 2B, use of the mm-call button to originate will cause the same destination address to be used for both channels of the 2B call. See the section below on the mm-multinbr button/FAC for information on originating a 2B call where the destination has a different address for each B-channel.

#### NOTE:

The mm-call feature button is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a multimedia call.

3. **Multimedia Call feature Access Code.** For stations that do not have an administered mm-call button, the Multimedia call feature access code may be used instead. The user goes off-hook on the station, waits for dialtone, then dials the MM-call FAC, receives dialtone again and then dials the call normally. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, station busy indicators, etc.

Originating a multimedia call with the mm-call button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

For calls with a bandwidth of 2B, use of the mm-call button to originate will cause the same destination address to be used for both channels of the 2B call. See the section below on the mm-multinbr button/FAC for information on originating a 2B call where the destination has a different address for each B-channel.

 **NOTE:**

The mm-call feature access code is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a multimedia call.

4. **mm-multinbr (Multimedia Multi-number) button.** The mm-multinbr button is similar to the mm-call button. It allows origination of a multimedia call from a voice station. It is used when the destination being dialed requires a different address for each of the 2 B-channels. An example of this is Central Office provided ISDN-BRI. This type of BRI line is provisioned with separate listed directory numbers for each B-channel. In order to make a 2B multimedia call to such a device, two sets of addresses must be entered.

The user goes off-hook and selects the mm-multinbr button. The user may select the mm-multinbr button and then go off-hook. If the user has a speakerphone on the station, the user may originate the call simply by selecting the mm-multinbr button. The speakerphone will automatically be placed off-hook and dialtone will be heard. Upon selection of the mm-multinbr button, the mm-multinbr and mm-call (if present) status lamp (green led) should light steadily. The user now dials the first destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc. The system will provide dialtone after the first address has been completed. The user now dials the second destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc. After the 2nd address has been collected the mm-multinbr status lamp will go off.

Originating a multimedia call with the mm-multinbr button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

 **NOTE:**

The mm-multinbr feature button is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a dual address multimedia call.

5. **Multimedia Multi-number Call feature Access Code.** For stations that do not have an administered mm-multinbr button, the Multimedia Multi-number call feature access code may be used instead. It allows origination of a multimedia call from a voice station. It is used when the destination being dialed requires a different address for each of the 2 B-channels. An example of this is Central Office provided ISDN-BRI. This type of BRI line is provisioned with separate listed directory numbers for each B-channel. In order to make a 2B multimedia call to such a device, two sets of addresses must be entered.

## 11 Multimedia

### Basic Mode MM complex

Page 11-62

The user goes off-hook and dials the MM-multinbr feature access code. Upon dialing of the MM-multinbr FAC, the mm-call (if present) status lamp (green led) should become solid. The user now dials the first destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc. The system will provide dialtone after the first address has been completed. The user now dials the second destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc.

Originating a multimedia call with the MM-multinbr FAC will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

#### NOTE:

The mm-multinbr FAC is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a dual address multimedia call.

6. **Multimedia parameter selection feature access code.** This FAC is used to originate a multimedia call that wishes to use a different bearer and bandwidth than the system default. For example, if the system has a default multimedia parameter of 2x64 and the user wishes to make a call to a destination that is known to only have 56K digital facilities, the MM parameter selection FAC can be used to select a bearer and bandwidth of 2x56 for this specific call.

The MM parameter selection FAC may be used in conjunction with the mm-multinbr button or FAC to make a single or dual address multimedia call at the desired bearer and bandwidth. The user goes off-hook and dials the MM-parameter selection feature access code. Dialtone is returned. The user enters a single digit, 1 or 2, where 1 = 2x64, 2 = 2x56. All other digits will produce reorder. Dialtone is returned. Upon dialing of the MM-parameter selection FAC, the mm-call (if present) status lamp (green led) should become solid. The user may indicate a dual-address call at this point with the mm-multinbr button or FAC. The user now dials one or two sets of destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc.

#### NOTE:

The mm-parameter selection FAC is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a dual address multimedia call.

7. Dialing sequences that include TACs, AAR, ARS, Authorization codes, CDR account codes, FRLs

■ **Dial TAC or AAR/ARS, Dial 2nd dest. digits**

**Receiving voice calls.** Any voice calls directed to the voice or data extension of a Basic multimedia complex will ring at the voice station.

**Receiving multimedia calls.** Any data calls directed to the voice or data extension of a Basic multimedia complex will ring at the multimedia equipped PC if it is available. You may answer the multimedia call at the PC and voice and video will connect to the PC. If the data endpoint is unavailable, the system verifies that the telephone of the complex is administered with the H.320 field set to **y**. If so, the system converts the call to voice and sends it to the telephone of the multimedia complex, where the call then alerts.

**Hourglass Tone.** When a voice station answers a converted multimedia call, the answering party may hear different things depending on the nature of the originator. If the origination is directly from an H.320 DVC system or if the originator is an Enhanced mode complex on a remote switch, an immediate audio path will not exist between the two parties. This is because the H.320 protocol must be established after the call is answered. It takes several seconds for the H.320 protocol to establish an audio path. During this interval the answering party will hear special ringback. When the audio path exists the special ringback will be removed and replaced with a short incoming call tone indicating that audio now exists. The combination of special ringback followed by incoming call tone is referred to as "hourglass tone." Hourglass tone is an indication to the answering party that they should wait for the H.320 call to establish audio.

**Early Answer.** The answering party may administer their station to avoid hearing hourglass tone. With the station form Early Answer field set to **y**, the system answers the incoming multimedia call on behalf of the station and establishes the H.320 protocol. After audio path has been established, the call will then alert at the voice station of the Basic complex destination. The station may then answer by going off-hook and will have immediate audio path. No hourglass tone will be heard by the answering party.

If the H.320 field is not set to **y** for the telephone of a Basic multimedia complex, H.320 calls alert at the multimedia endpoint until the caller drops. If an H.320 call is directed to a telephone with H.320 set to **n**, the system denies the call.

You can assign H.320 conversion to any voice station.

**Authorization.** Multimedia complexes require the same types of authorization (COR/COS) as standard telephones. If a call is addressed to the voice extension, the system checks the COR/COS of the telephone, whether the call is voice-only or multimedia. If a call is addressed to the data extension, the system checks the COR/COS of the data endpoint. If the call is subsequently redirected to the voice station, the system does a second COR/COS check for the authorization of the voice station. Calls originated from the PC use the COR/COS of the voice station.

## 11 Multimedia

### *Basic Mode MM complex*

Page 11-65

**Adjunct Switch Applications Interface .** ASAI is not expected to support call-association for data calls. Therefore Lucent Technologies does not recommend that you use ASAI for multimedia.

**Administered Connections.** Basic Multimedia endpoints may serve as the origination point or destination of an administered connection.

**Administration without Hardware.** You cannot use AWOH to administer a data module or the data endpoint in a multimedia complex. However, you can use AWOH to administer the telephone.

**Authorization and Barrier Codes.** Basic Mode multimedia users or off-premises PC users may not be able to respond to prompts for authorization or barrier codes. Multimedia endpoints do not recognize the prompts.

An on-premises user might be able to use Remote Access and enter the entire digit string at once before launching the call, but it would be better to eliminate the need for such codes for multimedia users who need to call off premises.

**Bridged Appearances.** Voice users can bridge onto a call if the user has a bridged appearance of a voice member of the call.

**Call redirection.** Calls directed to either member of the Basic multimedia complex are subject to redirection (coverage, forwarding). DEFINITY ECS converts calls to voice before sending them to coverage. Calls redirected through call forwarding maintain multimedia status if forwarded from the data endpoint.

**Conferencing .** A multimedia conference can consist of multimedia and voice-only conferees. All multimedia conferees are added to a multimedia conference by a voice-terminal user on the switch, who acts as the controller of the multimedia conference. When the controller is a Basic complex voice station, the controller must remain on the conference until all parties have joined. Once all endpoints are on the conference, the voice-terminal user may put the call on hold or drop, if the user wishes.

Video conferees can see only their local video and one other party. If more than two people are involved in a video conference, the person who is speaking is the one whose video appears to other conferees. The speaker's video shows the previous speaker. This changes dynamically as the speaker changes.

### **Creating a multi-party video conference**

All multimedia conferences must be controlled by a voice phone. Multimedia conferees may be added by calling the voice phone or by having the voice phone make a multimedia call to other DVC endpoints. The controller can then conference together individual parties to create a multimedia conference.

To set up a multimedia conference:

1. Determine who is going to be the conference controller.

## 11 Multimedia

### Basic Mode MM complex

Page 11-66

2. At the appointed time, the conference controller calls his or her telephone from the multimedia endpoint by dialing the 1-number extension. Once this call is established, the controller conferences in other calls as if this were a voice conference. The controller continues to add conferees in this manner until all conferees have joined, or until the number of conferees reaches the administered limit.
3. The conference controller may also add voice or multimedia parties to the conference spontaneously. The controller hits CONFERENCE, makes a voice or multimedia call to a new party. To make a multimedia call, the controller must originate a call using the mm-call button or FAC or the mm-multinbr button or FAC. After the new party begins alerting, the controller may hit CONFERENCE to add the party to the existing conference on hold.

**Coverage.** Multimedia calls to a Basic mode complex are subject to the same coverage criteria as voice calls and follow the coverage path administered for the voice station of the Basic multimedia mode complex.

If a plain voice station or a Basic mode complex is the covering party, the answering voice station will receive audio only. If all voice stations in the coverage path have the station form Early Answer field set to **n** and the originator of the multimedia call was not a local Enhanced mode complex, the answering station will hear hourglass tone.

If an Enhanced mode complex is the covering party, the answering voice station will receive voice and video. If all voice stations in the coverage path have the station form Early Answer field set to **n** and the originator of the multimedia call was not a local Enhanced mode complex, the answering station will hear hourglass tone.

**Coverage: Multimedia calls and off-net call coverage.** If the principal station's coverage path include a remote coverage point, the multimedia call will cover off-switch as voice only. If the call is unanswered off-switch and proceeds to the next coverage point on-switch, the multimedia nature of the call is preserved.

**Coverage: Multimedia calls and coverage to voice mail.** Voice mail systems such as AUDIX are typically the last point in a coverage path and are usually implemented as a hunt group. In order to guarantee that the originator of an H.320 multimedia call hears the voice mail greeting, the hunt group that defines the list of voice mail ports should have the Early Answer field on the hunt group set to **y**. This field will have no effect on voice calls to the voice mail system.

**Call Detail Recording.** Each channel of a 2-channel call generates a separate CDR record.

### Data Collaboration

Once you have established a multi-point video conference, multi-point T.120 data collaboration may be enabled for that call. This will allow all video parties on the current conference to collaborate.

## 11 Multimedia

### Basic Mode MM complex

Page 11-67

T.120 Data conferencing is made possible through the Expansion Services Module (ESM) which is an adjunct to the DEFINITY ECS. Up to six parties may participate in a single data conference, and up to 24 parties may use ESM facilities for data collaboration at any given time.

#### Adding data sharing to a video conference

1. Set up a multimedia conference.
2. Once a multimedia call is active, any voice station in the conference, can initiate data collaboration by pressing the mm-datacnf button. Or, to use the feature access code to initiate a data conference, press the Transfer button. A second line-appearance becomes active and you hear dial tone. Dial the multimedia data conference feature access code. Confirmation tone is heard and the system automatically reselects the held call appearance of the multimedia conference. The DEFINITY ECS will select a data rate which is acceptable to all H.320 DVC systems in the current call.

If the system does not have sufficient ESM resources available for all parties currently in the call, activation of T.120 data sharing will be denied. The mm-datacnf status lamp will flash denial or the mm-datacnf FAC will produce reorder.

3. Each H.320 DVC system in the conference call is joined to the data conference. On many DVC systems, the provided GUI may prompt the user with a dialog box, requesting the user to select a specific conference to join. With DEFINITY MMCH, there should only be one conference available to select.
4. The user must now use the PC's GUI to begin application sharing. The method for beginning application sharing or file transfer is different for each H.320 multimedia application. One of the H.320 DVC systems activates data sharing from the H.320 DVC vendor provided GUI. See your H.320 DVC system documentation for details.
5. The same H.320 DVC system as in step 4, opens an application, whiteboard, etc. to share and the image of the application is displayed on all H.320 DVC systems in the conference.

For details on how multiple users may control the shared application, see the vendor provided documentation for your specific H.320 DVC system.

6. To end the data collaboration session and retain the voice/video conference, **the station that selected the mm-datacnf button or FAC may press the mm-datacnf button or hit transfer and dial the mm-datacnf deactivation FAC.**

#### NOTE:

As of this writing, many endpoints do not respond correctly to ending the data collaboration session and retaining voice/video. Some H.320 DVC systems drop the entire call. It is recommended that once T.120 data sharing has been enabled for a conference, that it remain active for the duration of the conference call. When all

endpoints have dropped from the call, the T.120 resources will be released.

**Joining a multimedia conference after T.120 data sharing has been enabled.**

If a multimedia conference with T.120 data sharing is already active and it is desired to conference in a new video endpoint, the new video endpoint can be conferenced into the existing call. The new endpoint will be allowed into the data conference if there exists sufficient ESM resources for the new endpoint. The new endpoint will get voice/video and data sharing if the new endpoint supports the MLP data rate chosen by the system when T.120 data collaboration was activated. If the endpoint does not support the pre-existing MLP data rate, the new endpoint will only receive voice and video.

**Single switch data collaboration.** When all parties involved in data collaboration conference are located on the same physical DEFINITY ECS, there is no restriction on the type of user. The parties may be any combination of Enhanced multimedia complexes, Basic multimedia complexes or stand-alone H.320 DVC systems.

**Multi- switch data collaboration.** When all parties involved in data collaboration conference are **not** located on the same physical DEFINITY ECS, the parties located on the DEFINITY ECS hosting the data conference (i.e. the switch that activated mm-datacnf) may be any combination of Enhanced multimedia complexes, Basic multimedia complexes or stand-alone H.320 DVC systems. All parties on remote switches must not be Enhanced multimedia complexes: they must be Basic multimedia complexes or stand-alone H.320 DVC systems. Prior to originating or receiving a multimedia mode call, the mm-basic feature button or feature access code can be used to dynamically change an Enhanced mode complex into a Basic mode complex and back again.

**Forwarding of voice/multimedia calls.** In Basic mode you can forward calls from either the voice terminal or the multimedia endpoint. To forward a call from the multimedia endpoint:

1. At the PC's multimedia application, enter the call-forwarding feature access code (FAC)
2. Enter the forward-to number in the dialed number field on the endpoint software
3. Click the Dial button (or equivalent)

 **NOTE:**

The PC multimedia software will probably respond with a message that the call failed, since it does not recognize the FAC. In fact, DEFINITY ECS *does* receive the message, and forwards all multimedia calls addressed to the 1-number.

If a call is forwarded from the voice terminal, the call converts to voice first. If using the multimedia endpoint to forward, the calls arrive at the forwarded-to

## 11 Multimedia

### *Basic Mode MM complex*

Page 11-69

extension as a data call. Such calls continue to ring until answered or abandoned, rather than follow a coverage path.

Users can forward calls from the multimedia endpoint using the call forward FAC. You can also assign a call-forward button at the voice station to forward calls for the data endpoint. If a Basic multimedia complex has console permissions, that user can forward calls for others by dialing the FAC, the data extension, and then the forwarded-to number.

**Call Park.** A voice-terminal user can park any active call, voice or multimedia, and unpark the call from another telephone. Users cannot park or unpark calls using multimedia endpoints.

**Call Pickup.** Members of a pickup group can answer an H.320 call using a telephone after the call has been converted to voice. This is true for standard or directed call pickup.

**Consult.** After a call is converted to voice, consult may be used when transferring or conferencing the call.

**COR/COS.** The Class of Restriction and Class of Service for H.320 calls originated from a 1-number complex are the same as those of the telephone in the complex.

**Data Call Setup.** Basic complex multimedia endpoints are BRI data endpoints, and may use data call-setup procedures as provided by the software vendor.

**Data Hotline.** If endpoint software allows users to select the dial function without entering a number, the endpoint can be used for hotline dialing.

**Dial Access to Attendant.** Access to Attendant is blocked for a data call from a Basic mode multimedia endpoint.

**Data Trunk Groups.** Data trunk groups may be used to carry H.320 calls of a fixed (administered) bearer capability.

**Hold.** The voice station and multimedia endpoint of a Basic complex are each independent devices with respect to call control. When a Basic multimedia complex voice station executes hold only the voice station is held. If the user has conferenced their multimedia endpoint into a multimedia conference, activating hold will *not* disconnect the multimedia endpoint from the conference, it will only disconnect the Basic multimedia complex voice station. Executing hold with an Enhanced mode complex will fully disconnect voice and video from the current active call.

**Hunt Groups using Basic Mode complexes.** Since Basic mode complexes may receive point to point multimedia calls at the DVC system and voice calls to the station simultaneously, the voice station extension may be placed in any normal voice hunt group or ACD skill and the data extension may be placed in a simple hunt group made up of only data extensions.

## 11 Multimedia

### *Basic Mode MM complex*

Page 11-70

Basic mode complex data extensions or stand-alone data extensions may be used to create simple data hunt groups. Data extensions are not allowed in ACD hunt groups. It is recommended that you do not mix voice and data stations in a hunt group.

If you want multimedia calls to hunt to multimedia endpoints (i.e. 2B point to point data hunting), put the data extension in the hunt group. If you place the voice extension in a hunt group, only voice calls hunt to that extension. Multimedia calls to a hunt group with a Basic mode voice station as the hunt group member will *not* be offered to the DVC system of the Basic mode complex. If either the voice or data extension of a Basic mode complex is busy, the entire complex is considered busy for hunting purposes.

In order to guarantee that all members of a voice hunt group or skill can receive voice or multimedia calls, all members should have the H.320 field on the station form set to "y". Simple voice stations and Basic complex mode voice stations will receive voice only. Enhanced mode stations will receive voice and video.

The MM Early Answer field (on the Hunt Group form) tells the system to answer the incoming multimedia call and establish audio before it reaches the first member of the hunt group. Thus, when the talk path is established, the caller is able to speak with an agent immediately. This is not necessary for hunt groups comprised of data extensions.

**Hunting, Other considerations.** Agents that are part of a Basic mode complex may dial a feature access code to remove themselves from availability (and to indicate that they are available again) from both the multimedia endpoint and the telephone independently. This allows the voice member or the data member to be individually made unavailable. To make the data extension unavailable, the agent must dial the FAC from the DVC system.

CMS measurements may indicate unusually slow ASA, because of the time required for the system to establish early-answer before offering the call to an agent.

**Hunting Call association (routing).** Typically incoming voice calls consist of 2 B-channel calls to the same address, to provide greater bandwidth and better video resolution. DEFINITY ECS attempts to correctly pair up incoming calls and offer them as a unit to a single agent. MMCH uses call association to route both calls to the extension that answered the first call, regardless of how the call was routed internally.

Two 56K/64K data calls with the same calling party number to the same destination number are considered to be associated. The system makes every attempt to route both calls of a 2-channel call to the same answering party. If the first call terminates at a member of a hunt group, the second call does not have to hunt, but goes directly to the same member. In order for 2B multimedia calls to be correctly given to a single agent, incoming calls to the hunt group must have ANI information. The ANI information may be in the form of ISDN calling party number or DCS calling party number. Multimedia calls made on the same switch

## 11 Multimedia

### Basic Mode MM complex

Page 11-71

as the hunt group are easily associated. If multimedia calls into a hunt group have incorrect ANI information (i.e. all calls from switch X to switch Y include the LDN for switch X), then as the volume of calls increases, the number of mis-associated calls will increase. If multimedia calls into a hunt group have no ANI information, the switch will never associate pairs of calls and all calls will be treated independently and routed to separate agents. This is not a recommended configuration.

**Hunting with Multimedia vectors.** Very often, calls are routed to hunt groups or skills via a vector. The existing VDNs and vectors which exist for routing voice calls can be used to route multimedia calls.

In order to use a vector for multimedia calls that will terminate to voice stations, you must set the Multimedia field on the vector form to **y**. This field has no effect on voice calls routing through the vector. This field will cause multimedia calls routed through the vector to receive early answer treatment prior to processing the vector steps. This provides a talk path to the caller for announcements or immediate conversation with an agent.

#### NOTE:

Vectors which have the Multimedia field set to **y** must eventually route to hunt groups, skills or numbers which are voice extensions. A vector with the multimedia field set to **y** should never be set up to route to a hunt group or number which is a data extension.

When a vector is used to route video (56K/64K) calls to a hunt group comprised of data extensions, the vector *must* have the multimedia field set to **n**.

**Intercept Treatment.** H.320 calls that receive intercept treatment are treated like other data calls. H.320 calls cannot be directed to an attendant for service because the attendant cannot have H.320 conversion service.

**ISDN Trunk Groups.** Lucent Technologies highly recommends that you use ISDN trunks for multimedia calls. ISDN PRI trunks allow complete 1-number access for an Enhanced multimedia complex. ANI provided over PRI trunks allows correct routing of multiple bearer channels to the correct destination device. ISDN also provides the bearer capability on a call by call basis which can be used to distinguish voice calls from multimedia calls.

**Malicious Call Trace.** If a malicious call terminates at a Basic multimedia complex endpoint, the user can dial the feature access code from the telephone to activate malicious call trace, followed by the extension of the multimedia endpoint. If the user does not dial the multimedia extension, MCT traces any call held on the telephone.

**Message Waiting.** Message Waiting indication is handled at the telephone. Because H.320 calls are converted to voice before going to coverage, all messages are voice only.

## 11 Multimedia

### *Basic Mode MM complex*

Page 11-72

**Night Service.** Incoming Basic mode data calls follow established night-service processing for data calls.

**Remote Access.** The switch does not prevent Basic multimedia complexes from attempting to use remote access. However, these Basic mode endpoints will most likely not be able to dial the necessary codes.

**Station Hunting .** Basic mode data calls to endpoints that have an extension administered in the hunt-to-station field hunt based on established hunting criteria. The call is converted to voice before station hunting.

**Tenant Partitioning.** Permission to make multimedia calls or add parties of any type to a conference is subject to standard tenant-partitioning restrictions.

**Terminating Extension Groups.** Basic mode data calls to a TEG are converted to voice and can terminate only at a voice endpoint. Effectively, DEFINITY ECS treats the multimedia-complex extension as a voice-only endpoint.

**Telephone Display.** Display information for calls to or from a Basic multimedia complex contains the 1-number.

## Enhanced Mode MM complex

---

The Enhanced multimedia complex provides a much greater unified and integrated interface for control of voice and multimedia calls. The multifunction voice station is used to control all calls, whether voice or multimedia. The H.320 desktop video system is used to present the video stream, data stream and (optionally) audio stream to the user. The H.320 desktop video system is *not* used for call control. The Enhanced multimedia complex allows the multifunction voice station to handle voice or multimedia calls in an almost identical manner. Each call appearance on the voice station may represent a voice or multimedia call, allowing multiple voice or multimedia calls to be present simultaneously on the station. The user may manage the separate call appearances without regard to the voice or multimedia nature of the specific call. The standard HOLD/TRANSFER/CONFERENCE/DROP actions may be applied to any call without regard to the voice or multimedia nature of the call.

### 1-number access

1-number access permits originating users to make voice or multimedia calls to an Enhanced multimedia complex by dialing the same number for either type of call. The number may be the voice station extension or the data module extension. If the incoming call is a voice call, DEFINITY ECS alerts the station of an incoming voice call. If the incoming call is 56K or 64K data call, DEFINITY ECS recognizes it as a multimedia call and inserts resources to terminate the H.320 protocol and then alerts the voice station with a multimedia call.

Calls originating on the same switch as the Enhanced mode complex destination may always use 1-number access for voice or video. In order to take advantage of 1-number access for calls originating from a remote location, the incoming calls must arrive over ISDN-PRI trunks. If the system is setup with separate non-PRI digital facilities for data, multimedia calls must be made to the data extension of the Enhanced mode complex.

AVD (Alternate voice/data) trunk groups cannot be used to provide 1-number access with MMCH. If the AVD trunk group has a BCC of 0, all calls arriving over the AVD trunk to the Basic mode complex will be assumed to be voice calls. If the AVD trunk group has a BCC of 1 or 4, all calls arriving over the AVD trunk to the Basic mode complex will be assumed to be multimedia calls.

### ORIGINATION

The basic call sequence from an Enhanced mode complex is to originate a multimedia call and alert the destination. When the destination answers the call, the originating station's H.320 desktop video system will be alerted (that is, called by the switch to establish the service link). If the H.320 desktop video system is not configured for auto-answer, the user must answer the H.320 calls via the DVC GUI. If the H.320 DVC is configured for auto-answer, no action is needed via the DVC GUI. It is recommended, but not required, that Enhanced mode complexes place their desktop video system into an auto-answer mode of operation. If the far-end is providing a video signal, the 2-way video will be observed. If the

## 11 Multimedia

### *Enhanced Mode MM complex*

Page 11-74

destination is not providing a video signal (call was answered by a simple voice station), then loopback video will be provided at the Enhanced mode complex originator. The audio signal will exist at the handset of the voice station. The audio signal may be moved to the H.320 DVC system via activation of a mm-pcaudio button on the voice station. See the section below on mm-pcaudio.

**Hourglass tone.** The originating party may hear different things when the incoming multimedia call is answered depending on the nature of the answering party. If the call is being answered directly by an H.320 DVC system or if the answering party is an Enhanced mode complex on a remote switch, an immediate audio path will not exist between the two parties. This is because the H.320 protocol must be established after the call is answered. It takes several seconds for the H.320 protocol to establish an audio path. During this interval the originating party will hear special ringback. When the audio path exists the special ringback will be removed and replaced with a short incoming call tone indicating that audio path now exists. The combination of special ringback followed by incoming call tone is referred to as "hourglass tone." Hourglass tone is an indication to the originating party that they should wait for the H.320 call to establish audio.

#### **- originating voice calls**

Voice calls are originated from the voice station of an Enhanced mode complex in the normal manner as for any voice station.

#### **- originating multimedia calls**

Multimedia calls from an Enhanced multimedia complex are originated from the VOICE STATION, NOT the H.320 desktop video system. All multimedia originations require the user to indicate the multimedia nature of the call prior to providing any address digits. There are several different ways to originate a multimedia call from the voice station.

1. **mm-call (Multimedia Call) button.** If the station has an mm-call button administered, the user goes off-hook and selects the mm-call button. The user may select the mm-call button and then go off-hook. If the user has a speakerphone on the station, the user may originate the call simply by selecting the mm-call button. The speakerphone will automatically be placed off-hook and dialtone will be heard. Upon selection of the mm-call button, the mm-call status lamp (green led) will light steadily, indicating a multimedia call.

The user now dials the destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, station busy indicators, etc. Originating a multimedia call with the mm-call button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

For calls with a bandwidth of 2B, use of the mm-call button to originate will cause the same destination address to be used for both channels of the 2B call. See the section below on the mm-multinbr button/FAC for information on originating a 2B call where the destination has a different address for each B-channel.

 **NOTE:**

The mm-call feature button is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a multimedia call.

2. **Multimedia Call feature Access Code.** For stations that do not have an administered mm-call button, the Multimedia call feature access code may be used instead. The user goes off-hook on the station, waits for dialtone, then dials the MM-call FAC, receives dialtone again and then dials the call normally. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, station busy indicators, etc.

Originating a multimedia call with the mm-call button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

For calls with a bandwidth of 2B, use of the mm-call button to originate will cause the same destination address to be used for both channels of the 2B call. See the section below on the mm-multinbr button/FAC for information on originating a 2B call where the destination has a different address for each B-channel.

 **NOTE:**

The mm-call feature access code is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a multimedia call.

3. **mm-multinbr (Multimedia Multi-number) button.** The mm-multinbr button is similar to the mm-call button. It allows origination of a multimedia call from a voice station. It is used when the destination being dialed requires a different address for each of the 2 B-channels. An example of this is Central Office provided ISDN-BRI. This type of BRI line is provisioned with separate listed directory numbers for each B-channel. In order to make a 2B multimedia call to such a device, two sets of addresses must be entered.

The user goes off-hook and selects the mm-multinbr button. The user may select the mm-multinbr button and then go off-hook. If the user has a speakerphone on the station, the user may originate the call simply by selecting the mm-multinbr button. The speakerphone will automatically be placed off-hook and dialtone will be heard. Upon selection of the mm-multinbr button, the mm-multinbr and mm-call (if present) status lamp

## 11 Multimedia

### Enhanced Mode MM complex

Page 11-76

(green led) should become solid. The user now dials the first destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc. The system will provide dialtone after the first address has been completed. The user now dials the second destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc. After the 2nd address has been collected the mm-multinbr status lamp will go off.

Originating a multimedia call with the mm-multinbr button will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

#### NOTE:

The mm-multinbr feature button is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a dual address multimedia call.

4. **Multimedia Multi-number Call feature Access Code.** For stations that do not have an administered mm-multinbr button, the Multimedia Multi-number call feature access code may be used instead. It allows origination of a multimedia call from a voice station. It is used when the destination being dialed requires a different address for each of the 2 B-channels. An example of this is Central Office provided ISDN-BRI. This type of BRI line is provisioned with separate listed directory numbers for each B-channel. In order to make a 2B multimedia call to such a device, two sets of addresses must be entered.

The user goes off-hook and dials the MM-multinbr feature access code. Upon dialing of the MM-multinbr FAC, the mm-call (if present) status lamp (green led) should become solid. The user now dials the first destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc. The system will provide dialtone after the first address has been completed. The user now dials the second destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc.

Originating a multimedia call with the MM-multinbr FAC will originate a call according to the Default Multimedia Parameters selected on the System Parameters Features form. This default parameter will be either 2x56 or 2x64. The bearer capability of the multimedia calls will either be 56K or 64K and the bandwidth will be 2B channels.

#### NOTE:

The mm-multinbr FAC is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a dual address multimedia call.

11 Multimedia

Enhanced Mode MM complex

Page 11-77

5. **Multimedia parameter selection feature access code.** This FAC is used to originate a multimedia call that wishes to use a different bearer and bandwidth than the system default. For example, if the system has a default multimedia parameter of 2x64 and the user wishes to make a call to a destination that is known to only have 56K digital facilities, the MM parameter selection FAC can be used to select a bearer and bandwidth of 2x56 for this specific call.

The MM parameter selection FAC may be used in conjunction with the mm-multinbr button or FAC to make a single or dual address multimedia call at the desired bearer and bandwidth. The user goes off-hook and dials the MM-parameter selection feature access code. Dialtone is returned. The user enters a single digit, 1 or 2, where 1 = 2x64, 2 = 2x56. All other digits will produce reorder. Dialtone is returned. Upon dialing of the MM-parameter selection FAC, the mm-call (if present) status lamp (green led) should become solid. The user may indicate a dual-address call at this point with the mm-multinbr button or FAC. The user now dials one or two sets of destination address digits. The destination address may be provided by dialing digits, using abbreviated dial entries, last number dialed, etc.

**NOTE:**

The mm-parameter selection FAC is generally used by stations that are part of an Enhanced multimedia complex, but may be used by any station to originate a dual address multimedia call.

6. Dialing sequences that include TACs, AAR, ARS, Authorization codes, CDR account codes, FRLS
  1. Single address with TAC
    - **Dial** mm-call button or FAC, **Hear** dialtone
    - **Dial** TAC, **Dial** destination digits
  2. Dual address with TAC
    - **Dial** mm-multinbr button or FAC, **Hear** dialtone
    - **Dial** TAC, **Dial** 1st dest. digits, **Hear** dialtone
    - **Dial** TAC, **Dial** 2nd dest. digits
  3. Single address with AAR/ARS
    - **Dial** mm-call button or FAC, **Hear** dialtone
    - **Dial** AAR/ARS, **Dial** destination digits
  4. Dual address with AAR/ARS
    - **Dial** mm-multinbr button or FAC, **Hear** dialtone
    - **Dial** AAR/ARS, **Dial** 1st dest. digits, **Hear** dialtone
    - **Dial** AAR/ARS, **Dial** 2nd dest. digits
  5. Single address with AAR/ARS and authorization code

## 11 Multimedia

### Enhanced Mode MM complex

Page 11-78

- **Dial** mm-call button or FAC, **Hear** dialtone
  - **Dial** AAR/ARS FAC, **Dial** destination digits, **Hear** stutter dialtone
  - **Dial** authorization code
6. Dual address with AAR/ARS and authorization code
- **Dial** mm-multinbr button or FAC, **Hear** dialtone
  - **Dial** AAR/ARS, **Dial** 1st dest. digits, **Hear** dialtone
  - **Dial** AAR/ARS, **Dial** 2nd dest. digits, **Hear** stutter dialtone
  - **Dial** authorization code
7. Single address with TAC or AAR/ARS and CDR account code
- **Dial** mm-call button or FAC, **Hear** dialtone
  - **Dial** CDR FAC, **Hear** dialtone
  - **Dial** CDR account code, **Hear** dialtone
  - **Dial** TAC or AAR/ARS, **Dial** destination digits
8. Dual address with TAC or AAR/ARS and CDR account code
- **Dial** mm-multinbr button or FAC, **Hear** dialtone
  - **Dial** CDR FAC, **Hear** dialtone
  - **Dial** CDR account code, **Hear** dialtone
  - **Dial** TAC or AAR/ARS, **Dial** 1st dest. digits
  - **Dial** TAC or AAR/ARS, **Dial** 2nd dest. digits

### Answering

The user actions required to answer voice or multimedia calls at an Enhanced multimedia complex are identical if the H.320 DVC system is configured for auto-answer. If the H.320 DVC system is not configured for auto-answer an additional step is required. See answering multimedia calls below. It is recommended, but not required, that Enhanced mode complexes place their desktop video system into an auto-answer mode of operation.

### Answering voice calls

Incoming voice calls will alert at the voice station of the Enhanced multimedia complex in the normal manner. Standard alerting and call appearance flashing will occur. They are answered in the normal manner by selecting the alerting call appearance and going off-hook on the voice station.

### Answering multimedia calls

Incoming multimedia calls will alert at the voice station of the Enhanced multimedia complex in the same manner as voice calls with one addition. If the alerting station has an administered mm-call button and the alerting call

## 11 Multimedia

### *Enhanced Mode MM complex*

Page 11-79

appearance is the selected call appearance (i.e. the red led is lit, on the alerting call appearance), then the mm-call button status lamp will go on indicating that the call on the selected call appearance is a multimedia call.

The incoming multimedia call is answered in the normal manner by selecting the alerting call appearance and going off-hook on the voice station. If the H.320 DVC system for the answering party is configured for auto-answer, no other action is needed to complete the multimedia call. If the H.320 DVC system for the answering party is not configured for auto-answer, the H.320 DVC system will alert and must also be answered by the user. It is recommended, but not required, that Enhanced mode complexes place their desktop video system into an auto-answer mode of operation.

If the originating party is providing a video signal, then a complete 2-way multimedia call will exist. If the originating party is not providing a video signal, the answering party will receive loopback video. The audio signal will exist at the handset of the voice station. The audio signal may be moved to the H.320 DVC system via activation of a mm-pcaudio button on the voice station. (See the section below on mm-pcaudio [11-83](#), [11-52](#).)

**Hourglass Tone.** The answering party may hear different things when the incoming multimedia call is answered depending on the nature of the originator. If the origination is directly from an H.320 DVC system or if the originator is an Enhanced mode complex on a remote switch, an immediate audio path will not exist between the two parties. This is because the H.320 protocol must be established after the call is answered. It takes several seconds for the H.320 protocol to establish an audio path. During this interval the answering party will hear special ringback. When the audio path exists the special ringback will be removed and replaced with a short "incoming call tone" indicating that audio now exists. The combination of special ringback followed by incoming call tone is referred to as "hourglass tone." Hourglass tone is an indication to the answering party that they should wait for the H.320 call to establish audio.

**Early Answer.** The answering party may administer their station in such a way as to avoid hearing hourglass tone. If the station form has set the Early Answer field to **y**, then the system will answer the incoming multimedia call on behalf of the station and proceed to establish the H.320 protocol. After audio path has been established, the call will then alert at the voice station of the Enhanced mode complex destination. The station may then answer by going off-hook and will have immediate audio path. No hourglass tone will be heard by the answering party.

### **- multiple call appearance operation**

With an Enhanced mode complex all calls to or from the complex are controlled via the voice station. Each voice or multimedia call has its own call appearance which may be selected without regard for the nature of the call using the specific call appearance. This allows a multifunction station to control multiple voice or multimedia calls in exactly the same way they would control multiple voice calls.

## 11 Multimedia

### Enhanced Mode MM complex

Page 11-80

As an example, a user may originate a simple voice call on the first call appearance. A multimedia call may then arrive on the second call appearance. The user activates HOLD on the first call appearance and selects the second call appearance to answer the multimedia call. The user may then activate HOLD on the second call appearance and reselect the first call appearance or select a third call appearance and originate another call.

### - creating a multi-party video conference

An Enhanced multimedia complex can create a spontaneous video conference in the same way that a spontaneous voice conference is created. Given an active call, the user activates the CONFERENCE button. This puts the current call on HOLD and activates a new call appearance. The user makes a multimedia call according to the instructions for originating a multimedia call and then selects CONFERENCE to combine or merge the two call appearances. This results in a 3-way conference.

If all three parties are video equipped, then a 3-way video conference results. Conference members see the current speaker on video. The current speaker sees the last speaker on video. If one of the parties is not video equipped, then a 3-way audio conference exists and the two video equipped parties have 2-way video. The CONFERENCE action may be repeated until 6 parties have been conferenced together. The 6 parties may be any mix of voice or video, local or remote parties.

The following steps create a multi-party voice/video conference:

1. Enhanced mode complex station A originates a multimedia call to, or receives a multimedia call from, party B. Station A and party B have 2-way voice and video.
2. Station A, activates CONFERENCE.
3. Station A originates a multimedia call (i.e. uses the mm-call button/FAC/etc.) and dials the party to be added, Enhanced multimedia complex C.
4. Party C, answers the call from station A.
5. Station A selects CONFERENCE to complete the 3-way conference. Parties A,B and C will be in a 3-way voice/video conference.

### NOTE:

If party C is another Enhanced mode complex on the same switch as station A, station A does not need to indicate a multimedia call prior to dialing the new party in step 3. While A consults with C, the call will be audio only. When A completes the conference in step 5, party C's video will be activated.

A multi-party video conference uses voice activated switching to determine which parties are seen. The current speaker is seen by all other parties. The current speaker sees the previous speaker.

Additional voice or video parties may be added by repeating these steps.

### Data Collaboration

Once you have established a multi-point video conference, multi-point T.120 data collaboration may be enabled for that call. This will allow all video parties on the current conference to collaborate.

T.120 Data conferencing is made possible through the Expansion Services Module (ESM) which is an adjunct to the DEFINITY ECS. Up to six parties may participate in a single data conference, and up to 24 parties may use ESM facilities for data collaboration at any given time.

The following steps add data sharing to a video conference:

1. Set up a multimedia conference.
2. Once a multimedia call is active, any member can initiate data collaboration by pressing the mm-datacnf button. Or, to use the feature access code to initiate a data conference, press the Transfer button. A second line-appearance becomes active and you hear dial tone. Dial the multimedia data conference feature access code. Confirmation tone is heard and the system automatically reselects the held call appearance of the multimedia conference. The DEFINITY ECS will select an MLP data rate which is acceptable to all H.320 DVC systems in the current call.

If the system does not have sufficient ESM resources available for all parties currently in the call, activation of T.120 data sharing will be denied. The mm-datacnf status lamp will flash denial or the mm-datacnf FAC will produce reorder.

3. Each H.320 DVC system in the conference call is joined to the data conference. On many DVC systems, the provided GUI may prompt the user with a dialog box, requesting the user to select a specific conference to join. With DEFINITY MMCH, there should only be one conference available to select.
4. The user must now use the PC's GUI to begin application sharing. The method for beginning application sharing or file transfer is different for each H.320 multimedia application. One of the H.320 DVC systems activates data sharing from the H.320 DVC vendor provided GUI. See your H.320 DVC system documentation for details.
5. The same H.320 DVC system as in step 4, opens an application, whiteboard, etc. to share and the image of the application is displayed on all H.320 DVC systems in the conference.

For details on how multiple users may control the shared application, see the vendor provided documentation for your specific H.320 DVC system.

6. To end the data collaboration session and retain the voice/video conference, the station that selected the mm-datacnf button or FAC may press the mm-datacnf button or hit transfer and dial the mm-datacnf deactivation FAC.

**NOTE:**

Currently, many endpoints do not respond correctly to ending the data collaboration session and retaining voice/video. Some H.320 DVC systems drop the entire call. It is recommended that once T.120 data sharing has been enabled for a conference, that it remain active for the duration of the conference call. When all endpoints have dropped from the call, the T.120 resources will be released.

**Joining a multimedia conference after T.120 data sharing has been enabled.**

If a multimedia conference with T.120 data sharing is already active and it is desired to conference in a new video endpoint, the new video endpoint can be conferenced into the existing call. The new endpoint will be allowed into the data conference if there exists sufficient ESM resources for the new endpoint. The new endpoint will get voice/video and data sharing if the new endpoint supports the data rate chosen by the system when T.120 data collaboration was activated. If the endpoint does not support the pre-existing data rate, the new endpoint will only receive voice and video.

**Activating HOLD while on a T.120 data collaboration conference.**

If an Enhanced multimedia complex is active on a multimedia call and the call has activated T.120 data collaboration, the user should be receiving voice/video and data. If the station places this existing call on hold, audio and video will be disconnected for the current call. The data collaboration portion of the call will remain intact and unaffected. While this T.120 data conference is on hold, the user will only be allowed to receive audio on all other call appearances. Thus a user is limited to one call appearance that has T.120 data collaboration active.

**Single switch data collaboration.** When all parties involved in data collaboration conference are located on the same physical DEFINITY ECS, there is no restriction on the type of user. The parties may be any combination of Enhanced multimedia complexes, Basic multimedia complexes or stand-alone H.320 DVC systems.

**Multi- switch data collaboration.** When all parties involved in data collaboration conference are *not* located on the same physical DEFINITY ECS, the parties located on the DEFINITY ECS hosting the data conference (i.e. the switch that activated mm-datacnf) may be any combination of Enhanced multimedia complexes, Basic multimedia complexes or stand-alone H.320 DVC systems.

**NOTE:**

All parties on remote switches must not be Enhanced multimedia complexes. They must be Basic multimedia complexes or stand-alone H.320 DVC systems.

Prior to originating or receiving a multimedia mode call, the mm-basic feature button or feature access code can be used to dynamically change an Enhanced mode complex into a Basic mode complex and back again.

## Voice station audio vs. H.320 DVC system audio

When an Enhanced mode complex originates or receives a voice or multimedia call, the call is originated with the station handset or answered with the station handset. The audio path will be through the handset. If the user's H.320 DVC system has speakers and a microphone, the user may wish to use the H.320 DVC system for audio in much the same manner as a built-in or separate telephone speakerphone. The user can move the station's audio to the H.320 DVC system by selecting an mm-pcaudio feature button on the voice station. There is no feature access code for this function.

The mm-pcaudio feature button works very much like a speakerphone on/off button. If the station is off-hook and selects mm-pcaudio, audio is directed to the PC DVC system. The switch-hook may be placed on-hook. If the handset is taken off-hook, the audio moves back to the handset. If the mm-pcaudio button is selected while audio is already on the DVC system and the handset is on-hook, this acts as a speakerphone off action and disconnects the current call.

The mm-pcaudio feature button may be used for voice as well as multimedia calls. If the mm-pcaudio feature button is selected while on a voice only call, the DVC system is alerted and brought into the call. No video will be transmitted or displayed. Audio will be directed through the PC DVC system.

## Switching between Basic and Enhanced modes

There may exist occasions when an Enhanced mode complex needs to switch to Basic mode operation temporarily. One example is when a user wishes to make a direct point to point multimedia call originated directly from the H.320 DVC. Basic mode operation allows this functionality at the expense of losing multimedia call handling capabilities (i.e. hold/xfer/conf). To switch from Enhanced mode to Basic mode, the station may either select a mm-basic feature button or dial the mm-basic feature access code. Both of these actions are valid only if the Enhanced mode station has no multimedia calls active.

When in Basic mode, the status lamp for the mm-basic button, if present, will be on solid. The mm-basic feature button acts as a toggle. If the status lamp is on, when the button is selected, the lamp will go off and the station will return to Enhanced mode. The mm-enhanced feature access code will set the state of the station back to Enhanced. Switching to Enhanced mode is only valid if the associated H.320 DVC system is idle.

### NOTE:

Toggling between Basic and Enhanced mode changes the station's administered Multimedia mode. When in Basic mode this field on the station form will show *basic*. When in Enhanced mode this field on the station form will show *enhanced*. The current station Multimedia mode will be saved to translation when a **save translation** command is executed.

## 11 Multimedia

*Enhanced Mode MM complex*

Page 11-84

### Forwarding of voice and multimedia calls

The Enhanced multimedia mode complex voice station may use the existing standard call forwarding mechanisms to activate forwarding for voice calls. If the forwarding destination is on the same switch then this will also forward multimedia calls as multimedia calls to the destination. If the forwarding destination is off switch, multimedia calls will forward off switch as voice only calls. This is appropriate when the user will be at a location that is not able to receive multimedia calls.

To forward multimedia calls off switch as multimedia calls, the user must activate multimedia call forwarding. This may be done with an mm-cfwd button or feature access code. The user may also activate standard voice call forwarding and select the mm-call button prior to entering the forwarding address.

### Coverage

Multimedia calls to an Enhanced mode complex are subject to the same coverage criteria as voice calls and follow the coverage path administered for the voice station of the Enhanced multimedia mode complex.

If a plain voice station or a Basic mode complex is the covering party, the answering voice station will receive audio only. If all voice stations in the coverage path have the station form Early Answer field set to **n** and the originator of the multimedia call was not a local Enhanced mode complex, the answering station will hear hourglass tone.

If an Enhanced mode complex is the covering party, the answering voice station will receive voice and video. If all voice stations in the coverage path have the station form Early Answer field set to **n** and the originator of the multimedia call was not a local Enhanced mode complex, the answering station will hear hourglass tone.

**Multimedia calls and off-net call coverage.** If the principal station's coverage path include a remote coverage point, the multimedia call will cover off-switch as voice only. If the call is unanswered off-switch and proceeds to the next coverage point on-switch, the multimedia nature of the call is preserved.

**Multimedia calls and coverage to voice mail.** Voice mail systems such as AUDIX are typically the last point in a coverage path and are usually implemented as a hunt group. In order to guarantee that the originator of an H.320 multimedia call hears the voice mail greeting, the hunt group that defines the list of voice mail ports should have the Early Answer field on the hunt group set to **y**. This field will have no effect on voice calls to the voice mail system.

### Hunt Groups using Enhanced Mode Complexes

When creating hunt groups with Enhanced multimedia mode complexes, only the station extension should ever be entered as a hunt group member. Any hunt group or ACD skill can include the voice station of an Enhanced multimedia complex as a member. The data extension of an Enhanced mode complex

## 11 Multimedia

### *Enhanced Mode MM complex*

Page 11-85

should never be entered as any hunt group member. A hunt group or skill may have a mix of members that are stand-alone stations and Enhanced mode complex stations. In order to guarantee that all members of the hunt group or skill can receive voice or multimedia calls, all members should have the H.320 field on the station form set to **y**. Simple voice stations will receive voice only. Enhanced mode stations will receive voice and video.

The MM Early Answer field (on the Hunt Group form) tells the system to answer an incoming multimedia call and establish audio before it reaches the first member of the hunt group. Thus, when the talk path is established, the caller is able to speak with an agent immediately.

**Other considerations.** CMS measurements may indicate unusually slow ASA, because of the time required for the system to establish early-answer before offering the call to an agent.

**Call association (routing).** Typically incoming voice calls consist of 2 B-channel calls to the same address, to provide greater bandwidth and better video resolution. DEFINITY ECS attempts to correctly pair up incoming calls and offer them as a unit to a single agent. MMCH uses call association to route both calls to the extension that answered the first call, regardless of how the call was routed internally.

Two 56K/64K data calls with the same calling party number to the same destination number are considered to be associated. The system makes every attempt to route both calls of a 2-channel call to the same answering party. If the first call terminates at a member of a hunt group, the second call does not have to hunt, but goes directly to the same member.

In order for 2B multimedia calls to be correctly given to a single agent, incoming calls to the hunt group must have ANI information. The ANI information may be in the form of ISDN calling party number or DCS calling party number. Multimedia calls made on the same switch as the hunt group are easily associated. If multimedia calls into a hunt group have insufficient ANI information (i.e. all calls from switch X to switch Y include the LDN for switch X), then as the volume of calls increases the number of mis-associated calls will increase. If multimedia calls into a hunt group have no ANI information, the switch will never associate pairs of calls and all calls will be treated independently and routed to separate agents. This is not a recommended configuration.

**Multimedia vectors.** Very often, calls are routed to hunt groups or skills via a vector. The existing VDNs and vectors which exist for routing voice calls can be used to route multimedia calls.

In order to use a vector for multimedia calls, you must set the Multimedia field on the vector form to **y**. This field has no effect on voice calls routing through the vector. This field will cause multimedia calls routed through the vector to receive early answer treatment prior to processing the vector steps. This provides a talk path to the caller for announcements or immediate conversation with an agent.

 NOTE:

Vectors which have the Multimedia field set must eventually route to hunt groups, skills or numbers which are voice extensions. A vector with the multimedia field set to y should never be set up to route to a hunt group or number which is a data extension.

## Interactions

Interactions are listed here only if the operation is different from standard.

- Administered Connections

An Enhanced multimedia complex voice station may serve as the origination point or destination of an administered connection. If the Multimedia call feature access code is included in the administration of the administered connection, this will result in a video AC.

An Enhanced multimedia complex H.320 DVC system may not serve as the origination point of an administered connection.

- Administration without Hardware

You cannot use AWOH to administer a data module or the data endpoint in a multimedia complex. However, you can use AWOH to administer the telephone.

- Bridged Appearances

Enhanced multimedia complex voice station users can bridge onto a call if the user has a bridged appearance. If the bridged appearance is for a multimedia call, selecting the bridged appearance will result in a multimedia call.

- Call Detail Recording

Each channel of a 2-channel multimedia call generates a separate CDR record that is tagged as data.

- Call Park

Any station can park a multimedia call, and unpark the call from another telephone. If a multimedia call is unparked by an Enhanced mode complex station, a multimedia call will result. Users cannot park or unpark calls using multimedia endpoints.

- Call Pickup

Any member of a pickup group can answer a multimedia call after the call has begun alerting at a station call appearance. If the station picking up the call is an Enhanced mode complex station and the call is multimedia, a multimedia call will result. This is true for standard or directed call pickup.

- Consult

After a multimedia call has been answered, consult may be used when transferring or conferencing the call.

## 11 Multimedia

### *Enhanced Mode MM complex*

Page 11-87

- **COR/COS**

The Class of Restriction and Class of Service for a multimedia call originated from an Enhanced multimedia complex are those of the voice station in the complex.

- **Data Call Setup**

An Enhanced mode multimedia H.320 DVC system may not originate calls from the DVC system. All calls, both voice or video are originated from the voice station.

- **Data Hotline**

An Enhanced multimedia complex H.320 DVC endpoint may not be used to originate a call for hotline dialing. In order to setup a video hotline function with an Enhanced mode complex, the hotline number administered for the voice station should include the Multimedia call feature access code.

- **Data Trunk Groups**

Data trunk groups may be used to carry H.320 calls of a fixed (administered) bearer capability.

- **ISDN Trunk Groups**

Lucent Technologies highly recommends that you use ISDN trunks for multimedia calls. ISDN PRI trunks allow complete 1-number access for an Enhanced multimedia complex. ANI provided over PRI trunks allows correct routing of multiple bearer channels to the correct destination device. ISDN also provides the bearer capability on a call by call basis that can be used to distinguish voice calls from multimedia calls.

- **Night Service**

Incoming H.320 calls follow established night-service processing for data calls.

- **Remote Access**

The switch does not prevent Enhanced multimedia complexes from attempting to use remote access. However, these endpoints will most likely not be able to dial the necessary codes.

- **Station Hunting**

Multimedia calls to Enhanced mode complex voice stations that have an extension administered in the hunt-to-station field hunt based on established hunting criteria. If the hunt-to-station is also an Enhanced mode complex station, a multimedia call will result when the call is answered.

- **Terminating Extension Groups**

A multimedia call to a TEG may be answered by any member of the TEG. If the member answering the call is an Enhanced mode complex station, a multimedia call will result.

11 Multimedia

Enhanced Mode MM complex

Page 11-88

- Telephone Display

Display information for calls to or from an Enhanced multimedia complex contains the display information associated with the voice station.

## Troubleshooting

If one channel of a 2 B-channel call goes down, your choices are to continue with reduced transmission quality, or to hang up the call and start over. It is not possible to re-establish the second channel while the call is still active.

If you cannot share data with others, it may be that both parties do not have the same endpoint software. This is true for some data collaboration, but most whiteboard and file transfer software implementations are compatible.

## Monitoring MMCH

This section briefly discusses some of the commands you can use to monitor multimedia complexes and conferences. *DEFINITY Enterprise Communications Server Release 6 — Maintenance for R6vs/si* and *DEFINITY Enterprise Communications Server Release 6 — Maintenance for R6r* discuss these commands and their output in detail.

| Action  | Objects   | Qualifier  |
|---------|---|--|

### Screen 11-30. Status Station 1002 — General Status Form

The following fields specific to multimedia appear on the status station, attendant, data module and trunk screens.

- **MM Conference ID** — This field appears only if the station is active on a multimedia conference. It displays the ID for the conference. Enter this number with the status conference command to get more information about this conference.
- **MM Endpoint ID** — This field appears only if the station is active on a multimedia conference. It displays the endpoint ID for the station. Enter this number with the status conference endpoint command to learn more about this endpoint's involvement in the conference.

## List commands

The **list multimedia endpoints** command shows you all the multimedia data modules that exist in your system, and their associated telephones, if any. The **list multimedia H.320-stations** command shows you all the stations that are administered for H.320 conversion.

**List measurements commands**

---

Several reports are available to help you determine the amount of traffic your switch carries for multimedia conferences and conversion calls. All reports show traffic over multimedia circuit packs housed within the same switch, although not necessarily in the same port network. You can use these reports to determine if you have adequate resources to handle the multimedia traffic on your system.

**NOTE:**

Point-to-point multimedia calls between Basic mode or standalone multimedia endpoints do not use MMIs or VCs, and therefore do not count in these measurements.

The following reports are available:

- MMI Hourly and Summary
- ESM-MMI Hourly and Summary
- VC Hourly and Summary

The Hourly and Summary reports provide the same types of information. The hourly report shows measurements for the last 24 hours, whereas the summary reports show measurements for one hour, according to the type of summary you request.

**Table 11-3. MMI Summary Report**

| Field                  | Description   |
|------------------------|---|
| Switch Name            | The name of the switch that contains the MMIs.  |
| Date                   | The date and time that you requested the report, or that the report was run, if scheduled.  |
| Peak Hour For All MMIs | If you use the yesterday-peak or today-peak qualifiers, this field displays the hour of greatest usage for the specified day.   |
| Meas Hour              | The hour for which these measurements apply, on the 24-hour clock.  |
| Avail Ports            | Total network MMI ports in the system. This does not include any MMIs that are cabled to an ESM. ESM-MMIs are measured separately.  |
| Avail Usage            | Total time that is available in the system for network MMI ports, in CCS units.   |
| Total Usage            | The total time, in CCS units, that MMI ports are in use on a call. Includes the time that the ports are out of service or maintenance busy. Usage is measured from the time the port is allocated until it is released.   |
| Total Alloc            | The total number of times that an MMI port was allocated to a call. Keep in mind that a 2-channel call occupies 2 ports, so this number does not necessarily reflect the number of calls that took place. Also, point-to-point calls do not use MMI resources, so these allocations are for conversion calls of multimedia conferences. |
| MMI Denials            | Total number of times an MMI port was needed but could not be allocated because all ports were busy. Ideally, this number should be zero. If you see denials on a regular basis, you should consider adding MMIs to your system.  |
| Out of Srv - CCS       | The total time, in CCS units, that any MMI ports were out of service during any part of the measured interval.  |
| % APB                  | Percent All Ports Busy. The percentage of time during the measured interval that all MMI ports are unavailable to carry a new call.   |
| % Blockage             | The percentage of attempted allocations of MMI ports that are not successful. This value is calculated as % blockage = (MMI Denials / Total Alloc + MMI Denials) * 100  |

**Table 11-5. VC Summary**

| Field                | Description  |
|----------------------|--|
| Switch Name          | The name of the switch that contains the VCs.  |
| Date                 | The date and time that you requested the report, or that the report was run, if scheduled.   |
| Peak Hour For All VC | If you use the yesterday-peak or today-peak qualifiers, this field displays the hour of greatest usage for the specified day.  |
| Meas Hour            | The hour for which these measurements apply, on the 24-hour clock.   |
| # Prt                | Total number of VC ports in the system.  |
| Usage - Avail        | Total time, in CCS, that all VC ports are available in the system. Calculated as #MMI ports x 36.  |
| Usage - H320         | Total time that VC ports are allocated to H320 endpoints.  |
| Usage - Voice        | Total time VC ports are allocated to voice endpoints.  |
| Usage -Total         | Total time, in CCS units, that VC ports are unavailable to carry a new call. This includes time that the ports are busy on a call, out of service or maintenance busy. Measured from the time that the port is allocated until it is released. |
| Allocation s - Total | Total number of times a VC port was allocated to a call. Each B-channel used on a multimedia call counts as one allocation.  |
| Denials-H320         | Number of times a port was needed for an H320 call, but was not available.   |
| Denials -voice       | Number of times a port was needed for a voice call, but was not available.   |
| Denials-To tal       | Total number of times a VC port was needed for any call, but was not allocated because all VC ports were busy.   |

*Continued on next page*

**Table 11-5. VC Summary**

| Field                 | Description  |
|-----------------------|--|
| Out Srv               | The total time, in CCS units, that any MMI ports were out of service during any part of the measured interval.   |
| %APB (all ports busy) | The percentage of time during the measured interval that all MMI ports are unavailable to carry a new call.  |
| % Blockage            | The percentage of attempted allocations of MMI ports that are not successful. This value is calculated as % blockage = (MMI Denials / Total Alloc + MMI Denials) * 100 |

## Considerations

Each channel of a 2-channel BRI call takes one port on an MMI circuit pack. This alone limits the number of multimedia calls your system can handle. In addition, each conference takes one port on a voice-conditioner circuit pack.

Also, there is a limit to the number of conversion calls that the system can handle simultaneously. If you experience traffic problems after installing multimedia, you may want to lower the number of stations that use H.320 conversion.

## References

---

Other information about MMCH is available in the following books:

*DEFINITY ECS Release 6 — Overview* contains a high-level description of the MMCH feature.

*DEFINITY ECS Release 6 — Installation for Adjuncts and Peripherals* describes how to install necessary circuit packs, and how to set up endpoint hardware and software.

*DEFINITY ECS Release 6 — Maintenance*

*DEFINITY ECS Release 6 — System Description Pocket Reference* describes the hardware components that are required for MMCH.

## ATM-PNC

---

Port network connectivity (PNC) enables you to connect the processor port network (PPN) to each of the expansion port networks (EPNs). The ATM-PNC feature uses an asynchronous transfer mode (ATM) switch to perform the function of the center-stage switch between the PPN and EPNs.

---

---

**Figure 12-1. ATM-PNC Hardware Configuration**

### How to Administer ATM-PNC

---

The initial administration of an ATM-PNC system is performed by service technicians at installation. See *Installation for Adjuncts and Peripherals* for details. For a description of maintenance procedures including troubleshooting for ATM-PNC, see *Maintenance for R6r*, 555-230-126, Issue 3.

## Centralized Attendant Service

## Detailed description

Each branch in a CAS has its own LDN or other type of access from the public network. Incoming trunk calls to the branch, as well as attendant-seeking voice terminal calls, route to the centralized attendants over release link trunks (RLT).

The CAS attendants are at the main location. The main location can be a DEFINITY ECS, a DEFINITY System Generic 1 or 3, a DEFINITY System Generic 2.1, a System 85, a DIMENSION PBX, or a System 75 (V3).

The CAS main switch operates independently of the CAS branch switches. Operation for CAS main-switch traffic is identical to operation of a stand-alone switch.

Each branch in a CAS network connects to the main by way of RLTs. These trunks provide paths for:

- Sending incoming attendant-seeking trunk calls at the branch to the main for processing and extending them back to the branch (both parts of a call use the same trunk)
- Returning timed-out waiting and held calls from the branch to the main
- Routing calls from the branch to the main

Two queues are associated with CAS calls: one at the main and one at the branch. If idle RLTs are available from the branch to the main, RLTs are seized and CAS calls are queued at the main along with other attendant-seeking calls. If all RLTs are in use, CAS calls to the attendant are queued at the branch in a RLT queue. The length of the queue can vary from 1 to 100, as set during administration of the RLT group.

Backup service provides for all CAS calls can be sent to a backup extension in the branch if all RLTs are maintenance-busy or out of service, or if the attendant presses a Backup button that is not lighted.

- To activate the feature and provide notification that backup service is in effect, assign the backup extension to a Backup button and associated status lamp.
- The status lamp remains lighted as long as backup service is in effect.
- To deactivate the feature, the attendant presses the Backup button while the status lamp is lighted. Calls are not sent to the backup extension unless all RLTs are maintenance-busy or out of service.

The attendant can put a CAS call from a branch on Remote Hold. The branch holds the call and drops the RLT. After a time-out (same as the timed reminder for an attendant-held call), the branch automatically attempts to route the call back to the attendant. The returning call can queue for the RLT. Attendants should use Remote Hold when they have to put a call on hold to keep RLTs from being tied up unnecessarily.

## Branch-generated call-identification tones

The branch in a CAS network generates call-identification tones and transmits them to the CAS attendant by way of the RLT. These tones indicate the type of call coming from the branch or the status of a call extended to or held at the branch. The attendant hears these tones in the console handset before being connected to the caller. The tones may vary by country.

- Incoming trunk call: 480 Hz (100 ms), 440 Hz (100 ms), 480 Hz (100 ms) in sequence; heard immediately after attendant lifts handset
- Call from branch terminal to attendant or transferred by branch terminal to attendant: 440 Hz (100 ms), silence (100 ms), 440 Hz (100 ms) in sequence; heard immediately after attendant lifts handset
- Call extended to idle station or recall on does not answer ringback tone (300 ms) followed by connection to normal ringing cycle
- Call extended to busy terminal — automatically waiting or recall on attendant call waiting: 440 Hz (100 ms)
- Call extended to busy terminal — waiting denied or not provided: busy tone
- Remote hold or remote hold recall: a series of four to six cycles of 440 Hz (50 ms), silence (50 ms)
- Recall on does not answer: burst of ringback (300 ms), then connection to normal ringback at any point in its cycle
- Recall from a call on remote hold: a series of four to six cycles of 440 Hz (50 ms), silence (50 ms)
- Recall from a call waiting at a single-line terminal: burst of 440 Hz (100ms)

The centralized attendant at the main has access, through RLTs, to all outgoing trunk facilities at the branches in a CAS network. The attendant can extend an incoming LDN call to an outgoing trunk at a branch by dialing the access code and allowing the caller to dial the rest of the number or by dialing the complete outgoing number.

Calls extended to busy single-line voice terminals at the branch wait automatically. If there is a call in queue, the user hears a busy signal. When station hunting and send all calls is administered, the call routes along the administered path. Not answering any waiting extended call within an administered interval causes the branch switch to return the call to the attendant. Call Waiting does not apply to multiappearance terminals; if no appearances are available, busy tone is sent to the attendant, who tells the caller that the line is busy.

Calls from voice terminals at the branch to an attendant also route over RLTs seized by the branch switch. A branch caller reaches the attendant by dialing the attendant-group access code. The access code is administrable; the default is 0. The conversation between the branch caller and the attendant ties up the seized RLT, but calls of this type are usually short.

## Considerations

---

- CAS reduces the number of attendants required at a branch. For example, a chain of department stores can have a centralized attendant location at the main store to handle calls for the branch stores.
- In a CAS network, DEFINITY switches can function as branches or as the main. A branch can connect to only one main.
- A branch can have an attendant. Access to the branch attendant must be by way of an individual attendant extension. Incoming trunk calls in a CAS network can bypass branch attendants but can be routed back to them by the centralized attendant.
- Branch calls terminate on the CAS main switch based on the incoming RLT trunk-group day-destination or night-service destination. An attendant console is not always answering or extending incoming CAS calls. If someone other than an attendant answers a CAS call, that person can extend the call back to the branch by pressing the FLASH button on a multiappearance voice terminal or flashing the switchhook on a single-line voice terminal. The branch reaction to Flash Signals and the branch application of tones is the same whether an attendant or someone other than an attendant answers or extends the call.
- If an extended call returns to the main attendant unanswered, the called party at the branch does not drop but continues to be alerted until the caller releases. This allows the attendant to talk to the caller, then extend the call again, if the caller wishes, without redialing the number.
- If an extended CAS call recall times out and goes to coverage but no one answers, then the branch leaves the extended-to party ringing and drops coverage.
- When an analog-station call goes to coverage, the station drops from the call. This is the exception to the branch leaving the extended-to party ringing. If the main attendant extends a call to an analog station and that call goes to coverage and later returns to the main attendant, the call is treated as an incoming LDN call and the attendant must re-extend the call, if requested by the user.
- On an incoming CAS call to the main attendant, the Name field from the trunk-group form for that RLT displays to the attendant. Therefore, you should administer the field to provide meaningful branch identification information.
- Music-on-Hold feature at branch applies to two stages of LDN calls: during call extension and Remote Hold.

## Interactions

---

- Abbreviated Dialing

## 12 Private Networking

### Centralized Attendant Service

Page 12-8

The main attendant can use an Abbreviated Dialing button to extend CAS calls after obtaining branch dial tone.

- Attendant Auto-Manual Splitting

The SPLIT lamp and button do not function on CAS main calls extended via the RLT trunk. Attendant conference does not function on CAS calls.

- Attendant Control of Trunk-Group Access

If a branch attendant has control of an outgoing RLT trunk group, new attendant-seeking calls route to the branch attendant.

- Attendant Override of Diversion

Use Attendant Override of Diversion with CAS.

- Attendant Serial Calling

Attendant Serial Calling does not work for CAS calls.

- Automatic Alternate Routing and Automatic Route Selection

CAS calls can be routed using AAR and ARS.

- Busy-Indicator Buttons

Busy indicators can identify incoming calls over an RLT. You can also use Busy indicators to dial after the attendant starts to extend a call.

- Call Coverage

Redirect calls to a centralized attendant by Call Coverage. Do not redirect calls to a CAS backup extension for backup service via Send All Calls to the backup extension's coverage path.

- Call Detail Recording

If the CAS main RLT trunk has the CDR option selected, CDR records generate for incoming CAS calls.

- Call Forwarding

Do not forward calls to a CAS extension.

- Call Park

If a CAS attendant parks a call and the call returns to the attendant after the Call Park expiration interval, the attendant hears incoming trunk-call notification.

- DCS Operation

If an RLT trunk group is administered as a DCS trunk, the following interaction applies: On an incoming CAS call to the attendant, the DCS message displays instead of the name of the incoming RLT trunk group. Upon answering the call, the attendant hears call-identification tones, indicating that the call is a CAS call. Use a TRUNK-NAME button to obtain the name of the RLT trunk group.

- DXS and DTGS Buttons

## 12 Private Networking

### Centralized Attendant Service

Page 12-9

DXS and DTGS buttons at the main attendant console can be used with CAS. However, with DXS buttons, it takes a few seconds before the attendant hears ringback tone.

- Emergency Access to the Attendant

CAS Branch Emergency Access calls generated by a Feature Access Code route Off-Hook Alert to the branch attendant group. If there is no attendant in the branch, the call routes to the branch's administered Emergency Access Redirection Extension. When the branch switch is in CAS Backup Service, the calls route to the backup station and the call is treated as a normal call.

- Hunt Groups

If an incoming CAS call directs to a hunt group, the call does not redirect to the hunt group's coverage path. Depending on the circumstances, the attendant can get a busy tone or ringing.

- Last Number Dialed

An attendant cannot extend calls using Last Number Dialed.

- Leave Word Calling

If a message is left for a branch user and the attendant at the CAS switch tries to retrieve the message by using LWC message retrieval, permission is denied.

- Night Service — Night Console Service

When the CAS main enters night service, CAS calls terminate at the CAS main night-service destination. When the branch enters Night Service, CAS calls route to the branch night console, the LDN night station, or the TAAS.

- Night Service — Trunk Answer from Any Station

In a multiswitch DCS environment with CAS, the result of transferring incoming trunk calls via Night Service Extension or Trunk Answer from Any Station varies depending on the home switch of the transferred-to station, the home switch of the connected trunk, and the type of night-service function chosen (Night Service Extension, Trunk Answer From Any Station, or both).

- Nonattendant Console Handling of CAS Calls

The CAS branch calls terminate at the CAS main based on the incoming RLT trunk-group day destination or night-service destination. You can also answer a CAS call by the Trunk Answer Any Station feature.

Normally, a nonattendant extends a CAS call by pressing the Flash button. However, if the nonattendant does not have a Flash button, extend the call as follows:

## 12 Private Networking

### Centralized Attendant Service

Page 12-10

- Multiappearance voice-terminal users press the Conference or Transfer button and then dial the desired extension. To complete the call, the user drops the call. To drop the extended-to party, the user presses the Conference or Transfer button again.
- Single-line voice-terminal users flash the switchhook and then dial the extension. To complete the call, the user drops the call. To drop the extended-to party, the user flashes the switchhook again.
- **Non-Attendant Console Holds Call**

A multifunction nonattendant can hold a CAS call by pressing the hold button.
- **Nonattendant Console Releases Call**

A nonattendant can drop the RLT by going on-hook, using the DISCONNECT or DROP button, or selecting another call appearance.
- **Nonattendant — Display Trunk Name**

If the nonattendant with a display presses the TRUNK-NAME button while active on a trunk call, the switch displays *Name* from the trunk-group form.
- **Timed Reminder**

The timer value for recalling held calls at the attendant console that can be set on the console form.

If an attendant at the CAS main transfers a call from a branch to an extension at the main, the timed reminder does not apply and the call does not return to the attendant if unanswered. If a branch call is unanswered, the branch timed reminder times out and the call routes to a new RLT trunk and back to a CAS main attendant.
- **Trunk-Name Button**

Use the trunk-name button when an outgoing call is made over a trunk administered to have no outgoing display.

## Distributed Communications System

---

Distributed Communications System (DCS) allows you to configure 2 or more switches as if they were a single, large DEFINITY ECS. DCS provides attendant and voice-terminal features between these switch locations. DCS simplifies dialing procedures and allows transparent use of some of the DEFINITY ECS features. (Feature transparency means that features are available to all users on DCS regardless of the switch location.)

Configuring a DCS network is a complex process that involves 4 major steps:

- Planning your DCS network
- Connecting the physical equipment in the network
- Administering the physical layer (hardware connections)
- Administering the link layer to create a DCS

### How to administer DCS

---

To administer your DCS, complete the following steps:

1. Connect the switches using the necessary circuit packs, data modules, and boards, and trunks.

For more information about what hardware you need for your physical DCS network and how to connect the network, see *DEFINITY Enterprise Communications Server Release 6 Terminals and Adjuncts Reference*.

2. Administer any packet gateway (pgate) boards, processor data modules (PDM), X.25 data modules, processor interface data modules, and trunks you have in the DCS network.

**NOTE:**

Trunk group member numbers and trunk group numbers must match on both ends of each connection.

For information about administering this equipment, see the following sections in this book.

| Form   | Page                  |
|--|-----------------------|
| DS1 Circuit Pack   | <a href="#">7-79</a>  |
| Trunk Groups   | <a href="#">7-115</a> |
| Data Modules   | <a href="#">6-226</a> |
| X.25 (R5r and later configurations only)                 | <a href="#">6-249</a> |
| Processor Interface (R5si and later configurations only) | <a href="#">6-246</a> |
| Netcon (R5si and later configurations only)              | <a href="#">6-245</a> |
| Processor (if both R5si and R5r in the DCS)              | <a href="#">6-243</a> |
| Packet Gateway Board (R5r and later configurations only) | <a href="#">5-246</a> |

- Plan and implement a Dial Plan and Uniform Dial Plan for each switch in the DCS network.

For more information about administering the dial plans, see [“Dial Plan” on page 4-311](#) and [“Uniform Dial Plan” on page 12-103](#).

Plan your network so you can easily expand and administer the dial plan table. All nodes within the DCS network must be assigned compatible but different dial plans. It is recommended that:

- All feature access codes be identical
- Design routing patterns consistently at each node to make outward dialing transparent

Use the Uniform Dial Plan (UDP) to assign extensions. The UDP design has to be coordinated among the switches in the DCS network to obtain a common 4- or 5-digit dial plan. For example, if you have three switches (nodes) in your DCS network, plan to use unique groups of extensions for each switch (such as, 4xxx on one switch, 5xxx on the second switch, and 6xxx on the third switch).

 **NOTE:**

Be sure to record the value in `Local PBX ID` for each switch. You need to use this ID to identify the node number on the Route Pattern form.

The Local PBX ID is the value assigned to the nearest switch (node). For example, if switch A is connected to B, the Local PBX ID at A identifies the node number for B. Similarly, you can find the node number for A, by looking for the Local PBX ID on B (be sure to look at the connection to A, if it has more than one connection).

4. Complete a route pattern for each ultimate destination in the network.

For example, if you have four switches in your DCS — switches A, B, C, and D — you need route patterns for each of the following connections:

|        |        |        |        |
|--------|--------|--------|--------|
| A to B | A to C | A to D | B to C |
| B to D | C to D | B to A | C to A |
| D to A | C to B | D to B | D to C |

5. Administer the following forms to configure the links in the DCS:

**NOTE:**

Complete the Administered Connections form if you use a PDM and you set the Destination (or Destination Number for R5r and later configurations) to external on the Interface Links form.

**Required forms**

| Form            | Field   | Page                  |
|-----------------|---|-----------------------|
| Interface Links | ■ Enable  | <a href="#">5-179</a> |
|                 | ■ X.25 Connection<br>(R5r and later configurations)       |                       |
|                 | ■ Destination Number<br>(R5r and later configurations)    |                       |
|                 | ■ Establish Connection<br>(R5r and later configurations)  |                       |
|                 | ■ Connected Data Module<br>(R5r and later configurations) |                       |
|                 | ■ Est Conn<br>(R5si and later configurations)             |                       |
|                 | ■ PI Ext<br>(R5si and later configurations)               |                       |
|                 | ■ Prot<br>(R5si and later configurations)                 |                       |
|                 | ■ Destination<br>(R5si and later configurations)          |                       |
|                 | ■ DCE/DTE<br>(R5si and later configurations)              |                       |

### Required forms

| Form                         | Field   | Page   |
|------------------------------|---|--|
| Administered Connection      | ■ Connection Number                                     | <a href="#">5-17</a>                                     |
|                              | ■ Originator  |  |
|                              | ■ Destination   |  |
|                              | ■ Name  |  |
|                              | ■ Retry Interval  |  |
|                              | ■ Auto Restoration?                                     |  |
| Processor Channel Assignment | ■ All Proc Chan fields that you want to be assigned DCS | <a href="#">5-248</a><br>(R5r and later configurations)  |
|                              |   | <a href="#">5-252</a><br>(R5si and later configurations) |

- Complete the Processor Channel Assignment form on each switch to establish dialogs from the switch to other nodes on the network.

This step involves extensive planning as you must map each link, channel, and remote port throughout the network.

- Administer the Hop Channels.

For more information, see [“Hop Channel Assignments Form” on page 12-116](#).

- If you are using ISDN, administer the gateway functions.

For more information, see [“ISDN TSC Gateway Channel Assignments” on page 7-98](#).

### Detailed description of DCS

DCS network configurations can be:

- Traditional DCS network — A DCS network configured with 2 or more switches using BX.25 signaling for transporting DCS feature transparency information.
- D-channel DCS network (private network only) — A DCS network that includes DEFINITY ECS using the ISDN-PRI D-channel DCS transparency information (D-channel signaling). ISDN-PRI facilities with this type of network use only private-line facilities.
- D-channel DCS network (public network access/egress) — A DCS network that includes DEFINITY ECS using D-channel signaling. At least one of these ISDN-PRI facilities uses a public network ISDN-PRI.

## **12 Private Networking**

### *Distributed Communications System*

*Page 12-15*

- Integrated DCS network (private network only) — A DCS network that contains a variety of switches using BX.25 or D-channel signaling methods. At least one DEFINITY ECS serves as an ISDN-PRI DCS Gateway node. This node can interwork DCS transparency information between a BX.25 connection and one of the ISDN-PRI user-to-user signaling methods over the D-channel.  
  
An ISDN-PRI DCS Gateway node provides backward compatibility to existing traditional DCS networks.
- Integrated DCS network (public network access) — The same as D-channel DCS Network (Private Network Only), but the D-channel of at least one ISDN- PRI facility uses a public network ISDN-PRI.

Once you have connected and set up your DCS network, you can provide the following features across the network:

- DCS Alphanumeric Display for Terminals
- DCS Attendant Control of Trunk Group Access
- DCS Attendant Direct Trunk Group Selection
- DCS Attendant Display
- DCS Automatic Callback
- DCS Automatic Circuit Assurance
- DCS Busy Verification of Terminals and Trunks
- DCS Call Coverage
- DCS Call Forwarding
- DCS Call Waiting
- DCS Distinctive Ringing
- DCS Leave Word Calling
- DCS Multiappearance Conference/ Transfer
- DCS Over ISDN-PRI D-channel
- DCS Trunk Group Busy/Warning Indication
- DCS with Rerouting
- Enhanced DCS

### **DCS/AUDIX gateway**

DEFINITY ECS can serve as an interface between PBXs that support the D-channel signaling feature and those that do not support this feature. The switch providing this interface is known as the ISDN-DCS Gateway node and provides backward compatibility to existing traditional DCS networks.

It maintains a mapping between processor channels and Administered NCA-TSCs. When a DCS D-channel message arrives on an Administered NCA-TSC acting as a gateway, it is converted to a traditional DCS message and sent out through the processor channel that has been administered to map to this Administered NCA-TSC. Likewise, when a traditional DCS message arrives at the gateway node on a processor channel acting as a gateway, it is converted to a DCS D-channel message and sent out through the Administered NCA-TSC that has been associated with this processor channel on the ISDN Gateway Channel form.

In summary, a gateway is required whenever a transition is being made from BX.25 signaling to D-channel signaling. When the transition takes place at a switch that sits between that part of the network that supports D-channel DCS and that part that does not, that switch is an ISDN-DCS Gateway. A DCS network consisting entirely of switches that support D-channel DCS never requires an ISDN-DCS Gateway because none of the switches require "translation" to/from BX.25.

## Example DCS configurations

The following two examples provide details for setting up two basic DCS networks. The first is a two-node network and the second is a three-node network.

### 2-Node private network with AUDIX

[Figure 12-2](#) shows a 2-node DCS/AUDIX D-channel network. In this configuration, DCS feature transparency is achieved exclusively through the exchange of user-to-user information on the D-channel using one of the three methods discussed earlier — MA-UUI, CA-TSCs or NCA-TSCs. Although NCA-TSCs are nothing more than virtual connections on the D-channel, they are shown as independent entities in the diagram for the purposes of clarity. Administered TSC 2/1 (that is, the first Administered NCA-TSC of signaling group 2) of Switch A is connected to TSC 4/1 of Switch B. This virtual connection is used in the exchange of user-to-user information for DCS features not associated with any current B-channel connection.

Notice that for AUDIX, a BX.25 data link is no longer required between the host switch and the remote switch(es). AUDIX messages between the AUDIX and the remote switch will use the AUDIX Gateway functionality of the host switch and will be transported to the remote switch via an NCA-TSC. Specifically, AUDIX messages destined for Switch B will arrive at Switch A on Link 1, Channel 2 (processor channel 57), be converted to ISDN-PRI Q.931 format and sent out via Administered NCA-TSC 2/2.

This is accomplished by administering processor channel 57 as a gateway and mapping it on the gateway form to Administered NCA-TSC 2 of signaling group 2 that is also administered as a gateway.

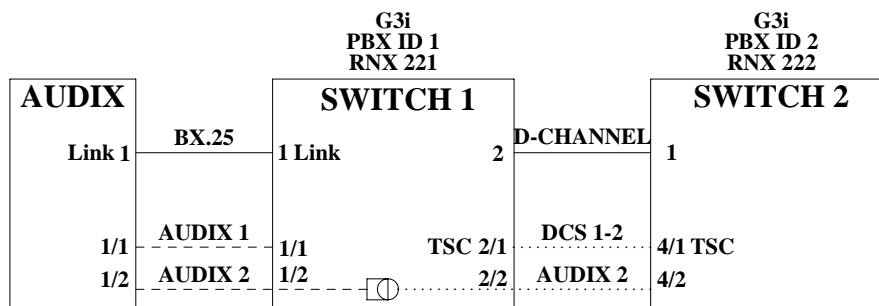

Figure 12-2. 2-Node private network

The following tables show you how you would complete each of the necessary forms.

### AUDIX administration

- AUDIX Translations for,

| Switch Number | AUDIX Port | Switch Port <sup>1</sup> | Logical Channel | Data Link |
|---------------|------------|--------------------------|-----------------|-----------|
| 1             | 1          | 59                       | 1               | 1         |
| 2             | 2          | 57                       | 2               | 1         |

1. Switch Port refers to the processor channel that is used for AUDIX in the PBX.

### Administration for switch 1

- Dial Plan form

| Start Dig. | Len | Usage |
|------------|-----|-------|
| 4          | 4   | ext   |

### 3-Node public/private network with AUDIX

The D-channel signaling feature expands the domain of DCS networks by supporting configurations that include public network ISDN facilities utilizing network services including Software Defined Network (SDN). By eliminating the need for dedicated private line facilities, this feature allows geographically dispersed DCS networks to be cost effective. [Figure 12-3](#) shows a 3-node network.

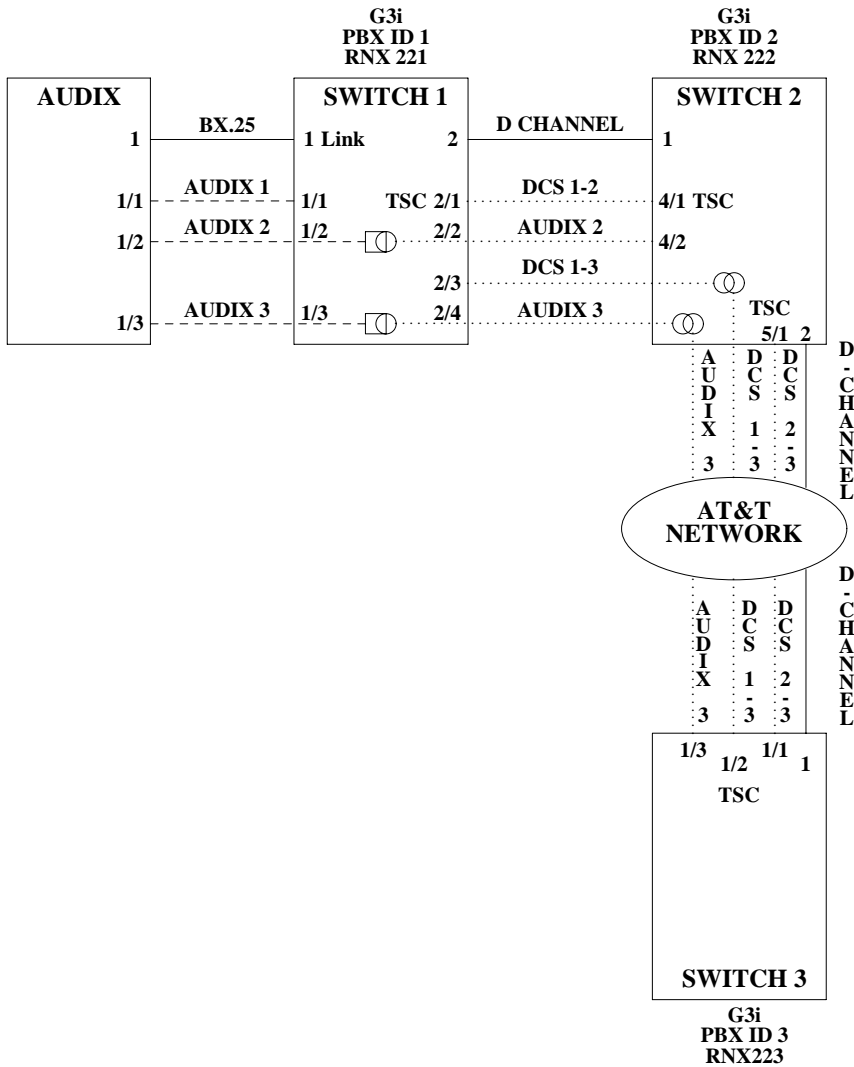

Figure 12-3. 3-Node public/private network

The following tables show you how you would complete each of the necessary forms.

### AUDIX administration

- AUDIX Translations form

| Switch Number | AUDIX Port | Switch Port <sup>1</sup> | Logical Channel | Data Link |
|---------------|------------|--------------------------|-----------------|-----------|
| 1             | 1          | 59                       | 1               | 1         |
| 2             | 2          | 57                       | 2               | 1         |
| 3             | 3          | 58                       | 3               | 1         |

- 
1. Switch Port refers to the processor channel that is used for AUDIX in the PBX.

1. Should be blank if SDN network routing requires 7 digits.

**Interactions**

---

See the specific DCS features for interactions with each DCS feature.

## DCS Alphanumeric Display for Terminals

---

DCS Alphanumeric Display for Terminals allows calls to or from alphanumeric-display terminals to have transparency for call-related data.

The transparency allows calling-name display, called-name display, and miscellaneous identifiers to be transferred from a terminal on one node to a terminal on another node.

The following DCS configurations provide transparency of alphanumeric displays.

- Networks of 2 or more DEFINITY ECS
- Networks of 2 or more DEFINITY switches: (Generic 1 or Generic 3i) with a System 75 Version 3 or later, Generic 2, System 85 Release 2 Version 2 or later, or a Generic 2.1 as an intermediate node
- A DEFINITY system Generic 1 connected to a System 85 Release 2 Version 2 or later, or a Generic 2 or later.

### How to administer DCS Alphanumeric Display for Terminals

---

#### Required forms

| Form                       | Field            | Page                  |
|----------------------------|------------------|-----------------------|
| Trunk Group - Tie (DCS TG) | Outgoing Display | <a href="#">7-262</a> |

## DCS Attendant Control of Trunk Group Access

---

DCS Attendant Control of Trunk Group Access allows an attendant at any node in the DCS to control an outgoing trunk group at an adjacent node in the cluster.

To use this feature, you must have a DCS Trunk Group between the local and remote switches, and the trunks in that trunk group cannot insert digits on incoming calls. If you need digit insertion on these trunks, it should be added on the outgoing trunk based on the dialed string.

 **NOTE:**

DCS Attendant Control of Trunk Group Access is not available if you are using D-channel DCS.

### How to administer DCS Attendant Control of Trunk Group Access

---

---

## DCS Attendant Direct Trunk Group Selection

---

DCS Attendant Direct Trunk Group Selection allows attendants at one node to have direct access to an idle outgoing trunk at a different node in the DCS. This feature functions the same as regular Direct Trunk Group Selection, except attendants can access trunk groups at remote nodes.

### NOTE:

DCS Attendant Direct Trunk Group Selection is not available if you are using D-channel DCS.

To use this feature, you must have a DCS Trunk Group between the local and remote switches, and the trunks in that trunk group cannot insert digits on incoming calls. If you need digit insertion on these trunks, it should be added on the outgoing trunk based on the dialed digits.

You can assign a Trunk Hundreds Select button to access a trunk group at the local node or a trunk group at a remote node. A Trunk Group Select button assigned to access a remote node is referred to as a remote Trunk Hundreds Select button. Pressing a remote Trunk Group Select button is the same as dialing the tie trunk group access code for the remote node and the trunk access code of the selected trunk.

Each attendant console has 12 Trunk Hundreds Select buttons for Attendant Direct Trunk Group selection. Each button allows the attendant to directly access an outgoing trunk group by pressing the button assigned to that trunk group. Each button's Busy lamp lights when all trunks in its associated trunk group are busy. On a basic console, 6 of these buttons have 2 additional lamps for Attendant Control of Trunk Group Access. On an enhanced console, all 12 buttons have the additional lamps. The two additional lamps are:

- Warn (warning) lamp  
Lights when a preset number of trunks are busy in the associated trunk group.
- Cont (control) lamp  
Lights when the attendant activates Attendant Control of Trunk Group Access for the associated trunk group.

Users can activate attendant control of a remote trunk group in the DCS network by pressing the Cont button followed by the desired Remote Trunk Hundreds Select button. The initiating node sends a message to the remote node where the trunk group to be controlled resides to indicate that control of that trunk group was initiated.

When the remote node receives the activation message from the initiating node, it has 4 seconds to reply back to the initiating node whether control of the remote trunk group can be activated. If control of the remote trunk group can be

12 Private Networking

DCS Attendant Direct Trunk Group Selection

activated, a confirmation message is sent to the initiating node and the Cont lamp lights at the remote node. An error message is sent to the attendant at the initiating node if the trunk access code is invalid or if the trunk group is already controlled. An error message is also sent if the remote node is a System 85 or Enhanced DIMENSION PBX and the attendant does not have a Trunk Hundreds Select button with Cont lamp for that trunk group.

When a trunk group is controlled in a DCS environment, calls to the trunk group by anyone other than an attendant route to the local attendant at the node where the trunk group resides. If that node does not have an attendant, the call routes to a CAS main attendant or an attendant for Inter-PBX Attendant Calls. However, if CAS or Inter-PBX Attendant Calls is not provided, the party attempting to call on the controlled trunk receives intercept tone.

## How to administer DCS Attendant Direct Trunk Group Selection

---

---

## DCS Attendant Display

---

The DCS Attendant Display provides transparency for displaying call-related information.

Calls to and from DEFINITY ECS in a DCS environment have calling-party ID and called-party ID transparency when:

- The other party is at another Generic 1, Generic 3, or System 75, and the intermediate node is a Generic 1, Generic 2, Generic 3, System 75 Version 3 or later, or a System 85 Release 2 Version 2 or later.
- The other party is at a System 85 Release 2 Version 2 or later, or a DEFINITY system Generic 2 or later.
- The call is not routed through an intermediate System 85 Release 2 Version 1 or Enhanced DIMENSION PBX node. (These calls display only the extension of the calling party or called party.)

### How to administer DCS Attendant Display

---

#### Required forms

---

| Form              | Field                               | Page                 |
|-------------------|-------------------------------------|----------------------|
| Attendant Console | ■ Display Module Button Assignments | <a href="#">5-35</a> |
|                   | ■ Display Language                  |                      |

---

You administer DCS Attendant Display the same as you do Attendant Display. See [“Attendant Display” on page 4-74](#) for more information.

## DCS Automatic Callback

---

DCS Automatic Callback allows a user at one node to make an automatic callback call to a user at another node in the DCS.

A DCS Automatic Callback call can be initiated from a terminal at one node to a terminal at another node in the same way as if at a local node under the following conditions.

- If the called party is at a System 85, Generic 2, or Enhanced DIMENSION PBX node, the callback call can only be activated if the called node is returning busy tone or special audible ringback.
- If the called party is at a Generic 3, Generic 1 or System 75 node, the callback call can be activated if the called node is returning busy tone, Call Waiting ringback tone, or ringback tone.
- The calling party must disconnect within 6 seconds after hearing the confirmation tone for Automatic Callback activation.

Automatic Callback uses the following rules when the callback call is made to a user at another node:

- When the calling party answers the callback call, and no tie trunk to the called-party's node is available, Automatic Callback is reactivated toward the called party. The calling party hears confirmation tone instead of ringback when this occurs.
- If the calling party is on a System 85, Generic 2, or Enhanced DIMENSION PBX node and is unable to receive the callback call (for example, a busy single-line voice terminal without Call Waiting), Automatic Callback is reactivated by the calling party's node. If the calling party is on a Generic 3, Generic 1, or System 75 node and is unable to receive the callback call, the callback call is canceled.
- If the called party is unable to receive the callback call because they are busy again (for example, the called party goes on hook and then off hook immediately to place another call), the calling party hears busy tone again and can choose to reactivate Auto Callback, if desired.

## How to administer DCS Automatic Callback

### Required forms

| Form                              | Field  | Page                  |
|-----------------------------------|--|-----------------------|
| Feature-Related System Parameters | ■ Automatic Callback — No Answer Timeout Interval                    | <a href="#">5-123</a> |
| Feature Access Code (FAC)         | ■ Automatic Callback Activation<br>■ Automatic Callback Deactivation | <a href="#">5-113</a> |
| Station (multiappearance)         | ■ Button/Feature Button Assignments — auto-cback                     | <a href="#">6-14</a>  |
| Class of Service                  | ■ Automatic Callback (0–15)  | <a href="#">5-81</a>  |

You administer DCS Automatic Callback the same as you do Automatic Callback. See [“Automatic Callback” on page 4-100](#) for more information.

## DCS Automatic Circuit Assurance

---

DCS Automatic Circuit Assurance (ACA) allows a voice-terminal user or attendant at a node to activate and deactivate ACA referral calls for the entire DCS network. This transparency allows the referral calls to originate at a node other than the node that detects the problem.

If referral calls are generated at a node for one or more remote nodes, the remote nodes are notified when ACA referral is activated or deactivated. If referral calls are generated at a remote node for a DEFINITY ECS node, the DEFINITY ECS node is notified when ACA referral is activated or deactivated at the remote node. The lamp associated with the ACA button lights when ACA referral is activated and goes dark when ACA referral is deactivated. The ACA button serves no other purpose when a remote node generates the DEFINITY ECS referral calls.

### How to administer DCS ACA

---

#### Required forms

---

| Form                              | Field  | Page                  |

## DCS Busy Verification of Terminals and Trunks

---

DCS Busy Verification of Terminals and Trunks allows attendants and multiappearance voice-terminal users to make test calls to voice terminals and trunk groups that are located at other nodes in the DCS.

To use this feature, you must have a DCS Trunk Group between the local and remote switches, and the trunks in that trunk group cannot insert digits on incoming calls. If you need digit insertion on these trunks, it should be added on the outgoing trunk based on the dialed digits.

Attendants and voice-terminal users can busy-verify voice terminals at a remote location by pressing Verify and dialing the UDP extension. Verification continues as if the voice terminal is on the same node.

Multiappearance voice terminal users can busy-verify an adjunct at a remote location by pressing Verify and dialing the TAC of the tie trunk group to the remote node. Then they must press Verify a second time and dial the desired TAC and the trunk group member number to be verified. Verification of the trunk then continues as if the trunk is on the same node.

### How to administer DCS Busy Verification of Terminals and Trunks

---

#### Required forms

---

| Form                          | Field   | Page                 |
|-------------------------------|---|----------------------|
| Attendant Console             | Feature Button Assignments<br>— verify        | <a href="#">5-35</a> |
| Station<br>(multi-appearance) | Button/Feature Button Assignments<br>— verify | <a href="#">6-14</a> |

You administer DCS Busy Verification of Terminals and Trunks the same as you do Busy Verification of Terminals and Trunks. See [“Busy Verification of Terminals and Trunks” on page 4-130](#) for more information.

## DCS Call Coverage

---

DCS Call Coverage provides DCS messaging required for calls to be covered on remote systems when there is a DCS signaling link (BX.25 or ISDN-PRI) for the trunk groups. Calls to an extension on one system are covered by extensions on remote systems that are administered as coverage points.

### How to administer DCS Call Coverage

---

#### Required forms

---

| Form                                 | Field | Page                  |
|--------------------------------------|-------|-----------------------|
| All forms required for DCS           | All   | <a href="#">12-11</a> |
| All forms required for Call Coverage | All   | <a href="#">4-146</a> |

To administer DCS Call Coverage, you must have DCS software and UDP or PNA software. DCS Call Coverage must be enabled on all systems having principals or coverage points and on all intervening systems.

### Detailed description of DCS Call Coverage

---

DCS Call Coverage is similar to Call Coverage, with the following exceptions:

- Coverage Answer Groups across nodes are not supported.
- Under some conditions, a call follows the coverage point's coverage path. (See ["Operation Under Error Conditions" on page 12-40](#) for more information.)
- Under some conditions, Consult does not work properly. (See ["Operation Under Error Conditions" on page 12-40](#) for more information.)
- Displays differ in some cases. (See ["How to administer DCS Alphanumeric Display for Terminals" on page 12-27](#) for more details.)
- DCS Call Coverage does not support Coverage Call Back from a remote node.
- DCS Call Coverage supports Consult.

#### NOTE:

In releases prior to DEFINITY ECS and G3V4, DCS Call Coverage was limited to coverage of a single point and that point had to be an AUDIX, AUDIX DEFINITY, or INTUITY.

## DCS Call Coverage applications

Without DCS Call Coverage, the following coverage cannot be achieved:

- You spend time in multiple locations and want calls to Station B to be covered first by Station A and then by AUDIX, DEFINITY AUDIX, or INTUITY.
- You move from location A to location B and want calls to Station A to be covered first at Station B, then at AUDIX.
- You are normally located at Station B, but want calls to first be answered by an administrative assistant at Station A, and then by the AUDIX at location B.

See [Figure 12-4](#) for an example of a DCS Call Coverage configuration.

| 3. Station A                 |                                     |

Figure 12-4. Configuration for DCS Call Coverage

## DCS Call Coverage Operation

DCS Call Coverage allows calls to cover to points other than AUDIX on a remote system. Through DCS messaging, it provides transparency for Call Coverage. [Figure 12-5](#) shows an example of DCS Call Coverage.

sys\_a8 CJL 081596

### Figure Notes

- |                            |  |
|----------------------------|--|
| 1. Station A               | 7. PGATE or PI Board                   |
| 2. System A - DEFINITY ECS | 8. X.25 or ISDN PRI DCS Signaling Link |
| 3. DCS Tie Trunk Groups    | 9. Hop or ISDN TSC Gateway             |
| 4. System B - DEFINITY ECS | 10. Station D                          |
| 5. Station C               | 11. AUDIX Voice Lines                  |
| 6. Station B               | 12. AUDIX - x34000                     |

**Figure 12-5. DCS Call Coverage**

In [Figure 12-5](#), calls to Station A can be covered first by Station B, then by Station C or D, and finally by the AUDIX on system A. Alternatively, calls could be covered by Station C, then Station B, then Station D, and so on.

If the called party answers after the call goes to coverage and the coverage point has answered, then the called party, calling party, and coverage point are all conferenced together.

If the called party answers and the coverage point has not answered, the call to the coverage point drops and the called party connects to the calling party.

### Operation under Normal Conditions

In a normal DCS Call Coverage configuration where the DCS link is up, the DCS trunk group is available, and DCS Call Coverage is active on the local and remote systems, DCS Call Coverage works as follows:

1. A call comes into the principal.
2. The principal does not answer within the administered number of rings or has Send All Calls active.
3. The call is redirected to the first coverage point, which is on the remote system. Also, at this time the DCS distinctive ringing message is sent to the coverage point along with 2 messages conveying the caller's name and the principal's name.
4. The coverage point rings with internal ringing (if the caller is on a DCS node) or with external ringing.
5. The covering station answers and receives the calling party's name and principal's name on the display.

Other DCS Call Coverage situations can occur which deviate from the normal operation, including:

- A call to the principal redirects to the remote coverage point, which is unavailable. The coverage point is considered unavailable when:
  - The coverage point is not a valid extension, QDN, or VDN.
  - The coverage point is busy with no hunting, forwarded, or has send all calls activated, or activates send all calls after ringing.
  - The coverage point has no staffed agents or an invalid vector.

When the coverage point is unavailable, the local system determines the availability status from a time-out or from a message from the remote system. When the local system discovers that the coverage point is unavailable, it tries the next coverage point. If the last coverage point is unavailable, the previous coverage point rings until it is answered or until the caller hangs up. If only one coverage point exists in the path and it is unavailable, the principal's station rings until it is answered or until the caller hangs up.

- A call to the principal is forwarded and the forwarded-to extension is not available. In this case, the first coverage point in the principal's path is tried. Note that the coverage does not follow the forwarded-to extension's coverage path.

- A call to the principal redirects to the remote coverage point, which answers. Subsequently, the principal goes off hook. In this case, the local system bridges the principal onto the call between the calling party and coverage point creating a conference among the three. The principal receives the call on the same call appearance as the original call.
- A call to the principal redirects to the remote coverage point. While the remote coverage point is ringing, the principal answers the call. In this case the call is not cut through to the coverage point. Instead, ringing and ringback is removed from the coverage point and the call is cut through to the principal.

### Operation Under Error Conditions

[Table 12-2](#) describes the DCS Call Coverage under error conditions.

**Table 12-2. Error Conditions**

| Error Condition   | Action   |
|---|--|
| DCS link not up.<br>or<br>DCS trunk is not available.<br>or<br>DCS Call Coverage feature is not activated on the remote system. | The call is routed to the remote coverage point. If the call is answered, it is treated as Call Coverage Off Premises (also called Remote Call Coverage). If the call is redirected at the remote coverage point before the DCS SRI expires, the remote point's path is followed. If the call is not answered within the DCS SRI time-out period, the next coverage point is tried with DCS Call Coverage from the local system. |
| All trunks to the remote system, DCS or otherwise, are busy   | The next coverage point is tried with DCS Call Coverage from the local system.   |

In addition, when the DCS link is down, call consult operates differently. If Station A calls Station B but the call covers to Station C, then Station C consults back to Station B and Station B receives the consult call on the next call appearance.

## DCS Call Forwarding

---

DCS Call Forwarding allows all calls to an extension to be forwarded to a selected extension in the DCS network or to an external (off-premises) number.

If the Call Forwarding and DCS Call Forwarding are both active, and if a call is forwarded between extensions on the same node, the Call Forwarding coverage path is used. If the nodes are different, the DCS Call Forwarding coverage path is used.

Voice-terminal users in the DCS can activate/deactivate this feature with a dial access code or with a Call Forwarding button.

### NOTE:

Calls can be forwarded to a Vector Directory Number (VDN) anywhere in the DCS network. An attendant cannot activate/deactivate Call Forwarding for a VDN.

## How to administer DCS Call Forwarding

---

### Required forms

---

| Form                      | Field   | Page                  |
|---------------------------|---|-----------------------|
| Feature Access Code (FAC) | ■ Call Forwarding Activation                      | <a href="#">5-113</a> |
|                           | ■ Call Forwarding Deactivation                    |                       |
| Station                   | ■ Redirect Notification                           | <a href="#">6-28</a>  |
|                           | ■ Button/Feature Button Assignments<br>— call-fwd |                       |
| Class of Service          | ■ Call Fwd-All Calls (0-15)                       | <a href="#">5-81</a>  |

You administer DCS Call Forwarding the same as you do Call Forwarding. See [“Call Forwarding” on page 4-224](#) for more information.

## DCS Call Waiting

---

DCS Call Waiting allows calls from one node to busy single-line voice terminals at another node to wait until the called party is available to accept the call. With DCS Call Waiting, a single-line voice terminal user, by knowing a call is waiting, can quickly process calls from locations within the DCS. DCS Call Waiting functions the same as normal Call Waiting.

DCS Call Waiting includes the following features:

- Attendant Call Waiting
- Call Waiting — Termination
- Priority Calling

DCS priority calling from the attendant station is *not* available.

### How to administer DCS Call Waiting

---

None

## **DCS Distinctive Ringing**

---

DCS Distinctive Ringing activates the called-terminal alerting or ringing device to indicate the type of incoming call to the user before they answer it. Distinctive Alerting functions in a DCS environment the same as it does within a single system.

By default, internal calls are identified by a 1-burst ringing pattern, external calls by a 2-burst ringing pattern, and priority calls by a 3-burst ringing pattern. However, you can administer these patterns.

### **How to administer DCS Distinctive Ringing**

---

None.

## DCS Leave Word Calling

---

DCS Leave Word Calling (LWC) enables users to leave preprogrammed “call me” messages at other terminals within the DCS network. Messages can be left by calling, called, or covering users.

LWC transparency in a DCS configuration allows messages from a DEFINITY switch to another node, depending on the storage capability of the remote node.

### How to administer DCS LWC

---

#### Required forms

---

|                   | — lwc-store                |                      |
|                   | — aut-msg-wt (Ext: __)     |                      |

---

You administer DCS LWC the same as you do LWC. See [“Leave Word Calling” on page 4-405](#) for more information.

## **DCS Multiappearance Conference/ Transfer**

---

DCS Multiappearance Conference/Transfer provides transparency for transferring calls and conferencing calls within a DCS network. A user in the DCS can initiate conference calls among or transfer calls originated from extensions in the DCS network to another extension within the DCS by dialing the UDP extension. (For transferred calls, the destination need not be within the DCS.)

In a DCS, if a party in a conference hangs up or completes a transfer leaving only outgoing trunks on the call, the system attempts to preserve the connection if any of the remaining parties on the call is a DCS tie trunk.

The display transparency is not preserved after a conference of transfer across the DCS network.

### **How to administer DCS Multiappearance Conference/Transfer**

---

None.

## DCS Over ISDN-PRI D-channel

---

DCS Over ISDN-PRI D-channel (DCS+) enhances DCS by allowing access to the public network for DCS connectivity between DCS switch nodes. With this feature, DCS features are no longer restricted to private facilities.

The ISDN-PRI B-channel is used for voice communications, and the ISDN-PRI D-channel transports DCS control information. The only difference between DCS networks that do not utilize the DCS Over ISDN-PRI and those that do is in the method of signaling. The DCS Over ISDN-PRI D-channel uses Message-Associated User-to-User Information (MA-UUI) and Temporary Signaling Connections (TSC) to transport certain DCS control information. MA-UUI allows additional user-specific information to be transported along with certain ISDN call-control messages.

 **NOTE:**

Use this feature only over DS1/E1 or T1 circuit packs that are administered to Country Protocol Option 1 (even in a private network environment) independent of what country the system is in.

### How to administer DCS Over ISDN-PRI D-channel

---

**NOTE:**

There are several differences in administration between switches. For example, PRI is translated a little differently in G3r when traditional DCS and this feature are used in combination. On systems with AUDIX in a DCS environment, an additional column has been added to the Signaling Group form so you can specify which AUDIX and switch to use. When traditional DCS and DCS over ISDN are used in combination, translations are also different.

**Detailed description**

A TSC provides a temporary signaling path through ISDN switches for exchanging supplementary service information on ISDN-PRI D-channels. There is no B-channel related to the connection; no data or voice transmissions take place.

There are two types of temporary signaling connections:

- Call Associated (CA-TSC)
- Non-Call Associated (NCA-TSC)

A CA-TSC refers to a service for exchanging USER INFORMATION messages associated with an ISDN B-channel connection by the call reference value of the call control data packets. On DEFINITY ECS, this type of TSC is used only for DCS features on ISDN-PRI Signaling Groups administered with Supplementary Service Protocol a.

An NCA-TSC is a connection not related with any ISDN B-channel connections. DEFINITY ECS supports two types of NCA-TSC that conform to two different protocol standards:

## 12 Private Networking

### DCS Over ISDN-PRI D-channel

Page 12-49

- The AT&T type of NCA-TSC is used for the DCS Over ISDN-PRI D-channel and DCS AUDIX applications. Only ISDN-PRI Signaling Groups administered with Supplementary Service Protocol a support AT&T NCA-TSCs.
- The QSIG type of NCA-TSC is used for certain QSIG features such as Call Completion (Automatic Call Back). This type of NCA-TSC is referred to in the QSIG protocol standards as a Call-Independent Signaling Connection (CISC). Only ISDN-PRI Signaling Groups administered with Supplementary Service Protocol b support QSIG NCA-TSCs.

For further information, see [“QSIG NCA-TSC” on page 12-80](#).

## AT&T NCA-TSC

An AT&T NCA-TSC is an administered virtual connection established for exchanging USER INFORMATION messages on the ISDN D-channel. Once an AT&T NCA-TSC has been administered and enabled, it is active for an extended period of time. There are two types of administered NCA-TSCs depending on their setup mechanism:

- Permanent (can be established by Near-end or Far-end)
- As-needed

Once enabled, a permanent NCA-TSC remains established while the system is running. If the permanent NCA-TSC drops for any reason, the system attempts to reestablish the connection. An as-needed administered NCA-TSC is established based on user request and the availability of TSC facilities. The connection drops after an administered period of inactivity.

The system can transport DCS or DCS AUDIX messages over an ISDN-PRI D-channel and over BX.25 data links when functioning as a gateway between a switch equipped with DCS Over ISDN-PRI D-channel and a switch equipped with traditional DCS using BX.25 data links. In this situation, the messages travel from the gateway through the NCA-TSCs or CA-TSCs to TSC-capable switches and from the gateway to switches that support only traditional DCS via a BX.25 logical channel.

At least one switch must be configured as an ISDN DCS Gateway node in a DCS network that consists of switches that support DCS Over ISDN-PRI D-channel and PBXs that do not support the feature. Switches directly connected to AUDIX serve as Gateway nodes.

## DCS with Rerouting

---

Distributed Communications System (DCS) with Rerouting allows a call's connection between two DEFINITY systems to be replaced by a new connection. All of the trunks used in the original path must be DCS and the new path utilizes only DCS trunks. DCS with Rerouting provides the following capabilities:

- Attempts to obtain a better (generally less expensive) connection.
- May replace the current path of a call with a route that is better in terms of Automatic Alternate Routing/Automatic Route Selection (AAR/ARS) routing preferences administered on a DEFINITY ECS.
- Frees up resources being used unnecessarily.

### How to administer DCS with Rerouting

---

#### Required forms

| Form        | Field | Page                  |
|-------------|-------|-----------------------|
| Trunk Group |       |                       |
| ISDN-PRI    | All   | <a href="#">7-219</a> |

### Detailed description

---

DCS with Rerouting primarily provides you with the ability to attempt to be more effective with the usage of Trunk groups administered for Supplementary Services Protocol Option E (SSE) during the existence of an active call. This means using a more preferred route (in terms of UDP/AAR/ARS routing preferences administered on the PBX) between the PBXs involved.

Your users invoke DCS with Rerouting by Call Transfer, Transfer out of Audix, and dial 0 out of Audix. DCS with Rerouting must be enabled on a switch-wide basis and the trunk groups involved must be administered as SSE.

### Considerations

---

- DCS with Rerouting could fail.
- Depending upon administration of routing patterns, the new route could be worse than the original.

## Interactions

---

- When interworking with non-ISDN trunks or non-Supplementary Service Option E ISDN trunks, DEFINITY acts as a gateway in the following sense:
  - When a call is tandeming through a DEFINITY system from a non-ISDN trunk to an SSE trunk or from a non-Option E to an SSE trunk, the system acts as an incoming gateway.
  - When a call is tandeming through a DEFINITY system from an SSE trunk to a non-ISDN trunk or from an SSE trunk to a non-Option E trunk, the system acts as an outgoing gateway.

As an example, when calls come in from the public network to the DCS network and then are transferred to another extension within the private network, DEFINITY functions as an incoming gateway and rerouting occurs.
- If a conference call is transferred, rerouting will not occur.
- Trunks or endpoints measured by the Call Management System (CMS) will not have rerouting take place.
- Trunks or endpoints that are involved with vectoring or announcements will not have rerouting take place.

## DCS Trunk Group Busy/Warning Indication

---

DCS Trunk Group Busy/Warning Indication provides attendants with a visual indication that the number of busy trunks in a remote group reached an administered level. A visual indication is also provided when all trunks in a trunk group are busy.

### NOTE:

DCS Trunk Group Busy/Warning Indication is not available if you are using DCS over ISDN-PRI.

To use this feature, you must have a DCS Trunk Group between the local and remote switches, and the trunks in that trunk group cannot insert digits on incoming calls. If you need digit insertion on these trunks, it should be added on the outgoing trunk based on the dialed digits.

You can administer DCS Trunk Group Busy/Warning Indication only for remote trunk groups that are directly connected to the local switch. Trunk group access codes for these trunk groups must be 3 digits or less.

If an attendant has a Trunk Hundreds Select button assigned to a remote trunk group, the button's Busy lamp lights when all trunks in the trunk group are busy. If an attendant has a 3-lamp Trunk Hundreds Select button assigned to a remote trunk group, the button's Warn lamp lights when the number of busy trunks in the trunk group reaches the Busy Warning Threshold.

To ensure that the busy, warning, and control status of all Trunk Hundreds Select buttons in the DCS remain consistent with the status of the corresponding trunk groups, some nodes in the DCS broadcast the status of a different local trunk group, every 50 seconds, to all directly connected nodes. (A pair of DCS nodes are directly-connected if the voice tie trunks between them are not connected through another switch). For example, a node with 30 trunk groups would take 1,500 (50 x 30) seconds to broadcast the status of all 30 trunk groups. This is called a lamp audit. When a node receives a lamp audit message, its TGB/TGW lamps update accordingly.

## How to administer DCS Trunk Group Busy/Warning Indication

## Emergency (911) Calls

---

The Enhanced 911 (E911) systems installed in many jurisdictions in the U.S. are equipped so that by dialing a service code (911 in the U.S.) a victim of a fire, accident, crime, or medical emergency may quickly access a public safety agency that will dispatch the appropriate response. The public E911 system maintains a database that stores location and background information to aid public safety agencies in responding quickly with the appropriate assistance. Information about the calling party can be triggered by the transmission of a Caller's Emergency Service Identification (CESID) number over Centralized Automatic Message Accounting (CAMA) trunks when the call originates from behind a PBX. 911 calls from a station on a PBX not equipped with CAMA trunks (or an adjunct computer system associated with CAMA trunks) will not provide the E911 system with the information required to identify the location of the person placing the call. Instead, the E911 system will only be able to identify the location of the trunk termination at the PBX.

This feature allows transmission of identifying information in the form of the CESID over CAMA trunks as to the extension number of a DID station associated with the calling party. The calling party may be at or near a station on a remote port network, or may be at a remote location served by an off-premises station.

### How to administer Emergency (911) Calls

---

#### Required forms

| Form                     | Field                                    | Page                  |

### Interactions

---

None.

## Enhanced DCS

---

Enhanced DCS (EDCS) adds features to the existing DCS capabilities.EDCS is used primarily in Italy. EDCS adds the following features:

- Exchanging information to provide class of restriction (COR) checking between switches in the EDCS network
- Providing call-progress information for the attendant
- Allowing attendant intrusion between a main and a satellite
- Allowing a main PBX to provide DID/CO intercept treatment rather than the satellite PBX.

 **NOTE:**

EDCS is not compatible with DCS Over/Under ISDN-PRI. If used with ISDN-PRI, configure the switch as a DCS node. Also, DCS-ISDN display enhancements are not currently available in EDCS.

### How to administer Enhanced DCS

---

#### Required forms

---

| Form                              | Field                              | Page                  |

---

## DCS feature considerations

---

- The DS1 Circuit Pack form must be completed if DS1 tie trunks are used for DCS signaling.
- The Synchronization Plan form must be completed if DS1 tie trunks are used for DCS signaling. You assign a secondary circuit pack that the system can use if the primary circuit pack fails.
- If you call an attendant on another switch in the DCS network, your display shows the attendant's name, but does not show the attendant's extension, instead you see a zero where the extension should be.

### DCS Alphanumeric Display considerations

- Calls to and from a DEFINITY ECS in a DCS network have Calling/Called Name Display transparency under the following conditions:
  - The other party is at another DEFINITY ECS or a DEFINITY Generic 3 and the tandem node is a System 75 Version 3 or later, DEFINITY Generic 1, DEFINITY Generic 3, System 85 Release 2 Version 2 or later, or a DEFINITY Generic 2.1.
  - The call is not routed through a tandem System 85 Release 2 Version 1 or Enhanced DIMENSION PBX node. (Such calls display only the extension number of the calling or called party.)
- On outgoing DCS calls, display of the called name may be delayed for a few seconds until the required information arrives from the distant node. The called name display only works between DEFINITY ECS, DEFINITY Generic 1 and Generic 3 Systems, and System 75s.
- Within the same DEFINITY ECS, DEFINITY Generic 1 or Generic 3 nodes in a DCS, complete transparency of Calling and Called Name Display exists.

### DCS Attendant Control of Trunk Group Access considerations

- This feature is not available for trunk groups with 4-digit trunk access codes or for trunk members 100 through 999.
- There must be direct DCS tie trunk connections between the initiating node and the remote node where the trunk group to be controlled originates. Otherwise, control of remote trunk groups is denied.
- If the remote node (where the trunk group to be controlled resides) is a System 75, Generic 1, or Generic 3, it is not necessary for that node to have an attendant console with corresponding three-lamp Trunk Hundreds Select button. However, if the remote node is a System 85, Generic 2.1, or Enhanced DIMENSION PBX, control of the trunk group is not allowed unless an attendant at that node has a corresponding three-lamp Trunk Group Select button.

## **12 Private Networking**

### *DCS feature considerations*

*Page 12-57*

- The attendant must use the Remote Trunk Hundreds Select button to directly access the controlled remote trunk group. If an attendant controls a remote trunk group, and that attendant dials the trunk access codes of the DCS tie trunk and the controlled remote trunk group, the call is routed to the attendant at the node where the trunk group resides.
- If Attendant Control of Trunk Group Access is activated, and no attendant is assigned, or the attendant is later removed, calls to a controlled trunk group route to the attendant queue.

### **DCS Attendant Direct Trunk Group Selection considerations**

- This feature is not available for trunk groups with 4-digit trunk access codes or for trunk members 100 through 999.
- There must be a direct DCS tie trunk connection between the initializing node and the remote node where the trunk group to be accessed originates. Otherwise, access to the remote trunk group is denied.

### **DCS Attendant Display considerations**

- CORs for a DEFINITY switch may not correspond to those used by an Enhanced DIMENSION PBX, System 85, or DEFINITY system Generic 2.1. Therefore, if the DCS network contains nodes other than Generic 1 or Generic 3, the display CORs may be misinterpreted. If it is important that certain CORs between various systems correspond with each other, those CORs should be administered accordingly.
- On outgoing calls, the display of called party information may be delayed a few seconds until the required information arrives from the remote node. The called party information is displayed only if both nodes are Generic 1 or System 75.
- DCS tie trunks between nodes must be administered with the Outgoing Display enabled. This enables the called party's name to be displayed at the calling attendant's display.

### **DCS Automatic Callback considerations**

- An Automatic Callback request is canceled automatically if the called party does not become available within 40 minutes, or if the calling party does not hang up within six seconds after activating Automatic Callback.
- DCS Automatic Callback does not work on the last trunk between nodes. Thus, if  $n$  trunks are provided, there can be up to  $n - 1$  Automatic Callback calls.

### **DCS Busy Verification of Terminals and Trunks considerations**

- This feature is not available for trunk groups with 4-digit trunk access codes or for trunk members 100 through 999.

### DCS Call Coverage considerations

- The following software is required for DCS Call Coverage.
  - DCS software
  - UDP or PNA software
  - DCS Call Coverage must be enabled on all systems having principals or coverage points and on all intervening systems.

### DCS Call Forwarding considerations

- With DCS Call Forwarding, voice terminal users can have their calls follow them to any location within the DCS network or outside the DCS network.
- Calls to an attendant cannot be forwarded. However, an attendant can activate or deactivate the feature for other extension numbers within the DCS.

### DCS Distinctive Ringing considerations

- When DCS transparency is lost for any reason, terminal-to-terminal calls made between nodes produce external ringing instead of the usual internal ringing. Loss of transparency may occur when the data link between nodes is down or when data transmission delay exceeds the trunk signaling time.

### DCS LWC considerations

- LWC cannot be successfully activated toward any system that is not capable of storing the messages, either internally or in an associated adjunct.
- Messages from one node, through an intermediate node, to a remote node do not require storage capability at the intermediate node.
- LWC transparency is supported for all DCS configurations except for cases when either the activating node or the remote node is either an ENHANCED DIMENSION PBX or a System 85 R2V1.
- Retrieval of LWC messages is permitted only from a terminal at the node where the messages are stored.
- DCS LWC cannot be activated from an attendant console.

### DCS Multiappearance Conference/Transfer considerations

- DCS Multi-Appearance Conference/Transfer is useful when it is necessary to talk to more than one party at one time within a DCS. Multiappearance voice terminals must have an idle appearance in order to transfer a call.

## DCS Over ISDN-PRI D-channel considerations

- Users should not notice any difference between DCS features over ISDN-PRI and traditional DCS features.
- The gateway node serves as the terminating node to the D-channel DCS network as well as the terminating node to the traditional DCS network.

A PBX serving as an ISDN DCS Gateway node introduces some interesting situations when administering processor channels in an associated traditional DCS PBX. In a traditional DCS network, (BX.25 processor channel links) `Remote Port` in the "Processor Channel Assignments" form refers to the processor channel of the destination PBX. In an Integrated DCS network, `Remote Proc Chan` in the "Processor Channel Assignments" form refers to the processor channel of the Gateway PBX (if the destination PBX is an ISDN DCS PBX), *not* the destination PBX.

On the contrary, `Machine-ID` in the "Processor Channel Assignments" form refers to the destination PBX, either an ISDN DCS PBX or a traditional DCS PBX. The Gateway PBX number *must not* be used in this field if the destination PBX is an ISDN DCS PBX.

## DCS Trunk Group Busy/Warning Indication considerations

- This feature is not available for trunk groups with 4-digit trunk access codes or for trunk members 100 through 999.
- Trunk Group Busy and Trunk Group Warning Indication is particularly useful with the Attendant Control of Trunk Group Access feature. The indicators alert the attendant when control of access to local and remote trunk groups is necessary.
- Except for remote S75 R1V3, S85/G2 and S75 R1V2 switches, this feature is only transparent if the remote switch is directly connected by voice tie trunks. For S75 R1V3 and S85/G2 remote switches, Trunk Group Busy and Trunk Group Warning Indication is provided regardless of whether the voice tie trunks are directly-connected or in tandem through an intermediate node; For S75 R1V2 remote switches, no Trunk Group Busy and Trunk Group Warning Indication transparency is provided.

## Enhanced DCS considerations

- If the DCS link fails, the administrator can choose to allow calls to continue without class of restriction checking or to block all DCS calls to inward-restricted stations.
- Enhanced DCS is not available with DCS over an ISDN-PRI D-channel. When EDCS is used, all nodes in the DCS network must use EDCS.
- The DCS Transfer display enhancements and DCS Conference display enhancements do not apply when EDCS is enabled.

## DCS Interactions

---

### DCS Alphanumeric Display interactions

The following features allow transparency with respect to Calling or Called Name Display and miscellaneous ID.

- Automatic Callback  
Complete display transparency.
- Call Coverage  
At the calling terminal, the miscellaneous id “cover” is not displayed.
- Call Forwarding  
When a system user calls a party on a different node in the DCS and the call is forwarded, the miscellaneous ID “forward” is not displayed. At the covering (forwarded-to) user’s terminal, only the calling party’s name is shown; the called party’s name is not displayed.
- Call Park  
When a DCS call between a local system user and a user on another node is parked by the remote user, the miscellaneous ID “park” is not displayed at the local terminal.
- Call Pickup  
When a DCS call from a system user to another node is answered by way of Call Pickup, the miscellaneous ID “cover” is not displayed at the caller’s terminal.
- Call Waiting  
When a DCS call from a system user to another node is waiting at the called terminal, the miscellaneous ID “wait” is not displayed at the caller’s terminal.
- CAS  
When a user dials the extension for CAS, a RLT is seized or the caller is queued for an RLT. The caller’s terminal displays the trunk group identifier, such as OPERATOR.
- Conference  
When two DCS and/or ISDN-PRI calls (or any possible combination of each) are conferenced and revert to a two-party call, the trunk group of the remaining call is displayed.
- DDC/UCD  
Complete display transparency.
- Internal Terminal-to-Terminal Calling  
Complete display transparency.

- ISDN-PRI

If both DCS and ISDN-PRI features are provided with a system, the ISDN-PRI display information displays in DCS format.

### **DCS Attendant Control of Trunk Group Access interactions**

- DCS Attendant Display

When a user attempts to access a controlled trunk group and is routed to the local attendant, the display shows the reason the call was redirected. If the call is routed via CAS or the Inter-PBX Attendant Calls feature, the display does not show the reason the call was redirected.

- UDP

DCS tie trunks should not be attendant controlled. This would result in all UDP calls on the controlled tie trunk being routed to the controlling attendant instead of to the desired destination.

### **DCS Attendant Display interactions**

- When both ISDN and DCS display information, or only DCS display information, is received, the switch displays the DCS display information in the DCS format. If ISDN display information is received, and no DCS display information is received, then the ISDN display information displays in the ISDN formats.

### **DCS Automatic Callback interactions**

- Attendant Control of Trunk Group Access and DCS Attendant Control of Trunk Group Access

Automatic Callback cannot be activated if the call uses a controlled trunk group.

- Call Forwarding and DCS Call Forwarding

Automatic Callback calls cannot be activated on a voice terminal at a DEFINITY switch or System 75 node that has Call Forwarding activated.

- Vector Directory Number

Automatic callback calls do not apply for VDNs.

### **DCS Automatic Circuit Assurance interactions**

- None.

### **DCS Busy Verification interactions**

- If the Trunk Identification by Attendant feature is used during busy verification of a trunk (Trunk ID button is pressed), the trunk access code and trunk group member number of the DCS tie trunk being used is displayed.

- DCS Busy Verification of Terminals and Trunks transparency is lost if the routing pattern is administered to not delete the RNX and the AAR prefix is inserted on the terminating switch trunk group. The voice terminal display at the terminating switch displays only **a=station name**. `Extension` is left blank.

## DCS Call Coverage interactions

DCS Call Coverage has the same interactions as Call Coverage plus the following additional interactions.

- Call Coverage Off Premises

If the coverage point is a non-UDP number in the remote call coverage table, Call Coverage Off Premises is applied to the call rather than DCS Call Coverage, even if a DCS link exists to the remote system.

- Coverage Answer Groups

DCS Call Coverage to Coverage Answer Groups on remote systems are not supported by DCS Call Coverage. Coverage answer groups cannot be administered on a system other than the principal's system.

- Coverage Call Back

DCS Call Coverage does not support Coverage Call Back from a remote node. This is because the coverage point's system has no way of knowing whether the caller can respond to Leave Word Calling. For example, the coverage point's system does not know whether the calling party is a trunk or a station.

- Displays

The displays on the DCS Call Coverage point's terminal may be different than those associated with the Call Coverage feature in the following situations:

- When the call from the calling party to the principal or the redirected call to the coverage point travel over ISDN-PRI trunk groups.
- When the calling party is on a System 85 or Generic 2.
- When the DCS name message is not received by the remote (coverage point's) system.

- Go to Cover

Go to Cover is not supported over DCS and therefore is not supported with DCS Call Coverage.

- Leave Word Calling Back to Principal

With DCS Call Coverage, a covering user on a different node cannot press their LWC button to leave a message for the principal to call the covering user.

## 12 Private Networking

### DCS feature considerations

Page 12-63

- **Queuing**

DCS Call Coverage interacts with queuing in the following way. If a call is queued to a coverage point, such as a queue to a hunt group or an ACD split, and the queue is not full, the call remains in the queue without subsequent redirection until answered or until the caller hangs up.

### DCS Call Forwarding interactions

- If the forwarding extension and the designated extension are at different nodes, and the designated extension's coverage criteria are met on a forwarded call, the call is redirected to a point in the designated extension's coverage path.
- If the forwarding extension and the designated extension are at different nodes, LWC and Coverage Callback cannot be activated at the designated extension for a forwarded call.
- There is a 30-second interval during which calls forwarded from the DEFINITY switch to another DCS node is denied. This prevents forwarded incoming trunk calls from being forwarded ad infinitum between two extensions.

### DCS Call Waiting interactions

- DCS Call Waiting is denied when the following features are activated at the single-line voice terminal:
  - Automatic Callback (to or from the voice terminal)
  - Data Privacy
  - Data Restriction
- On incoming trunk calls to the attendant extended over DCS trunks, Attendant Call Waiting interacts with the EDCS feature.

### DCS Distinctive Ringing interactions

- **Distinctive Ringing**

Distinctive Ringing treats a call from another switch in a DCS arrangement as external; DCS Distinctive Ringing treats such calls as internal. If both features are administered, DCS Distinctive Ringing takes precedence. If EDCS is activated, DID treatment may be different. See ["Enhanced DCS" on page 12-55](#).

- **Tie Trunk Access**

On DEFINITY ECS, tie trunk groups can be administered as either internal or external tie trunk groups. Calls from internal tie trunk groups are treated as terminal-originated calls and receive one-burst ringing. Calls from external tie trunk groups are treated as externally originated calls and receive two-burst ringing.

## 12 Private Networking

### DCS feature considerations

Page 12-64

- The following distinctive ringing features cannot be provided between nodes in a DCS:
  - Intercom — Automatic
  - Intercom — Dial
  - Manual Signaling

### DCS LWC interactions

- DCS Multi-appearance Conference/Transfer

Activation of LWC is denied after a DCS call has been conferenced or transferred.
- DCS Call Forwarding

If the forwarding extension and the designated extension are at different nodes, LWC cannot be activated at the designated extension for a forwarded call.

### DCS Multiappearance Conference/Transfer interactions

- Voice Terminal Display

No display transparency is provided for DCS Multi-Appearance Conference/Transfer.
- EDCS

On calls to or from Public Network Trunks, calling/called party restrictions are checked when EDCS is active.

### DCS Over ISDN-PRI D-channel interactions

- ASAI

For incoming calls on DCS over ISDN-PRI, ASAI applications receive the ISDN-PRI Calling Party Information, not the DCS Calling Party Information.
- Attendant DXS with Busy Lamp Field

An attempt by the attendant to directly select an extension that has been previously administered as belonging to a administered NCA-TSC results in intercept tone being received.
- CDR

CDR records both the status and the utilization of TSCs. Both CA-TSCs and NCA-TSCs can be recorded. For more information, consult the CDR description in this manual or the CDR manual.
- D-channel Backup

In the event of a D-channel switchover (primary to secondary or secondary back to primary) in a private network, administered NCA-TSCs that were active are assumed to have remained active. Any unacknowledged user-user service requests are assumed to be rejected,

## 12 Private Networking

### DCS feature considerations

Page 12-65

and administered NCA-TSCs which were in the process of being established at the time of the switchover are dropped when the switchover occurs. Those administered NCA-TSCs that were dropped are reattempted again.

If a D-channel switchover occurs on a D-channel going to the public network then all TSCs are dropped. A maintenance-provided "heartbeat" message periodically is sent over each permanent administered NCA-TSC to ensure that such a situation is detected and recovered from.

- Distributed Communications System AUDIX (DCS AUDIX)

The DCS over ISDN-PRI D-channel feature can be used to support DCS AUDIX. (The connection between G3si and AUDIX should be BX.25.)

- GRS

GRS selects TSC compatible facilities when routing NCA-TSCs. In other words, a NCA-TSC request can only select a routing preference that supports TSCs.

In a tandem node, GRS first selects facilities that support TSCs if the call falls into any one of the following two conditions:

- It requests a CA-TSC explicitly
- It contains a DCS information element in the SETUP message

Once a trunk group with available members is selected, the call proceeds even if all the TSCs belonging to the associated signaling group are active. In other words, the completion of a call is given priority over DCS transparency.

- ISDN-PRI

This feature uses ISDN-PRI call control protocol and messages.

- SDN

The DCS over ISDN-PRI D-channel feature allows the system to access public networks such as SDN. SDN supports all DCS features except for the following:

- DCS Attendant Control of Trunk Group Access
- DCS Attendant Direct Trunk Group Selection
- DCS Busy Verification of Terminals and Trunks

- Voice Terminals

An attempt to dial an extension that has been previously administered as belonging to an administered NCA-TSC results in intercept tone being received.

### **DCS Trunk Group Busy/Warning Indication interactions**

- **Loudspeaker Paging Access**

If Trunk Hundreds Select buttons are assigned for Loudspeaker Paging Access zones, Trunk Group Busy Indicators provide a visual indication of the busy or idle status of the zones at the remote location as well as at the local node.

### **Enhanced DCS interactions**

- **Class of Restriction**

When a call goes to coverage, it is the called party's (not the covering party's) restrictions that are used.

## Extended Trunk Access

---

Use Extended Trunk Access (ETA) in conjunction with Uniform Dial Plan (UDP) to allow DEFINITY ECS to send any unrecognized number (such as an extension not administered locally) to another switch for analysis and routing. Such unrecognized numbers can be Facility Access Codes, Trunk Access Codes, or extensions that are not in the UDP table. Non-UDP numbers are administered on either the First Digit Table (on the Dial Plan Record form) or the Second Digit Table. They also are not administered on the ETA Call Screening Table. ETA helps you make full use of automatic routing and UDP.

### How to administer ETA

---

#### Required forms

---

| Form  | Field  | Page                   |
|---|--|------------------------|
| Dial Plan Record<br>(First Digit and Second Digit Tables) | <ul style="list-style-type: none"> <li>■ ETA Routing Pattern</li> <li>■ ETA Node Number</li> </ul> | <a href="#">5-99</a>   |
| ETA Call Screening Table                                  | <ul style="list-style-type: none"> <li>■ Call Screening Entry</li> </ul>                           | <a href="#">12-113</a> |

#### CAUTION:

*Switches can be chained together using ETA. However, you must ensure that switches do not route in a circular ETA call setup. Switch A can route to switch B, and switch B can route to switch C. But, if switch A routes to switch B and switch B routes to switch A, you create a circular ETA call setup.*

### Detailed description

---

Historically, ETA has been used by satellite switches to access stations, trunks, and features at the main switch. ETA frees you from having to enumerate the entire dial plan for the main or satellite complex. Calls that would get intercept treatment without ETA are routed to a remote switch to be reprocessed. The following processing takes place when ETA is administered:

- ETA call is identified because it fails all other routing possibilities.
- The dialed string is not in the ETA Call Screening Table.
- An available route pattern is selected based on the Dial Plan form ETA Routing Pattern or ETA Node Number entries.
- The dialed string is sent to the remote switch.

## Examples of ETA administration

### CASE #1

- ETA Route Pattern — Not administered
- ETA Node Number — Not administered

In this case, ETA is not active. It is not used to route undefined dialed strings.

### CASE #2

- ETA Route Pattern — Administered
- ETA Node Number — Not administered

In this case, the ETA Route Pattern routes undefined dialed strings. However, since an ETA Node Number is not specified, non-call-related DCS messages are not routed.

### CASE #3

- ETA Route Pattern — Not administered
- ETA Node Number — Administered

In this case, the ETA Node Number provides the route pattern. Non-call-related DCS messages also can route since a node number is supplied.

### CASE #4

- ETA Route Pattern — Administered
- ETA Node Number — Administered

In this case, the ETA Route Pattern routes undefined dialed strings while the ETA Node Number routes DCS messages. Nodes themselves do not have to be administered for ETA. ETA should not be used over tandem-tie trunks.

## Interactions

- Abbreviated Dialing  
Abbreviated Dialing calls are routed via ETA.
- Attendant  
Attendants calls are routed via ETA.
- Data-Call Setup  
Analog and digital endpoints can access ETA. The digit string goes to the remote switch like any other digit string is sent. The remote switch handles the data-call setup from that point forward.

- Facility Restriction Levels

It is possible to restrict trunks that are being used in conjunction with ETA by assigning FRLs.

- Last Number Dialed

If a number is routed via ETA to a remote switch and you want to reaccess that number, then reaccess uses ETA.

- Modem Pooling

Modems in Modem Pools are treated like all other trunks.

- Remote Access

Remote-access trunks are able to access the ETA feature just as any other trunk or station does.

## Extension Number Portability

Extension Number Portability (ENP) gives you the ability to assign any extension to any switch in an ENP subnetwork. Stations can be moved across switches while retaining the original extension number, as long as the switches are part of the ENP subnetwork. ENP is used in conjunction with Automatic Alternate Routing (AAR) and Uniform Dial Plan (UDP).

### How to administer ENP

#### Required forms

| Form  | Field      | Page                   |
|---|------------|------------------------|
| AAR and ARS Digit Conversion Table          | ■ All      | <a href="#">8-63</a>   |
| Extension Number Portability Numbering Plan | ■ All      | <a href="#">12-115</a> |
| Node Number Routing                         | ■ All      | <a href="#">12-119</a> |
| Uniform Dialing Plan                        | ■ Ext Code | <a href="#">12-121</a> |

- AAR Digit Conversion form — Assign all 3-digit ENP codes as home, and if using a 5-digit UDP, associate the ENP codes with the leading, or 10 thousands, digit (that is, the fifth digit of the extension). For example, for extension number 73446, “7” is the 10 thousands digit.
- ENP Numbering Plan form — Associate the leading one or two digits of extensions in the ENP subnetwork with a 3-digit ENP code, used to construct a 7-digit AAR-like ENP number.
- Node Number Routing form — Associate a route pattern with each node in the ENP subnetwork.
- Uniform Dialing Plan form — Enter the number of digits in the plan (4 or 5) and the Extension Codes for non-home extensions in the ENP subnetwork as ENPNode (node number routed).

### Detailed description

The ENP Numbering Plan allows you to set 4- or 5-digit extensions in the ENP subnetwork to a 7-digit AAR-like number that is sent to other nodes in the network. Only the first 1 or 2 leading digits of the extension are significant.

ENP Codes are distinguished from AAR location codes because ENP Codes are home on every node within the ENP subnetwork, and ENP Codes are administered in the ENP Numbering Plan table as well as in the AAR Analysis table. Since ENP Codes are home on every node, they cannot be used as AAR location codes.

## 12 Private Networking

### *Extension Number Portability*

Page 12-71

UDP extensions are converted to ENP numbers if node number routing is specified for the extensions in88

the UDP table.

**NOTE:**

One ENP code is required for a 4-digit ENP subnetwork. A 5-digit UDP requires one ENP code for each leading digit of extensions used within the ENP subnetwork.

DCS message signaling links are not required to support ENP. As a result, many multiple switch configurations are possible with ENP. Typically the ENP network will be a subnetwork of a UDP or Electronic Tandem Network (ETN).

## **Interactions**

---

- **Distributed Communications System**

If you use DCS, the ENP node numbers must correspond to DCS node numbers.

## Inter-PBX Attendant Service

---

Inter-PBX Attendant Service (IAS) allows attendants for multiple branches to be concentrated at a main location. Incoming trunk calls to the branch, as well as attendant-seeking voice-terminal calls, route over tie trunks to the main location.

### How to administer Inter-PBX Attendant Service

---

#### Required forms

---

| Form                        | Field   | Page                  |
|-----------------------------|---|-----------------------|

### Detailed description

---

Inter-PBX Attendant Service calls are incoming tie-trunk calls from a branch location to the main-location attendant group. If no attendant in the group is immediately available, the calls are queued. When an attendant becomes available, the call routes to that attendant. Extended calls are treated as incoming calls to the main location.

DEFINITY ECS can be a branch or main location. Users at each branch can access other branch locations through the main location. A branch can have local attendants. You access these local attendants using Individual Attendant Access.

### Interactions

---

- Attendant Control of Trunk-Group Access  
If a call at a branch attempts to access a controlled trunk group, the call routes to a branch attendant, if there is one. If there is no branch attendant, the call routes to the attendant group at the main location.
- Attendant Display and DCS Attendant Display  
In a DCS environment, an incoming call from a branch displays at the attendant console at the main location as a local call.  
In a non-DCS environment, an incoming call displays at the attendant console at the main location as an incoming tie-trunk call.

## 12 Private Networking

### *Inter-PBX Attendant Service*

Page 12-73

- **Attendant Recall**

If an attendant at the main location holds a call, the calling parties at the branch cannot recall the attendant.

- **Call Coverage**

A call redirected to a coverage path with the attendant group as a coverage point skips that coverage point. It goes to the next coverage point at the branch, if administered, or continues to ring at the previous coverage point. If the attendant group 0 is the only coverage point, it continues to ring at the principal's extension.

- **Centralized Attendant Service**

CAS and Inter-PBX attendant calling cannot be used at the same time.

- **Dial Access to Attendant**

Administer Dial Access to Attendant via the dial platform to the same digit on both the IAS main switch and the IAS branch switch. On the branch switch, administer the PBX attendant access code (Console Parameters form) to match the main PBX attendant-group dial access code.

- **Electronic Tandem Network**

Inter-PBX Attendant Calls can be used within an ETN. The attendant group for the network can be located at the main switch and serve other tandem switches connected by tie trunks.

- **Night Service**

Inter-PBX Attendant Calls deactivates when a branch goes into night service, and reactivates when the branch comes out of night service.

## Node Number Routing

---

Use Node Number Routing (NNR) to specify the route pattern associated with each node in a private network. NNR is a required capability for Extension Number Portability (ENP) and is used in conjunction with Automatic Route Selection (ARS), AAR and ARS Partitioning, Private Networking, and Uniform Dial Plan (UDP). UDP extensions can be routed to a specified node using its associated pattern. NNR allows a UDP route pattern based on node numbers or on location codes. On the AAR and ARS Digit Analysis Tables, you also can specify a Node Number instead of a Route Pattern.

### How to administer NNR

---

#### Required forms

---

None.

## Private Network Access

Use Private Network Access to allow calls to other switching systems in a private network. These calls do not use the public network. They are routed over customer-dedicated facilities.

### How to administer Private Network Access

#### Required forms

| Form                               | Field                                     | Page                   |

- Trunk Group Forms — Set `Group Type` to **access**, **aplt**, **tandem**, **tie**, or **isdn** and `Service Type` to **access**, **tie**, or **tandem**. Complete COR digit treatment and common type fields for tie trunk groups associated with a private network.

### Detailed description

Private networks can include:

- Common-control switching arrangement (CCSA)
- Distributed Communications Systems (DCS) and Enhanced DCS (EDCS)
- Electronic tandem network (ETN)
- Enhanced private-switched communications service (EPSCS)
- Tandem-tie-trunk network (TTTN)
- Italian Traslatore Giunzione Uscente/Entrante/Interno (TGU/TGE/TGI) trunks

Unless prohibited by the COR, all incoming private network trunks, except CCSA, can access outgoing trunks without attendant or terminal-user assistance. All incoming CCSA calls must route to an attendant or a terminal user.

When off-network calling is part of the CCSA and EPSCS, long-distance calls route as far as possible over these networks before terminating on the public network. Thus, charges for toll calls are reduced. The COR you administer to individual system users determines whether access to this capability is allowed or denied.

In Italy, TGU/TGE/TGI trunks provide private network access between 2 switching systems. They also provide some feature transparency for COR (Inward Restriction), DID (when reaching busy stations), and Intrusion.

## Interactions

---

- Attendant Call Waiting

Call Waiting is provided via Italian TGU/TGE (main and satellite) trunks. Call Waiting also is provided in Italy and all other countries through DCS.

- Attendant Intrusion

Attendant Intrusion is provided on satellite switches via TGU/TGE trunks. Attendant Intrusion also is provided through DCS.

## QSIG

---

QSIG provides compliance to the International Organization for Standardization (ISO) Integrated Services Digital Network private-networking specifications. QSIG is defined by ISO as the worldwide standard for private networks.

QSIG is the generic name for a family of signaling protocols. The Q-reference point or interface is the logical point where signaling is passed between two peer entities in a private network. QSIG signaling provides feature transparency in a single-vendor or multi-vendor environment.

QSIG provides call-related supplementary services. These are services that provide features in addition to voice or data connectivity and number transport and display. Examples of supplementary services include Name Identification, Call Forwarding (Diversion), and Call Transfer.

DEFINITY ECS provides three levels of QSIG functionality:

- Basic Call Setup — Supports basic call setup and number transport
- Basic Supplementary Services — Supports Name Identification Services, Call Forwarding (Diversion), and Call Transfer
- Supplementary Services with Rerouting — Supports Call Forwarding (Diversion) with Reroute (using Path Replacement) and Call Transfer with Reroute (using Path Replacement)

### How to administer QSIG

---

DEFINITY ECS supports QSIG over both ISDN-PRI trunks (using the DS1 circuit pack) and ISDN-BRI trunks (using the ISDN-BRI trunk circuit pack).

#### Required forms for Basic Call Setup

---

| Form                                  | Field              | Page                  |

- DEFINITY ECS provides QSIG in addition to some national public network protocols and the European Telecommunications Standards Institute (ETSI) protocols for supplementary services. *The protocols are mutually exclusive.* On the Trunk Group form, set the Group Type to **isdn** and one of the following Supplementary Service Protocols. For a more complete list of options, see Supplementary Service Protocol on page [7-207](#) for ISDN-BRI trunks and page [7-231](#) for ISDN-PRI trunks.

- b ISO/ETSI QSIG Private Network
- d European Computer Manufacturer's Association (ECMA) QSIG private network (supports only Name Identification and Additional Network Feature Transit Counter (ANF-TC))

## Additional Network Features

DEFINITY ECS also includes QSIG Additional Network Feature (ANF) capability. ANFs are used for networking; they operate behind the scene. You are not always aware that DEFINITY ECS is using them. They provide services in addition to the basic call. DEFINITY ECS includes the following ANFs: Transit Counter (ANF-TC) and Path Replacement (ANF-PR). Path Replacement is a mechanism used for routing.

### Detailed description

QSIG signaling protocols are based on ITU-T (formerly CCITT) Q.931 access protocols across the Q-reference point. QSIG standards are also supported by the ISDN Private Networking Specification (IPNS) Forum. DEFINITY ECS QSIG complies with a number of international regulations. For example, QSIG:

- Complies with ISO standard 11572 for layer 3 to support private-network connectivity.
- Meets requirements for the ISO Private Network Generic Functional Procedures (ISO standard 11582) for call-related supplementary services.
- Supports call-related supplementary service transport, Abstract Syntax Notation 1 (ASN.1)/Basic Encoding Rules (BER), and Remote Operation Service Element (ROSE) services/protocols.
- Provides the Name and Number Identification supplementary service as defined by ISO Standards 13864, 13868, and 11572.
- Provides Call Forwarding (Diversion) as defined by ISO Standards 13872 and 13873.
- Provides Call Transfer as defined by ISO Standards 13865 and 13869.

A Temporary Signaling Connection (TSC) provides a temporary signaling path through ISDN switches for exchanging supplementary service information on ISDN-PRI D-channels. There is no B-channel related to the connection; no data or voice transmissions take place.

There are two types of temporary signaling connections:

- Call Associated (CA-TSC)
- Non-Call Associated (NCA-TSC)

A CA-TSC refers to a service for exchanging USER INFORMATION messages associated with an ISDN B-channel connection by the call reference value of the call control data packets. On DEFINITY ECS, this type of TSC is used only for DCS features on ISDN-PRI Signaling Groups administered with Supplementary Service Protocol a.

An NCA-TSC is a connection not related with any ISDN B-channel connections. DEFINITY ECS supports two types of NCA-TSC that conform to two different protocol standards:

- The AT&T type of NCA-TSC is used for the DCS over ISDN-PRI D-channel and DCS AUDIX applications. Only ISDN-PRI Signaling Groups administered with Supplementary Service Protocol support AT&T NCA-TSCs. For further information, see [“AT&T NCA-TSC” on page 12-49](#).
- The QSIG type of NCA-TSC is used for certain QSIG features such as Call Completion (Automatic Call Back). This type of NCA-TSC is referred to in the QSIG protocol standards as a Call-Independent Signaling Connection (CISC). Only ISDN-PRI Signaling Groups administered with Supplementary Service Protocol support QSIG NCA-TSCs.

## QSIG NCA-TSC

Used to exchange Facility Information Elements in call control messages, FACILITY messages, or a combination of both. NCA-TSC is not administered ahead of time, but is invoked dynamically by the QSIG feature that needs it. Some QSIG features remove the NCA-TSC when it is no longer needed; others leave the NCA-TSC active for a longer period of time.

DEFINITY ECS does not provide gateway functionality between a QSIG NCA-TSC and an AT&T NCA-TSC. For example, although a call can be routed from a DCS network into a QSIG network, it is not possible for the caller in this case to invoke an automatic callback.

## Called Name

Enables the calling party to see the name of the called party while the call is ringing at the called party's terminal. Called Name is similar to the display provided for local on-switch calls, as well as for the DCS calls, with the following exceptions:

- Names longer than 15 characters are truncated; only the first 15 characters display.
- The number never displays.

## Busy Name

Enables the calling party to see the name of the called party while listening to a busy tone because the called party's terminal was busy. Busy Name is similar to the display provided for local on-switch calls, as well as for DCS calls, with the exceptions noted for Called Name.

## QSIG Path Retention

Path Retention is a generic mechanism that can be used by supplementary services during call establishment.

The Originating PBX invokes path retention for one supplementary service or for several simultaneous supplementary services. Invoking a particular supplementary service means retaining the network connection if the Terminating

PBX encounters the appropriate conditions. The Originating PBX is informed of the reason for retaining the connection. It then decides (for example, by consulting the calling user) whether to invoke the supplementary service. Under some circumstances in which the network connection is retained, more than one of the supplementary services for which path retention has been invoked may be applicable.

Successive retentions of the network connection by the Terminating PBX following a single path-retention invocation by the Originating PBX are possible. This is a result of different conditions being encountered at the Terminating PBX. When an attempt is made to invoke a supplementary service for which the network connection has been retained, a further condition can be encountered that can cause the network connection to be retained again for the same or a different supplementary service.

Path retention is specified in terms of a Path Retention entity existing within the Coordination Function at the Originating PBX and at the Terminating PBX.

## QSIG Call Forwarding (Diversion)

---

QSIG Call Forwarding (Diversion) is based on the DEFINITY ECS Call Forwarding feature. It extends the feature transparency aspects of Call Forwarding over a QSIG trunk.

- If QSIG Call Forwarding Unconditional is activate, all calls are diverted immediately.
- If QSIG Call Forwarding with busy/don't answer is activate and a station is busy, a call is diverted immediately.
- If QSIG Call Forwarding with busy/don't answer is activate and a station is idle but the call is not answered, a call is diverted after a specified number of rings.

These features are activated either by dialing a feature access code or by pressing a button. See [“Call Forwarding” on page 4-224](#) for detailed descriptions of how to use these features.

ANF-PR applies to all QSIG Call Forwarding features. A forwarded call can be rerouted in a private network to find a more cost-effective or resource-efficient path.

QSIG Call Forwarding (Diversion) provides additional call information to both the caller and the diverted-to station above what is provided if the call is forwarded over a trunk that is not administered for QSIG Supplementary Service Protocol b. The caller sees “forward” on the display when a call is forwarded. The diverted-to user receives information that the call has been forwarded with the redirection symbol “f.” Depending upon QSIG Name and Number Identification Services administration, the originator can see the connected party's name or number followed by “forward.” The diverted-to user can see the originator's identification (name or number) and the diverting user's (called party) identification (name or number) followed by “f.”

When a call has already been forwarded 3 times over a QSIG trunk, it is not forwarded again but instead terminates at the final forwarded-to terminal. Remote activation and deactivation of this feature are not supported.

Because QSIG Call Forwarding (Diversion) is compatible with the ISO QSIG standards, DEFINITY ECS provides feature transparency for Call Forwarding with any switch that follows these standards.

If an incoming QSIG call is forwarded to another extension, the Called Name sent in ALERTING or DISCONNECT is the name of the forwarding extension. If the original Called Name is not available, the Redirecting Name is available, the Redirecting Name is sent instead. This applies to Call Forward All Calls and Call Forward Busy/Don't Answer.

## How to administer QSIG Call Forwarding (Diversion)

---

### Required forms

|                                       | ■ Supplementary Service Protocol  |                       |
|                                       | ■ Disconnect Supervision  |                       |

 **NOTE:**

The QSIG b and d protocols are not allowed with DCS.

## QSIG Call Transfer

---

QSIG Call Transfer is based on the current DEFINITY ECS Transfer and Trunk-to-Trunk Transfer features. QSIG Transfer signaling occurs as long as one of the calls involves a QSIG trunk between the two switches.

Once a call is transferred, the transferring switch is unnecessary. Additional Network Feature-Path Replacement (ANF-PR) is invoked automatically to connect the transferred call more efficiently in the private network. QSIG Call Transfer attempts to connect the two parties more efficiently and drops the unnecessary switches.

When you use this feature, you see no difference between QSIG Call Transfer and the standard DEFINITY ECS Transfer or Trunk-to-Trunk Transfer features. See the basic features: [“Transfer” on page 4-597](#) and [“Transfer — Outgoing Trunk to Outgoing Trunk” on page 4-599](#).

QSIG Call Transfer differs from standard DEFINITY ECS Transfer in that additional call information is available for the connected parties after the transfer completes.

Depending upon QSIG Identification Services administration, the connected parties' displays show each other's name and/or number. If the name and number are not available, the display of a connected party updates with the name of the involved trunk group.

## How to administer QSIG Call Transfer

### Required forms

| Form                                  | Field   | Page                  |
|---------------------------------------|---|-----------------------|

| Feature-Related<br>System Parameters  | <ul style="list-style-type: none"><li>■ Trunk-to-Trunk Transfer</li></ul>   | <a href="#">5-123</a> |
| ISDN-BRI trunk group                  | <ul style="list-style-type: none"><li>■ Group Type</li><li>■ Supplementary Service Protocol</li><li>■ Disconnect Supervision</li></ul>  | <a href="#">7-198</a> |
| ISDN-PRI trunk group                  | <ul style="list-style-type: none"><li>■ Group Type</li><li>■ Supplementary Service Protocol</li><li>■ Disconnect Supervision</li></ul>  | <a href="#">7-219</a> |

### NOTE:

Unless QSIG Name and Number Identification is also administered, name and number information do not display when a call is transferred. Also, DCS does not allow the QSIG b and d protocols.

## QSIG Name and Number Identification

---

QSIG Name and Number Identification allows a switch to send and receive the calling number, calling name, connected number, and connected name. Additional parameters that control the display of the connected name and number are administered on the Feature-Related System-Parameters form.

You can administer “yes”, “no”, or “restricted.” Restricted means that DEFINITY ECS sends the information but sends it “presentation restricted,” which indicates to the receiving switch that the information should not be displayed. A received restricted name or number is included on the Call Detail Record (CDR). Due to current networking limitations, a received Restricted Calling Party Number displays. However, a received Restricted Connected Party Number or Calling/Connected Name is *not* displayed.

QSIG Name and Number Identification displays up to 15 characters for the calling and connected name and up to 15 digits for the calling and connected number across ISDN interfaces.

### Transit switch information

When DEFINITY ECS acts as a transit switch, the QSIG standards require it to pass on all supplementary service information that is not addressed to it. This includes name information. (A “transit” switch is a switch that routes an incoming call administered for Supplementary Services Protocol B to a trunk also administered for Supplementary Services Protocol B.) However, Basic Call Setup and number information is subject to modification by the transit switch. This means that trunk group administration on a transit switch does not override incoming name information, but may override incoming number information (as long as this does not lower the restriction on the information).

**Example.** If a non-restricted calling name and number are received by a DEFINITY ECS acting as a transit switch, and if the outgoing trunk is administered for presentation restricted for both name and number, the number is passed on as “restricted” and name is passed on as “unrestricted.”

### Tandem switch information

However, in the case of tandemed calls (calls involving two ISDN trunks that are not both administered for Supplementary Service Protocol B), trunk group administration may override both incoming name and number information, as long as doing so does not lower the restriction on the information. For example, a tandemed call that comes in with restricted name information is sent out with restricted name information even if the outgoing trunk is administered for presentation unrestricted. However, non-restricted data is sent restricted if the trunk group administration is set for “presentation restricted.”

## ISDN numbering formats

The ability to send calling name, connected number, and calling number, or to restrict their display, is administered on the ISDN Trunk Group form. The ISDN system parameters are administered on the Feature-Related System-Parameters form. Numbering is specified on the ISDN Public-Unknown-Numbering and/or ISDN Private-Numbering forms. The numbering form you use depends on how you administer the ISDN trunk group Numbering Format field.

- On the ISDN trunk group form, if you set `Numbering Format` to one of the public or unknown numbering formats, use the ISDN Public-Unknown-Numbering form.
- On the ISDN trunk group form, if you set `Numbering Format` to one of the private numbering formats, use the ISDN Private-Numbering form.

However, there is an exception. If the Called Party Number is formatted with the public numbering format, the Calling/Connected Party Number is created in the public format even if “private” is specified on the ISDN trunk group form. This provides the caller or called party a number that can be used to reach the other party. Since the call routes through the public network, the public Calling/Connected Party Number is a more accurate address.

## Called/Busy Name Display

A QSIG Called Name or Busy Name displays on the calling party's display as soon as the ALERTING or DISCONNECT message has been received. The display format matches exactly the format used to display a QSIG Connected Name. If the name received in ALERTING or DISCONNECT is longer than 15 characters, the leftmost 15 characters display.

If a CONNECT message is received while a QSIG Called Name displays, and if the CONNECT contains a Connected Name and/or Number, DEFINITY ECS updates the calling station display with the connected information. If no Connected Name or Number is received, the displays continues to show the Called Name (and Called Number, if applicable).

## **How to administer QSIG Name and Number Identification**

---

 **NOTE:**

The QSIG b and d protocols are not allowed with DCS.

## QSIG Path Replacement (ANF-PR)

---

DEFINITY ECS provides QSIG Additional Network Feature Path Replacement (ANF-PR) as defined in ISO/IEC 13863 and 13874. With this feature, a call's connections between switches in a private network can be replaced with new connections while the call is active.

ANF-PR is invoked when a call is transferred and improvements may be made in the routes. For example, after a call is transferred, the two parties on the transferred call can be connected directly and the unnecessary trunks are dropped off the call. The routing administered at the endpoints allows for a more efficient route connection. See ["QSIG Call Transfer" on page 12-84](#) for more information.

ANF-PR selects the best route based on the preference assigned to routes in the Route Pattern form. Least cost Supplementary Service B (SSB) routes must be first, followed by more expensive routes.

### NOTE:

When routes to SSB trunks are included with routes to non-SSB trunks, SSB trunks must appear first on the Route Pattern form. This is because as soon as ANF-PR encounters a non-SSB trunk in the route pattern, it stops looking.

Class of Restriction (COR) and Facility Restriction Levels (FRL) are adhered to in routing calls. ANF-PR is not invoked on data calls because there is a period of time when information can be lost.

| Feature-Related System Parameters  | ■ QSIG TSC Extension                                      | <a href="#">5-123</a> |
|                                    | ■ Automatic Callback - No Answer Timeout Interval (rings) |                       |
| Feature Access Code                | ■ Automatic Callback Activation and Deactivation          | <a href="#">5-113</a> |
| Station                            | ■ Button/Feature Button Assignments - Auto-cback          | <a href="#">6-28</a>  |
| Class of Service                   | ■ Auto Callback   | <a href="#">5-81</a>  |
| System-Parameters Customer-Options | ■ ISDN-PRI  | <a href="#">5-277</a> |
|                                    | ■ Basic Supplementary Services                            |                       |
|                                    | ■ Basic Call Setup  |                       |
| Trunk group                        | ■ Supplementary Service Protocol                          | <a href="#">7-198</a> |
|                                    | ■ NCA-TSC Trunk Member                                    | <a href="#">7-219</a> |

For voice terminals, administer the following:

- For the Signaling Group form, set `Supplementary Service Protocol` to **b** and `Max Number of NCA TSC` to greater than 0.
- For the Feature-Related System Parameters form, set `QSIG TSC Extension` to the dedicated number for QSIG calls.
- For the Trunk Group form, set `Supplementary Service Protocol` to **b**.
- For the Route Pattern form, set `TSC` to **y** (only if the PBX is a transit node for QSIG CISC).

For digital voice terminals, you also must use the Station form, and administer for Automatic Callback button.

## Detailed description

---

The Supplementary Service - Completion of Calls to Busy Subscribers (SS-CCBS) and Supplementary Service - Completion of Calls on No Reply (SS-CCNR) are the equivalent QSIG features of Automatic Callback On Busy and Automatic Callback on No Answer, respectively.

SS-CCBS and SS-CCNR allow any QSIG network voice user who placed a call to a busy or unanswered voice terminal over the QSIG network to be called back automatically when the called voice terminal becomes available.

An analog voice terminal user activates SS-CCBS or SS-CCNR by pressing the Recall button or flashing the switchhook and then dialing the Automatic Callback (ACB) Activation feature access code. The type of supplementary service being invoked (CCBS versus CCNR) depends on the busy or unanswered condition of the call. DEFINITY ECS identifies which supplementary service to invoke as a consequence of the ACB activation request. An analog user can activate only one ACB call at any given time.

A multiappearance voice terminal user can activate SS-CCBS or SS-CCNR for the number of ACB buttons assigned to the terminal. After placing a call to a voice terminal over the QSIG network that is busy or not answering, the caller can activate SS-CCBS or SS-CCNR by pressing an idle ACB button. DEFINITY ECS identifies which supplementary service to invoke as a consequence of the ACB activation request.

The requested supplementary service remains activated until the Call Completion performs, or until the Service Duration Timer expires (40 minutes).

When SS-CCBS or SS-CCNR activates towards the busy or not answering station on the terminating PBX, the terminating PBX monitors the called voice terminal. A busy voice terminal becomes available when the user hangs up after completing the current call. An unanswered voice terminal becomes available after being used for another call and then hung up. When the called voice terminal becomes available to receive a call, the terminating PBX notifies the originating PBX to initiate a Call Completion call attempt.

After the called voice terminal at the terminating PBX becomes available and the initiation of the Call Completion call, the calling party at the originating PBX receives a priority ringing callback call. If the calling party lifts the handset, ringing starts at the terminating PBX.

An SS-CCBS or SS-CCNR request cancels at both PBXs for any of the following user-related reasons:

- A successful Call Completion call.

## 12 Private Networking

### QSIG Supplementary Service - Call Completion

Page 12-93

- The called party at the terminating PBX does not become available within 40 minutes.
- The calling party does not answer the priority callback call within the administered interval (2 to 9 ringing cycles).
- The calling party decides not to wait and presses the same ACB button a second time (multiappearance voice terminal) or dials the ACB Cancel feature access code (analog voice terminal).
- The calling party is unable to receive the callback call because it is busy during the attempted priority callback call.
- After the calling party receives the priority callback call, but before alerting the called user at the terminating PBX, the called party becomes busy again.

## Interactions

---

- Adjunct Switch Applications Interface (ASAI)  
ASAI cannot invoke/initiate QSIG-CC.
- Attendant Calling Waiting and Call Waiting Termination  
If you activate QSIG SS-CC to a single line voice terminal, the Attendant Call Waiting and Call Waiting Termination features are denied.
- Attendant Console Group  
You cannot activate QSIG SS-CC toward the attendant console group or towards the individual attendant.
- Attendant Control of Trunk Group Access  
You cannot activate QSIG SS-CC if the call uses a controlled trunk group.
- AUDIX  
You cannot activate QSIG SS-CC towards AUDIX. SS-CC to any transferred-to station is not allowed.
- Automatic Call Distribution (ACD)  
You cannot activate QSIG SS-CC towards a voice terminal after dialing the ACD group extension. It is possible to invoke SS-CC towards a station when dialing the individual's extension number. You can activate SS-CC from any ACD agent.

## 12 Private Networking

### QSIG Supplementary Service - Call Completion

Page 12-94

- **Bridged Call Appearance**

You cannot activate QSIG SS-CC from a bridged call appearance. When a call originates from a primary extension number, the return call notification rings at all bridged call appearances.
- **Call Coverage**

QSIG SS-CC requests are always activated at the principal user and not coverage points. Similar to ACB, QSIG SS-CC Call Completion calls to the called user can redirect to coverage.
- **Call Forwarding**

You cannot activate SS-CCBS or SS-CCNR towards a called station that has Call Forwarding enabled.
- **Call Pickup**

On recall at the originating side, a group member cannot answer a QSIG SS-CC call for another group member.
- **Call Waiting**

Call Waiting is denied when QSIG SS-CC is activated to the single-line voice terminal.
- **Conference and Transfer**

You cannot activate QSIG SS-CC towards a transferred-to party.
- **Hold**

A single-line voice terminal cannot receive a QSIG SS-CC call while it has a call on hold.
- **Hotline Service**

A hotline service cannot request SS-CC.
- **Internal Automatic Answer (IAA)**

If the IAA feature is enabled, QSIG SS-CC calls are not answered automatically.
- **Manual Originating Line Service**

A manual originating service cannot request QSIG SS-CC.
- **Multimedia Endpoints**

You cannot activate QSIG-CC towards multimedia data endpoints.
- **Outgoing Trunk Queueing**

Outgoing Trunk Queueing cannot be invoked after the calling party answers the priority call back call and no trunks are available. The SS-CCBS and SS-CCNR request cancels at both PBXs.

**12 Private Networking**

*QSIG Supplementary Service - Call Completion*

*Page 12-95*

- Termination Extension Group (TEG)

You cannot activate QSIG SS-CC towards a TEG extension, but QSIG-CC requests can be activated towards a single member in the group.

- Uniform Call Distribution and Direct Department Calling

You cannot activate QSIG SS-CC towards a uniform call distribution group or a direct department calling group extension, but you can activate towards a single member in the group.

- Vector Directory Number (VDN)

You cannot activate SS-CC towards a VDN extension.

## QSIG Supplementary Service - Call Offer

---

This feature, on request from the calling user (or on that user's behalf), enables a call to be offered to a busy called user and to wait for that person to accept the call, after the necessary resources have become available.

The busy called user is given an indication of the offered call. During the time that the call is offered, the called user may ignore the offered call or may attempt to make the necessary resources available (for instance, by releasing or placing another call on hold). When and if the necessary resources become available, the call completes as a normal incoming call.

There are four ways of invoking QSIG Supplementary Service - Call Offer (SS-CO). A Private Telecommunication Network (PTN) offers one or more of these ways. They are:

- Network invocation (immediate) — the PTN automatically invokes SS-CO whenever the calling user makes a call to a user that is busy, if required by the service profile of the calling user.
- Consultation — the calling user, on being informed that a call has failed because it is busy at the destination and that SS-CO may be possible, is able, within a defined time period (consultation timer), to request invocation of SS-CO.
- Immediate invocation — the calling user is able to request invocation of SS-CO as part of the initial call set-up.
- Network invocation (delayed) — the network, having informed the calling user that a call has failed because it is busy at the destination, invokes SS-CO automatically unless the calling user initiates call clearing within a defined time period (automatic call offer invocation timer).

DEFINITY ECS supports immediate invocation on outgoing QSIG originations if the originator's Class of Service (COS) is so optioned. DEFINITY ECS supports all of the above for incoming QSIG calls.

SS-CO is considered completed when any of the following occurs:

- The offered call starts alerting
- The offered call is answered
- The calling user releases the offered call
- The terminating end PBX rejects the offered call

When a QSIG Call Offer service terminates, the service is considered successful if one of the following occurs:

- The called user is an Analog set, busy, and *Call Waiting Termination* on the Station form is enabled

## 12 Private Networking

### QSIG Supplementary Service - Call Offer

Page 12-97

- The called user is a Multi Call-appearance set, at least one call-appearance is busy for an active call, and at least one call-appearance is available for incoming calls
- If the call cannot be offered to the original called user due to call deflection (for instance, Send All Calls active, Call Coverage due to “busy” condition), but it can be offered/terminated to another user within the same PBX which satisfies either condition (1) or (2)
- If the called number is a group number (for instance, Hunt group (UCD/DDC), Coverage Answer Group, Attendant group, and so forth) and the offered call can be queued or terminated to one of the group member which satisfies either condition (1) or (2)

The effect of QSIG SS-CO on the terminating end is similar to the DCS Call Waiting feature with the exception that for Call Waiting, the calling side (user or PBX) does not have to convey any special message to invoke the feature. The Call Waiting Termination feature is driven based on the terminating user (for instance, single line analog set user with Call Waiting enabled).

For internal calls (for instance, intra-PBX calls) within DEFINITY for the Call Waiting feature, if Call Waiting is invoked successfully at the called user, the calling user's display (for display equipped terminal) is updated with call progress message “wait” and a special audible ringback tone is provided. For DCS Call Waiting, the calling user is provided with special audible ringback tone but is not provided with a display update. For QSIG Call Offer, DEFINITY takes advantage of the additional information available from the far end, if QSIG Call Offer invokes successfully, and provides similar information to the calling user as the Call Waiting feature provides for on internal calls, with the exception that the display update will be “offered” instead of “wait” to reflect invocation of QSIG Call Offer service.

On successful invocation of the QSIG Call Offer service, the called user receives an indication of the terminated offered call. Currently, DEFINITY provides an administrable tone (one, two, or three bursts) to the called busy user when Call Waiting Termination is invoked. When the QSIG Call Offer service is invoked successfully, DEFINITY provides the following:

- To the busy analog set user, the same tone as Call Waiting Termination feature, or
- To the busy Multi call-appearance set (for instance, at least one call-appearance is busy for an active call and at least one call-appearance is available for incoming calls) user, a normal incoming call tone

For incoming QSIG calls, the QSIG Call Offer service may use path retention which is a generic mechanism to retain the signaling connection so that the originating party can decide whether to invoke the supplementary service. The network connection can be retained for more than one of the supplementary services for which path retention has been invoked.

## How to administer QSIG SS-CO

---

**Table 12-3. Required forms for Basic Call Setup**

| Form                                  | Field   | Page                  |

| Class of Service                      | ■ QSIG Call Offer Originations                                  | <a href="#">5-81</a>  |
| System-Parameters<br>Customer-Options | ■ ISDN<br>■ Basic Call Setup<br>■ Basic Supplementary Services  | <a href="#">5-277</a> |
| DS1 Circuit Pack form                 | ■ Connect<br>■ Interface<br>■ Peer Protocol<br>■ Signaling Mode | <a href="#">7-79</a>  |
| Station                               | ■ Call Waiting Indication                                       | <a href="#">6-28</a>  |

### Detailed description

---

- DS1 Circuit Pack form — Set **Connect** to **pbx**, **Interface** to **peer-master** or **peer-slave**, **Peer Protocol** to **q-sig**, and **Signaling Mode** to **isdn-pri** or **isdn-ext**, as required.
- For outgoing call offer call originations:
  - System Parameters Customer-Option form — on QSIG OPTIONAL FEATURES (page 4), set **Basic Call Setup** to **y** and **Basic Supplementary Services** to **y**.
  - Class of Service form — set **QSIG Call Offer Originations** to **y**.
- For incoming call offer calls to a single line appearance:
  - System Parameters Customer-Option form — on QSIG OPTIONAL FEATURES (page 4), set **Basic Supplementary Services** to **y**.
  - Station form — set **Call Waiting Indication** to **y**.
- For incoming call offer calls to a multiple line appearance:
  - System Parameters Customer-Option form — on QSIG OPTIONAL FEATURES (page 4), set **Basic Supplementary Services** to **y**.

## QSIG Transit Counter (ANF-TC)

DEFINITY ECS provides QSIG ANF-TC as defined in ISO/IEC 6B032 and 6B033. It prevents indefinite looping, connections giving poor transmission performance, and inefficient use of network resources.

ANF-TC is invoked automatically for ISDN basic calls and the Route Pattern form indicates the number of switches through which a call may be routed.

| ISDN-PRI Trunk Group | ■ Group Type                     | <a href="#">7-219</a> |
|                      | ■ Hop Dgt                        |                       |
|                      | ■ Supplementary Service Protocol |                       |
| Route Pattern        | ■ Hop Lmt                        | <a href="#">8-67</a>  |

- On ISDN trunk group form, set `Group Type` to **isdn**, `Hop Dgt` to **y**, and `Supplementary Service` to **b** for QSIG or **d** for ECMA.
- On Route Pattern form, set `Hop Lmt`.

### QSIG Interactions

#### QSIG Call Forwarding (Diversion) interactions

The interactions that apply to the standard DEFINITY ECS Call Forwarding features also apply to Call Forwarding (Diversion) with QSIG. See [“Call Forwarding” on page 4-224](#) for a description of these interactions. The following are additional interactions.

- Alternate Facilities Restriction Levels
 

The AFRL of the original call is the AFRL used for Call Forwarding with Reroute.
- Authorization Codes
 

Call Forwarding with Reroute is denied to calls that require an Authorization Code.

## 12 Private Networking

### QSIG Transit Counter (ANF-TC)

Page 12-100

- Automatic Alternate Routing and Automatic Route Selection  
Call Forwarding with Reroute uses AAR and ARS to reroute the original call.
- Call Detail Recording  
Call Forwarding with Reroute is denied to calls that require Forced Entry of Account Codes.
- Call Transfer  
When a forwarded call transfers, the forwarding indication displays to the caller until the call is answered. This display includes the trunk group name and word "forward." When the call is answered, the word "forward" is removed and the name and number of the answering party displays.
- Distributed Communications Systems  
Call Forwarding feature transparency does not exist on calls tandemed between a QSIG (Supplementary Service protocol b) network and a traditional DCS network. However, the basic call continues.
- Facility Restriction Levels and Traveling Class Marks  
The FRL (and TCM) of the original call is the FRL used for Call Forwarding with Reroute.
- Forwarding and Coverage  
If a coverage point is a number that routes over an ISDN (Supplementary Service protocol b) trunk, QSIG diversion information is not passed to the coverage switch.
- QSIG Name and Number Identification  
Availability of name and/or number display at the originating and diverted-to users depends upon how QSIG Name and Number Identification has been administered for the switches involved.
- Terminating Call has Coverage Active  
If a call is forwarded off switch, the terminating switch has call coverage activated, and the criteria are met, the call does not route to the forwarding party's coverage path. It routes to the terminating station's coverage path.

### QSIG Call Transfer interactions

- Call Forwarding (Diversion)  
When a call is forwarded and transferred or transferred and forwarded, the forwarding indication displays to the caller until the call is answered. This display includes the trunk group name and word "forward." When the call is answered, the word "forward" is removed and the name and number of the answering party displays.

- Distributed Communications Systems  
The only DCS transparency that exists when a call is transferred in a DCS network and passed over a QSIG administered trunk is calling name.
- QSIG Path Replacement  
ANF-PR is invoked whenever a QSIG transferred call is answered.
- QSIG Name and Number Identification  
Availability of name and/or number display at the connected parties depends upon how QSIG Name and Number Identification has been administered for the switches involved.

### QSIG Name and Number Identification interactions

- Distributed Communications Systems (DCS)  
DEFINITY ECS can display DCS called name/number information or ISDN connected name/number information in a DCS (ISDN) network.  
When an incoming ISDN call is routed back out over a non-ISDN trunk group, DEFINITY ECS can send the name of the non-ISDN trunk group as the connected name if the `Send Non-ISDN Trunk Group Name as Connected Name` is enabled on the Feature-Related System-Parameters form.

### QSIG Path Replacement interactions

- Basic Call Management System  
If the old connection is monitored by a BCMS entity, ANF-PR is blocked due to BCMS measurements.
- Call Detail Recording  
Codes for recording the new connections of ANF-PR calls are code J for incoming trunk calls and code K for outgoing trunk calls. When a path is replaced, you also may receive records for short-duration calls that are not directly linked to the J and K records.
- Call Management System  
If the old connection is monitored by a CMS entity, ANF-PR is blocked due to CMS measurements.
- Call Vectoring
- A transferred call that terminates at a vector and is answered cannot have its path replaced.
- Data-Call Setup  
A data call is denied ANF-PR.

- Data Privacy  
If Data Privacy is active, ANF-PR is denied.
- Data Restriction  
If Data Restriction is active, ANF-PR is denied.
- Malicious Call Trace  
If MCT is active, ANF-PR is denied.
- Recorded Announcement  
A call that is receiving a recorded announcement cannot have its path replaced.
- Trunk Access Code  
The paths of outgoing calls made using a TAC are not replaced.
- Voice Terminals  
Voice terminal displays that show trunk group name should update with new trunk group information after ANF-PR occurs. Calling and connected party displays are not disturbed when ANF-PR takes place if the original display shows the connected party name, number, or both.

### QSIG Transit Counter interactions

- Call Forwarding (Diversion)  
When call forwarding (Diversion) occurs and the ANF-TC feature is enabled, the transit counter is set to zero.
- ISDN Trunk Group Administration  
If all of the conditions are satisfied for both the Tandem Hop Limitation and ANF-TC, ANF-TC takes precedence. In situations where DEFINITY ECS is an Incoming or Outgoing Gateway, either makes use of the hop count/transit count information provided by the other.
- Trunk Access Code  
ANF-TC does not apply to TAC calls.

## Uniform Dial Plan

Uniform Dial Plan (UDP) provides a common 4- or 5-digit dial plan (specified in the Dial Plan Record) that can be shared among a group of switches. Interswitch dialing and intraswitch dialing both require 4- or 5-digit dialing. UDP is used with an electronic tandem network (ETN); main, satellite, and tributary switches; and Distributed Communications Systems (DCS). In addition, UDP can provide uniform 4- or 5-digit dialing between 2 or more private-switching systems without ETN, main, satellite, and tributary switches, or DCS.

### How to administer UDP

#### Required forms

| Form   | Field   | Page  |
|--|---|---|
| Dial Plan Record<br>Second Digit Table         | <ul style="list-style-type: none"> <li>■ Uniform Dial Plan</li> <li>■ UDP Extension Search Order</li> </ul> | <a href="#">5-99</a><br><a href="#">5-264</a> |
| Uniform Dial Plan                              | <ul style="list-style-type: none"> <li>■ All</li> </ul>   | <a href="#">12-121</a>                        |
| AAR and ARS Digit Analysis Table               | <ul style="list-style-type: none"> <li>■ All</li> </ul>   | <a href="#">8-54</a>                          |
| AAR and ARS Digit Conversion Table             | <ul style="list-style-type: none"> <li>■ All</li> </ul>   | <a href="#">8-63</a>                          |
| Node Number Routing                            | <ul style="list-style-type: none"> <li>■ Route Pat</li> </ul>   | <a href="#">12-119</a>                        |
| Extension Number Portability<br>Numbering Plan | <ul style="list-style-type: none"> <li>■ All</li> </ul>   | <a href="#">12-115</a>                        |
| Route Pattern                                  | <ul style="list-style-type: none"> <li>■ All</li> </ul>   | <a href="#">8-67</a>                          |

#### NOTE:

On the Uniform Dialing Plan form, if you change `Ext Code` and `Type` from a 4-digit or 5-digit extension number to **none**, a warning message informs you that all UDP extension codes will be lost. The same warning message displays when you change `Ext Code` and `Type` extension numbers from 4-digits to 5-digits or from 5-digits to 4-digits.

## Detailed description

---

UDP routes calls off the local switch by converting the extension number into a private-network number with 7 digits. This number is formed by prepending a 3-digit code (of the form XXX) to the (last) 4 digits of the extension number. 3 types of conversion are supported: UDPCode, AACode, and ENPCode.

- For UDPCode and AACode, XXX is a 3-digit private-network location code, and the result is analyzed and routed via Automatic Alternate Routing (AAR). UDPCode conversion prohibits digit conversion via AAR; AACode conversion permits it, just as if you dialed the AAR number instead of the extension.
- For ENPCode, XXX is called an Extension Number Portability (ENP) code. It is not used for routing; node-number routing is used instead. The ENP code is chosen based on the first 1 or 2 digits of the dialed string. Because it is not used for routing, the ENPCode can be independent of location.

UDP conversion is specified for individual extensions or groups of extensions sharing the same leading digits, via the UDP form and extension codes. An extension code is the desired leading digits of an extension followed by an "x" (wildcard). For example, "123xx" "12345" is the extension code for all 100 possible extensions beginning with "123" plus two wild cards. "12345" is an extension code specifying one extension.

Each extension code can be assigned to 1 of 6 possible treatments.

- UDPCode — Conversion to AAR with given location code, further conversion suppressed
- AACode — Conversion to AAR with given location code, further conversion allowed
- ENPCode — Conversion to private network number (via ENP form), route to given node number routing
- TempOOS — Temporarily out of service, give reorder
- Local — Local range of extensions
- blank — Similar to local, however, this extension is not chosen when the system is asked to "add a station"

When a user at a switch that is included in a UDP dials an extension, DEFINITY ECS first checks to see if the extension is assigned to a local station on that switch. If so, the call is routed to the station, and UDP is not invoked. If the extension is not found locally, the system checks to see if the extension matches an assigned extension code. If the extension matches an assigned extension code, the system performs the specified conversion into a private network number and routes the call as specified. If more than one extension code matches, the "best" match (most explicit digits) is used. For example, 1234x is chosen over 123xx if 12345 is dialed. However, 123xx is chosen if 12355 is

dialed. If no matching extension code is found, the user receives intercept treatment. Or, if Extended Trunk Access (ETA) is enabled, the call routes via ETA.

### Example of how UDP works

To administer, assign each UDP code:

- To a private network location code (RNX) or node number. (The RNX is equivalent to an office code of a central office in a public network. This RNX determines how a UDP call is routed.)
- Assign each UDP code as either local or remote to the switch.

To understand the function of a UDP, review the following example.

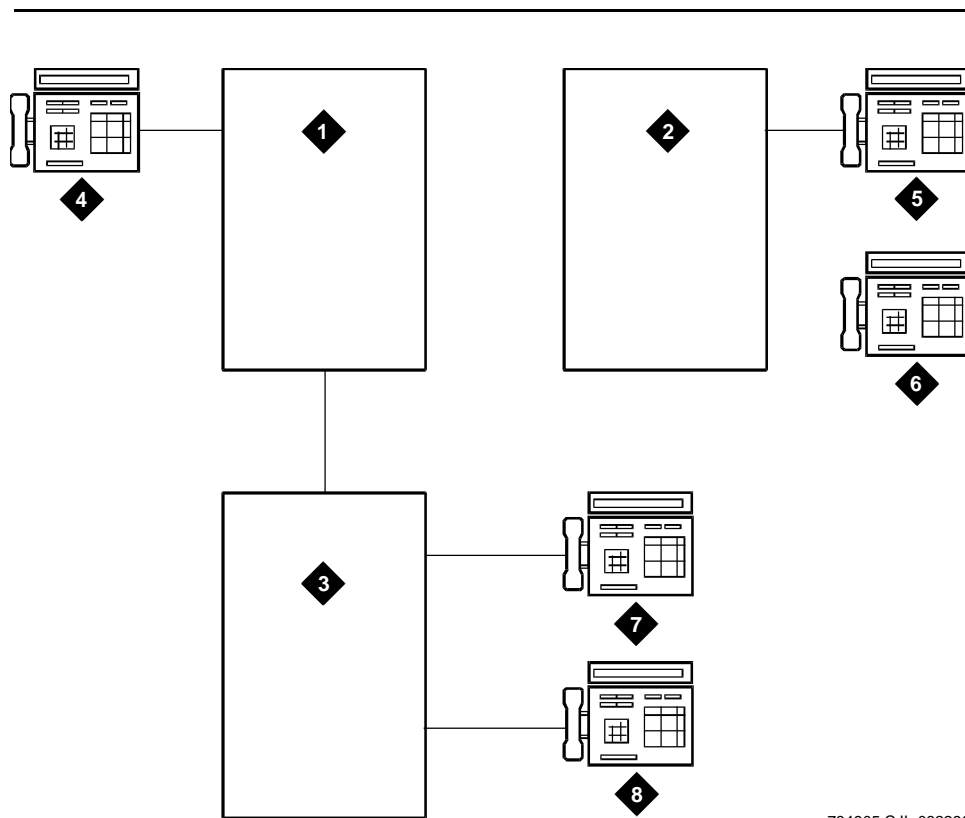

A given station is called using the same 5-digit extension regardless of where in the ETN the call originates. Three switches are included in [Table 12-4](#). Each has been assigned a list of RNX and UDP codes. See [Table 12-4](#) and [Figure 12-6](#).

**Table 12-4. Switch/RMX/UDP Codes**

---

| SWITCH | RNX | UDP CODE |
|--------|-----|----------|
| A      | 224 | 41       |
| C      | 223 | 51       |
| C      | 223 | 52       |
| B      | 222 | 60       |
| B      | 222 | 61       |

---

r764905 C.JL 062296

### Figure Notes

- |  |                    |
|--|--------------------|
| 1. Switch A<br>Dial Plan for extensions is 41XXX<br>RNX=224            | 4. Extension 41000 |
| 2. Switch B:<br>Dial Plan for Extensions is 60XXX and 61XXX<br>RNX=222 | 5. Extension 61234 |
| 3. Switch C:<br>Dial Plan for extensions is 51XXX and 52XXX<br>RNX=223 | 6. Extension 60123 |
|  | 7. Extension 51234 |
|  | 8. Extension 5200  |

### Figure 12-6. UDP Example

If a user at extension 41000 wants to call extension 61234, there are two choices:

- Dial 61234
- Dial the AAR access code followed by 222-1234

If 61234 is dialed, the system recognizes 61 as a remote UDP, determines the associated RNX (222), and uses AAR to route the call to 222-1234.

If the AAR access code and 222-1234 are dialed, the system finds the route pattern for RNX 222 and routes the call to the switch associated with that RNX.

Whenever UDP is used to route a call to another switch, the correct digit deletion and insertion must be specified within the route pattern so that the receiving switch gets digits in the format it expects. DEFINITY ECS can be configured in several different ways.

- If AAR is available on the receiving switch, Subnet Trunking can be used to insert the AAR feature access code on the originating switch or digit insertion may be used to insert it on the receiving switch. The receiving switch then uses AAR digit conversion to convert 222 with 7 digits to an extension by deleting 3 digits and inserting a 6.
- If AAR is not available on the receiving switch, Subnet Trunking must be used on the originating switch to delete the 222 and insert the digit 6 at the beginning of the extension number so that the receiving switch can continue to route correctly.

If the user at extension 51234 on Switch C dials extension 61234, the call must first go through Switch A before proceeding to Switch B. When 61234 is dialed, the system recognizes 61 as a UDP code, determines the associated RNX (222), and uses AAR to route the call. The AAR feature access code plus 222-1234 are outpulsed to Switch A. Switch A then recognizes the RNX 222 as a remote switch and routes the call to Switch B and extension 61234. This same type of call routing occurs when an extension at Switch B calls an extension at Switch C.

If extension 61234 on Switch B calls extension 61235, the system recognizes 61 as a local UDP code and routes the call directly to extension 61235.

## Considerations

---

- In North American network environments, extensions beginning with 0 may route to an attendant. You are encouraged to use another number as the leading digit when assigning extensions.
- When you call an extension on another switch, there may be a slight delay before call-progress tones are applied. This delay is due to the trunk signaling necessary to complete the call to the remote switch.
- When you select the option to look at the UDP table first, calls that might otherwise terminate at a local extension route over the network. This is easily reversed. When you remove the extensions from the UDP table, the local extension can be dialed again.

- If AAR is active, FRLs and Traveling Class Marks (TCMs) can be sent along with the private network number. UDPCode and AARCode conversions use the FRL assigned to the caller. ENPNode conversion always raises the FRL to the maximum (7).

If an FRL is insufficient to access the facility, access is denied. There is no prompt for an authorization code even if authorization codes are enabled and administered.

- If AAR is not active, tandem-tie trunks should not be used to transport UDP numbers. The TCM is not recognized at the terminating switch.

**NOTE:**

Never use tandem-tie trunks to transport UDP numbers (the TCM and Hop count will not be recognized as such following the extension received at the receiving switch).

## Interactions

---

- Automatic Alternate Routing

AAR routes UDP calls. (Included with UDP is the required AAR subset.) If AAR is enabled in addition to UDP, then the 7-digit AAR number provides the same routing as UDP.
- Dial Plan
  - All of the extension numbers on a switch are not necessarily part of UDP. Any that do not belong to UDP are handled by a regular, non-UDP Dial Plan associated with the switch.
  - When administering the Dial Plan form and designating a group of extensions as UDP non-local, you can specify whether you want to search for local extensions first or last. This allows flexibility to change extensions from local to non-local and vice-versa.
- DID Trunk Group

DID calls to 5-digit UDP extension numbers require that the DID trunk group insert enough digits to make a 5-digit extension number.
- Distributed Communications System

UDP is required when DCS is provided. The necessary UDP software is provided with the DCS software.
- Extension Number Portability

If an extension code is administered to use ENP node routing, ENP routes the call to the correct switch. If AAR is enabled in addition to UDP, the 7-digit AAR number provides the same routing as UDP (that is, via ENP).

## **Private Networking Forms**

This section describes the following forms related to private networking:

- ATM PNC
- ATM Measurements
- Extended Trunk Access Call Screening Form
- Extension Number Portability Numbering Plan
- Hop Channel Assignments
- Node Number Routing

## .ATM-PNC Form

This form is used to administer the TN2238 circuit pack associated with a port network connectivity (PNC) configuration using an ATM switch. The ATM PNC form is identical for processor port network (PPN) and the expansion port network (EPN).

### Administration Commands

Use the following commands to administer the ATM PNC form.

| Action  | Object  | Qualifier                |
|---------|---------|--------------------------|
| change  | atm pnc | <i>connection-number</i> |
| display | atm pnc | <i>connection-number</i> |
| add     | atm pnc | <i>connection-number</i> |
| remove  | atm pnc | <i>connection-number</i> |
| list    | atm pnc |                          |

#### NOTE:

These commands are available only if the “Asynch. Transfer Mode (ATM) PNC?” field on the Customer Options form is set to “y”.

### Form Description

| AFI:               | AFI:               |
| E.164:             | E.164:             |
| HO-DSP:            | HO-DSP:            |
| ESI:               | ESI:               |
| SEL:               | SEL:               |

### Screen 12-2. ATM PNC Form — Critical Reliability

Make assignments as required for the following fields on the form:

- **Connection Number** — 1–44 entered from the command line. Display only.
- **Location** — Enter cabinet(1–x); carrier(A–E); slot(01–03. Default is blank.
- **Name** — Enter 1–15 alphanumeric characters. Default is blank.
- **Address Format** — Enter **E.164 ATM Private**, **DCC ATM**, or **ICD ATM**. Default is E.164 ATM Private.
- **AFI** — Authority and Format Identifier. Valid values are 39, 45, or 47. Default is 45. Display only.
- **E.164** — Field name may also be DCC or ICD, depending on the value of the Address Format field. Enter 1–15 decimal digits. Default is blank.
- **DCC** — Data Country Code. Enter 1–4 decimal digits. Default is blank.
- **ICD** — International Code Designator. Enter 1–4 decimal digits. Default is blank.
- **HO-DSP** — High-Order Domain-Specific Part. Enter 8 hexadecimal digits if Address Format is **E.164**; otherwise enter 20 hexadecimal digits. Default is blank.
- **ESI** — End System Identifier. Enter 12 hexadecimal digits. Default is blank.
- **SEL** — Selector. Enter 2 hexadecimal digits. Default is blank.

#### NOTE:

For critical reliability, the A-PNC field values cannot be changed; the B-PNC field values can be changed only if A-PNC is active and B-PNC has been busied-out.

## Extended Trunk Access Call Screening Form

---

This form allows a set of digit strings to be identified that should not be routed via ETA. This form can also block the routing of certain FACs or TACs. For example, if the system administrator were to notice a digit string being mistakenly dialed repeatedly that ended up being routed via ETA to a remote PBX only to have the remote PBX return intercept treatment, then that digit string would be a candidate for the entry into the ETA call screening table. Entry into this table would have the effect of return intercept treatment to the caller without first attempting to route the digits to the remote PBX for interpretation via ETA.

### Administration Commands

---

Use the following commands to administer the Extended Trunk Access Call Screening form.

| Action  | Object         | Qualifier |
|---------|----------------|-----------|
| change  | call-screening |           |
| display | call-screening |           |

### Form Instructions

12 Private Networking Forms

*Extended Trunk Access Call Screening Form*

Page 12-114

Make assignments as required for the following fields on the form:

- **Call Screening Entry** — Assign those digit strings (up to 10) that should be blocked for this RNX. Each string can have up to 6 digits and/or special or wildcard characters. Valid entries are the digits **0** through **9**, **x**, **X**, **\***, and **#**. The **"#"** character may only be used as the first character.

# Extension Number Portability Numbering Plan Form

## Administration Commands

Use the following commands to administer the ENP Numbering Plan form.

| Action  | Object          | Qualifier <sup>1</sup>  |
|---------|-----------------|-------------------------|
| change  | enp-number-plan |                         |
| display | enp-number-plan | ['print' or 'schedule'] |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.

Screen 12-4. Extension Number Portability Numbering Plan Form (Page 1 of 1)

Make assignments as required for the following fields on the form.

- **ENP Code** — Assign a 3-digit code to translate each 4- or 5-digit UDP extension that is node number routed to a 7 digit, AAR-like number used for outpulsing a call within an ENP sub network. This field maps each leading digit of a UDP extension to an ENP Code or blank.

## Hop Channel Assignments Form

This form assigns Hop Channels. The maximum number of connections that may be established between channels on the system's interface links varies depending on System configuration.

### Administration Commands

Use the following commands to administer the Hop Channel Assignment form.

| Action  | Object                  | Qualifier <sup>1</sup>               |
|---------|-------------------------|--------------------------------------|
| change  | communication-interface | hop-channels                         |
| display | communication-interface | hop-channels ['print' or 'schedule'] |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered.

Screen 12-5. Hop Channel Assignment Form (Page 1 of 4)

THE INTERFACE CHANNELS ON THE TANDEM SWITCH SHOULD MATCH THE INTERFACE CHANNELS ON SWITCHES A AND B. THE PROCESSOR CHANNELS DO NOT HAVE TO MATCH.

Figure 12-1. Interface Channel Assignments Between Switches

## Node Number Routing Form

---

This form specifies the routing pattern associated with each node in a public or private network. NNR is a required capability for Extension Number Portability (ENP) and is associated with the Uniform Dial Plan (UDP).

### Administration Commands

---

Use the following commands to administer the Node Number Routing form.

| Action  | Object       | Qualifier <sup>1</sup>                       |
|---------|--------------|--|
| change  | node-routing | Enter digits between 1-MAX ['partition' 1-8] |
| display | node-routing | Enter digits between 1-MAX ['partition' 1-8] |
| list    | node-routing | Enter digits between 1-MAX ['partition' 1-8] |

- 
1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ' ) indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

**Form Instructions**

```

Screen 12-7. Node Number Routing Form (Page 1 of 2)

Make assignments as required for the following fields on the form.

- **Partitioned Group Number** — This read-only field displays the partitioned group number associated with the node numbers being administered. The partitioned group number is either specified on the command line or defaults to partitioned group number 1.
- **Node Number** — This display-only field lists the node number to be changed.

**NOTE:**

Two pages display simultaneously for a total of 200 nodes (100 per page). For example, entering **change node-routing 87** displays nodes 1 through 199, and entering **change node-routing 151** displays nodes 100 through 299. However, entering **change node-routing 999** displays nodes 900 through 999 on one page.

- **Route Pat** — Enter the routing pattern associated with the corresponding node number. This field repeats the same number of times as there are node numbers on the page; default is blank

## Uniform Dial Plan Form

This form administers the Uniform Dial Plan (UDP).

### Administration Commands

Use the following commands to administer the Uniform Dial Plan form.

| Action  | Object | Qualifier <sup>1</sup>  |
|---------|--------|---|
| change  | udp    | Enter 1-MAX digits between 0-9, 'x' or 'X'  |
| display | udp    | Enter 1-MAX digits between 0-9, 'x' or 'X' ['print' or 'schedule']                        |
| list    | udp    | Enter ['ext' x]['to-ext' x][ 'type' x [[ 'dest' x][to-dest' x]] ] ['print' or 'schedule'] |

1. Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration.

Screen 12-9. Uniform Dial Plan Form (Page 2 of 2)

Make assignments as required for the following fields on each page of the form:

- **Ext Codes** — Displays a string of digits, "x", and "dd." The position of the dd shows which digit positions of the Ext Codes are being administered. For example, **512dd** means that the last two digits of the Ext Codes, for the leading digits 512, are being administered on the form. The string, **5ddxx**, shows that the second and third digits of the Ext Codes, for the leading digit 5, are being administered on the form (these entries would all be wildcard entries).
- **Ext Code, Type** (and associated data) — Displays what rules apply if the entries on the form are not administered. For example, shows a form for Ext Codes starting with 512. If these entries are not administered, the entry for Ext Code 51xxx applies to these entries, and if Ext Code 51xxx is not administered, the entry for Ext Code 5xxxx applies to these entries. In a 5-digit UDP, these read-only fields display only if at least 3 digits are specified in the command-line key, although one set (the set on the left) of these fields would still display if 2 digits are specified in the command-line key. If only 1 digit is specified or if 'x' or 'X' is specified in the command-line key, then neither of these sets of fields display, since there is no Ext Code more general than those listed on the form.
- **dd** — Displays the two digits (or x's) representing the extension or group of extensions to be administered. For this field, "xx:" is repeated on both pages, since it is the default for all other entries on both pages. Changing the type associated with this field on one page changes it on both pages.
- **Type** — Specify the type of treatment for the extension (**AARCode**, **ENPNode**, **Local**, **TempOOS**, **UDPCode**, or blank). That is, specify whether the extension should receive intercept treatment, be converted to AAR, or be converted via ENP. The difference between AAR Location Codes and UDP Location Codes is that 7-digit AAR Numbers created from

AAR Location Codes may be changed during AAR analysis by AAR digit conversion before being routed. Seven-digit AAR Numbers created from UDP Location Codes are not subject to digit conversion before being routed with AAR digit analysis.

When an extension code that is displayed on the UDP form is not administrable because it conflicts with the translations in the first and/or second digit tables, then the type field for that extension code displays "NotInDP."

The entry **TempOOS** indicates an extension is temporarily out-of-service. Calls to these extensions receive reorder.

A blank entry indicates this Ext code is not administered. If no matching code can be found, then the call receives intercept treatment.

- **Location Code** — Specify the 3-digit location code for Ext Codes administered with a type of AARCode or UDPCode. This field displays if AARCode or UDPCode is entered as the type.
- **Node Number** — Specify the node number for Ext Codes administered with a type of ENPNode. This field pops up if ENPNode is entered as the type.

**NOTE:**

This node number must not be the same as the local node number on the dial plan form.

## **Transition Reference**

---

### **DEFINITY ECS R6.1 to R6.3 Transition Reference**

This appendix presents two types of information. First, it lists all DEFINITY ECS Release 6.3 features, and notes which are new or changed for Release 6.3. Second, it provides a brief description of feature changes. See the individual feature descriptions for a detailed explanation of new and changed features.

### **Release 6.3 Features**

[Table A-1](#) lists R6.3 enhancements to existing features.

**Table A-1. Release 5.4 to Release 6.3 Transition Reference**

| <b>Feature Name</b>   | <b>New R6.3 Feature</b> | <b>Changed for R6.3</b> |
|---|-------------------------|-------------------------|
| 6400-Series Voice Terminals   |                         |                         |

## Release 6.3 Enhancements

---

### Abbreviated Dialing, Enhanced

- Users of 8400 and 6400 display phones can create menu-display labels for AD and other buttons. Abbreviated dialing and display messages can be programmed on these phones with the handset in place.

### 6402D Voice Terminal

- This is a 2-line display terminal that supports 1-way speakerphone.

### Best Service Routing™ (BSR)

- This feature automatically compares splits or skills in ACD environments to find the one that can provide the best service to each caller. BSR can operate at a single site, or it can be used with Look-Ahead Interflow to integrate a network of geographically distributed locations into a virtual call center.

### DIOD Data on Digital Trunk

- Direct Inward and Outward Dialing (DIOD) trunk groups now support both voice and data transmissions.

### Incoming Call Line Identification on Analog Trunks

- ICLID provides the calling party name and number received from the central office (CO) over the TN429D DIOD Trunk circuit pack.

### Information Forwarding

- Whenever DEFINITY ECS interflows a call over ISDN trunk facilities (for example, PRI or BRI) by means of a *route-to* (with Look-Ahead Interflow active), *queue-to best*, or *check best* command, user data is sent with the call via user-to-user information transport (via UUI IE or QSIG MSI) and can be used by adjuncts or displayed at the receiving switch.

### ISDN-BRI Trunk Group

- Now supports DCS over BRI trunks using BX.25 and TCP/IP links, and BRI trunks over the two-wire U interface using the TN2198 circuit pack. Country Protocol 1 (Bellcore National ISDN) was added including support of Service Profile Identifiers (SPIDs) and Endpoint Identifiers, and QSIG features developed for ISDN-PRI in R6.2 and R6.3 (Call Offer, Call Completion, and Message Waiting) are supported on BRI trunks.

### Look-Ahead Interflow

- Balances the load of ACD calls across multiple locations. Enhanced Look-Ahead Interflow (with DEFINITY R6.3) results in First in First Out (FIFO) or near FIFO call routing via a new conditional and uses less computer processing resources.

#### Mode Code Related System Parameters Form

- Three new fields are added to this form: System In Day Service, System In Night Service, and VMS Hunt Group Extension.

#### Multimedia Call Handling

- The new Enhanced mode of operation allows a multifunction user to control a multimedia call like a standard voice call.

#### Multimedia Call Handling — Enhanced Mode

- The Enhanced mode of operation allows a multifunction voice terminal to control a multimedia call like a standard voice call.

#### QSIG Call Independent Signaling Connections

- CISCs are functionally equivalent to the Temporary Signaling Connection supported on DEFINITY ECS. These are used to pass QSIG Supplementary Service information that is independent of an active call between two QSIG compliant nodes.

#### QSIG Supplementary Service - Call Completion

- Completion of Calls to Busy Subscribers and Completion of Calls on No Reply are the equivalent QSIG features of Automatic Callback on Busy and Automatic Callback on No Answer, respectively. Both allow any QSIG network voice user who placed a call to a busy or unanswered voice terminal over the QSIG network to be called back automatically when the called voice terminal becomes available.

#### Russian Incoming ANI

- Provides the switch with the capability to receive the calling party's number from incoming Russian trunks.

#### Russian Multiple ANI

- Allows MF ANI (calling party number, signaled via multifrequency signaling) prefix digits to be defined on a class of restriction basis. This allows a PBX servicing multiple COs to provide different ANIs to each.

#### Universal Call ID

- Tags a call with a unique identifier. In simple call scenarios, the tag stays with that call within a DEFINITY-based network connected by ISDN lines. In complex call scenarios, the tag often merges with other tags.

## Administration Commands

# B

---

### Commands

---

The following pages provide a summary of the available commands and their associated objects.

You can display a list of the available actions, objects and qualifiers at any time by pressing the Help key. The list that appears contains only those words that are appropriate, based on your login permissions and the words already entered on the command line.

### Restrictions

---

You will not be able to execute a command if:

- You do not have permission to execute the command
- The system configuration does not require a command
- The command is a member of a set of commands that is being used by another user.

## Add

---

The add command allows you to add objects to the system. The object you add must not already exist in the system. For example, if you enter the command, **add attendant 3**, there must not already be an "attendant 3." If the name you selected already exists, an error message appears and you will need to rename the attendant or other object.

The following objects are available for use with the *add* command. You can display this list by pressing the Help key after entering the action word "add."

- |                           |                             |                   |
|---------------------------|-----------------------------|-------------------|
| ■ abbreviated-dialing     | ■ eda-external-device-alarm | ■ pgate           |
| ■ access-endpoint         | ■ fiber-link                | ■ pickup-group    |
| ■ administered-connection | ■ hunt-group                | ■ second-digit    |
| ■ agent-loginID           | ■ intercom-group            | ■ signaling-group |
| ■ attendant               | ■ intra-switch-cdr          | ■ station         |
| ■ best-service-routing    | ■ login-ID                  | ■ term-ext-group  |
| ■ cabinet                 | ■ modem-pool                | ■ test-schedule   |
| ■ coverage                | ■ personal-CO-line          | ■ trunk-group     |
| ■ data-module             | ■ pri-endpoint              | ■ vdn             |
| ■ ds1                     | ■ prec                      | ■ vrt             |

## Change

---

The object you want to change must be currently administered in the system. In addition to the objects listed below, you can change adjunct information by entering the command **change adjunct-name**, where adjunct-name is the name of the administered adjunct.

- |                            |                             |                          |
|----------------------------|-----------------------------|--------------------------|
| ■ aar                      | ■ digit-absorption          | ■ remote access          |
| ■ abbreviated-dialing      | ■ display-messages          | ■ report-scheduler       |
| ■ access-endpoint          | ■ ds1                       | ■ rhnpa                  |
| ■ adjunct-controlled-agent | ■ enp-number-plan           | ■ route-pattern          |
| ■ administered-connection  | ■ eda-external-device-alarm | ■ second-digit           |
| ■ agent-loginID            | ■ feature-access-code       | ■ signaling-group        |
| ■ alias                    | ■ fiber-link                | ■ sit-treatment          |
| ■ alphanumeric-dial-table  | ■ hunt-group                | ■ site-data              |
| ■ alternate-frl            | ■ intercom-group            | ■ station                |
| ■ announcements            | ■ integ-annc-brd-loc        | ■ synchronization        |
| ■ ars                      | ■ intra-switch-cdr          | ■ system-parameters      |
| ■ best-service-routing     | ■ isdn                      | ■ telecommuting-access   |
| ■ bulletin-board           | ■ ixc-codes                 | ■ tenant                 |
| ■ attendant                | ■ listed-directory-numbers  | ■ term-ext-group         |
| ■ authorization-code       | ■ login                     | ■ terminal-parameters    |
| ■ cabinet                  | ■ mct-group-extensions      | ■ test-schedule          |
| ■ call-screening           | ■ meas-selection            | ■ time-of-day            |
| ■ circuit-packs            | ■ modem-pool                | ■ toll                   |
| ■ communication-interface  | ■ mst                       | ■ trunk-group            |
| ■ console-parameters       | ■ music-source              | ■ udp                    |
| ■ cor                      | ■ node-routing              | ■ vdn                    |
| ■ cos                      | ■ paging password           | ■ vector                 |
| ■ coverage                 | ■ permissions               | ■ vrt                    |
| ■ data-module              | ■ personal-CO-line          | ■ vustats-display-format |
| ■ dialplan                 | ■ pickup-group              |                          |
|                            | ■ pri-endpoint              |                          |

## Clear

---

The clear command allows you to clear measurements for security violations and to clear (turn off) message waiting lamps.

- amw
- measurements

## Display

---

Allows viewing of parameters associated with a specific object/qualifier. If the command *display station 4444* is entered, for example, the voice terminal screen form currently administered for extension 4444 is displayed. If you use the "print" qualifier, for example, *display station 4444 print*, the form is printed on the printer associated with the administration terminal.

The following object words are available for use with the *display* command. In addition to the words listed below, you can display adjunct information by entering the command **display adjunct-name**, where adjunct-name is the name of the administered adjunct.

- |                           |                                 |                            |
|---------------------------|---------------------------------|----------------------------|
| ■ aar                     | ■ coverage                      | ■ listed-directory-numbers |
| ■ abbreviated-dialing     | ■ data-module                   | ■ login                    |
| ■ access-endpoint         | ■ dialplan                      | ■ mct-group-extensions     |
| ■ administered-connection | ■ digit-absorption              | ■ meas-selection           |
| ■ agent-loginID           | ■ disabled-tests                | ■ memory-configuration     |
| ■ alias                   | ■ display-messages              | ■ modem-pool               |
| ■ alphanumeric-dial-table | ■ ds1                           | ■ mst                      |
| ■ alternate-frl           | ■ enp-number-plan               | ■ node-routing             |
| ■ announcements           | ■ errors                        | ■ paging                   |
| ■ ars                     | ■ events                        | ■ permissions              |
| ■ attendant               | ■ eda-external-device-<br>alarm | ■ personal-CO-line         |
| ■ authorization-code      | ■ feature-access-codes          | ■ pgate                    |
| ■ best-service-routing    | ■ fiber-link                    | ■ pickup-group             |
| ■ bulletin-board          | ■ hunt-group                    | ■ port                     |
| ■ buttons-location-aca    | ■ initcauses                    | ■ pri-endpoint             |
| ■ cabinet                 | ■ integrated-annc-boards        | ■ reason-code-names        |
| ■ call-screening          | ■ intercom-group                | ■ remote-access            |
| ■ capacity                | ■ internal-data                 | ■ rhnpa                    |
| ■ circuit-packs           | ■ intra-switch-cdr              | ■ route-pattern            |
| ■ communication-interface | ■ isdn                          | ■ second-digit             |
| ■ console-parameters      | ■ ixc-codes                     | ■ signaling-group          |
| ■ cor                     |                                 | ■ sit-treatment            |
| ■ cos                     |                                 |                            |

- |                       |                        |                          |
|-----------------------|------------------------|--------------------------|
| ■ site-data           | ■ telecommuting-access | ■ toll                   |
| ■ software            | ■ term-ext-group       | ■ trunk-group            |
| ■ station             | ■ terminal-parameters  | ■ udp                    |
| ■ svn-button-location | ■ tenant               | ■ vdn                    |
| ■ synchronization     | ■ test-schedule        | ■ vector                 |
| ■ system-parameters   | ■ time                 | ■ vrt                    |
|                       | ■ time-of-day          | ■ vustats-display-format |

## Duplicate

---

Allows duplication of existing objects and must be used with a qualifying extension to automatically establish service for multiple voice terminals and data modules. Only one data module can be duplicated at a time. Up to 16 stations can be duplicated at one time. The objects that can be duplicated are:

- access-endpoint
- administered-connection
- data-modules
- station

## List

---

Displays parameters associated with groups of objects. Use this command to obtain a list of all, or a range of, voice terminals, trunks, and other features that have been administered. The list command and its associated qualifiers can be used to retrieve data for all the ports in the system, or for a specified subset of ports. The following objects are available for use with the *list* command.

- |                             |                         |                          |
|-----------------------------|-------------------------|--------------------------|
| ■ aar                       | ■ integrated-ann-boards | ■ set-data               |
| ■ abbreviated-dialing       | ■ intercom-group        | ■ signaling-group        |
| ■ aca-parameters            | ■ intra-switch-cdr      | ■ sys-link               |
| ■ access-endpoint           | ■ isdn-testcall         | ■ station                |
| ■ administered-connection   | ■ logins                | ■ tenant                 |
| ■ agent-loginID             | ■ marked-ports          | ■ term-ext-group         |

| ■ groups-of-extension       | ■ report scheduler      |                          |
| ■ historyhunt-group         | ■ route-pattern         |                          |

## Remove

---

Displays the form for the associated object. For example, if you type the command *remove station 8000*, the form for station 8000 appears. If you want to remove this station, press ENTER to delete it from the system. Press CANCEL to leave the station as it is. The following objects are available for use with the *remove* command.

- |                             |                    |                    |
|-----------------------------|--------------------|--------------------|
| ■ abbreviated-dialing       | ■ fiber-link       | ■ report scheduler |
| ■ access-endpoint           | ■ hunt-group       | ■ second-digit     |
| ■ administered-connection   | ■ intercom-group   | ■ signaling-group  |
| ■ agent-loginID             | ■ login            | ■ station          |
| ■ attendant                 | ■ modem-pool       | ■ term-ext-group   |
| ■ best-service-routing      | ■ personal-CO-line | ■ test-schedule    |
| ■ cabinet                   | ■ pgate            | ■ trunk-group      |

## Status

---

Displays the operational status of the facility indicated by the object word. A complete description of all status commands is provided in *DEFINITY Enterprise Communications Server Maintenance*. The following object words are available for use with the *status* command. You can display this list by pressing the Help key after entering the action word "status."

- |                           |                      |                    |

## References

---

This section contains a list of user documents for the DEFINITY Enterprise Communications Server (ECS) Release 6. (Most of these documents are backward compatible with, and can be used with, the DEFINITY ECS Release 5 systems.)

To order these or other DEFINITY documents, contact the Lucent Technologies Publications Center at the address and phone number on the back of the title page of this document. A complete catalog of Business Communications Systems (BCS) documents, including previous issues of the documents listed here, is available on the World Wide Web. Ask your account team for the web address.

### **Basic DEFINITY ECS Documents**

---

These documents are issued for all new and upgrade DEFINITY ECS Release 6 systems.

#### **Administration**

##### ***DEFINITY ECS Release 6 — Overview, Issue 5, 555-230-024***

Provides a detailed overview of the ECS including descriptions of many of the major features, applications, hardware, system capabilities, and the support provided with the system. This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Latin Spanish (SPL), Italian (IT), Russian (RU), and Japanese (JA). To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

***DEFINITY ECS Release 6.2 — Change Description, Issue 1, 555-230-476***

Gives a high-level overview of what is new in DEFINITY ECS Release 6. Describes the hardware and software enhancements and lists the problem corrections for this release.

***DEFINITY ECS Release 6 — System Description Pocket Reference, Issue 2, 555-230-211***

Provides hardware descriptions, system parameters, listing of hardware required to use features, system configurations, and environmental requirements. This compact reference combines and replaces Release 6 *System Description and Specifications* and Release 6 *Pocket Reference*.

***DEFINITY ECS Release 6 — Administration and Feature Description, Issue 3, 555-230-522***

Provides descriptions of system features. Also provides step-by-step procedures for preparing the screens that are required to implement the features, functions, and services of the system. Includes the applications and benefits, feature interactions, administration requirements, hardware requirements, and procedures for voice terminal, data module, and trunk group administration.

***DEFINITY System's Little Instruction Book, Issue 3, 555-230-727***

Provides step-by-step procedures for performing basic switch administration tasks. Includes managing phones, managing features, generating reports, enhancing system security, and troubleshooting.

***DEFINITY ECS Release 5 — System Monitoring and Reporting, Issue 4, 555-230-511***

Provides detailed descriptions of the measurement, status, security, and recent change history reports available in the system and is intended for administrators who validate traffic reports and evaluate system performance. Includes corrective actions for potential problems. Issue 2 of this document was titled *Traffic Reports*. The Release 5 version of this document applies to Release 6 as well.

***DEFINITY ECS Release 6 — Implementation Blank Forms, Issue 3, 555-230-303***

Provides blank paper forms corresponding to the screens that are required to implement the features, functions, and services of the system. The Release 5 forms apply to Release 6 as well.

***BCS Products Security Handbook, Issue 6, 555-025-600***

Provides information about the risks of telecommunications fraud and measures for addressing those risks and preventing unauthorized use of BCS products. This document is intended for telecommunications managers, console operators, and security organizations within companies.

***DEFINITY ECS Release 6— Terminals and Adjuncts Reference, Issue 9, 555-015-201***

Provides descriptions of the peripheral equipment that can be used with System 75, System 85, DEFINITY Communications System, and DEFINITY ECS. This document is intended for customers and Lucent Technologies account teams for selecting the correct peripherals to accompany an ECS. The Release 5 version of this document applies to Release 6 as well.

***DEFINITY ECS — Telephone Guide Builder, Issue 4, 555-230-755***

Provides capability to produce laser-printed documentation for specific telephones. The software is supported by a comprehensive user's guide and on-line help. This product requires a 386 PC, minimum of 6MB disk space, minimum of 4MB RAM, a printer supported by Microsoft GDI printer drive, and Microsoft Windows 3.1 or higher. A mouse is recommended. This document applies to Release 6 as well as earlier DEFINITY systems.

***DEFINITY ECS — International Telephone Guide Builder, Issue 1, 555-230-742***

Same as 555-230-755 but customized for international locations.

***Guide Builder Software for DEFINITY ECS Telephones, Issue 1, 555-230-755***

Guide Builder is software used to produce laser-printed documentation for specific voice terminals. It is supported by a quick reference guide and online help.

## Installation and Maintenance

***DEFINITY ECS Release 6 — Installation and Test for Single-Carrier Cabinets, Issue 3, 555-230-894***

Provides procedures and information for hardware installation and initial testing of single-carrier cabinets. The Release 5 version of this document applies to Release 6 as well.

This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Castillian Spanish (SP), Italian (IT), Russian (RU), and Japanese (JA). To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

***DEFINITY ECS Release 6 — Installation and Upgrades for CSCC, Issue 1, 555-230-124***

Provides procedures and information for hardware installation, upgrades, and initial testing of compact single-carrier cabinets. The Release 5 version of this document applies to Release 6 as well.

***DEFINITY ECS Release 6 — Installation and Test for Multi-Carrier Cabinets, Issue 4, 555-230-112***

Provides procedures and information for hardware installation and initial testing of multi-carrier cabinets.

***DEFINITY ECS Release 6 — Installation and Test for Compact Modular Cabinets, Issue 2, 555-230-128***

Provides procedures and information for hardware installation and initial testing of compact modular cabinets.

***DEFINITY ECS Release 6 — Installation for Adjuncts and Peripherals, Issue 3, 555-230-125***

Provides procedures and information for hardware installation and initial testing of ECS adjunct and peripheral systems and equipment.

***DEFINITY ECS Release 6 — Upgrades and Additions for R6r, Issue 4, 555-230-121***

Provides procedures for an installation technician to convert an existing Generic 3 Version 4 DEFINITY Communications System to DEFINITY ECS and from DEFINITY ECS Release 5 to DEFINITY ECS Release 6.

Included are upgrade considerations, lists of required hardware, and step-by-step upgrade procedures. Also included are procedures to add control carriers, switch node carriers, port carriers, circuit packs, auxiliary cabinets, and other equipment.

***DEFINITY ECS Release 6 — Upgrades and Additions for R6vs/si, Issue 4, 555-230-120***

Provides procedures for an installation technician to convert an existing DEFINITY Communications System Generic 3 Version 4 to DEFINITY ECS and from DEFINITY ECS Release 5 to DEFINITY ECS Release 6.

Included are upgrade considerations, lists of required hardware, and step-by-step upgrade procedures. Also included are procedures to add control carriers, switch node carriers, port carriers, circuit packs, auxiliary cabinets, and other equipment.

***DEFINITY ECS Release 6 — Maintenance for R6r, Issue 2, 555-230-126***

Provides detailed descriptions of the procedures for monitoring, testing, troubleshooting, and maintaining the R6r ECS. Included are maintenance commands, step-by-step trouble-clearing procedures, the procedures for using all tests, and explanations of the system's error codes.

***DEFINITY ECS Release 6 — Maintenance for R6vs/si, Issue 2, 555-204-127***

Provides detailed descriptions of the procedures for monitoring, testing, troubleshooting, and maintaining the R6vs/si ECS. Included are maintenance commands, step-by-step trouble-clearing procedures, the procedures for using all tests, and explanations of the system's error codes.

***DEFINITY ECS Release 6 — Maintenance for R6csi (Compact Modular Cabinets), Issue 2, 555-204-129***

Provides detailed descriptions of the procedures for monitoring, testing, troubleshooting, and maintaining the R6csi ECS. Included are maintenance commands, step-by-step trouble-clearing procedures, the procedures for using all tests, and explanations of the system's error codes.

***DEFINITY ECS — International Telephone Guide Builder, Issue 1, 555-230-742***

Same as 555-230-755 above but customized for international locations.

## **Call Center Documents**

---

These documents are issued for DEFINITY ECS Call Center applications.

### **DEFINITY**

***DEFINITY ECS Release 6 — Call Vectoring/EAS Guide, Issue 1, 585-230-521***

Provides information on how to write, use, and troubleshoot vectors, which are command sequences that process telephone calls in an Automatic Call Distribution (ACD) environment. This document applies to Release 6 as well as earlier DEFINITY systems.

It is provided in two parts: tutorial and reference. The tutorial provides step-by-step procedures for writing and implementing basic vectors. The reference includes detailed descriptions of the call vectoring features, vector management, vector administration, adjunct routing, troubleshooting, and interactions with management information systems (including the Call Management System).

***DEFINITY ECS Release 6 — Basic Call Management System (BCMS) Operations, Issue 1, 555-230-706***

Provides detailed instructions on how to generate reports and manage the system. It is intended for telecommunications managers who wish to use BCMS (Basic Call Management System) reports and for system managers responsible for maintaining the system. This documentation applies to Release 6 as well as earlier DEFINITY systems.

## CentreVu CMS

***CentreVu Call Management System Release 3 Version 5 — Administration, Issue 1, 585-215-820***

***CentreVu Call Management System Release 3 Version 5 — Reports, Issue 1, 585-215-821***

***CentreVu Call Management System Release 3 Version 5 — Custom Reports, Issue 1, 585-215-822***

***CentreVu Call Management System Release 3 Version 5 — Upgrades and Migrations, Issue 3, 585-215-826***

***CentreVu Call Management System Release 3 Version 5 — External Call History Reference, Issue 1, 585-215-824***

***CentreVu Call Management System Release 3 Version 5 — Forecast, Issue 1, 585-215-825***

## Application-Specific Documents

These documents support specific DEFINITY applications.

***DEFINITY ECS Generic 2 to Release 5 — Transition Reference, Issue 1, 555-230-523***

Provides information on the differences in features and administration between the old and new systems when upgrading from a Generic 2 system to DEFINITY ECS Release 5.

## ASAI

***DEFINITY ECS Release 6 — CallVisor ASAI Planning Guide, Issue 4, 555-230-222***

Provides procedures and directions for the account team and customer personnel for effectively planning and implementing the CallVisor Adjunct/Switch Application Interface (ASAI) PBX-Host environment. The CallVisor ASAI is a communications interface that allows adjunct processors to access switch features and to control switch calls. It is implemented using an Integrated Services Digital Network (ISDN) Basic Rate Interface (BRI). Hardware and software requirements are included.

***DEFINITY ECS Release 6 — CallVisor ASAI Protocol Reference, Issue 7, 555-230-221***

Provides detailed layer 3 protocol information regarding the CallVisor Adjunct/Switch Application Interface (ASAI) for the systems and is intended for the library or driver programmer of an adjunct processor to create the library of commands used by the applications programmers. Describes the ISDN message, facility information elements, and information elements.

***DEFINITY ECS Release 6 — CallVisor ASAI Technical Reference, Issue 7, 555-230-220***

Provides detailed information regarding the CallVisor Adjunct/Switch Application Interface (ASAI) for the systems and is intended for the application designer responsible for building and/or programming custom applications and features.

***DEFINITY ECS Release 6 — CallVisor ASAI DEFINITY LAN Gateway over MAP-D Installation, Administration, and Maintenance of, Issue 1, 555-230-114***

Provides procedures for installation, administration, and maintenance of the CallVisor Adjunct/Switch Application Interface (ASAI) Ethernet application over the DEFINITY LAN Gateway and is intended for system administrators, telecommunications managers, Management Information System (MIS) managers, LAN managers, and Lucent personnel. The ASAI-Ethernet application provides ASAI functionality using 10Base-T Ethernet rather than BRI as a transport media.

***DEFINITY ECS Release 6 — CallVisor ASAI PC LAN over MAP-D Installation, Administration, and Maintenance of, Issue 1, 555-230-113***

Provides procedures for installation, administration, and maintenance of the CallVisor Adjunct/Switch Application Interface (ASAI) Ethernet application over the PC LAN and is intended for system administrators, telecommunications managers, Management Information System (MIS) managers, LAN managers, and Lucent personnel. The ASAI-Ethernet application provides ASAI functionality using 10Base-T Ethernet rather than BRI as a transport media.

***DEFINITY ECS Release 6 — Call Visor ASAI Overview, Issue 2, 555-230-225***

Provides a general description of Call Visor ASAI.

This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Colombian Spanish (SPL), and Japanese (JA). To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

***DEFINITY ECS Release 6 — CallVisor PC ASAI Installation and Reference, Issue 3, 555-230-227***

Provides procedural and reference information for installers, Tier 3 support personnel, and application designers.

## ACD

### ***DEFINITY ECS Release 6 — Automatic Call Distribution (ACD) Agent Instructions, Issue 5, 555-230-722***

Provides information for use by agents after they have completed ACD training. Includes descriptions of ACD features and the procedures for using them.

### ***DEFINITY ECS Release 6 — Automatic Call Distribution (ACD) Supervisor Instructions, Issue 4, 555-230-724***

Provides information for use by supervisors after they have completed ACD training. Includes descriptions of ACD features and the procedures for using them.

## Call Detail Recording

### ***Call Detail Acquisition & Processing Reference, Issue 2, 555-006-202***

Provides a general technical description of the ECS call detail recording feature and of the products that collect, store, poll, and process call records.

## Console Operations

### ***DEFINITY ECS Console Operations, Issue 3, 555-230-700***

Provides operating instructions for the attendant console. Included are descriptions of the console control keys and functions, call-handling procedures, basic system troubleshooting information, and routine maintenance procedures.

### ***DEFINITY ECS Release 6 — Console Operations Quick Reference, Issue 2, 555-230-890***

Provides operating instructions for the attendant console. Included are descriptions of the console control keys and functions, call handling, basic system-troubleshooting information, and routine maintenance procedures.

This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Colombian Spanish (SPL), and Japanese (JA). To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

## Hospitality

### ***An Introduction to DEFINITY Communications System Generic 3 Hospitality Services, Issue 1, 555-230-021***

Provides an overview of the features available for use by the lodging and health industries to improve their property management and to provide assistance to their employees and clients. Included are brief definitions of many of the system features, descriptions of the hardware, planning considerations, and list of the system capabilities. This documentation also applies to Release 6.

***DEFINITY ECS Release 6 — Hospitality Operations, Issue 4, 555-230-723***

Provides step-by-step procedures for using the features available for the lodging and health industries to improve their property management and to provide assistance to their employees and clients. Includes detailed descriptions of reports.

## Documents on CD-ROM

---

The following CD-ROMs are available from the Publications Center.

***Administration and Call Center CD-ROM, Issue 3, 555-230-828***

Includes the documents listed in the Administration, Call Center, Console Operations, and Hospitality sections above.

***DEFINITY ECS Release 6 Documentation Library CD-ROM, Issue 1, 555-230-833***

A comprehensive set of DEFINITY documentation. Includes the documents in the Administration and Call Center CD-ROM *and* the documents listed in the Installation and Maintenance sections above.

# Glossary and Abbreviations

---

## Numerics

### 800 service

A service in the United States that allows incoming calls from certain areas to an assigned number for a flat-rate charge based on usage.

---

## A

### AA

Archangel. See [angel](#).

### AAC

ATM access concentrator

### AAR

See [Automatic Alternate Routing \(AAR\)](#).

### abandoned call

An incoming call in which the caller hangs up before the call is answered.

### Abbreviated Dialing (AD)

A feature that allows callers to place calls by dialing just one or two digits.

### AC

1. Alternating current.
2. See [Administered Connection \(AC\)](#).

### AAR

Automatic Alternate Routing

### ACA

See [Automatic Circuit Assurance \(ACA\)](#).

### ACB

See [Automatic Callback \(ACB\)](#).

### ACD

See [Automatic Call Distribution \(ACD\)](#).

### ACD agent

See [agent](#).

### ACU

See [Automatic calling unit \(ACU\)](#)

### ACW

See [after-call work \(ACW\) mode](#).

### access code

A 1-, 2-, or 3-digit dial code used to activate or cancel a feature, or access an outgoing trunk.

**access endpoint**

Either a nonsignaling channel on a DS1 interface or a nonsignaling port on an analog tie-trunk circuit pack that is assigned a unique extension.

**access tie trunk**

A trunk that connects a main communications system with a tandem communications system in an electronic tandem network (ETN). An access tie trunk can also be used to connect a system or tandem to a serving office or service node. Also called access trunk.

**access trunk**

See [access tie trunk](#).

**ACCUNET**

A trademarked name for a family of digital services offered by AT&T in the United States.

**ACD**

See [Automatic Call Distribution \(ACD\)](#). ACD also refers to a work state in which an agent is on an ACD call.

**ACD work mode**

See [work mode](#).

**active-notification association**

A link that is initiated by an adjunct, allowing it to receive event reports for a specific switch entity, such as an outgoing call.

**active-notification call**

A call for which event reports are sent over an active-notification association (communication channel) to the adjunct. Sometimes referred to as a monitored call.

**active notification domain**

VDN or ACD split extension for which event notification has been requested.

**ACU**

See [Automatic calling unit \(ACU\)](#).

**AD**

See [Abbreviated Dialing \(AD\)](#).

**ADAP**

AUDIX Data Acquisition Package

**ADC**

See [analog-to-digital converter \(ADC\)](#).

**adjunct**

A processor that does one or more tasks for another processor and that is optional in the configuration of the other processor. See also [application](#).

**adjunct-control association**

A relationship initiated by an application via *Third Party Make Call*, the *Third Party Take Control*, or *Domain (Station) Control* capabilities to set up calls and control calls already in progress.

**adjunct-controlled call**

Call that can be controlled using an adjunct-control association. Call must have been originated via *Third Party Make Call* or *Domain (Station) Control* capabilities or must have been taken control of via *Third Party Take Control* or *Domain (Station) Control* capabilities.

**adjunct-controlled split**

An ACD split that is administered to be under adjunct control. Agents logged into such splits must do all telephony work, ACD login/ logout, and changes of work mode through the adjunct (except for auto-available adjunct-controlled splits, whose agents may not log in/out or change work mode).

**adjunct-monitored call**

An adjunct-controlled call, active-notification call, or call that provides event reporting over a domain-control association.

**Adjunct-Switch Application Interface (ASAI)**

A recommendation for interfacing adjuncts and communications systems, based on the CCITT Q.932 specification for layer 3.

**ADM**

Asynchronous data module

**administer**

To access and change parameters associated with the services or features of a system.

**Administered Connection (AC)**

A feature that allows the switch to automatically establish and maintain end-to-end connections between access endpoints (trunks) and/or data endpoints (data modules).

**administration group**

See [capability group](#).

**administration terminal**

A terminal that is used to administer and maintain a system. See also [terminal](#).

**Administration Without Hardware (AWOH)**

A feature that allows administration of ports without associated terminals or other hardware.

**ADU**

See [asynchronous data unit \(ADU\)](#).

**AE**

See [access endpoint](#).

**after-call work (ACW) mode**

A mode in which agents are unavailable to receive ACD calls. Agents enter the ACW mode to perform ACD-related activities such as filling out a form after an ACD call.

**AG**

ASAI Gateway

**agent**

A person who receives calls directed to a split. A member of an ACD hunt group or ACD split. Also called an ACD agent.

**agent report**

A report that provides historical traffic information for internally measured agents.

**AIM**

Asynchronous interface module

**AIOD**

Automatic Identification of Outward Dialing

**ALBO**

Automatic Line Build Out

**All trunks busy (ATB)**

The state in which no trunks are available for call handling.

**ALM-ACK**

Alarm acknowledge

**American Standard Code for Information Interchange**

See [ASCII \(American Standard Code for Information Interchange\)](#).

**AMW**

Automatic Message Waiting

**AN**

Analog

**analog**

The representation of information by continuously variable physical quantities such as amplitude, frequency, and phase. See also [digital](#).

**analog data**

Data that is transmitted over a digital facility in analog (PCM) form. The data must pass through a modem either at both ends or at a modem pool at the distant end.

**analog telephone**

A telephone that receives acoustic voice signals and sends analog electrical signals along the telephone line. Analog telephones are usually served by a single wire pair (tip and ring). The model-2500 telephone set is a typical example of an analog telephone.

**analog-to-digital converter (ADC)**

A device that converts an analog signal to digital form. See also [digital-to-analog converter \(DAC\)](#).

**angel**

A microprocessor located on each port card in a processor port network (PPN). The angel uses the control-channel message set (CCMS) to manage communications between the port card and the archangel on the controlling switch-processing element (SPE). The angel also monitors the status of other microprocessors on a port card and maintains error counters and thresholds.

**ANI**

See [Automatic Number Identification \(ANI\)](#).

**ANSI**

American National Standards Institute. A United States professional/technical association supporting a variety of standards.

**answerback code**

A number used to respond to a page from a code-calling or loudspeaker-paging system, or to retrieve a parked call.

**AOL**

Attendant-offered load

**AP**

Applications processor

**APLT**

Advanced Private-Line Termination

**appearance**

A software process that is associated with an extension and whose purpose is to supervise a call. An extension can have multiple appearances. Also called call appearance, line appearance, and occurrence. See also [call appearance](#).

**application**

An adjunct that requests and receives ASAI services or capabilities. One or more applications can reside on a single adjunct. However, the switch cannot distinguish among several applications residing on the same adjunct and treats the adjunct, and all resident applications, as a single application. The terms application and adjunct are used interchangeably throughout this document.

**applications processor**

A micro-computer based, program controlled computer providing application services for the DEFINITY switch. The processor is used with several user-controlled applications such as traffic analysis and electronic documentation.

**application service element**

See [capability group](#).

**architecture**

The organizational structure of a system, including hardware and software.

**ARS**

See [Automatic Route Selection \(ARS\)](#).

**ASAI**

See [Adjunct-Switch Application Interface \(ASAI\)](#)

**ASCII (American Standard Code for Information Interchange)**

The standard code for representing characters in digital form. Each character is represented by an 8-bit code (including parity bit).

**association**

A communication channel between adjunct and switch for messaging purposes. An active association is one that applies to an existing call on the switch or to an extension on the call.

**asynchronous data transmission**

A method of transmitting data in which each character is preceded by a start bit and followed by a stop bit, thus permitting data characters to be transmitted at irregular intervals. This type transmission is advantageous when transmission is not regular (characters typed at a keyboard). Also called asynchronous transmission. See also [synchronous data transmission](#).

**asynchronous data unit (ADU)**

A device that allows direct connection between RS-232C equipment and a digital switch.

**Asynchronous Transfer Mode (ATM)**

A packet-like switching technology in which data is transmitted in fixed-size (53-byte) cells. ATM provides high-speed access for data communication in LAN, campus, and WAN environments.

**ATB**

See [All trunks busy \(ATB\)](#).

**ATD**

See [Attention dial \(ATD\)](#).

**attendant**

A person at a console who provides personalized service for incoming callers and voice-services users by performing switching and signaling operations. See also [attendant console](#).

## **ATM**

See [Asynchronous Transfer Mode \(ATM\)](#).

## **attendant console**

The workstation used by an attendant. The attendant console allows the attendant to originate a call, answer an incoming call, transfer a call to another extension or trunk, put a call on hold, and remove a call from hold. Attendants using the console can also manage and monitor some system operations. Also called console. See also [attendant](#).

## **Attention dial (ATD)**

A command in the Hayes modem command set for asynchronous modems.

## **Audio Information Exchange (AUDIX)**

A fully integrated voice-mail system. Can be used with a variety of communications systems to provide call-history data, such as subscriber identification and reason for redirection.

## **AUDIX**

See [Audio Information Exchange \(AUDIX\)](#).

## **auto-in trunk group**

Trunk group for which the CO processes all of the digits for an incoming call. When a CO seizes a trunk from an auto-in trunk group, the switch automatically connects the trunk to the destination — typically an ACD split where, if no agents are available, the call goes into a queue in which callers are answered in the order in which they arrive.

## **Auto-In Work mode**

One of four agent work modes: the mode in which an agent is ready to process another call as soon as the current call is completed.

## **Automatic Alternate Routing (AAR)**

A feature that routes calls to other than the first-choice route when facilities are unavailable.\*\*\*

## **Automatic Callback (ACB)**

A feature that enables internal callers, upon reaching a busy extension, to have the system automatically connect and ring both parties when the called party becomes available.

## **Automatic Call Distribution (ACD)**

A feature that answers calls, and then, depending on administered instructions, delivers messages appropriate for the caller and routes the call to an agent when one becomes available.

## **Automatic Call Distribution (ACD) split**

A method of routing calls of a similar type among agents in a call center. Also, a group of extensions that are staffed by agents trained to handle a certain type of incoming call.

## **Automatic calling unit (ACU)**

A device that places a telephone call.

## **Automatic Circuit Assurance (ACA)**

A feature that tracks calls of unusual duration to facilitate troubleshooting. A high number of very short calls or a low number of very long calls may signify a faulty trunk.

## **Automatic Number Identification (ANI)**

Representation of the calling number, for display or for further use to access information about the caller.

**automatic restoration**

A service that restores disrupted connections between access endpoints (nonsignaling trunks) and data endpoints (devices that connect the switch to data terminal and/or communications equipment). Restoration is done within seconds of a service disruption so that critical data applications can remain operational.

**Automatic Route Selection (ARS)**

A feature that allows the system to automatically choose the least-cost way to send a toll call.

**automatic trunk**

A trunk that does not require addressing information because the destination is predetermined. A request for service on the trunk, called a seizure, is sufficient to route the call. The normal destination of an automatic trunk is the communications-system attendant group. Also called automatic incoming trunk and automatic tie trunk.

**AUX**

Auxiliary

**auxiliary equipment**

Equipment used for optional system features, such as Loudspeaker Paging and Music-on-Hold.

**auxiliary trunk**

A trunk used to connect auxiliary equipment, such as radio-paging equipment, to a communications system.

**Aux-Work mode**

A work mode in which agents are unavailable to receive ACD calls. Agents enter Aux-Work mode when involved in non-ACD activities such as taking a break, going to lunch, or placing an outgoing call.

**AVD**

Alternate voice/data

**AWOH**

See [Administration Without Hardware \(AWOH\)](#).

**AWG**

American Wire Gauge

**AWT**

Average work time

---

## B

**B8ZS**

Bipolar Eight Zero Substitution.

**bandwidth**

The difference, expressed in hertz, between the defined highest and lowest frequencies in a range.

**barrier code**

A security code used with the Remote Access feature to prevent unauthorized access to the system.

**Basic Rate Interface (BRI)**

A standard ISDN frame format that specifies the protocol used between two or more communications systems. BRI runs at 192 Mbps and provides two 64-kbps B-channels (voice and data) and one 16-kbps D-channel (signaling). The D-channel connects, monitors, and disconnects all calls. It also can carry low-speed packet data at 9.6 kbps.

**baud**

A unit of transmission rate equal to the number of signal events per second. See also [bit rate](#) and [bits per second \(bps\)](#).

**BCC**

See [Bearer capability class \(BCC\)](#).

**BCMS**

Basic Call Management System

**BCT**

See [business communications terminal \(BCT\)](#).

**Bearer capability class (BCC)**

Code that identifies the type of a call (for example, voice and different types of data). Determination of BCC is based on the caller's characteristics for non-ISDN endpoints and on the Bearer Capability and Low-Layer Compatibility Information Elements of an ISDN endpoint. Current BCCs are 0 (voice-grade data and voice), 1 (DMI mode 1, 56 kbps data transmission), 2 (DMI mode 2, synchronous/asynchronous data transmission up to 19.2 kbps) 3 (DMI mode 3, 64 kbps circuit/packet data transmission), 4 (DMI mode 0, 64 kbps synchronous data), 5 (temporary signaling connection, and 6 (wideband call, 128–1984 kbps synchronous data).

**BER**

Bit error rate

**BHCC**

Busy-hour call completions

**bit (binary digit)**

One unit of information in binary notation, having two possible values: 0 or 1.

**bits per second (bps)**

The number of binary units of information that are transmitted or received per second. See also [baud](#) and [bit rate](#).

**bit rate**

The speed at which bits are transmitted, usually expressed in bits per second. Also called data rate. See also [baud](#) and [bits per second \(bps\)](#).

**BLF**

Busy Lamp Field

**BN**

Billing number

**BOS**

Bit-oriented signaling

**BPN**

Billed-party number

**bps**

See [bits per second \(bps\)](#).

**bridge (bridging)**

The appearance of a voice terminal's extension at one or more other voice terminals.

**BRI**

The ISDN Basic Rate Interface specification.

**bridged appearance**

A call appearance on a voice terminal that matches a call appearance on another voice terminal for the duration of a call.

**BTU**

British Thermal Unit

**buffer**

1. In hardware, a circuit or component that isolates one electrical circuit from another. Typically, a buffer holds data from one circuit or process until another circuit or process is ready to accept the data.
2. In software, an area of memory that is used for temporary storage.

**bus**

A multiconductor electrical path used to transfer information over a common connection from any of several sources to any of several destinations.

**business communications terminal (BCT)**

A digital data terminal used for business applications. A BCT can function via a data module as a special-purpose terminal for services provided by a processor or as a terminal for data entry and retrieval.

**BX.25**

A version of the CCITT X.25 protocol for data communications. BX.25 adds a fourth level to the standard X.25 interface. This uppermost level combines levels 4, 5, and 6 of the ISO reference model.

**bypass tie trunks**

A 1-way, outgoing tie trunk from a tandem switch to a main switch in an ETN. Bypass tie trunks, provided in limited quantities, are used as a last-choice route when all trunks to another tandem switch are busy. Bypass tie trunks are used only if all applicable intertandem trunks are busy.

**byte**

A sequence of (usually eight) bits processed together.

---

## C

**cabinet**

Housing for racks, shelves, or carriers that hold electronic equipment.

**cable**

Physical connection between two pieces of equipment (for example, data terminal and modem) or between a piece of equipment and a termination field.

**cable connector**

A jack (female) or plug (male) on the end of a cable. A cable connector connects wires on a cable to specific leads on telephone or data equipment.

**CACR**

Cancellation of Authorization Code Request

## **CAG**

Coverage answer group

## **call appearance**

1. For the attendant console, six buttons, labeled a–f, used to originate, receive, and hold calls. Two lights next to the button show the status of the call appearance.
2. For the voice terminal, a button labeled with an extension and used to place outgoing calls, receive incoming calls, or hold calls. Two lights next to the button show the status of the call appearance.

## **call-control capabilities**

Capabilities (*Third Party Selective Hold, Third Party Reconnect, Third Party Merge*) that can be used in either of the Third Party Call Control ASE (cluster) subsets (Call Control and Domain Control).

## **Call Detail Recording (CDR)**

A feature that uses software and hardware to record call data (same as CDRU).

## **Call Detail Recording utility (CDRU)**

Software that collects, stores, optionally filters, and outputs call-detail records.

## **Call Management System (CMS)**

An application, running on an adjunct processor, that collects information from an ACD unit. CMS enables customers to monitor and manage telemarketing centers by generating reports on the status of agents, splits, trunks, trunk groups, vectors, and VDNs, and enables customers to partially administer the ACD feature for a communications system.

## **call-reference value (CRV)**

An identifier present in ISDN messages that associates a related sequence of messages. In ASAI, CRVs distinguish between associations.

## **call vector**

A set of up to 15 vector commands to be performed for an incoming or internal call.

## **callback call**

A call that automatically returns to a voice-terminal user who activated the Automatic Callback or Ringback Queuing feature.

## **call-waiting ringback tone**

A low-pitched tone identical to ringback tone except that the tone decreases in the last 0.2 seconds (in the United States). Call-waiting ringback tone notifies the attendant that the Attendant Call Waiting feature is activated and that the called party is aware of the waiting call. Tones in international countries may sound different.

## **call work code**

A number, up to 16 digits, entered by ACD agents to record the occurrence of customer-defined events (such as account codes, social security numbers, or phone numbers) on ACD calls.

## **CAMA**

Centralized Automatic Message Accounting

## **carrier**

An enclosed shelf containing vertical slots that hold circuit packs.

## **carried load**

The amount of traffic served by traffic-sensitive facilities during a given interval.

## **CARR-POW**

Carrier Port and Power Unit for AC Powered Systems

## CAS

Centralized Attendant Service or Call Accounting System

## capability

A request or indication of an operation. For example, *Third Party Make Call* is a request for setting up a call; *event report* is an indication that an event has occurred.

## capability group

Set of capabilities, determined by switch administration, that can be requested by an application. Capability groups denote association types. For example, *Call Control* is a type of association that allows certain functions (the ones in the capability group) to be performed over this type of association. Also referred to as administration groups or application service elements (ASEs).

## CA-TSC

Call-Associated Temporary Signaling Connection

## cause value

A value is returned in response to requests or in event reports when a denial or unexpected condition occurs. ASAI cause values fall into two coding standards: Coding Standard 0 includes any cause values that are part of AT&T and CCITT ISDN specifications; Coding standard 3 includes any other ASAI cause values. This document uses a notation for cause value where the coding standard for the cause is given first, then a slash, then the cause value. Example: CS0/100 is coding standard 0, cause value 100.

## CBC

Call-by-call or coupled bonding conductor

## CC

Country code

## CCIS

Common-Channel Interoffice Signaling

## CCITT

CCITT (Comite Consultatif International Telephonique et Telegraphique), now called *International Telecommunications Union* (ITU). See [International Telecommunications Union \(ITU\)](#).

## CCMS

Control-Channel Message Set

## CCS

See [capability](#).

## CCS or hundred call seconds

A unit of call traffic. Call traffic for a facility is scanned every 100 seconds. If the facility is busy, it is assumed to have been busy for the entire scan interval. There are 3600 seconds per hour. The Roman numeral for 100 is the capital letter C. The abbreviation for call seconds is CS. Therefore, 100 call seconds is abbreviated CCS. If a facility is busy for an entire hour, then it is said to have been busy for 36 CCS. See also [Erlang](#).

## CCSA

Common-Control Switching Arrangement

## CDM

Channel-division multiplexing

## CDOS

Customer-dialed and operator serviced

**CDPD**

Customer database-provided digits

**CDR**

See [Call Detail Recording \(CDR\)](#).

**CDRP**

Call Detail Record Poller

**CDRR**

Call Detail Recording and Reporting

**CDRU**

See [Call Detail Recording utility \(CDRU\)](#).

**CED**

Caller entered digits

**CEM**

Channel-expansion multiplexing

**center-stage switch (CSS)**

The central interface between the processor port network and expansion port networks in a CSS-connected system.

**central office (CO)**

The location housing telephone switching equipment that provides local telephone service and access to toll facilities for long-distance calling.

**central office (CO) codes**

The first three digits of a 7-digit public-network telephone number in the United States.

**central office (CO) trunk**

A telecommunications channel that provides access from the system to the public network through the local CO.

**CEPT1**

European Conference of Postal and Telecommunications Rate 1

**CESID**

Caller's Emergency Service Identification

**channel**

1. A circuit-switched call.
2. A communications path for transmitting voice and data.
3. In wideband, all of the time slots (contiguous or noncontiguous) necessary to support a call. Example: an H0-channel uses six 64-kbps time slots.
4. A DS0 on a T1 or E1 facility not specifically associated with a logical circuit-switched call; analogous to a single trunk.

**channel negotiation**

The process by which the channel offered in the Channel Identification Information Element (CIIE) in the SETUP message is negotiated to be another channel acceptable to the switch that receives the SETUP message and ultimately to the switch that sent the SETUP. Negotiation is attempted only if the CIIE is encoded as *Preferred*. Channel negotiation is not attempted for wideband calls.

**CI**

Clock input

**circuit**

1. An arrangement of electrical elements through which electric current flows.
2. A channel or transmission path between two or more points.

**circuit pack**

A card on which electrical circuits are printed, and IC chips and electrical components are installed. A circuit pack is installed in a switch carrier.

**CISPR**

International Special Committee on Radio Interference

**Class of Restriction (COR)**

A feature that allows up to 96 classes of call-origination and call-termination restrictions for voice terminals, voice-terminal groups, data modules, and trunk groups. See also [Class of Service \(COS\)](#).

**Class of Service (COS)**

A feature that uses a number to specify if voice-terminal users can activate the Automatic Callback, Call Forwarding All Calls, Data Privacy, or Priority Calling features. See also [Class of Restriction \(COR\)](#).

**cm**

Centimeter

**CM**

Connection Manager

**CMC**

Compact Modular Cabinet

**CMDR**

Centralized Message Detail Recording

**CMS**

Call Management System

**CO**

See [central office \(CO\)](#).

**common-control switching arrangement (CCSA)**

A private telecommunications network using dedicated trunks and a shared switching center for interconnecting company locations.

**communications system**

The software-controlled processor complex that interprets dialing pulses, tones, and keyboard characters and makes the proper connections both within the system and external to the system. The communications system itself consists of a digital computer, software, storage device, and carriers with special hardware to perform the connections. A communications system provides voice and data communications services, including access to public and private networks, for telephones and data terminals on a customer's premises. See also [switch](#).

**confirmation tone**

A tone confirming that feature activation, deactivation, or cancellation has been accepted.

**connectivity**

The connection of disparate devices within a single system.

**console**

See [attendant console](#).

**contiguous**

Adjacent DS0s within one T1 or E1 facility or adjacent TDM or fiber time slots. The first and last TDM bus, DS0, or fiber time slots are not considered contiguous (no wraparound). For an E1 facility with a D-channel, DS0s 15 and 17 are considered contiguous.

**control cabinet**

See [control carrier](#).

**control carrier**

A carrier in a multi-carrier cabinet that contains the SPE circuit packs and, unlike an R5r control carrier, port circuit packs. Also called control cabinet in a single-carrier cabinet. See also [switch-processing element \(SPE\)](#).

**controlled station**

A station that is monitored and controlled via a domain-control association.

**COR**

See [Class of Restriction \(COR\)](#).

**COS**

See [Class of Service \(COS\)](#).

**coverage answer group**

A group of up to eight voice terminals that ring simultaneously when a call is redirected to it by Call Coverage. Any one of the group can answer the call.

**coverage call**

A call that is automatically redirected from the called party's extension to an alternate answering position when certain coverage criteria are met.

**coverage path**

The order in which calls are redirected to alternate answering positions.

**coverage point**

An extension or attendant group, VDN, or ACD split designated as an alternate answering position in a coverage path.

**covering user**

A person at a coverage point who answers a redirected call.

**CP**

Circuit pack

**CPE**

Customer-premises equipment

**CPN**

Called-party number

**CPN/BN**

Calling-party number/billing number

**CPTR**

Call-progress-tone receiver

**CRC**

Cyclical Redundancy Checking

**critical-reliability system**

A system that has the following duplicated items: control carriers, tone clocks, EI circuit packs, and cabling between port networks and center-stage switch in a CSS-connected system. See also [duplicated common control](#), and [duplication](#).

**CSA**

Canadian Safety Association or Customer Software Administrator

**CSCC**

Compact single-carrier cabinet

**CSCN**

Center-stage control network

**CSD**

Customer-service document

**CSM**

Centralized System Management

**CSS**

See [center-stage switch \(CSS\)](#).

**CSSO**

Customer Services Support Organization

**CSU**

Channel service unit

**CTS**

Clear to Send

**CWC**

See [call work code](#).

---

## D

**DAC**

1. Dial access code or Direct Agent Calling
2. See [digital-to-analog converter \(DAC\)](#).

**data channel**

A communications path between two points used to transmit digital signals.

**data-communications equipment (DCE)**

The equipment (usually a modem, data module, or packet assembler/disassembler) on the network side of a communications link that makes the binary serial data from the source or transmitter compatible with the communications channel.

**data link**

The configuration of physical facilities enabling end terminals to communicate directly with each other.

**data module**

An interconnection device between a BRI or DCP interface of the switch and data terminal equipment or data communications equipment.

**data path**

The end-to-end connection used for a data communications link. A data path is the combination of all elements of an interprocessor communication in a DCS.

**data port**

A point of access to a computer that uses trunks or lines for transmitting or receiving data.

**data rate**

See [bit rate](#).

**data service unit (DSU)**

A device that transmits digital data on transmission facilities.

**data terminal**

An input/output (I/O) device that has either switched or direct access to a host computer or to a processor interface.

**data terminal equipment (DTE)**

Equipment consisting of the endpoints in a connection over a data circuit. In a connection between a data terminal and host, the terminal, the host, and their associated modems or data modules make up the DTE.

**dB**

Decibel

**dBa**

Decibels in reference to amperes.

**dBnC**

Decibels above reference noise with C filter.

**DC**

Direct current

**DCE**

Data-communications equipment

**D-channel backup**

Type of backup used with Non-Facility Associated Signaling (NFAS). A primary D-channel provides signaling for an NFAS D-channel group (two or more PRI facilities). A second D-channel, on a separate PRI facility of the NFAS D-channel group, is designated as backup for the D-channel. Failure of the primary D-channel causes automatic transfer of call-control signaling to the backup D-channel. The backup becomes the primary D-channel. When the failed channel returns to service, it becomes the backup D-channel.

**DCO**

Digital central office

**DCP**

Digital Communications Protocol

**DCS**

Distributed Communications System

**DDC**

Direct Department Calling

**DDD**

Direct Distance Dialing

**delay-dial trunk**

A trunk that allows dialing directly into a communications system (digits are received as they are dialed).

**denying a request**

Sending a negative acknowledgement (NAK), done by sending an FIE with a *return error* component (and a cause value). It should not be confused with the denial event report that applies to calls.

**designated voice terminal**

The specific voice terminal to which calls, originally directed to a certain extension, are redirected. Commonly used to mean the forwarded-to terminal when Call Forwarding All Calls is active.

**dial-repeating trunks**

A PBX tie trunk that is capable of handling PBX station-signaling information without attendant assistance.

**dial-repeating tie trunk**

A tie trunk that transmits called-party addressing information between two communications systems.

**DID**

Direct Inward Dialing

**digit conversion**

A process used to convert specific dialed numbers into other dialed numbers.

**digital**

The representation of information by discrete steps. See also [analog](#).

**digital communications protocol (DCP)**

- A proprietary protocol used to transmit both digitized voice and digitized data over the same communications link. A DCP link is made up of two 64-kbps information (I-) channels and one 8-kbps signaling (S-) channel. The DCP protocol supports two information-bearing channels, and thus two telephones/data modules. The I1 channel is the DCP channel assigned on the first page of the 8411 station form. The I2 channel is the DCP channel assigned on the analog adjunct page of the 8411 station form or on the data module page.
- Digital Communications Protocol. The DCP protocol supports two information-bearing channels, and thus two telephones/data modules. The I1 channel is the DCP channel assigned on the first page of the 8411 station form. The I2 channel is the DCP channel assigned on the analog adjunct page of the 8411 station form or on the data module page.

**digital data endpoints**

In DEFINITY ECS, devices such as the 510D terminal or the 515-type business communications terminal (BCT).

**digital multiplexed interface (DMI)**

An interface that provides connectivity between a communications system and a host computer or between two communications systems using DS1 24th-channel signaling. DMI provides 23 64-kbps data channels and 1 common-signaling channel over a twisted-pair connection. DMI is offered through two capabilities: bit-oriented signaling (DMI-BOS) and message-oriented signaling (DMI-MOS).

**digital signal level 0 (DS0)**

A single 64-kbps voice channel. A DS0 is a single 64-kbps channel in a T1 or E1 facility and consists of eight bits in a T1 or E1 frame every 125 microseconds.

**digital signal level 1 (DS1)**

A single 1.544-Mbps (United States) or 2.048-Mbps (outside the United States) digital signal carried on a T1 transmission facility. A DS1 converter complex consists of a pair, one at each end, of DS1 converter circuit packs and the associated T1/E1 facilities.

**digital terminal data module (DTDM)**

An integrated or adjunct data module that shares with a digital telephone the same physical port for connection to a communications system. The function of a DTDM is similar to that of a PDM and MPDM in that it converts RS-232C signals to DCP signals.

**digital-to-analog converter (DAC)**

A device that converts data in digital form to the corresponding analog signals. See also [analog-to-digital converter \(ADC\)](#).

**digital transmission**

A mode of transmission in which information to be transmitted is first converted to digital form and then transmitted as a serial stream of pulses.

**digital trunk**

A circuit that carries digital voice and/or digital data in a telecommunications channel.

**DIOD**

Direct Inward and Outward Dialing

**direct agent**

A feature, accessed only via ASAI, that allows a call to be placed in a split queue but routed only to a specific agent in that split. The call receives normal ACD call treatment (for example, announcements) and is measured as an ACD call while ensuring that a particular agent answers.

**Direct Extension Selection (DXS)**

A feature on an attendant console that allows an attendant direct access to voice terminals by pressing a group-select button and a DXS button.

**Direct Inward Dialing (DID)**

A feature that allows an incoming call from the public network (not FX or WATS) to reach a specific telephone without attendant assistance.

**Direct Inward Dialing (DID) trunk**

An incoming trunk used for dialing directly from the public network into a communications system without help from the attendant.

**disk drive**

An electromechanical device that stores data on and retrieves data from one or more disks.

**distributed communications system (DCS)**

A network configuration linking two or more communications systems in such a way that selected features appear to operate as if the network were one system.

**DIVA**

Data In/Voice Answer

**DLC**

Data line circuit

**DLDM**

Data-line data module

**DMI**

Digital-multiplexed interface

**DND**

Do not disturb

**DNIS**

Dialed-Number Identification Service

**DOD**

Direct Outward Dialing

**domain**

VDNs, ACD splits, and stations. The VDN domain is used for active-notification associations. The ACD-split domain is for active-notification associations and domain-control associations. The station domain is used for the domain-control associations.

**domain-control association**

A *Third Party Domain Control Request* capability initiates a unique CRV/link number combination, which is referred to as a domain-control association.

**domain-controlled split**

A split for which *Third Party Domain Control* request has been accepted. A domain-controlled split provides an event report for logout.

**domain-controlled station**

A station for which a *Third\_Party\_Domain\_Control* request has been accepted. A domain-controlled station provides event reports for calls that are alerting, connected, or held at the station.

**domain-controlled station on a call**

A station that is active on a call, and which provides event reports over one or two domain-control associations.

**DOSS**

Delivery Operations Support System

**DOT**

Duplication Option Terminal

**DPM**

Dial Plan Manager

**DPR**

Dual-port RAM

**DS1**

Digital Signal Level 1

**DS1C**

Digital Signal Level-1 protocol C

**DS1 CONV**

Digital Signal Level-1 converter

**DSI**

Digital signal interface

**DSU**

Data service unit

**DTDM**

Digital-terminal data module

**DTE**

Data-terminal equipment

**DTGS**

Direct Trunk Group Select

**DTMF**

Dual-tone multifrequency

**DTS**

Disk-tape system

**deduplicated common control**

Two processors ensuring continuous operation of a communications system. While one processor is online, the other functions as a backup. The backup processor goes online periodically or when a problem occurs.

**duplication**

The use of redundant components to improve availability. When a duplicated subsystem fails, its backup redundant system automatically takes over.

**duplication option**

A system option that duplicates the following: control carrier containing the SPE, EI circuit packs in carriers, fiber-optic cabling between port networks, and center-stage switch in a CSS-connected system.

**DWBS**

DEFINITY Wireless Business System

**DXS**

Direct extension selection

---

**E**

**E1**

A digital transmission standard that carries traffic at 2.048 Mbps. The E1 facility is divided into 32 channels (DS0s) of 64 kbps information. Channel 0 is reserved for framing and synchronization information. A D-channel occupies channel 16.

**E & M**

Ear and mouth (receive and transmit)

**EA**

Expansion archangel

**EAL**

Expansion archangel link

**ear and mouth (E & M) signaling**

Trunk supervisory signaling, used between two communications systems, whereby signaling information is transferred through 2-state voltage conditions (on the E and M leads) for analog applications and through a single bit for digital applications.

**EAS**

See "[Expert Agent Selection](#)".

**ECC**

Error Correct Code

**ECMA**

European Computer Manufacturers Association

**EBCDIC**

Extended Binary-Coded Decimal Interexchange Code

**EPF**

Electronic power feed

**EI**

Expansion interface

**EIA**

Electronic Industries Association

**EIA-232**

A physical interface specified by the EIA. EIA-232 transmits and receives asynchronous data at speeds of up to 19.2 kbps over cable distances of up to 50 feet. EIA-232 replaces RS-232 protocol in some DEFINITY applications.

**electronic tandem network (ETN)**

A tandem tie-trunk network that has automatic call-routing capabilities based on the number dialed and the most preferred route available. Each switch in the network is assigned a unique private network office code (RNX), and each voice terminal is assigned a unique extension.

**Electronics Industries Association (EIA)**

A trade association of the electronics industry that establishes electrical and functional standards.

**emergency transfer**

If a major system failure occurs, automatic transfer is initiated to a group of telephones capable of making outgoing calls. The system operates in this mode until the failure is repaired and the system automatically returns to normal operation. Also called power-failure transfer.

**EMI**

Electromagnetic interference

**end-to-end signaling**

The transmission of touch-tone signals generated by dialing from a voice terminal to remote computer equipment. These digits are sent over the trunk as DTMF digits whether the trunk signaling type is marked as tone or rotary and whether the originating station is tone or rotary. Example: a call to a voice-mail machine or automated-attendant service. A connection is first established over an outgoing trunk. Then additional digits are dialed to transmit information to be processed by the computer equipment.

**enhanced private-switched communications service (EPSCS)**

An analog private telecommunications network based on the No. 5 crossbar and 1A ESS that provides advanced voice and data telecommunications services to companies with many locations.

**EPN**

Expansion-port network

**EPROM**

Erasable programmable read-only memory

**EPSCS**

Enhanced Private Switched Communications Services

**ERL**

Echo return loss

**Erlang**

A unit of traffic intensity, or load, used to express the amount of traffic needed to keep one facility busy for one hour. One Erlang is equal to 36 CCS. See also [capability](#).

**ESF**

Extended superframe format

**ESPA**

European Standard Paging Access

**ETA**

Extended Trunk Access; also Enhanced Terminal Administration

**ETN**

Electronic tandem network

**ETSI**

European Telecommunications Standards Institute

**expansion archangel (EAA)**

A network-control microprocessor located on an expansion interface (EI) port circuit pack in an expansion port network. The EA provides an interface between the EPN and its controlling switch-processing element.

**expansion-archangel link (EAL)**

A link-access function on the D-channel (LAPD) logical link that exists between a switch-processing element and an expansion archangel (EA). The EAL carries control messages from the SPE to the EA and to port circuit packs in an expansion port network.

**expansion control cabinet**

See [expansion control carrier](#).

**expansion control carrier**

A carrier in a multicarrier cabinet that contains extra port circuit packs and a maintenance interface. Also called expansion control cabinet in a single-carrier cabinet.

**expansion interface (EI)**

A port circuit pack in a port network that provides the interface between a PN's TDM bus/ packet bus and a fiber-optic link. The EI carries circuit-switched data, packet-switched data, network control, timing control, and DS1 control. In addition, an EI in an expansion port network communicates with the master maintenance circuit pack to provide the EPN's environmental and alarm status to the switch-processing element.

**expansion port network (EPN)**

A port network (PN) that is connected to the TDM bus and packet bus of a processor port network (PPN). Control is achieved by indirect connection of the EPN to the PPN via a port-network link (PNL). See also [port network \(PN\)](#).

**Expert Agent Selection**

A feature allowing incoming calls to be routed to specialized groups of agents within a larger pool of agents.

**extension-in**

Extension-In (ExtIn) is the work state agents go into when they answer (receive) a non-ACD call. If the agent is in Manual-In or Auto-In and receives an extension-in call, it is recorded by CMS as an AUX-In call.

**extension-out**

The work state that agents go into when they place (originate) a non-ACD call.

**external measurements**

Those ACD measurements that are made by the External CMS adjunct.

**extension**

A 1- to 5-digit number by which calls are routed through a communications system or, with a Uniform Dial Plan (UDP) or main-satellite dialing plan, through a private network.

**external call**

A connection between a communications system user and a party on the public network or on another communications system in a private network.

---

**F**

**FAC**

Feature Access Code

**facility**

A telecommunications transmission pathway and associated equipment.

**facility-associated signaling (FAS)**

Signaling for which a D-channel carries signaling only for those channels on the same physical interface.

**FAS**

Facility-associated signaling

**FAT**

Facility access trunk

**FAX**

Facsimile

**FCC**

Federal Communications Commission

**FEAC**

Forced Entry of Account Codes

**feature**

A specifically defined function or service provided by the system.

**feature button**

A labeled button on a telephone or attendant console used to access a specific feature.

**FEP**

Front-end processor

**fiber optics**

A technology using materials that transmit ultrawideband electromagnetic light-frequency ranges for high-capacity carrier systems.

**FIC**

Facility interface codes

**fixed**

A trunk allocation term. In the fixed allocation scheme, the time slots necessary to support a wideband call are contiguous, and the first time slot is constrained to certain starting points.

**flexible**

A trunk allocation term. In the flexible allocation scheme, the time slots of a wideband call can occupy noncontiguous positions within a single T1 or E1 facility.

**floating**

A trunk allocation term. In the floating allocation scheme, the time slots of a wideband call are contiguous, but the position of the first time slot is not fixed.

**FNPA**

Foreign Numbering-Plan Area

**foreign-exchange (FX)**

A CO other than the one providing local access to the public telephone network.

**foreign-exchange trunk**

A telecommunications channel that directly connects the system to a CO other than its local CO.

**foreign numbering-plan area code (FNPAC)**

An area code other than the local area code, that must be dialed to call outside the local geographical area.

**FRL**

Facilities Restriction Level

**FX**

Foreign exchange

---

**G**

**G3-MA**

Generic 3 Management Applications

**G3-MT**

Generic 3 Management Terminal

**G3r**

Generic 3, RISC (Reduced Instruction Set Computer)

**generalized route selection (GRS)**

An enhancement to Automatic Alternate Routing/Automatic Route Selection (AAR/ARS) that performs routing based on call attributes, such as Bearer Capability Classes (BCCs), in addition to the address and facilities restriction level (FRL), thus facilitating a Uniform Dial Plan (UDP) that is independent of the type of call being placed.

**glare**

The simultaneous seizure of a 2-way trunk by two communications systems, resulting in a standoff.

## GM

Group manager

## GPTR

General-purpose tone receiver

## grade of service

The number of call attempts that fail to receive service immediately. Grade of service is also expressed as the quantity of all calls that are blocked or delayed.

## ground-start trunk

A trunk on which, for outgoing calls, the system transmits a request for services to a distant switching system by grounding the trunk ring lead. To receive the digits of the called number, that system grounds the trunk tip lead. When the system detects this ground, the digits are sent.

## GRS

Generalized Route Selection

---

# H

## H0

An ISDN information transfer rate for 384-kbps data defined by CCITT and ANSI standards.

## H11

An ISDN information transfer rate for 1536-kbps data defined by CCITT and ANSI standards.

## H12

An ISDN information transfer rate for 1920-kbps data defined by CCITT and ANSI standards.

## handshaking logic

A format used to initiate a data connection between two data module devices.

## hertz (Hz)

A unit of frequency equal to one cycle per second.

## high-reliability system

A system having the following: two control carriers, duplicate expansion interface (EI) circuit packs in the PPN (in R5r with CSS), and duplicate switch node clock circuit packs in the switch node (SN) carriers. See also [duplicated common control](#), [duplication](#), [duplication option](#), and [critical-reliability system](#).

## HNPA

See [home numbering-plan area code \(HNPA\)](#).

## holding time

The total length of time in minutes and seconds that a facility is used during a call.

## home numbering-plan area code (HNPA)

The local area code. The area code does not have to be dialed to call numbers within the local geographical area.

## hop

Nondirect communication between two switch communications interfaces (SCI) where the SCI message passes automatically without intermediate processing through one or more intermediate SCIs.

**host computer**

A computer, connected to a network, that processes data from data-entry devices.

**hunt group**

A group of extensions that are assigned the Station Hunting feature so that a call to a busy extension reroutes to an idle extension in the group. See also [ACD work mode](#).

**Hz**

See [hertz \(Hz\)](#).

**I**

**I1**

The first information channel of DCP.

**I2**

The second information channel of DCP.

**I2 Interface**

A proprietary interface used for the DEFINITY Wireless Business System for the radio-controller circuit packs. Each interface provides communication between the radio-controller circuit pack and up to two wireless fixed bases.

**I3 Interface**

A proprietary interface used for the DEFINITY Wireless Business System for the cell antenna units. Each wireless fixed base can communicate to up to four cell antenna units.

**IAS**

Inter-PBX Attendant Service

**ICC**

Intercabinet cable or intercarrier cable

**ICD**

Inbound Call Director

**ICDOS**

International Customer-Dialed Operator Service

**ICHT**

Incoming call-handling table

**ICI**

Incoming call identifier

**ICM**

Inbound Call Management

**IDDD**

International Direct Distance Dialing

**IDF**

Intermediate distribution frame

**IE**

Information element

**immediate-start tie trunk**

A trunk on which, after making a connection with a distant switching system for an outgoing call, the system waits a nominal 65 ms before sending the digits of the called number. This allows time for the distant system to prepare to receive digits. On an incoming call, the system has less than 65 ms to prepare to receive the digits.

**IMT**

Intermachine trunk

**in**

Inch

**INADS**

Initialization and Administration System

**incoming gateway**

A PBX that routes an incoming call on a trunk *not* administered for Supplementary Services Protocol B to a trunk *not* administered for Supplementary Services Protocol B.

**information exchange**

The exchange of data between users of two different systems, such as the switch and a host computer, over a LAN.

**Information Systems Network (ISN)**

A WAN and LAN with an open architecture combining host computers, minicomputers, word processors, storage devices, PCs, high-speed printers, and nonintelligent terminals into a single packet-switching system.

**INS**

ISDN Network Service

**inside call**

A call placed from one telephone to another within the local communications system.

**Integrated Services Digital Network (ISDN)**

A public or private network that provides end-to-end digital communications for all services to which users have access by a limited set of standard multipurpose user-network interfaces defined by the CCITT. Through internationally accepted standard interfaces, ISDN provides digital circuit-switched or packet-switched communications within the network and links to other ISDNs to provide national and international digital communications. See also [Integrated Services Digital Network Basic Rate Interface \(ISDN-BRI\)](#) and [Integrated Services Digital Network Primary Rate Interface \(ISDN-PRI\)](#).

**Integrated Services Digital Network Basic Rate Interface (ISDN-BRI)**

The interface between a communications system and terminal that includes two 64-kbps B-channels for transmitting voice or data and one 16-kbps D-channel for transmitting associated B-channel call control and out-of-band signaling information. ISDN-BRI also includes 48 kbps for transmitting framing and D-channel contention information, for a total interface speed of 192 kbps. ISDN-BRI serves ISDN terminals and digital terminals fitted with ISDN terminal adapters. See also [Integrated Services Digital Network \(ISDN\)](#) and [Integrated Services Digital Network Primary Rate Interface \(ISDN-PRI\)](#).

### **Integrated Services Digital Network Primary Rate Interface (ISDN-PRI)**

The interface between multiple communications systems that in North America includes 24 64-kbps channels, corresponding to the North American digital signal level-1 (DS1) standard rate of 1.544 Mbps. The most common arrangement of channels in ISDN-PRI is 23 64-kbps B-channels for transmitting voice and data and 1 64-kbps D-channel for transmitting associated B-channel call control and out-of-band signaling information. With nonfacility-associated signaling (NFAS), ISDN-PRI can include 24 B-channels and no D-channel. See also [Integrated Services Digital Network \(ISDN\)](#) and [Integrated Services Digital Network Basic Rate Interface \(ISDN-BRI\)](#).

### **intercept tone**

A tone that indicates a dialing error or denial of the service requested.

### **interface**

A common boundary between two systems or pieces of equipment.

### **internal call**

A connection between two users within a system.

### **International Telecommunications Union (ITU)**

Formerly known as International Telegraph and Telephone Consultative Committee (CCITT), ITU is an international organization that sets universal standards for data communications, including ISDN. ITU members are from telecommunications companies and organizations around the world. See also [BX.25](#).

### **International Telegraph and Telephone Consultative Committee**

See [International Telecommunications Union \(ITU\)](#).

### **interflow**

The ability for calls to forward to other splits on the same PBX or a different PBX using the Call Forward All Calls feature.

### **intraflow**

The ability for calls to redirect to other splits on the same PBX on a conditional or unconditional basis using call coverage busy, don't answer, or all criteria.

### **internal measurements**

BCMS measurements that are made by the system. ACD measurements that are made external to the system (via External CMS) are referred to as external measurements.

### **in-use lamp**

A red light on a multiappearance voice terminal that lights to show which call appearance will be selected when the handset is lifted or which call appearance is active when a user is off-hook.

### **INWATS**

Inward Wide Area Telephone Service

### **IO**

Information outlet

### **ISDN**

See [Integrated Services Digital Network \(ISDN\)](#).

### **ISDN Gateway (IG)**

A feature allowing integration of the switch and a host-based telemarketing application via a link to a gateway adjunct. The gateway adjunct is a 3B-based product that notifies the host-based telemarketing application of call events.

### **ISDN trunk**

A trunk administered for use with ISDN-PRI. Also called ISDN facility.

**ISDN-PRI terminal adapter**

An interface between endpoint applications and an ISDN PRI facility. ISDN-PRI terminal adapters are currently available from other vendors and are primarily designed for video conferencing applications. Accordingly, currently available terminal adapters adapt the two pairs of video codec data (V.35) and dialing (RS-366) ports to an ISDN PRI facility.

**IS/DTT**

Integrated Services/digital tie trunk

**ISN**

Information Systems Network

**ISO**

International Standards Organization

**ISV**

Independent software vendor

**ITP**

Installation test procedure

**ITU**

International Telecommunications Union

**IXC**

Interexchange carrier code

---

**K**

**kHz**

Kilohertz

**kbps**

Kilobits per second

**kbyte**

Kilobyte

**kg**

Kilogram

---

**L**

**LAN**

Local area network

**LAP-D**

Link Access Procedure on the D-channel

**LAPD**

Link Access Procedure data

**LATA**

Local access and transport area

- lb**  
Pound
- LBO**  
Line buildout
- LDN**  
Listed directory number
- LDS**  
Long-distance service
- LEC**  
Local exchange carrier
- LED**  
See [light-emitting diode \(LED\)](#).
- light-emitting diode (LED)**  
A semiconductor device that produces light when voltage is applied. LEDs provide a visual indication of the operational status of hardware components, the results of maintenance tests, the alarm status of circuit packs, and the activation of telephone features.
- lightwave transceiver**  
Hardware that provides an interface to fiber-optic cable from port circuit packs and DS1 converter circuit packs. Lightwave transceivers convert electrical signals to light signals and vice versa.
- line**  
A transmission path between a communications system or CO switching system and a voice terminal or other terminal.
- line appearance**  
See [appearance](#).
- line buildout**  
A selectable output attenuation is generally required of DTE equipment because T1 circuits require the last span to lose 15–22.5 dB.
- line port**  
Hardware that provides the access point to a communications system for each circuit associated with a telephone or data terminal.
- link**  
A transmitter-receiver channel that connects two systems.
- link-access procedure on the D-channel (LAPD)**  
A link-layer protocol on the ISDN-BRI and ISDN-PRI data-link layer (level 2). LAPD provides data transfer between two devices, and error and flow control on multiple logical links. LAPD is used for signaling and low-speed packet data (X.25 and mode 3) on the signaling (D-) channel and for mode-3 data communications on a bearer (B-) channel.
- LINL**  
Local indirect neighbor link
- local area network (LAN)**  
A networking arrangement designed for a limited geographical area. Generally, a LAN is limited in range to a maximum of 6.2 miles and provides high-speed carrier service with low error rates. Common configurations include daisy chain, star (including circuit-switched), ring, and bus.

**logical link**

The communications path between a processor and a BRI terminal.

**loop-start trunk**

A trunk on which, after establishing a connection with a distant switching system for an outgoing call, the system waits for a signal on the loop formed by the trunk leads before sending the digits of the called number.

**LSU**

Local storage unit

**LWC**

Leave Word Calling

---

## M

**MAC**

Medium access

**MADU**

Modular asynchronous data unit

**main distribution frame (MDF)**

A device that mounts to the wall inside the system equipment room. The MDF provides a connection point from outside telephone lines to the PBX switch and to the inside telephone stations.

**main-satellite-tributary**

A private network configuration that can either stand alone or access an ETN. A main switch provides interconnection, via tie trunks, with one or more subtending switches, called satellites; all attendant positions for the main/satellite configuration; and access to and from the public network. To a user outside the complex, a main/satellite configuration appears as one switch, with one listed directory number (LDN). A tributary switch is connected to the main switch via tie trunks, but has its own attendant positions and LDN.

**maintenance**

Activities involved in keeping a telecommunications system in proper working condition: the detection and isolation of software and hardware faults, and automatic and manual recovery from these faults.

**management terminal**

The terminal that is used by the system administrator to administer the switch. The terminal may also be used to access the BCMS feature.

**major alarm**

An indication of a failure that has caused critical degradation of service and requires immediate attention. Major alarms are automatically displayed on LEDs on the attendant console and maintenance or alarming circuit pack, logged to the alarm log, and reported to a remote maintenance facility, if applicable.

**Manual-In work mode**

One of four agent work modes: the mode in which an agent is ready to process another call manually. See [Auto-In Work mode](#) for a contrast.

**MAP**

Maintenance action process

**MAPD**

Multiapplication platform for DEFINITY

**MA-UUI**

Message-Associated User-to-User Signaling

**Mbps**

Megabits per second

**M-Bus**

Memory bus

**Mbyte**

Megabyte

**MCC**

Multicarrier cabinet

**MCS**

Message Center Service

**MCT**

Malicious Call Trace

**MCU**

Multipoint control unit

**MDF**

Main distribution frame

**MDM**

Modular data module

**MDR**

Message detail record

**MEM**

Memory

**memory**

A device into which information can be copied and held, and from which information can later be obtained.

**memory shadowing link**

An operating-system condition that provides a method for memory-resident programs to be more quickly accessed, allowing a system to reboot faster.

**message center**

An answering service that supplies agents to and stores messages for later retrieval.

**message center agent**

A member of a message-center hunt group who takes and retrieves messages for voice-terminal users.

**MET**

Multibutton electronic telephone

**MF**  
Multifrequency

**MFB**  
Multifunction board

**MFC**  
Multifrequency code

**MHz**  
Megahertz

**MIM**  
Management information message

**minor alarm**  
An indication of a failure that could affect customer service. Minor alarms are automatically displayed on LEDs on the attendant console and maintenance or alarming circuit pack, sent to the alarm log, and reported to a remote maintenance facility, if applicable.

**MIPS**  
Million instructions per second

**MIS**  
Management information system

**MISCID**  
Miscellaneous identification

**MMCS**  
Multimedia Call Server

**MMCH**  
Multimedia call handling

**MMI**  
Multimedia interface

**MMS**  
Material Management Services

**MO**  
Maintenance object

**modem**  
A device that converts digital data signals to analog signals for transmission over telephone circuits. The analog signals are converted back to the original digital data signals by another modem at the other end of the circuit.

**modem pooling**  
A capability that provides shared conversion resources (modems and data modules) for cost-effective access to analog facilities by data terminals. When needed, modem pooling inserts a conversion resource into the path of a data call. Modem pooling serves both outgoing and incoming calls.

**modular processor data module (MPDM)**  
A processor data module (PDM) that can be configured to provide several kinds of interfaces (RS-232C, RS-449, and V.35) to customer-provided data terminal equipment (DTE). See also [processor data module \(PDM\)](#).

**modular trunk data module (MTDM)**

A trunk data module that can be configured to provide several kinds of interfaces (RS-232, RS-449, and V.35) to customer-provided data terminal equipment.

**modulator-demodulator**

See [modem](#).

**monitored call**

See [active-notification call](#).

**MOS**

Message-oriented signaling

**MPDM**

Modular processor data module

**MS**

Message server

**ms**

Millisecond

**MS/T**

Main satellite/tributary

**MSA**

Message servicing adjunct

**MSG**

Message service

**MSL**

Material stocking location

**MSM**

Modular System Management

**MSS**

Mass storage system

**MSSNET**

Mass storage/network control

**MT**

Management terminal

**MTDM**

Modular trunk data module

**MTP**

Maintenance tape processor

**MTT**

Multitasking terminal

**multiappearance voice terminal**

A terminal equipped with several call-appearance buttons for the same extension, allowing the user to handle more than one call on that same extension at the same time.

**Multicarrier cabinet**

A structure that holds one to five carriers. See also [single-carrier cabinet](#).

**Multifrequency Compelled (MFC) Release 2 (R2) signaling**

A signal consisting of two frequency components, such that when a signal is transmitted from a switch, another signal acknowledging the transmitted signal is received by the switch. R2 designates signaling used in the United States and in countries outside the United States.

**multiplexer**

A device used to combine a number of individual channels into a single common bit stream for transmission.

**multiplexing**

A process whereby a transmission facility is divided into two or more channels, either by splitting the frequency band into a number of narrower bands or by dividing the transmission channel into successive time slots. See also [time-division multiplexing \(TDM\)](#).

**multirate**

The new N x DS0 service (see N x DS0).

**MWL**

Message-waiting lamp

---

## N

**N+1**

Method of determining redundant backup requirements. Example: if four rectifier modules are required for a DC-powered single-carrier cabinet, a fifth rectifier module is installed for backup.

**N x DS0**

N x DS0, equivalently referred to as N x 64 kbps, is an emerging standard for wideband calls separate from H0, H11, and H12 ISDN channels. The emerging N x DS0 ISDN multirate circuit mode bearer service will provide circuit-switched calls with data-rate multiples of 64 kbps up to 1536 kbps on a T1 facility or up to 1920 kbps on an E1 facility. In the switch, N x DS0 channels will range up to 1984 kbps using NFAS E1 interfaces.

**NANP**

North American Numbering Plan

**narrowband**

A circuit-switched call at a data rate up to and including 64 kbps. All nonwideband switch calls are considered narrowband.

**native terminal support**

A predefined terminal type exists in switch software, eliminating the need to alias the terminal (that is, manually map call appearances and feature buttons onto some other natively supported terminal type).

**NAU**

Network access unit

**NCA/TSC**

Noncall-associated/temporary-signaling connection

**NCOSS**

Network Control Operations Support Center

**NCSSO**

National Customer Support Organization

**NEC**

National Engineering Center

**NEMA**

National Electrical Manufacturer's Association

**NETCON**

Network-control circuit pack

**network**

A series of points, nodes, or stations connected by communications channels.

**network-specific facility (NSF)**

An information element in an ISDN-PRI message that specifies which public-network service is used. NSF applies only when Call-by-Call Service Selection is used to access a public-network service.

**network interface**

A common boundary between two systems in an interconnected group of systems.

**NFAS**

See [Nonfacility-associated signaling \(NFAS\)](#).

**NI**

Network interface

**NID**

Network Inward Dialing

**NM**

Network management

**NN**

National number

**node**

A switching or control point for a network. Nodes are either tandem (they receive signals and pass them on) or terminal (they originate or terminate a transmission path).

**Nonfacility-associated signaling (NFAS)**

A method that allows multiple T1 and/or E1 facilities to share a single D-channel to form an ISDN-PRI. If D-channel backup is not used, one facility is configured with a D-channel, and the other facilities that share the D-channel are configured without D-channels. If D-channel backup is used, two facilities are configured to have D-channels (one D-channel on each facility), and the other facilities that share the D-channels are configured without D-channels.

**NPA**

Numbering-plan area

**NPE**

Network processing element

**NQC**

Number of queued calls

**NSE**

Night-service extension

**NSU**

Network sharing unit

**null modem cable**

Special wiring of an RS-232-C cable such that a computer can talk to another computer (or to a printer) without a modem.

**NXX**

Public-network office code

---

**O**

**OA**

Operator assisted

**occurrence**

See [appearance](#).

**OCM**

Outbound Call Management

**offered load**

The traffic that would be generated by all the requests for service occurring within a monitored interval, usually one hour.

**ONS**

On-premises station

**OPS**

Off-premises station

**OPX**

Off-premises extension

**OQT**

Oldest queued time

**OSHA**

Occupational Safety and Health Act

**OSI**

Open Systems Interconnect

**OSS**

Operations Support System

**OSSI**

Operational Support System Interface

**OTDR**

Optical time-domain reflectometer

**othersplit**

The work state that indicates that an agent is currently active on another split's call, or in ACW for another split.

**OTL**

Originating Test Line

## OTQ

Outgoing trunk queuing

## outgoing gateway

A PBX that routes an incoming call on a trunk administered for Supplementary Services Protocol B to a trunk *not* administered for Supplementary Services Protocol B.

---

## P

### PACCON

Packet control

### packet

A group of bits (including a message element, which is the data, and a control information element (IE), which is the header) used in packet switching and transmitted as a discrete unit. In each packet, the message element and control IE are arranged in a specified format. See also [packet bus](#) and [packet switching](#).

### packet bus

A wide-bandwidth bus that transmits packets.

### packet switching

A data-transmission technique whereby user information is segmented and routed in discrete data envelopes called packets, each with its own appended control information, for routing, sequencing, and error checking. Packet switching allows a channel to be occupied only during the transmission of a packet. On completion of the transmission, the channel is made available for the transfer of other packets. See also [BX.25](#) and [packet](#).

### PAD

Packet assembly/disassembly

### paging trunk

A telecommunications channel used to access an amplifier for loudspeaker paging.

### party/extension active on call

A party is on the call if he or she is actually connected to the call (in active talk or in held state). An originator of a call is always a party on the call. Alerting parties, busy parties, and tones are not parties on the call.

### PBX

Private branch exchange

### PC

See [personal computer \(PC\)](#).

### PCM

See [pulse-code modulation \(PCM\)](#).

### PCOL

Personal central-office line

### PCOLG

Personal central-office line group

### PCS

Permanent switched calls

**PDM**

See [processor data module \(PDM\)](#).

**PDS**

Premises Distribution System

**PE**

Processing element

**PEC**

Price element code

**PEI**

Processor element interchange

**personal computer (PC)**

A personally controllable microcomputer.

**PGATE**

Packet gateway

**PGN**

Partitioned group number

**PI**

Processor interface

**PIB**

Processor interface board

**pickup group**

A group of individuals authorized to answer any call directed to an extension within the group.

**PIDB**

Product image database

**PKTINT**

Packet interface

**PL**

Private line

**PLS**

Premises Lightwave System

**PMS**

Property Management System

**PN**

Port network

**PNA**

Private network access

**POE**

Processor occupancy evaluation

**POP**

Point of presence

**port**

A data- or voice-transmission access point on a device that is used for communicating with other devices.

**port carrier**

A carrier in a multicarrier cabinet or a single-carrier cabinet containing port circuit packs, power units, and service circuits. Also called a port cabinet in a single-carrier cabinet.

**port network (PN)**

A cabinet containing a TDM bus and packet bus to which the following components are connected: port circuit packs, one or two tone-clock circuit packs, a maintenance circuit pack, service circuit packs, and (optionally) up to four expansion interface (EI) circuit packs in DEFINITY ECS. Each PN is controlled either locally or remotely by a switch processing element (SPE). See also [expansion port network \(EPN\)](#) and [processor port network \(PPN\)](#).

**port-network connectivity**

The interconnection of port networks (PNs), regardless of whether the configuration uses direct or switched connectivity.

**PPM**

1. Parts per million
2. Periodic pulse metering

**PPN**

See [processor port network \(PPN\)](#).

**PRI**

See [Primary Rate Interface \(PRI\)](#).

**primary extension**

The main extension associated with the physical voice or data terminal.

**Primary Rate Interface (PRI)**

A standard ISDN frame format that specifies the protocol used between two or more communications systems. PRI runs at 1.544 Mbps and, as used in North America, provides 23 64-kbps B-channels (voice or data) and one 64-kbps D-channel (signaling). The D-channel is the 24th channel of the interface and contains multiplexed signaling information for the other 23 channels.

**PRI endpoint (PE)**

The wideband switching capability introduces PRI endpoints on switch line-side interfaces. A PRI endpoint consists of one or more contiguous B-channels on a line-side T1 or E1 ISDN PRI facility and has an extension. Endpoint applications have call-control capabilities over PRI endpoints.

**principal**

A terminal that has its primary extension bridged on one or more other terminals.

**principal (user)**

A person to whom a telephone is assigned and who has message-center coverage.

**private network**

A network used exclusively for the telecommunications needs of a particular customer.

**private network office code (RNX)**

The first three digits of a 7-digit private network number.

**processor carrier**

See [control carrier](#).

**processor data module (PDM)**

A device that provides an RS-232C DCE interface for connecting to data terminals, applications processors (APs), and host computers, and provides a DCP interface for connection to a communications system. See also [modular processor data module \(MPDM\)](#).

**processor port network (PPN)**

A port network controlled by a switch-processing element that is directly connected to that PN's TDM bus and LAN bus. See also [port network \(PN\)](#).

**processor port network (PPN) control carrier**

A carrier containing the maintenance circuit pack, tone/clock circuit pack, and SPE circuit packs for a processor port network (PPN) and, optionally, port circuit packs.

**PROCR**

Processor

**Property Management System (PMS)**

A stand-alone computer used by lodging and health-services organizations for services such as reservations, housekeeping, and billing.

**protocol**

A set of conventions or rules governing the format and timing of message exchanges to control data movement and correction of errors.

**PSC**

Premises service consultant

**PSDN**

Packet-switch public data network

**PT**

Personal terminal

**PTC**

Positive temperature coefficient

**PTT**

Postal Telephone and Telegraph

**public network**

The network that can be openly accessed by all customers for local and long-distance calling.

**pulse-code modulation (PCM)**

An extension of pulse-amplitude modulation (PAM) in which carrier-signal pulses modulated by an analog signal, such as speech, are quantized and encoded to a digital, usually binary, format.

---

## Q

**QPPCN**

Quality Protection Plan Change Notice

**quadrant**

A group of six contiguous DS0s in fixed locations on an ISDN-PRI facility. Note that this term comes from T1 terminology (one-fourth of a T1), but there are five quadrants on an E1 ISDN-PRI facility (30B + D).

**queue**

An ordered sequence of calls waiting to be processed.

**queuing**

The process of holding calls in order of their arrival to await connection to an attendant, to an answering group, or to an idle trunk. Calls are automatically connected in first-in, first-out sequence.

---

## R

**RAM**

See [random-access memory \(RAM\)](#).

**random-access memory (RAM)**

A storage arrangement whereby information can be retrieved at a speed independent of the location of the stored information.

**RBS**

Robbed-bit signaling

**RC**

Radio controller

**RCL**

Restricted call list

**read-only memory (ROM)**

A storage arrangement primarily for information-retrieval applications.

**recall dial tone**

Tones signalling that the system has completed a function (such as holding a call) and is ready to accept dialing.

**redirection criteria**

Information administered for each voice terminal's coverage path that determines when an incoming call is redirected to coverage.

**Redirection on No Answer**

An optional feature that redirects an unanswered ringing ACD call after an administered number of rings. The call is then redirected back to the agent.

**remote home numbering-plan area code (RHNPA)**

A foreign numbering-plan area code that is treated as a home area code by the Automatic Route Selection (ARS) feature. Calls can be allowed or denied based on the area code and the dialed CO code rather than just the area code. If the call is allowed, the ARS pattern used for the call is determined by these six digits.

**Remote Operations Service Element (ROSE)**

A CCITT and ISO standard that defines a notation and services that support interactions between the various entities that make up a distributed application.

**REN**

Ringer equivalency number

**reorder tone**

A tone to signal that at least one of the facilities, such as a trunk or a digit transmitter, needed for the call was not available.

**report scheduler**

Software that is used in conjunction with the system printer to schedule the days of the week and time of day that the desired reports are to be printed.

**RFP**

Request for proposal

**RHNPA**

See [remote home numbering-plan area code \(RHNPA\)](#).

**RINL**

Remote indirect neighbor link

**RISC**

Reduced-instruction-set computer

**RLT**

Release-link trunk

**RMATS**

Remote Maintenance, Administration, and Traffic System

**RNX**

Route-number index (private network office code)

**ROM**

See [read-only memory \(ROM\)](#).

**ROSE**

See [Remote Operations Service Element \(ROSE\)](#).

**RPN**

Routing-plan number

**RS-232C**

A physical interface specified by the Electronic Industries Association (EIA). RS-232C transmits and receives asynchronous data at speeds of up to 19.2 kbps over cable distances of up to 50 feet.

**RS-449**

Recommended Standard 449

**RSC**

Regional Support Center

---

## S

**S1**

The first logical signalling channel of DCP. The channel is used to provide signaling information for DCP's I1 channel.

- S2**  
The second logical signaling channel of DCP. The channel is used to provide signaling information for DCP's I2 channel.
- SABM**  
Set Asynchronous Balance Mode
- SAC**  
Send All Calls
- SAKI**  
See [sanity and control interface \(SAKI\)](#).
- sanity and control interface (SAKI)**  
A custom VLSI microchip located on each port circuit pack. The SAKI provides address recognition, buffering, and synchronization between the angel and the five control time slots that make up the control channel. The SAKI also scans and collects status information for the angel on its port circuit pack and, when polled, transmits this information to the archangel.
- SAT**  
System access terminal
- SCC**  
  1. See [single-carrier cabinet](#).
  2. Serial communications controller
- SCD**  
Switch-control driver
- SCI**  
Switch communications interface
- SCO**  
System control office
- SCOTCH**  
Switch Conferencing for TDM Bus in Concentration Highway
- SCSI**  
See [small computer system interface \(SCSI\)](#).
- SDDN**  
Software-Defined Data Network
- SDI**  
Switched Digital International
- SDLC**  
Synchronous data-link control
- SDN**  
Software-defined network
- SFRL**  
Single-frequency return loss
- SID**  
Station-identification number
- simplex system**  
A system that has no redundant hardware.

**simulated bridged appearance**

The same as a temporary bridged appearance; allows the terminal user (usually the principal) to bridge onto a call that had been answered by another party on his or her behalf.

**single-carrier cabinet**

A combined cabinet and carrier unit that contains one carrier. See also [Multicarrier cabinet](#).

**single-line voice terminal**

A voice terminal served by a single-line tip and ring circuit (models 500, 2500, 7101A, 7103A).

**SIT**

Special-information tones

**small computer system interface (SCSI)**

An ANSI bus standard that provides a high-level command interface between host computers and peripheral devices.

**SMDR**

Station Message Detail Recording

**SN**

Switch Node

**SNA**

Systems Network Architecture

**SNC**

Switch Node Clock

**SNI**

Switch Node Interface

**SNMP**

Simple Network Management Protocol

**software**

A set of computer programs that perform one or more tasks.

**SPE**

Switch Processing Element

**SPID**

Service Profile Identifier

**split**

See [ACD work mode](#).

**split condition**

A condition whereby a caller is temporarily separated from a connection with an attendant. A split condition automatically occurs when the attendant, active on a call, presses the start button.

**split number**

The split's identity to the switch and BCMS.

**split report**

A report that provides historical traffic information for internally measured splits.

**split (agent) status report**

A report that provides real-time status and measurement data for internally measured agents and the split to which they are assigned.

**SSI**

Standard serial interface

**SSM**

Single-site management

**SSV**

Station service

**ST3**

Stratum 3 clock board

**staffed**

Indicates that an agent position is logged in. A staffed agent functions in one of four work modes: Auto-In, Manual-In, ACW, or AUX-Work.

**STARLAN**

Star-Based Local Area Network

**Station Message Detail Recording (SMDR)**

An obsolete term now called CDR — a switch feature that uses software and hardware to record call data. See [Call Detail Recording \(CDR\)](#).

**standard serial interface (SSI)**

A communications protocol developed for use with 500-type business communications terminals (BCTs) and 400-series printers.

**status lamp**

A green light that shows the status of a call appearance or a feature button by the state of the light (lit, flashing, fluttering, broken flutter, or unlit).

**stroke counts**

A method used by ACD agents to record up to nine customer-defined events per call when CMS is active.

**SVN**

Security-violation notification

**switch**

Any kind of telephone switching system. See also [communications system](#).

**switchhook**

The buttons located under the receiver on a voice terminal.

**switch-node (SN) carrier**

A carrier containing a single switch node, power units, and, optionally, one or two DS1 converter circuit packs. An SN carrier is located in a center-stage switch.

**switch-node (SN) clock**

The circuit pack in an SN carrier that provides clock and maintenance alarm functions and environmental monitors.

**switch-node interface (SNI)**

The basic building block of a switch node. An SNI circuit pack controls the routing of circuit, packet, and control messages.

**switch-node link (SNL)**

The hardware that provides a bridge between two or more switch nodes. The SNL consists of the two SNI circuit packs residing on the switch nodes and the hardware connecting the SNIs. This hardware can include lightwave transceivers that convert the SNI's electrical signals to light signals, the copper wire that connects the SNIs to the lightwave transceivers, a full-duplex fiber-optic cable, DS1 converter circuit cards and DS1 facilities if a company does not have rights to lay cable, and appropriate connectors.

**switch-processing element (SPE)**

A complex of circuit packs (processor, memory, disk controller, and bus-interface cards) mounted in a PPN control carrier. The SPE serves as the control element for that PPN and, optionally, for one or more EPNs.

**SXS**

Step-by-step

**synchronous data transmission**

A method of sending data in which discrete signal elements are sent at a fixed and continuous rate and specified times. See also [association](#).

**SYSAM**

System Access and Administration

**system administrator**

The person who maintains overall customer responsibility for system administration. Generally, all administration functions are performed from the Management Terminal. The switch requires a special login, referred to as the system administrator login, to gain access to system-administration capabilities.

**system printer**

An optional printer that may be used to print scheduled reports via the report scheduler.

**system report**

A report that provides historical traffic information for internally measured splits.

**system-status report**

A report that provides real-time status information for internally measured splits.

**system manager**

A person responsible for specifying and administering features and services for a system.

**system reload**

A process that allows stored data to be written from a tape into the system memory (normally after a power outage).

---

**T**

**T1**

A digital transmission standard that in North America carries traffic at the DS1 rate of 1.544 Mbps. A T1 facility is divided into 24 channels (DS0s) of 64 kbps. These 24 channels, with an overall digital rate of 1.536 Mbps, and an 8-kbps framing and synchronization channel make up the 1.544-Mbps transmission. When a D-channel is present, it occupies channel 24. T1 facilities are also used in Japan and some Middle-Eastern countries.

**TAAS**

Trunk Answer from Any Station

**TABS**

Telemetry asynchronous block serial

**TAC**

Trunk-access code

**tandem switch**

A switch within an electronic tandem network (ETN) that provides the logic to determine the best route for a network call, possibly modifies the digits outpulsed, and allows or denies certain calls to certain users.

**tandem through**

The switched connection of an incoming trunk to an outgoing trunk without human intervention.

**tandem tie-trunk network (TTTN)**

A private network that interconnects several customer switching systems.

**TC**

Technical consultant

**TCM**

Traveling class mark

**TDM**

See [time-division multiplexing \(TDM\)](#).

**TDR**

Time-of-day routing

**TEG**

Terminating extension group

**terminal**

A device that sends and receives data within a system. See also [administration terminal](#).

**tie trunk**

A telecommunications channel that directly connects two private switching systems.

**time-division multiplex (TDM) bus**

A bus that is time-shared regularly by preallocating short time slots to each transmitter. In a PBX, all port circuits are connected to the TDM bus, permitting any port to send a signal to any other port.

**time-division multiplexing (TDM)**

Multiplexing that divides a transmission channel into successive time slots. See also [multiplexing](#).

**time interval**

The period of time, either one hour or one-half hour, that BCMS measurements are collected for a reports.

**time slice**

See [time interval](#).

**time slot**

64 kbps of digital information structured as eight bits every 125 microseconds. In the switch, a time slot refers to either a DS0 on a T1 or E1 facility or a 64-kbps unit on the TDM bus or fiber connection between port networks.

**time slot sequence integrity**

The situation whereby the N octets of a wideband call that are transmitted in one T1 or E1 frame arrive at the output in the same order that they were introduced.

**to control**

An application can invoke *Third Party Call Control* capabilities using either an adjunct-control or domain-control association.

**to monitor**

An application can receive *event reports* on an active-notification, adjunct-control, or domain-control association.

**TOD**

Time of day

**tone ringer**

A device with a speaker, used in electronic voice terminals to alert the user.

**TOP**

Task-oriented protocol

**trunk**

A dedicated telecommunications channel between two communications systems or COs.

**trunk allocation**

The manner in which trunks are selected to form wideband channels.

**trunk-data module**

A device that connects off-premises private-line trunk facilities and DEFINITY ECS. The trunk-data module converts between the RS-232C and the DCP, and can connect to DDD modems as the DCP member of a modem pool.

**trunk group**

Telecommunications channels assigned as a group for certain functions that can be used interchangeably between two communications systems or COs.

**TSC**

Technical Service Center

**TTI**

Terminal translation initialization

**TTR**

Touch-tone receiver

**TTT**

Terminating trunk transmission

**TTTN**

See [tandem tie-trunk network \(TTTN\)](#).

**TTY**

Teletypewriter

---

## U

### UAP

Usage-allocation plan

### UART

Universal asynchronous transmitter

### UCD

Uniform call distribution

### UCL

Unrestricted call list

### UDP

See [Uniform Dial Plan \(UDP\)](#).

### UL

Underwriter Laboratories

### UM

User manager

### Uniform Dial Plan (UDP)

A feature that allows a unique 4- or 5-digit number assignment for each terminal in a multiswitch configuration such as a DCS or main-satellite-tributary system.

### UNMA

Unified Network Management Architecture

### UNP

Uniform numbering plan

### UPS

Uninterruptible power supply

### USOP

User service-order profile

### UUCP

UNIX-to-UNIX Communications Protocol

### UUI

User-to-user information

---

## V

### VAR

Value-added reseller

### VDN

See [vector directory number \(VDN\)](#).

**vector directory number (VDN)**

An extension that provides access to the Vectoring feature on the switch. Vectoring allows a customer to specify the treatment of incoming calls based on the dialed number.

**vector-controlled split**

A hunt group or ACD split administered with the vector field enabled. Access to such a split is possible only by dialing a VDN extension.

**VIS**

Voice Information System

**VLSI**

Very-large-scale integration

**VM**

Voltmeter

**VNI**

Virtual nodepoint identifier

**voice terminal**

A single-line or multiappearance telephone.

---

## W

**WATS**

See [Wide Area Telecommunications Service \(WATS\)](#).

**WCC**

World-Class Core

**WCR**

World-Class Routing

**WCTD**

World-Class Tone Detection

**WFB**

Wireless fixed base

**Wide Area Telecommunications Service (WATS)**

A service in the United States that allows calls to certain areas for a flat-rate charge based on expected usage.

**wideband**

A circuit-switched call at a data rate greater than 64 kbps. A circuit-switched call on a single T1 or E1 facility with a bandwidth between 128 and 1536 (T1) or 1984 (E1) kbps in multiples of 64 kbps. H0, H11, H12, and N x DS0 calls are wideband.

**wideband access endpoint**

Access endpoints, extended with wideband switching to include wideband access endpoints. A wideband access endpoint consists of one or more contiguous DS0s on a line-side T1 or E1 facility and has an extension. The Administered Connections feature provides call control for calls originating from wideband access endpoints.

**wink-start tie trunk**

A trunk with which, after making a connection with a distant switching system for an outgoing call, the system waits for a momentary signal (wink) before sending the digits of the called number. Similarly, on an incoming call, the system sends the wink signal when ready to receive digits.

**work mode**

One of four states (Auto-In, Manual-In, ACW, AUX-Work) that an ACD agent can be in. Upon logging in, an agent enters AUX-Work mode. To become available to receive ACD calls, the agent enters Auto-In or Manual-In mode. To do work associated with a completed ACD call, an agent enters ACW mode.

**work state**

An ACD agent may be a member of up to three different splits. Each ACD agent continuously exhibits a work state for every split of which it is a member. Valid work states are Avail, Unstaffed, AUX-Work, ACW, ACD (answering an ACD call), ExtIn, ExtOut, and OtherSpl. An agent's work state for a particular split may change for a variety of reasons (example: when a call is answered or abandoned, or the agent changes work modes). The BCMS feature monitors work states and uses this information to provide BCMS reports.

**write operation**

The process of putting information onto a storage medium, such as a hard disk.

**WSA**

Waiting session accept

**WSS**

Wireless Subscriber System

---

**Z**

**ZCS**

Zero Code Suppression
