DIG-LINE maintenance monitors and tests ports on digital line circuit packs and the hardware connected to those ports for lines administered as a digital station. These include stations with just a digital voice terminal and stations with a digital voice terminal and a linked data module. Stand-alone data modules, and data adaptors in stand-alone mode, are covered by the PDMODULE and TDMODULE maintenance objects. Circuit pack-level maintenance is covered by “DIG-BD” whose strategy is described in the "XXX-BD (Common Port Circuit Pack)" section.

Only the TN754B or TN2136 should be used in out-of-building applications. For important information pertaining to protection required for out-of-building digital voice terminals, see *DEFINITY Enterprise Communications Server Release 5.4 Installation and Test for Multi-Carrier Cabinets*.

Only 2-wire Italtel Digital Telephone Models 1 and 2 (IDT1/2) or DAs can directly connect to a TN2136. Lucent DCP (4-wire) digital voice terminals and data modules can connect to these circuit packs via Italtel’s 2/4-wire adapter. DAs can operate in either of two modes which are covered by different MOs:

DA Mode	Administered as:	Endpoint	MO
Stand-alone	PDM	Data endpoint only	PDMODULE
Linked	DTDM	IDT1/2 and optional data terminal	DIG-LINE

Digital line maintenance interacts with digital line circuit pack (DIG-BD) maintenance, and results of DIG-LINE testing can be affected by the health of the digital line circuit pack. Keep this in mind when investigating digital line problems.

There are instances where the service state of a station is mentioned. It is helpful to understand what is meant by the different service states that may exist. The different service states which apply to digital line station are explained as follows:

Out-of-Service	The port, and thus the station, have been removed from service. Busyout puts the port in the out-of-service state.
Ready-for-Service	The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.
In-Service	The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally. It can also be forced into the in-service state by going off-hook.

Downloading of Terminal Parameters

Programmable Terminals

The following information is presented to help you understand how maintenance software interacts with terminal parameter downloading.

Terminal Types:

a. 84xx multibutton digital voice terminals (8403D01A, 8410B, 8410D02A, 8434D01A) with optional expansion module.

b. 603A1 and 603D1 Callmaster terminals for telemarketing applications.

c. 302B1 and 302C1 attendant console.

Circuit Packs:

1. 8400x, 302B1 Terminals

    a. TN754 (4-wire, mu-law)

    Minimum usable vintage for 8410D and 8434D terminals - V11

    b. TN413 (4-wire, A-law)

    c. TN754B (4-wire, A-law/mu-law selectable)

    d. TN2177 (2-wire, 16-port, A-law/mu-law selectable)

    e. TN2181 (2-wire, 16-port, A-law/mu-law selectable)

    f. TN2224 (2-wire, 24-port, A-law/mu-law selectable)

2. 603A1/D1 Terminals
    a. TN754 (4-wire, mu-law),
    b. TN413 (4-wire, A-law)
    c. TN754B (4-wire, A-law/mu-law selectable)

Downloadable Terminal Parameters

The following parameters are downloaded to programmable terminals:

Table 9-212. Parameters Downloadable to Programmable Terminals

Parameter	Scope	Terminal
International Flags (A-law/mu-law, Display Mode, DLI Voltage level)	System level	84xx, 603x, 302B1
Primary Levels (Transmission & Sidetone)	System level	84xx, 603x, 302B1
Adjunct Levels (Transmission & Sidetone)	System level	84xx
Handset Expander Option	System level	84xx
Administrable Options (Speakerphone & Mute Button)	Per-terminal	84xx
Administrable Softkeys	Per-terminal, System level	8410D, 8434D

Nonvolatile Memory

Nonvolatile memory stores downloadable parameters in programmable terminals. Once the terminal is downloaded, it is not be necessary to download it again, even if power is removed from the terminal. If nonvolatile memory fails with power still present, the terminal reverts to its default factory settings except for its A-law/mu-law companding settings which are stored in RAM. If power is removed after the nonvolatile memory fails, the terminal reverts to its factory default settings.

NOTE:
The mu-law companding mode is assigned as a default setting at the factory. For the United States, a programmable terminal can place calls even though it has not been downloaded from the system.

Download Actions

There are several different scenarios that cause a terminal to be downloaded. These can occur as part of background maintenance activity or on demand from the System Access Terminal or from a station.

For the background actions described below, the terminal downloads automatically if a download retry flag for the terminal is set in software. This flag is set at the time translation is loaded at boot time, when translation which affects the parameters of a terminal is changed as part of system administration actions, and when a port is inserted in software as a result of board insertion or translation change.

Automatic Download Actions

1. System Reboot/Restart

   A global download action is started when periodic maintenance tests start after a system reboot/restart regardless of whether the parameters have been downloaded previously.

2. Periodic Tests

   If the download flag is still set when periodic tests are run on a terminal, a download action will occur. This operation is required in case a terminal could not be downloaded previously because it was off-hook at the time the system first booted or because the terminal was off-hook at the time translation associated with downloadable parameters was changed.

   Note that it may take more than an hour for periodic tests to reach the terminal that needs to be downloaded.

3. Terminal Administration

   A downloadable terminal is automatically downloaded when translation changes associated with downloadable parameters are made as part of system administration. As shown in the previous table, these changes can be for a specified terminal or may be system-wide. If the change is for system-level parameter, a background global update request is made to download all programmable terminals.

   This global update may take more than an hour for a system with several thousand programmable terminals.

4. Port Insertion

   Whenever maintenance software initiates a request to place a port into service, a terminal download action is started on that terminal if that terminal is programmable. This port insertion action occurs under the following circumstances:

   a. A digital line circuit pack that is physically inserted into the system has ports currently administered for programmable terminals.

      If more than 20 port insertion requests are received within a few seconds, a global download request is started up as a background task. This action updates all programmable terminals instead of just those being inserted. This is done to avoid system overload for situations where there is massive board insertion. This could occur when connectivity to an EPN is reestablished after that EPN was down.

   b. A station port is added to the system by a "**add station**" or "**change station**" command.

   c. A TTI port is activated.

5. Audits

   As part of periodic maintenance, the hardware status audit test queries programmable terminals to determine which levels and/or options are being used. If the reported values are not equal to the administered values, the system will initiate a terminal download action. This audit does NOT check the parameters used for softkeys.

6. Activation of TTI

   A terminal is downloaded automatically when it is activated using the Terminal Translation Initialization feature. Therefore, no special user actions are required for TTI.

NOTE:
Plugging the station cord into a terminal does not automatically cause the terminal to be downloaded. If this terminal has factory defaults or if the terminal has been previously downloaded with parameters different than those desired, use one of the demand download actions described below to download the terminal.

Demand Download Actions

1. Busyout/Release Command

   A maintenance demand busyout/release request for a station will cause the terminal to be downloaded regardless of its previous download status.

2. Feature Access Code

   A Refresh Terminal Parameters Feature Access Code can be used to request a terminal download action. When this code is followed by a "#", the programmable parameters for the current terminal are downloaded when the terminal goes on hook. When this code is followed by an extension, the programmable parameters for the specified station are downloaded.

   This Refresh Terminal Parameters Feature Access Code is assigned on the second page of the "feature-access-codes" screen.

   A confirmation is returned if the download request is accepted. A busy tone is returned if the request is made from a different station when the target station is off-hook.

   The first three green call appearance LEDs on the 84xx 603x terminal will be turned on for three seconds if the station was successfully downloaded as a result of an entry of a Refresh Terminal Parameters Facility Access Code. This is not true for the 302B1 terminal.

   There is no visible display on a station for the other background or demand download actions. As described below, the "status station" and "status attendant" screens can be used to check the download status of a specified terminal.

Status of Parameter Downloads

The "status station" and "status attendant" screens display the current download status of individual 84xx, 603, and 301B1 terminals in the Download Status field. The possible download states are:

Status	Explanation
Complete	Terminal successfully downloaded sometime in the past.
Pending	System waiting to download the terminal. This may require the execution of a background periodic test which could take more than an hour. A demand download as described above may also be used to initiate an immediate download.
Not Applicable	Not a programmable terminal.

Possible reasons for terminal being not downloaded include:

— Terminal is off-hook.

— Terminal detected a bad checksum.

— Terminal detected a bad or missing EEPROM (refer to hardware error log).

— Terminal is busy programming data from a previous PROGRAM message.

— Terminal is in the Programming Disabled state.

— Terminal is in the Local Program Options Mode.

— Terminal is disconnected or out of service (use **status station** command).

Error Log Entries and Test to Clear Values

Table 9-213. Digital Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port *UUCSSpp* sh r 1
1 (a)	40987	None	WARNING	OFF	
1 (b)	1 to 20	None	WARNING	OFF	
18 (c)	0	busyout port *UUCSSpp*	WARNING	OFF	rel port *UUCSSpp*
130 (d)		None	WARNING	ON	test port *UUCSSpp* sh
257 (e)	40971	None			
513	0	Station (Digital) Audits Test (#17)	WARNING(o)	OFF	test port *UUCSSpp* sh r 6
767 (f)	40964	None	WARNING	OFF	
769 (g)	40963 40988	None	WARNING	OFF	
1026(o)		NONE	WARNING	OFF

Table 9-213. Digital Line Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3840 (k)	40965	None			
3840 (l)	40989	None			
3841 (m)	41029	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. Could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

b. This Error Type and Aux Data will occur when at least 15 off-board problems have been detected with the link to the terminal. When an error with the link is detected, an on-board counter is incremented.

   The user could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

c. This error type is logged when the port in question is busied out by maintenance personnel. Make sure port is released from busyout via the **release port UUCSS pp/PCSSpp** command.

d. This error type indicates that the circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.

e. Problems transmitting to the voice terminal. This problem can be caused by defective wiring. Defective wiring can cause varying degrees of problems on different types of sets. Sets such as the 7410 appear to be more susceptible to wiring problems than other sets. This is usually an on-board problem and can be ignored if no user complaints are received.

f. This is an in-line event that produces this error type when a favorable response is received from running the Digital Line Electronic Power Feed Test (#11). No craft action is necessary. This alarm will be resolved with the passing of time.

g. With Aux Data 40963, this error type is a result of an unfavorable response to the Electronic Power Feed/ Positive Temperature Coefficient Test (#11). With Aux Data 40988, this error type indicates that the EPF/PTC circuit has been turned off due to an overcurrent condition.

   For TN754 vintage 13 or earlier and TN413, the EPF circuit senses an overcurrent condition at the voice terminal. Check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

   For TN754 vintage 14 or later, TN754B and TN2136, the PTC will open if there is a short on the power line for 1/2 second or longer. The voice terminal is probably not operating properly. Unplug the voice terminal for 30 seconds and then plug it back in. If the voice terminal still does not operate, then check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

   Once the problem has been resolved, it may take up to 1 hour for the alarm to clear due to “leaky bucket” strategy. If the problem cannot be resolved by one of the steps above, then replace the circuit pack.

h. An in-line maintenance error has generated an off-board warning due to some problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal to a jack that is closer to the switch (in terms of feet of wiring between the jack and the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

i. This indicates that the station went off-hook while it was in the ready-for-service state. Use the **status station** command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No craft action is necessary.

j. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No craft action is necessary.

k. No terminal is connected to the Digital Line board. No maintenance action is required.

l. An uplink message has been logged indicating that the Electric Power Feed (EPF) is on with no load on it. No action is necessary.

m. The circuit pack's message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack. No action is necessary.

n. Internal system error. No action is necessary.

o. There is a problem with the voice terminal EEPROM. When the voice terminal is repaired the alarm will be resolved with the passing of time.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Voice and Control Channel Local Looparound Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Digital Terminal Remote Looparound Test (#1201)		X	D
Voice and Control Channel Local Looparound Test (#13)		X	ND
Digital Line NPE Crosstalk Test (#9)		X	ND
Digital Line Electronic Power Feed Test (#11)		X	ND
DIG-LINE Station Lamp Updates Test (#16)	X	X	ND
Station (Digital) Audits Test (#17)	X	X	ND

1. D = Destructive; ND = Nondestructive

Digital Terminal Remote Looparound Test (#1201)

This test checks the connection between the SPE and the digital terminal and the ability of the terminal and the associated port to send and receive data. This test is based on procedure 622 to isolate digital terminal problems.

A request is presented to the terminal to go into loopback mode. Data is sent to the terminal and when received back, checked for consistency. This test is run as a part of the "test long" procedure. It is not included in any error recovery strategy and generates no Error Log entries or alarms. To begin the test, Maintenance will ask call processing to make the associated endpoint and port " Maintenance Busy". This test succeeds if the endpoint is "idle". If the reserve request fails then the test aborts. If the request succeeds then the SPE sends a message to loop around both information channels for the digital terminal. First the primary information (voice, Information Channel 1 or I1) channel loopback test is run. The test is performed by sending a digital count from the Tone/Clock circuit pack on the primary information channel time slot and receiving the same digital count with a general purpose tone detector.

If the primary information channel test is successful, the loop around test for the secondary information (data, Information Channel 2 or I2) channel is then performed. This test is the same as the primary information channel loop around test and is performed only if a DTDM is administered. This is also the case for a linked DA.

Only one value (Pass. Fail, or Abort) is generated as a result of the two tests run. If any test fails aborts, the sequence is stopped. Upon completion of this test the associated endpoint and port are moved back into the previous service state.

Table 9-214. TEST #1201 Digital Terminal Remote Looparound Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-214. TEST #1201 Digital Terminal Remote Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	System resources required to run this test are not available. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out of service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exist, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. 1. Enter **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before resetting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	The installed circuit pack does not support this operation.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	System resources required to run this test are not available. 1. Make sure terminal is connected and repeat test. 2. If test fails replace terminal and repeat test. 3. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-214. TEST #1201 Digital Terminal Remote Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
14	FAIL	The primary channel is not operating properly. User impact may range from noticing nothing to not being able to use the port. Check the results of "Voice and Control Channel Local Loop Test (#13). If that test fails, suspect the Digital Line circuit pack. If that test passes then replace the terminal. If both tests fail, and component replacement does not change the results, then: 1. Run circuit pack tests to check the tone generator circuit pack and the Tone Detector circuit pack using **test board UUCSS** . 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack.
1015	ABORT	The station is not busied out (**busyout station**).
16	FAIL	The secondary channel is not operating properly. User impact may range from noticing nothing to not being able to use this terminal. Check the results of Voice and Control Channel Local Loop Test (#13). If that test fails, suspect the Digital Line circuit pack. If that test passes then replace the terminal. If both test fail, and component replacement does not change the results, then: 1. Run circuit pack tests to check the tone generator circuit pack and the Tone Detector circuit pack using **test board UUCSS** . 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack.
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of ten times to make sure it continues to pass. 2. If complaints persist (noisy connections for voice. corrupted data transfer for data), examine the station, connections, and wiring.

Digital Line NPE Crosstalk Test (#9)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-215. TEST #9 Digital Line NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	During testing of the primary information channel, system resources were not available. Also, the port may have been busy during the test. 1. Enter **display port UUCSSpp** to determine the station extension of the port. Use **status station** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
2	ABORT	During testing of DTDM, system resources may not have been available. Also, the port may have been busy during the test. 1. Check if port is being used. If possible, disconnect by toggling disconnect button on DTDM. Retry command after 1 minute. **WARNING:** *This action will drop the call in progress.*
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Enter **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic. Retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-215. TEST #9 Digital Line NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Enter **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out.
1020	ABORT	Test disabled via background testing. Use **status station** command to determine when station is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1 2	FAIL	The Network Processing Element (NPE) of the tested port was transmitting in error. Error code 1 = Crosstalk test failed on the primary channel. Error code 2 = Crosstalk test failed on the secondary channel. 1. Replace circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints persist, examine the station, connections, and wiring.

Digital Line Electronic Power Feed/Positive Temperature Coefficient/PPF Test(#11)

For TN413, and TN754 vintage 13 or earlier, this is an Electronic Power Feed (EPF) restoral test. In this test, the processor requests that the EPF be turned on for a given port, and an attempt is made to turn on the power supply to the station. If no current is drawn, the station is probably not connected. If an overcurrent condition is sensed, there may be a short in the loop. A message is returned reporting that either the EPF was successfully turned on, or that an overcurrent condition was sensed. This test is repeated again 5 seconds later.

For TN754 vintage 14 or later, TN754B and TN2136 this is a Positive Temperature Coefficient (PTC) restoral test. In this test, the processor requests that the PTC be turned on for a given port, and an attempt is made to turn on the power supply to the station. If an overcurrent condition is sensed, there is probably a short on the power line that causing the PTC to open and disconnect the voice terminal. Since the PTC does not have self-restoral capability, the voice terminal must be manually unplugged for 30 seconds and then plugged back in to restore the PTC. A message is returned reporting that either the PTC was successfully turned on successfully with no problem or an overcurrent condition was sensed. This test is repeated again 5 seconds later.

TN2181 and TN2224 boards carry a Protected Power Feed (PPF) relays, one for each port. Therefore this will be a Protected Power Feed restoral test. The test procedure and its response is same as that of EPF. One of differences between EFP and PPF is that, if the port goes into a overcurrent state, PPF does not report this change of state because it is a transient state which will not last more than 50ms. If the over current persists the power will be shut off automatically and an EPF_off_overcurrent message is sent uplink.

Table 9-216. TEST #11 Digital Line Electronic Power Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Enter **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-216. TEST #11 Digital Line Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Electronic Power Feed Test passed. The message to turn on the power to the station was successfully sent to the port. 1. Although this test will never actually return a FAIL result except for the **Internal system error** described above, it will log an error indicating the real results of the test. Check the Error Log for any entries with Error Types 767 or 769 after the test completes. 2. If Error Type 767 appears in the Error Log, this indicates that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station and check that all the feature buttons are operating. 3. If Error Type 769 appears in the Error Log, this indicates some problem with the power to the station. Check for a short in the wiring, a damaged jack, a defective voice terminal, or an incorrect type of terminal.

Voice and Control Channel Local Loop Test (#13)

These tests check the information and control channels between the Switch Processing Element (SPE) and the Digital Line port circuit. The SPE sends a message to loop around both the information and control channels for the port. First, the primary information (voice) channel loop back test is run. The test is performed by sending a digital count from the Tone-Clock circuit pack on the primary information channel time slot and receiving the same digital count with a general purpose Tone Detector.

While the primary information channel is still looped around, the Control Channel Looparound Test is performed. This test consists of sending four different transparent patterns to the on-board microprocessor, receiving them back, and comparing them.

The Looparound Test for the secondary information (data) channel is then performed. This test is the same as the primary information channel loop around test and is performed only if a DTDM is administered.

A Conference Test is done next for the primary information channel. This test is the same as Conference Test #6. Only one value (Pass, Fail, or Abort) is generated as a result of four tests run. If any test fails or aborts, the sequence is stopped.

Table 9-217. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Rerun the test at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-217. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	Conference Test failed on primary channel. In some cases, users may not notice disruption in service. In extreme cases, conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port.
15	FAIL	The control channel between the processor and digital circuit pack is not transmitting properly. User impact may range from noticing nothing to not being able to use the port. Could also be disruptive to other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using **test board UUCSS**. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Digital Line circuit pack.
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints persist (noisy connections for voice, corrupted data for data transfer), examine the station, connections, and wiring.

DIG-LINE Station Lamp Updates Test (#16)

This test lights all lamps on the terminal as specified. The lamp updates will run only if the station is in-service. The status of the station is checked and the lamp updates are blocked from taking place if the station is not in the in-service state. This test does not affect the status of the Message Waiting lamp.

Table 9-218. TEST #16 DIG-LINE Station Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
3	ABORT	Station may be in ready-for-service or out-of-service state. 1. Use **status station** command to verify state of station. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a "`t`" for the port). 2. If either **list config** or **display port** indicates that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The message to light all of the station lamps was sent successfully to the port. 1. Observe the station lamps being lit when running the test. If all lamps do not light, the other Digital Line test results may indicate related problems that do not allow the lamps to light. 2. Investigate by using other Digital Line port tests, and by examining the station, wiring, and connections.

Digital Station Audits Test (#17)

This is a series of six tests that are classified as audits. The SPE sends messages to the on-board microprocessor to perform the following tests. These audits run only if the station is in-service.

- Switchhook Inquiry Test — This is an update of the SPE records according to the circuit pack's records. This inquiry is sent all the way to the voice terminal.
- Bad Scan Inquiry Test — A message is sent uplink which contains a count that is generated due to certain events relating to the link conditions. This can be an indication of communications problems between the Processor and Digital Port circuit pack.
- EPF/PTC Inquiry Test — For a TN413 or a TN754 vintage 13 or earlier, the status of the Electronic Power Feed (EPF) is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, and EPF-no-load. For TN754 vintage 14 or later, TN754B or TN2136, TN2181, TN2224, the status of the PTC is sent uplink. Possible conditions are: PTC-on-ok, PTC-off, and PTC-no-load.
- ID Request Test — A request is made to the station for its status. The station sends its configuration information and health information back. This information is checked and a pass/fail result is provided.
- Ringer Update Test — This updates the digital telephone ringer state according to the processor records.
- DTMF Administration Update Test — This is a message to the digital station to refresh the default value that causes the station to send touch-tones only in the primary information channel. This value is set initially when the station is put in-service and every time the station's state changes from other states to in-service.

Table 9-219. TEST #17 Station (Digital) Audits Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switchhook audit timed out.
2	ABORT	ID request fails, health bit returned from voice terminal is bad. 1. Make sure voice terminal is connected and repeat test. 2. If test fails, replace voice terminal and repeat test.

Continued on next page

Table 9-219. TEST #17 Station (Digital) Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	ABORT	The EPF/PTC has detected an overcurrent condition. 1. For a TN754 vintage 13 or earlier Digital Line circuit pack, use **test UUCSSpp long**. If Test #11 passes, then the EPF/PTC condition was cleared. Rerun the Short Test Sequence. If Test #11 does not pass, follow the repair procedures described for Test #11. 2. Look for Error Type 769 logged against DIG-LINE and follow the procedures in the associated footnote. If any additional problems are found, rerun the test.
4	ABORT	Internal system error 1. Resolve any outstanding circuit pack maintenance problems. 2. Retry the command at 1-minute intervals a maximum of 5 times.
5	ABORT	Ringer update aborted due to station being in ready-for-service or out-of-service state.
6	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error is present, the release the port via **release station** 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required for this test are not available.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a “`t`” for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
2000	ABORT	Response to the test was not received in the allowable time period.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Station Audits passed. This Digital Port circuit pack is functioning properly. 1. If complaints persist, investigate by using other port tests, and by examining the station, wiring, and connections.

DIOD-BD (DIOD Trunk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DIOD-BD	MINOR	test port *UUCSSpp* s	DIOD Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 -44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

Refer to the "XXX-BD (Common Port Circuit Pack)") section at the end of this chapter.

DIOD-DS1 (DS1 DIOD Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DIOD-DS1	MAJOR[1]	test trunk *group# member#* l	DS1 DIOD Trunk
DIOD-DS1	MINOR	test trunk *group# member#* l	DS1 DIOD Trunk
DIOD-DS1	WARNING	test trunk *group# member#*	DS1 DIOD Trunk

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed. For more information on the **set options** command.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*, for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

A DS1 DIOD trunk provides a link for digitized voice or data communications between the system and a central office switch. There are two types of DS1 interfaces:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link
- 32-channel mode is supported only on TN464 circuit packs and on G3r V2 systems.

The DS1-DIOD maintenance object monitors and maintains a DIOD trunk port on a TN464 UDS1 Interface circuit pack. See "UDS1-BD (UDS1 Interface Circuit Pack)" in this chapter for more information about this circuit pack. The DS1 circuit pack supports low level CO trunk signaling interfaces for both ground-start and loop-start trunks. This maintenance strategy covers the in-line errors log, initialization tests, periodic tests, scheduled tests, demand tests, and alarm resolution and escalation.

Three trunk service states are specified by DS1 DIOD trunk maintenance:

out-of-service	The trunk is in a deactivated state and cannot be used for either incoming or outgoing calls.
in-service	The trunk is in an activated state and can be used for both incoming and outgoing calls.
disconnect (ready-for-service)	The trunk is in an activated state but can only be used for an incoming call.

Error Log Entries and Test to Clear Values

2049(j)	57473 57474 57475				

DS1 DIOD Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
2305(k)	50944				
2562(l)	16665				
2817(m)	52992				
3840(n)		Port Audit and Update Test (#36)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This alarm is only raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
3. Major alarms may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. Error Type 1—Aux Data 57408—No tip ground is detected on an outgoing call.

   Aux Data 57476—Rotary Dial before Wink.

   Aux Data 57477—Rotary Dial pulse too early.

   Aux Data 57485—Wink too short for a valid signal.

   Aux Data 57487—PBX could not get ‘‘loop close’’ signal.

   The DS1 Interface circuit pack detected a hardware fault. These errors will cause the Dial Tone Test (#314) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in the ready-for-service state (shown as ‘‘disconnected’’ by the status command), which allows only incoming calls. Run the Dial Tone Test (#314) and follow the procedures.

b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

c. Error Type 18—System Technician has busied out the trunk to the out-of-service state. No calls can be made on this trunk except the Facility Access Test Call. For details on this feature, refer to ‘‘Facility Test Calls’’ section in Chapter 6.

d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. Error Type 257—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57392 indicates no external release on PBX disconnect.

f. Error Type 513—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57393 indicates belated external release on PBX disconnect.

g. Error Type 769—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type:—57484, fault is detected on tip/ring.

h. The DS1Interface circuit pack detects a hardware fault, and the Aux Data field contains the following error type: 51200, port is unavailable. Run the Dial Tone Test (#314) and follow procedures.

i. Error Type 1793—DS1 Interface circuit pack is out-of-service. Look for UDS1-BD errors in the Hardware Error Log if the port is on a TN464 UDS1 board. Refer to "UDS1-BD (UDS1 Interface Circuit Pack)" (DS1 Trunk Circuit Pack) for details

j. Error Type 2049—With the following Aux Data:

    Aux Data 57473—Rotary dial rate below 8 pulses per second.

    Aux Data 57474—Rotary dial rate above 12 pulses per second.

    Aux Data 57475—Rotary Dial interdigit time is too short.

   The DS1 interface circuit pack detects a hardware error on the DS1 DIOD trunk. The trunk can not communicate with the far-end because it is unable to interpret digits sent from the far-end switch. Check with the far-end switch or Operating Company for proper trunk connection.

k. Error Type 2305—Recorder message, trunk could not be seized (Aux Data 50944). Run Test #314 and follow the outlined procedures.

l. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

m. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the Dial Tone Seizure Test (#314) and follow those procedures.

n. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back into in-service. Retry the test command.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-220. System Technician-Demanded Tests: DS1-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 Dial Tone Test (#314)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-221. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. 1. Use the **status station** or **status trunk** command to determine when the port is available for testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-221. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. The **status health** command can be used to determine if the system is experiencing heavy traffic. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some tone detectors may be out-of-service. The **list measurements tone-receiver** command will display information on the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: ■ 1281—Loss of signal ■ 1793—Blue Alarm ■ 2049—Red Alarm ■ 2305—Yellow Alarm ■ 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 9-221. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Conference Circuit Test (#7)

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 9-222. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. 1. Use the **status station** or **status trunk** command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. 1. Use the **status station** or **status trunk** command to determine when the port is available for testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via administration. This only applies to analog stations. 1. To enable test, set the `Test` field (**change station *extension***) to **y**. Use the command.

Continued on next page

Table 9-222. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: ■ 1281—Loss of signal ■ 1793—Blue Alarm ■ 2049—Red Alarm ■ 2305—Yellow Alarm ■ 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 Interface circuit pack and in the switch software.

Table 9-223. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Test failed due to internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run but will return PASS. To verify that the trunk is in-service: 1. Enter the **status trunk** command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to step 2. 2. Enter the **release trunk** command to put the trunk back into in-service. 3. Retry the test command.

DS1 CO Dial Tone Seizure Test (#314)

DS1 CO Dial Tone Seizure Test checks the trunk's signaling capability provided by the DS1 Interface circuit pack. The maintenance software initiates the test by sending a "seizure" message to the DS1 Interface circuit pack and expects an "active" reply from the DS1 interface circuit pack. If the "active" message is received, then the test passes. If no message is received and the timer expires, the test is aborted. If the DS1 Interface circuit pack sends a "reorder" message back to maintenance software, then the test fails.

This test cannot be run on a trunk in any of the following conditions:

a. The trunk direction is administered as an incoming only trunk.

b. The trunk has been seized by a normal trunk call.

c. The trunk is administered with maintenance test disabled.

Table 9-224. TEST #314 DS1 CO Dial Tone Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status trunk** command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Look at the trunk group administration form and see if the trunk is incoming only, port 24 on a DS1 Interface with common control channel signaling, or an automatic CO type such as FX. Under any of these conditions this is a normal abort.
1018	ABORT	Test has been disabled via administration. 1. Verify that the ‘‘Maintenance Tests’’ field on the Trunk Group Form is set to ‘‘n.’’ To enable the test, issue the **change trunk-group x** command where ‘‘x’’ equals the number of the trunk group to be tested. Then change the entry in the ‘‘Maintenance Tests’’ field on the form to ‘‘y.’’ 2. Repeat the test.
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for UDS1-BD errors in the Hardware Error Log. If present, refer to "UDS1-BD (UDS1 Interface Circuit Pack)" (DS1/UDS1 Trunk Circuit Pack). 2. Retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-224. TEST #314 DS1 CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: ■ 1281—Loss of signal ■ 1793—Blue Alarm ■ 2049—Red Alarm ■ 2305—Yellow Alarm ■ 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The trunk cannot be seized for an outgoing call. 1. Verify that the Trunk Type field on the trunk administration screen form matches the trunk type administered on far end switch. 2. Look for UDS1-BD errors in Hardware Error Log. If present, refer to the UDS1-BD (DS1/UDS1 Trunk Circuit Pack) Maintenance documentation. 3. Retry the test at 1-minute intervals for a maximum of 5 times.
	PASS	The trunk can be seized for an outgoing call.

DIOD-TRK (DIOD Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DIOD-TRK	MAJOR[2]	test port *UUCSSpp* l	DIOD Trunk
DIOD-TRK	MINOR	test port *UUCSSpp* l	DIOD Trunk
DIOD-TRK	WARNING	test port *UUCSSpp* l	DIOD Trunk

1. *UU* is the universal cabinet number (1 for PPN, 2 -44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).
2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to DEFINITY Communications System Generic 3 V2 Implementation, 555-230-653 for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

Direct inward and outward dial (DIOD) trunks are 2-wire analog lines to the CO which support the following services:

- Both incoming and outgoing CO calls
- DID trunk
- DID trunk and 1-way outgoing DIOD

TN429 DIOD trunk circuit packs provide eight ports for loop-start CO trunks and serve as an interface between the 2-wire analog CO line and the 4-wire TDM bus on the switch.

Loop Start Operation

Idle State: Tip = ground, Ring = CO Battery

Outgoing Call

1. PBX Off-Hook (Seize Message): Closes the Tip-Ring Loop CO Response: DC loop current + Dial tone
2. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current CO Response: CO goes to idle state (see Note)

Incoming Call

1. CO Applies Ringing Voltage PBX Response: Detect ringing current
2. PBX Off-Hook (Answer Message): Close loop CO Response: Trip ringing, provide loop current
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current CO Response: CO goes to idle state (see Note)

Direct Inward Dialing (DID)

1. CO Applies Ringing Voltage

   PBX Response: Detect ringing current and close loop

   CO Response: Send DTMF digits

   PBX Response: Acknowledge of Number dialed and open loop
2. PBX Off-Hook (Answer Message): Close loop CO Response: Trip ringing, provide loop current
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current CO Response: CO goes to idle state (see Note)

NOTE:
CO does not normally provide an On-Hook (Disconnect) signal.

Error Log Entries and Test to Clear Values

Table 9-225. DIOD Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port sh
15 (b)	any	Port Audit Update Test (#36)			
18	0	Busyout trunk *grp/mbr*	WARNING		release trunk
769 (a)	57392	None	MAJ/MIN/WRN[2]	ON	
1537		Dial Tone Test (#0)	MAJ/MIN/WRN[2]	ON	test port long r 2
1793		Looparound and Conference Test (#33)	MAJ/MIN/WRN[2]	ON	test port long r 3
2049		NPE Cross Talk Test (#6)	MAJ/MIN/WRN[2]	ON	test port long r 3
2561 (a,d)	57345	None			
2817 (a,e)	57393	None			
3073 (a,c)	57376	None			
3073 (a,c)	57424	None			
3585 (a,c)	57424	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

a. These are in-line errors that have no specific test associated with them. Refer to the following table for an explanation and appropriate action.

b. This is a software audit error and does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors.

c. Aux data 57376—No loop current on incoming call

   Aux data 57424—No loop current on outgoing call

   These errors cause the Dial Tone Test (#0) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1537 also appears). In this case, the trunk may be put in “Ready-for-Service” state (shown as “disconnected” by status command), which allows only incoming calls. Run the Dial Tone Test (#0) and follow its procedures.

d. Single polarity ringing current—This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. This error code is logged for information purposes only and does not cause additional testing to occur.

e. Late CO Trunk release—This indicates that the CO releases the trunk at least four minutes after the PBX dropped the call. This error code is only logged as an informational event and causes no other testing to occur.

Table 9-226. DIOD Trunk Errors without Associated Tests

Error Type	Aux Data	Description and Recommendation
769	57392	CO not releasing after call is dropped from PBX end (TN747B), or the loop is not open after a disconnect (TN765). After several occurrences, an off-board (TN747B) or on-board (TN465) warning alarm is generated. Refer problem to CO.
2561	57345	Single polarity ringing current. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) The other cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the dial tone test also fails. Check for other errors.
2817	57393	CO released the trunk at least four minutes after the PBX dropped the call. This error code is log only and causes no other testing to occur. No alarm is generated. Check for other errors.
3073	57376	No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the dial tone test and all outgoing calls should also fail. Check for other errors.
3585	57424	No loop current on outgoing call. This error occurs on attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected. Busyout the affected port, and run a Long test. If Dial Tone Test #0 passes, ignore this error. Release the port.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Dial Tone Test (#0)		X	ND
Looparound and Conference Test (#33)		X	ND
Audit Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

Dial Tone Test (#0)

This test attempts to seize a port and checks for the return of a dial tone.

Table 9-227. TEST #0 Dial Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the command **display port** UUCSSpp to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-227. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test has been disabled via administration. 1. The `Maintenance Tests?` field must be set to y on the trunk group form for this test to run. This form is accessed with the **change trunk-group** grp# command.
1005	ABORT	Trunk has been administered as incoming-only; or DID trunk group type; dial tone can only be obtained on outgoing trunks. This is a normal condition.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of five times.
	FAIL	Trunk was seized, but dial tone could not be detected. 1. Check for errors on TONE-BD or TONE-PT. Clear any errors and repeat test. 2. If error has still not cleared, refer problem to CO.
2002	FAIL	Seizure portion of test failed due to hardware problem. Fault is usually caused by a disconnected trunk. 1. Check trunk wiring to ensure good connection; repeat test if wiring correction made. 2. Locate another identical CO trunk and swap its wiring with one under test. Repeat test on both trunks and determine if problem follows trunk or remains at original port. If problem follows trunk, refer problem to CO. If problem remains at port, replace circuit pack and repeat test.
1009	PASS	Detected tone was not pure dial tone. No action required.
	PASS	Trunk was seized, and dial tone was detected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and noisy connections may be observed. This test is usually only part of a port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 9-228. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Enter **display port UUCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Enter **display port UUCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before retesting.
2000	ABORT	Response to the test was not received within the allowable time period.

Continued on next page

Table 9-228. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Looparound and Conference Circuit Test (#33)

This test checks the reflective loop and conference abilities of a CO port circuit. The test uses 404 Hz, 1004 Hz, and 2804 Hz tones. Each tone is transmitted separately through the loop and checked.

Table 9-229. TEST #33 Looparound and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test.
7	ABORT	Conference Circuit Test aborted.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. L 1. Enter **display port UUCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is unavailable, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of five times.

Continued on next page

Table 9-229. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	1. Check for errors on TONE-BD or TONE-PT. 2. If the Reflective Looparound Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, check the circuit pack for a red LED. If the red LED is on, then replace the appropriate power unit circuit pack. If neither the TN736 nor the TN752 power unit circuit pack is present, then the OLS631DB AC power unit may be defective. The system may contain a TN736 or TN752 power unit circuit pack *or* an OLS631DB AC power unit, *but not both*. Refer to "CARR-POW". 3. Rerun the test. 4. If the test fails again, replace the circuit pack.
	PASS	CO Trunk Looparound and Conference Test is successful. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Port Audit Update Test (#36)

This test sends updates of the CO port translation for all ports on the circuit pack which have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: ground or loop start trunk, tone or rotary dialing trunk, rotary dialing inter-digit timing, network balance R/RC, and disconnect timing.

Table 9-230. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT FAIL	Could not allocate the necessary system resources to run the test. Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter **status-command** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release-trunk** command to put trunk back into in-service. 3. Retry the test command.

DISK (MSS Disk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DISK	WARNING	test disk a|b long	MSS Disk Circuit Pack
DISK	MINOR	test disk a|b long	MSS Disk Circuit Pack

1. In a system with a simplex SPE, the carrier does not have to be specified. In a system configured with duplicated SPEs, the carrier (a or b) must be specified.

The TN1657 Disk circuit pack is part of the Generic 3r Mass Storage System (MSS). The MSS provides non-volatile storage for system software, translation data, announcement data and program update data. As shown in Figure 9-23, the MSS consists of a Host Adapter circuit on the UN332 MSS-Network Control circuit pack (MSSNET), a Small Computer System Interface (SCSI) bus, a TN1656 Tape circuit pack or a TN2211 Optical Disk circuit pack, and the TN1657 Disk Drive circuit pack. The Disk Drive acts as the primary storage device and the Optical Disk or Tape Drive serves as a backup device (also known as removable media device).

The system is usually booted from the bootimage stored on disk. The **save translation** and **save announcements** commands save to disk the memory-resident translation data and TN750-resident announcement data, respectively. The **backup disk** command copies data from the disk to the removable media for backup storage. The **restore disk** command copies data from the removable media back to disk. All MSS components reside in the SPE, or PPN control carrier (carrier A for a simplex SPE, carriers A and B for a duplicated SPE).

The Disk Drive circuit pack contains SCSI bus terminators, an industry standard SCSI-based Disk Drive, and interface circuitry to the private bus to control the LEDs, detect the presence of the circuit pack, and identify the vintage of the hardware.

A -48V to +12V converter circuit on the Removable Media circuit pack provides power for both the Removable Media Drive and the Disk Drive. The presence of +12V on these circuit packs is monitored separately by maintenance software so that a failure of the +12V converter on the Removable Media circuit pack can be identified or ruled out as the source of the problem when the Disk Drive loses +12V power.

The Host Adapter Circuit, Removable Media circuit pack, and Disk circuit pack are treated as separate, but related, maintenance objects (H-ADAPTER, R_MEDIA, and DISK). Since the Disk circuit pack is controlled by SCSI commands which are generated by the Host Adapter, problems with the Host Adapter can prevent communications with the Disk. Whenever the Host Adapter is taken out of service by the **busy-out host-adapter** command, or due to failure of a critical Host Adapter test, the Removable Media and Disk maintenance objects are also placed in a maintenance busyout state.

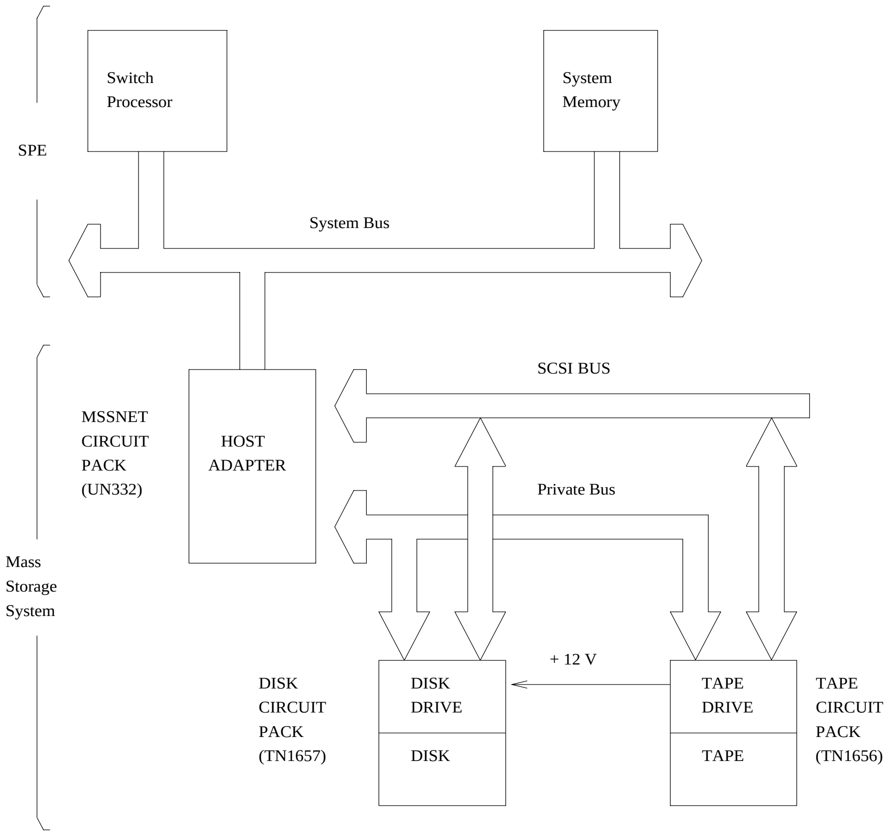

Figure 9-23. Mass Storage System Interactions

General Troubleshooting Information

Keep the following points in mind when troubleshooting disk problems.

1. *Do not save translations or announcements on the disk if unresolved Disk Drive or Host Adapter problems are present.*

   If there is something wrong with the MSS, any attempt to save translations or announcements could destroy a good copy of the files on disk.

2. When multiple error conditions are present, check for Host Adapter and Removable Media errors first.

   Maintenance software cannot always distinguish between errors caused by the Disk Drive, and errors caused by the Host Adapter or Removable Media Drive.

3. In a system with duplex SPEs, the tests run on the standby Disk circuit pack are identical to those run on the active Disk circuit pack. The DUPINT circuit pack handles communications between the active and standby SPEs for the control channel and memory shadowing. Therefore, problems with the DUPINT circuit pack may affect maintenance testing of the standby Disk circuit pack.

4. The *disk data will likely be destroyed* if:

   a. Power is removed from the Disk circuit pack while its yellow LED is on.

   b. The Disk circuit pack is removed while its yellow LED is on.

5. *Removable Media data may be destroyed* if the Disk circuit pack is removed while the yellow LED on the Removable Media Drive is on.

Replacing the Disk Circuit Pack

- If the SPE is not duplicated:

  1. Issue the **busyout host-adapter** command.

     The Host Adapter should be "busied out" to prevent other applications from trying to access the disk or removable media.

  2. Replace the Disk circuit pack.

  3. Issue the **reset host-adapter** command.

     This allows the disk to "spin up."

  4. Issue the **release host-adapter** command.

  5. Issue the **status spe** command and verify that the disk is now in service.

6. Issue the **restore disk** command to copy the boot image files, translation files, announcement files, and program update files from the removable media to the disk. This may take up to an hour to complete.
7. Issue the **test stored-data** command to verify that the files on all storage devices are consistent.

- If the SPE is duplicated:
  1. To replace the Disk circuit pack on a system equipped with duplicated SPEs, use the lock-and power-down procedure described in *Replacing SPE Circuit Packs* in Chapter 5.
  2. After the standby SPE is powered up and fully refreshed, enter the **restore disk** command to copy the bootimage files, translation files, announcement files, and program update files from the removable media to the disk.
  3. Test the standby Disk using the **test disk long** command.
  4. Verify that the files on all storage devices are consistent by issuing the **test stored-data** command.

1. In a system with simplex SPE, the carrier need not be specified. With duplicated SPEs, carrier a or b must be specified.

2. If error type 1 with aux data of 123 is present, this field will indicate the cause of the out-of-service condition. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

The *Service State* field in the Alarm Log refers to the accessibility of the device. IN (in service) means that users can access the device and all maintenance tests run. MTC (maintenance busy) means that the device is busied out; users cannot access it, but all demand maintenance tests run. OUT (out of service) means that users cannot access the device, but background and demand testing may run.

Notes:

a. Error type 1 means that the device is out of service as a result of maintenance tests detecting a critical failure of the disk drive.

b. Error type 18 means that the disk was busied out on demand from the System Access Terminal.

c. Error type 250 means that the Reset Test (#809 or #894) failed.

d. Error type 257 means that the device could not be accessed.

e. Error type 258 means an attempt was made to remove a disk that was physically present or failure during remove occurred.

f. Error type 513 means that on-board disk drive diagnostics tests requested by the Disk Diagnostic Test (#813) failed.

g. Error type 526 means that the Host Adapter was busied out. This also causes the disk to be busied out.

h. Error type 528 means that there was a failure to insert the disk at system initialization time. This is a software problem.

i. Error type 529 means that there was a failure to put the disk in service or to take it out of service. Execute the **reset disk** command and then execute the **status spe** command to verify that the disk is in service. If the disk is not in the expected state, first clear any other alarms against other MSS components and then execute the **reset disk** command.

j. Error type 769 means that the disk Loop-around Test (#814) failed.

k. Error type 1025 means that a disk medium error was detected when the disk was read or written. The Disk circuit pack should be replaced if this error continues to be reported.

l. Error type 1281 indicates that a hardware failure condition was detected by the Firmware Error Counters Read and Clear Test (#812). See the *MSS Error Actions* table at the end of the section on R-MEDIA.

m. Error type 1793 is an in-line error from the disk control software that indicates there was a problem with the SCSI Bus Access Failure or Memory Access Failure between the Host Adapter and the Disk Drive. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

n. Error type 2049 indicates that a bad command was sent to the disk drive. This may be caused by a software error or a hardware failure. Execute the **test disk long** command and fix any failures associated with those tests. Error type 2305 means that the system is equipped with more than 2 memory circuit packs and the disk is either not large enough or has not been configured correctly to support the larger memory size.

   1. If the value in the Auxiliary Data field is 5513, the vintage of the TN1657 Disk circuit pack is less than V4. This may be verified by executing the **list configuration control** command.

   2. If the value in the Auxiliary Data field is 5514, the disk capacity is adequate but the file system on the disk has not been configured for the large coredump file required when greater than 2 memory.

o. Error type 2306 means that a block has been reassigned on the disk or an attempt to reassign a block has failed. The Minor alarm may clear after executing the Status test (#815) but the data block will remain reassigned as a result of a medium error. The disk drive should be replaced if this Error Type is generated more than 3 times within an hour.

p. Error type 2561 indicates that the Data Write-Read Test (#810) failed.

q. Error 2817 indicates that the Disk Status Test (#815) detected a fault. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

r. Error type 3073 indicates in-line errors reported by the disk control software. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

s. Error type 3329 indicates that the Disk Audit Test (#811) detected a corrupted directory file. This is a serious failure of the disk so the disk should be restored from removable media.

t. Error type 3841 is used to record miscellaneous data when an out-of-service condition occurs. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Disk Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Disk Reset Test (#809)	X	X		ND
Disk Diagnostic Test (#813)	X	X		ND
Disk Looparound Test (#814)	X	X		ND
Disk Status Test (#815)	X	X		ND
Disk Firmware Error Counters Read and Clear Test (#812)	X	X		ND
Disk Write-Read Test (#810)		X		ND
Disk Audit Test (#811)		X		ND
Disk Reset Test (#894)			X	ND

1. D = Destructive; ND = Nondestructive

Disk Reset Test (#809 and #894)

The Disk Reset Test consists of the following steps controlled by firmware on the Host Adapter Circuit (located on the MSSNET circuit pack):

- Disk Drive reset: A SCSI BUS DEVICE RESET message is transmitted to the Disk circuit pack to reset it.
- Presence test: A SCSI INQUIRY command is sent to the Disk Drive to attempt to query it. If the Disk Drive is present, it will return information about the device type, whether or not its medium is removable, compatibility with established standards, vendor and product IDs, and other miscellaneous information.
- Start unit: This starts the disk drive spinning.

- Capacity test: A SCSI READ CAPACITY command is sent to the Disk Drive. It returns with the logical block address and the block length of the last logical block on the medium. This is necessary to restore the information lost after the reset and verify that the device can be accessed.

  A SCSI READ DATA BUFFERS command is sent to the Disk Drive. This returns the size of the controller memory data buffers.

  A SCSI READ DEFECT DATA command is sent to the Disk Drive. This returns the addresses of bad blocks on the disk that must be mapped around.

- Device Diagnostic Tests: A SCSI SEND DIAGNOSTICS command is sent to the Disk Drive to initiate a set of device-dependent self-tests that run as a unit. Failures can be for multiple reasons and the return code that indicates the cause of failure is vendor unique. A failure condition reports as single failure type since the only repair action is to replace the Disk Drive circuit pack

Table 9-232. TEST #809 Disk Reset Test

Error Code	Test Result	Description/ Recommendation
526	ABORT	The Host Adapter has been busied out. 1. Issue the **release host-adapter** command.
1316	ABORT	Could not get access to the MSS. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (use **display system-parameters maintenance** to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to “STBY-SPE”. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to “STBY-SPE”. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to “STBY-SPE”. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Continued on next page

Table 9-232. TEST #809 Disk Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (use the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The disk has been placed in the "uninstalled" state. 1. Verify that the disk drive is fully inserted and powered up. 2. Attempt a demand reset of the disk.
5513	FAIL	The system contains 3 memory boards but the capacity of the disk is not large enough for the coredump file. 1. Issue the **list configuration control** command and check if the carrier is equipped with 3 memory boards and the vintage of the TN1657 Disk circuit pack is less than Vintage 4. 2. Replace the Disk circuit pack with one of Vintage 4 or greater, issue the **reset disk** command, and perform the **restore disk** command. The restore operation may take up to 1 hour to complete.

Continued on next page

Table 9-232. TEST #809 Disk Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5514	FAIL	The system contains 3 memory boards but the disk has not been configured for a large coredump file. The removable media and disk should have been configured for the larger memory size as part of the procedures for installing 3 memory circuit packs. 1. Issue the **configure tape 3-mem** command to ensure that the file system on the removable media is configured for the large core dump file. This command cannot execute if the removable media is already configured. 2. Issue the **restore disk** command. This step may take up to 1 hour for a complete restore. 3. Execute the **test disk** command to clear the alarm.
Any Other[1]	FAIL	The disk configuration information shows the disk is missing or the disk LED test failed. 1. Retry the command for a maximum of 5 retries. 2. If the command continues to fail, replace the Disk circuit pack, issue the **reset disk** command and perform the **restore disk** command. This will take up to 1 hour for a complete restore. 3. Replace the MSSNET circuit pack.
	PASS	The Disk status test passed successfully. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions Table at the end of the R-MEDIA section.

Disk Write-Read Test (#810)

The Disk Write-Read Test verifies that data can be written to the disk and read back successfully. This test consists of the following steps:

1. Maintenance software in the SPE issues a request to the Host Adapter for a transfer of data between SPE memory and a specified block on the disk. The Host Adapter firmware issues a SCSI **WRITE** command to the Disk Drive which results in a transfer of data between the SPE memory and the disk.
2. Maintenance software in the SPE issues a request to the Host Adapter to run a checksum on the data previously written to the disk. The Host Adapter reads the data off the disk and computes a checksum which is returned to the SPE maintenance software.

3. Maintenance software compares the value of the checksum from the Host Adapter with the checksum it previously calculated on the data it stored on the disk.

Multiple failure conditions can occur during this test since it uses both the software and hardware functions used during normal operations

Table 9-233. TEST #810 Disk Write-Read Test

Error Code	Test Result	Description/ Recommendation
1301 1302	ABORT	Could not run the test—internal MSS error 1. Retry the command.
1304	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (Use the **display system-parameters maintenance** command to display the start time for scheduled maintenance and the "y/n" option for saving translation daily).
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the 'y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to “STBY-SPE”. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to “STBY-SPE”. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to “STBY-SPE”. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Continued on next page

Table 9-233. TEST #810 Disk Write-Read Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The disk has been placed in the "uninstalled" state. 1. Verify that the disk drive is fully inserted and powered up. 2. Attempt a demand reset of the disk.
[1]	FAIL	The disk could not be accessed, the checksum on the data written did not match the checksum in memory or the data read did not match the data written. 1. Retry the command for a maximum of 5 retries. 2. If the command continues to fail, replace the Disk circuit pack, issue the **reset disk** command and perform the **restore disk** command. This will take up to 1 hour for a complete restore. 3. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Disk write read test executed successfully. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions Table at the end of the R-MEDIA section.

Disk Audit Test (#811)

The Disk Audit Test verifies the following Disk Medium conditions.

- The directory can be read.
- There are no "dirty" files. What is meant by "dirty" is that the data in the file may not be complete or the directory entry was never updated after the data was written to the device

Table 9-234. TEST #811 Disk Audit Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to “STBY-SPE”. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to “STBY-SPE”. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to “STBY-SPE”. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-234. TEST #811 Disk Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The disk has been placed in the "uninstalled" state. 1. Verify that the disk drive is fully inserted and powered up. 2. Attempt a demand reset of the disk.
[1]	FAIL	The audit of the disk directory failed. 1. Perform a **restore disk full** command. This will take up to 1 hour for a complete restore (G3V3 full disk restore + or - 30 minutes). 2. If the test continues to fail, replace the Disk circuit pack, issue the **reset disk** command and perform the **restore disk** command. 3. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The disk directory audit passed successfully. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions Table at the end of the R-MEDIA section.

Disk Firmware Error Counters Read and Clear Test (#812)

The Host Adapter firmware is constantly running background tests on each of its devices. When an error is detected by one of these background tests, the appropriate counter in the host adapter dual port RAM is incremented. The Disk Firmware Error Counters Read and Clear Test requests that the firmware return these errors to the software and clear the area in dual port RAM. If any counter is non-zero, the software then increments the appropriate software counter. The 16 errors reported by the firmware are:

- Unexpected interrupt from the SCSI Bus Interface Controller Chip (SBICC)
- SBICC timed out during SCSI command
- Error interrupt from the Direct Memory Access Controller (DMAC)
- DMAC timeout without issuing interrupt
- Disk self-test failed

- Disk external looparound test failed
- Command failed with bad sense key
- Disk could not be accessed
- Flaw detected in disk medium
- Unrecoverable hardware error on disk
- Invalid parameter in SCSI command
- Media removed or device reset
- Disk is write protected
- Disk reached end of medium
- Block reassigned on disk
- Block reassignment on disk failed

Table 9-235. TEST #812 Disk Firmware Error Counters Read and Clear Test

Error Code	Test Result	Description/ Recommendation
1305	ABORT	Could not read firmware error counters. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1306	ABORT	Could not read configuration area for defect information. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1316	ABORT	Could not get access to the Mass Storage System. Other software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the ''y/n'' option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to “STBY-SPE”. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.

Continued on next page

Table 9-235. TEST #812 Disk Firmware Error Counters Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to “STBY-SPE”. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The disk has been placed in the "uninstalled" state. 1. Verify that the disk drive is fully inserted and powered up. 2. Attempt a demand reset of the disk.
[1]	FAIL	At least one of the firmware error counters was non-zero. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, replace the Disk circuit pack, issue the **reset disk** command and perform the **restore disk** command. This will take up to 1 hour for a complete restore. 3. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	All of the firmware error counters were zero. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions Table at the end of the R-MEDIA section.

Disk Diagnostic Test (#813)

The Disk Diagnostic test causes the Host Adapter to send a SCSI **send diagnostics** command to the DISK Drive circuit pack. This initiates a set of device-dependent self-tests that are run as a unit. Failures can be for multiple reasons. The return code which indicates the cause of failure is vendor unique. A failure condition will be reported as single failure type since the only repair action is to replace the Disk Drive circuit pack

Table 9-236. TEST #813 Disk Diagnostic Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the 'y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to “STBY-SPE”. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-236. TEST #813 Disk Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the 'y/n" option for saving translation daily).
	NO BOARD	The disk has been placed in the "uninstalled" state. 1. Verify that the disk drive is fully inserted and powered up. 2. Attempt a demand reset of the disk.
[1]	FAIL	A Disk diagnostic test failed. 1. Retry the command a maximum of 5 times. 2. If the command continues to fail, replace the Disk circuit pack, issue the **reset disk** command and perform the **restore disk** command. This will take up to 1 hour for a complete restore. 3. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Disk passed all diagnostic tests. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions Table at the end of the R-MEDIA section.

Disk Loop-Around Tests (#814)

This test extends the Host Adapter Loop-Around test to send data from the Host Adapter to buffers on the Disk Drive circuit pack and back to the Host Adapter. It may detect errors related to the Host Adapter, SCSI bus, and the Disk Drive circuit pack. It is intended to functionally test the Disk Drive circuit pack to the extent possible without actually writing data to the disk.

This test consists of two sets of tests:

- Disk Internal Loop-Around

  Data is generated in the RAM of the Host Adapter and transferred to its SCSI Data Memory. A SCSI **WRITE DATA BUFFERS** command is sent to the Disk Drive circuit pack which causes the Disk Drive circuit pack to copy the data to its buffers. A SCSI **READ DATA BUFFERS** command is then sent by the Host Adapter to the Disk Drive circuit pack which causes the Disk Drive circuit pack to transfer the data from its buffers back to the Host Adapter's SCSI Data Memory. The Host Adapter then copies the data back to its private RAM where it compares it with the original test data.

- Disk External Loop-Around

  This test is similar to the Internal Loop-around test except that the data originates in the Host Adapter's Dual Port RAM and it is transferred to and from the SCSI Data Memory using SPE system bus accesses. Only a small amount of data is sent to the Disk Drive circuit pack in order to keep system bus access to a minimum.

Table 9-237. TEST #814 Disk Loop-Around Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Table 9-237. TEST #814 Disk Loop-Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The disk has been placed in the "uninstalled" state. 1. Verify that the disk drive is fully inserted and powered up. 2. Attempt a demand reset of the disk.
[1]	FAIL	The Disk loop-around test failed. 1. Retry the command a maximum of 5 times. 2. If the command continues to fail, replace the Disk circuit pack, issue the **reset disk** command and perform the **restore disk** command. This will take up to 1 hour for a complete restore. 3. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Disk loop-around test passed. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions Table at the end of the R-MEDIA section.

Disk Status Test (#815)

The Disk Status Test verifies the following:

- The Host Adapter knows about the existence of the Disk Drive.
- The LEDs on the faceplate can be turned on and off correctly. This verifies only that the LED control and status logic is operating correctly. LED operation may also be tested visually with **test led**.
- The presence of +5V and +12V

Table 9-238. TEST #815 Disk Status Test

Error Code	Test Result	Description/ Recommendation
1306 1307 1308	ABORT	Internal software error between maintenance software and MSS driver. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Continued on next page

Table 9-238. TEST #815 Disk Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The disk has been placed in the "uninstalled" state. 1. Verify that the disk drive is fully inserted and powered up. 2. Attempt a demand reset of the disk.
5513	FAIL	The system is equipped with 3 memory circuit packs but the capacity of the disk is not large enough for the coredump file. 1. Use **list configuration control** and verify that the control carrier is equipped with 3 memory boards. Also check the vintage of the TN1657 Disk Drive circuit pack. 2. Replace the Disk Drive circuit pack with Vintage 4 or greater, issue the **reset disk** command, and perform the **restore disk** command. The restore operation may take up to 1 hour to complete.
5514	FAIL	The system is equipped with 3 memory circuit packs but the disk has not been configured for a large coredump file. The removable media and disk should be configured for the larger memory size as part of the procedures for installing 3 memory circuit packs. 1. Use **configure tape 3-mem** to ensure that the file system on the removable media has been configured for the large core dump file. This command will not execute if the removable media has already been configured. 2. Use **restore disk**. This step may take up to 1 hour for a complete restore. 3. Execute the **test disk R** command to clear the alarm.

Continued on next page

Table 9-238. TEST #815 Disk Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any Other[1]	FAIL	The disk configuration information shows the disk is missing or the disk LED test failed. 1. Retry the command a maximum of 5 times. 2. If the command continues to fail, replace the Disk Drive circuit pack, issue the **reset disk** command and perform the **restore disk** command. This will take up to 1 hour for a complete restore. 3. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Disk status test passed successfully. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions Table at the end of the R-MEDIA section.

Disk Reset Test (#894)

The Disk Reset Test is executed when the **reset disk** command is entered at the terminal. The test results for Test 894 are the same as those for Test 809. The only difference between Test 809, which is run as part of the test sequence for the **test disk** command, and Test 894 which is run in response to the **reset disk** command is that all disk alarms are resolved when Test 894 passes while only some disk alarms may be resolved when Test 809 passes.

Refer to the results for Test #809 for the appropriate repair procedures.

DLY-MTCE (MO-DAILY)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DLY-MTCE	MINOR	NONE	DLY-MTCE
DLY-MTCE	MAJOR	NONE	DLY-MTCE

The DLY-MTCE maintenance object monitors daily translation saves. If a translation save times out or fails to run, an error is logged against this maintenance object.

If Save Fails	Then System Raises
Three times in a row	MINOR Alarm
Seven times in a row	MAJOR Alarm

Daily Maintenance Interference

All of the actions used in DEFINITY R8 administration commands are listed in the table below. The command actions that, while active, interfere with daily maintenance are also indicated. They are the **add**, **change**, **duplicate**, **remove**, and **set** commands. These commands are frequently used by customer administrators while performing routine administration of DEFINITY.

Table 9-239. DEFINITY Command Actions

Likely to Disrupt	Less Likely to Disrupt	
add	backup	ping
change	busyout	recycle
duplicate	clear	release
remove	display	reset
set	enable	restore
	format	resume
	get	save
	list	status
	mark	test

Continued on next page

Table 9-239. DEFINITY Command Actions — *Continued*

Likely to Disrupt	Less Likely to Disrupt	
	monitor	upgrade
	netstat	

Some other command actions can also interfere with daily maintenance when certain qualifiers are used in the command, or under certain circumstances. For example, certain “test” commands, when used with the modifier “continuously”, could potentially interfere with daily maintenance. However, such command actions are not used typically by customer administrators doing routine administation, and are less likely to disrupt daily maintenance routines than are the **add**, **change**, **duplicate**, **remove**, and **set** command actions.

Incomplete Command Time-out

A time-out feature has been added to the MAINTENANCE-RELATED SYSTEM PARAMETERS form (accessed by the command **change system parameters maintenance**). This feature improves the operation of daily maintenance by allowing maintenance routines to run that might otherwise not run. It also helps to prevent the loss of translations that were not saved by the **save translation** command, and were also not saved because daily maintenance was prevented from running prior to the system reset. Highlights of the feature include:

- Options for blank, 1, 2, 3, 4, 5, or 6 hours (the default is 2 hours)
- The blank option indicates that the feature is not active
- Only commands that block the running of daily maintenance (add, change, duplicate, remove, and set) are affected
- All logins will time-out if any of these commands are active for the prescribed time (except for the “blank” option)
- The feature applies to all logins, regardless of type (init, dadmin, craft, inads) or permissions granted to the specific login ID of an administration or maintenance user
- The corresponding “time-out” entry is appended to the list history log

The new `Command Time-out` field can be viewed by customer administrators. A craft, init, dadmin, or inads login is required to change the option for the field. Screen 9-1 shows the MAINTENANCE-RELATED SYSTEM PARAMETERS screen for DEFINITY R8r. Screen 9-2 shows an example of the LIST HISTORY form with the "time-out" entry. The final line indicates that the command **change system-parameters maintenance** was being executed when the time-out period of 2 hours expired.

DS1-BD (DS1 Interface Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DS1-BD	MAJOR	test board UUCSS sh	DS1 Interface Circuit Pack
DS1-BD	MINOR	test board UUCSS l	DS1 Interface Circuit Pack
DS1-BD	WARNING	test board UUCSS sh	DS1 Interface Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The DS1 Interface circuit pack provides an interface to an external DS1 facility and supports 24 DS0 channels carried on a 1.544 Mbps DS1 link. These DS0 channels can be administered as either trunks to other switches or lines to off-premises stations. The TN464C and later suffix Universal DS1 Interface also supports a 32-channel interface on a 2.048Mbps link. The functions and maintenance strategy for the TN464 circuit packs are covered under a separate maintenance object, UDS1-BD.

DS1-BD maintenance logs in-line errors reported by the DS1 Interface circuit pack, runs tests for error diagnosis and recovery, and raises and clears alarms. The following table shows the capabilities of each DS1 circuit pack. The TN722 and TN722B are not supported on G3r V1 or later systems.

Circuit Pack Code	24 Channel	32 Channel	Tie Trunk Signaling	CO Trunk Signaling	DID Trunk Signaling	OPS Line Signaling
TN722/B	x		x			
TN767/B/C/D/E	x		x	x	x	x
TN464C/D/E/F	x	x	x	x	x	x (24-chl only)

ISDN-PRI Trunk signaling (for example, Q.921, Q.931) requires a TN464D and is handled by system software. The TN464 is covered in the "UDS1-BD (UDS1 Interface Circuit Pack)" section of Chapter 9.

Each trunk and line have their own maintenance strategies. However, they all depend on the health of the DS1 Interface circuit pack. Refer to the following sections for details: TIE-DS1, CO-DS1, DID-DS1, OPS-LINE, ISDN-TRK, and ISDN-PLK. Signaling over the DS1 link must be synchronized between the transmitting and receiving ends to ensure error-free communication. Refer to "SYNC (Synchronization)" for details.

The TN767E circuit pack combined with Lucent's new 120A1 CSU Module forms an Enhanced Integrated CSU. The new 120A1 CSU Module, when combined with the functionality provided by the TN767E hardware and firmware, and new switch software, provides functionality equivalent to an external stand-alone Lucent ESF T1 CSU. The 120A1 CSU Module connects to the TN767E circuit pack on the I/O connector panel on the back of the port carrier. The new CSU Module, thus becomes an integrated part of the DEFINITY. system. Throughout the document, the term 120A1 will mean a 120A1 or later suffix CSU Module.

The Enhanced Integrated CSU is for use in the United States of America with 1.544 Mbps DS1 service. For further details on the 120A1 CSU Module see *DEFINITY. Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 - Integrated CSU Module Installation and Operation, 555-230-193.*

The TN767E and 120A1 CSU Module support on-demand loopback tests that assist in the detection of faults between the TN767E circuit pack and the CSU Module, between the Integrated CSU and the optional Customer Premises Loopback Jack, or between the Integrated CSU and remote CSU. These loopback tests are explained in detail later in this DS1-BD section, but Figure 9-24 gives a high level overview of the loopback points.

The following list of acronym definitions are forFigure 9-24:

- PLB = Payload Loopback
- BLB = Board Loopback
- ELB = Equipment Loopback
- LLB = Line Loopback
- RLB = Repeater Loopback
- CLJ = Loopback Jack Loopback
- R-LLB = Remote Line Loopback
- SMRT = Smart Jack
- LPBK = Loopback

For more information about DS1 interfaces, see the *DEFINITY Communications System DS1/CEPT1/ISDN-PRI Reference*, 555-025-107.

3901(v)	Any	Far CSU Loopback Test (#1213)			
3902(w)	Any	One-Way Span Test (#1214)			
3999 (x)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates that the circuit pack has stopped functioning or is not completely administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI Test (#53) fails.

   To be completely administered, a DS1 circuit pack must meet all 3 of the following conditions:

   1. Have an entry in the circuit plan via the **change circuit pack** command
   2. Be administered via the **add ds1 UUCSS** command
   3. Be physically inserted in the appropriate slot

   If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

   1. Make sure all conditions for administration are met and that a functioning DS1 circuit pack is inserted in the correct slot.
   2. Completely remove the DS1-BD from the system using the following steps:
      a. Remove any administered DS1 trunks or access endpoints associated with the circuit pack from their trunk groups.
      b. Execute the **remove ds1 UUCSS** and **change circuit pack UUCSS commands.**

   If all the administration conditions are met for this circuit pack and the red LED is still on, follow the instructions for *LED Alarms with Error Type 1* in Chapter 7.

b. The DS1 Interface circuit pack has been busied out by a **busy-out board** UUCSS command.

c. The DS1-BD circuit pack is not completely administered. A completely administered DS1-BD circuit pack should have an entry in the circuit plan via the **change circuit pack** command, should have been administered via the **add ds1 UUCSS** command, and should have been inserted into the appropriate port slot.

d. The circuit pack in the slot does not match the type administered to that position. Either replace the circuit pack with one of the type administered, or use **change circuit-pack** to readminister the slot. This error may also indicate that the 24/32-channel selection on the DS1 administration form does not match the configuration of the circuit pack.

e. This error is associated with the Common Port Circuit Pack Maintenance Test. Refer to "XXX-BD (Common Port Circuit Pack)" for details.

f. The DS1 Interface circuit pack has detected a transient hardware problem (for example, external RAM failure, internal RAM failure, internal ROM failure, or instruction set failure). This error will disappear when no faults are detected for 30 minutes. The value in the Aux Data field indicates the type of hardware problem. However, when this error is reported with Aux Data in the range of 4352 to 4358, it indicates the circuit pack has reported a hardware failure. This problem should be escalated.

g. The DS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data field indicates the type of hardware problem.

h. CSU Module or T1 Sync Splitter missing. The `Near-End CSU Type` field on the **add ds1** form has been administered as `integrated` but the 120A1 CSU Module or T1 Sync Splitter is not physically connected (or is improperly connected) to the TN767E board on the back of the port carrier.

   If using the 120A1 CSU Module or T1 Sync Splitter, plug (or replug) the CSU Module/T1 Sync Splitter into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the `Near-End CSU Type` field using the **change ds1** form to `other`.

   If this error remains after plugging the CSU Module/ T1 Sync Splitter into the board's connector, there could be a problem with the I/O connector panel.

i. CSU Module/T1 Sync Splitter not expected. The 120A1 CSU Module/T1 Sync Splitter is physically connected to the TN767E board on the back of the port carrier but the `Near-End CSU Type` field on the **add ds1** form has not been administered as `integrated`.

   If the 120A1 CSU Module/T1 Sync Splitter is to be used, use the **change ds1** command to change the `Near-End CSU Type` field to `integrated`. Otherwise, physically remove the 120A1 CSU Module/T1 Sync Splitter from the back of the port carrier.

j. DS1 configuration error. Attempting to use the 120A1 CSU Module with a TN767E circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America.

k. DS1 circuit pack suffix incorrect for CSU Module/T1 Sync Splitter. The `Near-End CSU Type` field on the **add ds1** form has been administered as `integrated` but the DS1 circuit pack is not a TN767E or later suffix DS1 board.

   If the 120A1 CSU Module/T1 Sync Splitter is to be used, remove the circuit pack and replace it with a TN767E or later suffix board. Otherwise, use the **change ds1** command to change the `Near-End CSU Type` field to `other`.

l. BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using the following commands: **busyout board UUCSS**, **test ds1-loop UUCSS ds1/csu-loopback-tests**, **release board UUCSS**. If the BLB test continues to fail, then the TN767E circuit pack needs to be replaced.

m. ELB failure. This error occurs when the Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test fails. This test is executed during I-CSU/T1 Sync Splitter power-up/reset (i.e., the TN767E board is physically inserted and the CSU Module/T1 Sync Splitter is already installed) or when the CSU Module/T1 Sync Splitter is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command **test ds1-loop UUCSS ds1/csu-loopback-tests**.

   Attempt to clear the alarm via the following commands: **busyout board UUCSS**, **test ds1-loop UUCSS ds1/csu-loopback-tests**, and **release board UUCSS**. If the ELB test continues to fail, then either the TN767E board, the CSU Module, the T1 Sync Splitter, or the I/O cable between the backplane and the CSU Module/T1 Sync Splitter (or any combination thereof) has failed. Escalate this problem.

n. RLB failure. This error occurs when the Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test fails. This test is executed during I-CSU/T1 Sync Splitter power-up/reset (i.e., the TN767E board is physically inserted and the CSU Module/T1 Sync Splitter is already installed) or when the CSU Module/T1 Sync Splitter is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command **test ds1-loop UUCSS ds1/csu-loopback-tests**.

   Attempt to clear the alarm via the following commands: **busyout board UUCSS**, **test ds1-loop UUCSS ds1/csu-loopback-tests**, and **release board UUCSS**. If the RLB test continues to fail, then the CSU Module/T1 Sync Splitter needs to be replaced.

o. CPE Loopback Jack deactivation error. This error occurs when the TN767E circuit pack could not deactivate a CPE Loopback Jack loopback.

   Attempt to clear the alarm via the following commands: **busyout board UUCSS**, **test ds1-loop UUCSS end-loopback/span-test**, and **release board UUCSS**. If the attempt to deactivate the CPE Loopback Jack loopback continues to fail, other steps must be taken to deactivate the loopback.

p. Far CSU Loopback deactivation error. This error occurs when the TN767E circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

   Attempt to clear the alarm via the following commands: *busyout board UUCSS*, *test ds1-loop UUCSS end-loopback/span-test*, *release board UUCSS*. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

q. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with error code 2000.

   2. The tests run on the ports of this circuit pack are returning NO BOARD.

3. A busy-out/release of the circuit pack has no affect on test results.
4. A **list configuration** command shows that the circuit pack and ports are properly installed.

The circuit pack is isolated from the system and all trunks of this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 Interface circuit pack is restored to normal operation. All trunks of the DS1 Interface circuit pack are then returned to the in-service state. If the error recurs after 15 minutes, then escalate this problem.

r. For later releases of G3V4 and beyond, only error 3073 will show that this board is receiving Slips and the AUX data shows the last Slip count that was reported.

s. For later releases of G3V4 and beyond, only error 3329 will show that this board is receiving misframes and the AUX data shows the last misframe count that was reported.

t. This error is not service-affecting and can be ignored.

u. Error 3900 is used to give status information on a CPE Loopback Jack Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

v. Error 3901 is used to give status information on a Far CSU Loopback Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

w. Error 3902 is used to give status information on a One-Way Span Test. The value in the Aux Data field indicates the status of the span test.

1 — Test is currently running.

2 — Test has failed because test could not be activated.

3 — Test pattern was not received from the far end.

4 — Test has been terminated.

x. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in Table 9-241. By clearing error codes associated with the *NPE Connection Audit Test,* for example, you may also clear errors generated from other tests in the testing sequence

Table 9-241. System Technician-Demanded Tests: DS1-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	test ds1-loop Command	D/ND[1]
NPE Connection Audit Test (#50)		X			ND
Control Channel Loop Test (#52)		X			ND
Loss of Signal Alarm Inquiry Test (#138)	X	X			ND
Blue Alarm Inquiry Test (#139)	X	X			ND
Red Alarm Inquiry Test (#140)	X	X			ND
Yellow Alarm Inquiry Test (#141)	X	X			ND
Major Alarm Inquiry Test (#142)	X	X			ND
Minor Alarm Inquiry Test (#143)	X	X			ND

1. D = Destructive, ND = Non-destructive

NPE Connection Audit Test (#50):

The system sends a message to the on-board microprocessor to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

Table 9-242. TEST #50 NPE Connection Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available.
1019	ABORT	Test already in progress.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The circuit pack’s NPEs have been updated with their translation.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. Issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Control Channel Looparound Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 9-243. TEST #52 Control Channel Looparound Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The test failed because the circuit pack did not return the circuit pack code or vintage. **NOTE:** Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as Test 138 and Test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test result. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem. 1. Retry the command for a maximum of 5 times. 2. If the problem continues, check for hyperactivity. Resolve the problem, as appropriate. 3. If there is no longer hyperactivity, retry the command for a maximum of 5 times. 4. If the test continues to fail, escalate this problem.
	PASS	Communication with this circuit pack is successful.

Continued on next page

Table 9-243. TEST #52 Control Channel Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

SAKI Sanity Test (#53)

This test is destructive. This test resets the circuit pack.

Table 9-244. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Wrong circuit pack configuration to run this test. This error applies only to DS1 Interface circuit packs. It means the DS1 Interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions. 1. If the circuit pack needs to be reset, then set synchronization to another DS1 Interface circuit pack or to the Tone-Clock circuit pack and try again. Refer to "SYNC (Synchronization)".

Continued on next page

Table 9-244. TEST #53 SAKI Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack. 2. Execute the command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	The circuit pack failed to reset.
2	FAIL	The circuit pack failed to restart. 1. Execute the command again. 2. If the problem persists, escalate this problem.
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Internal Looparound Test (#135)

This test is destructive.

The Internal Looparound Test is run by looping the transmitted DS1 bit stream back into the DS1's board receiver. The loop occurs just before the DS1 facility interface. The test is highly destructive and can only be initiated by a system technician-demanded **reset board UUCSS** command.

All trunks on the DS1 Interface circuit pack must be busied out via the system technician **busy-out board** command before running the Internal Looparound Test. When the Internal Looparound Test is initiated, maintenance software sends appropriate messages to the DS1 Interface circuit pack to start the test. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk are different, the test fails.

When the test is complete, the maintenance software sends a stop loop around message to the DS1 Interface circuit pack to put the circuit pack back into the normal operation mode. All trunks of the DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

Table 9-245. TEST #135 Internal Looparound Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	Received an incoming call on a port of the DS1 circuit pack during the test. 1. Enter the **busy-out board UUCSS** command to put all trunks of DS1 Interface circuit pack to out-of-service state. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Ports on DS1 Interface circuit pack have not been busied out. 1. Enter the **busy-out board UUCSS** command to put all trunks of the DS1 Interface circuit pack into out-of-service state. 2. Retry the command.

Continued on next page

Table 9-245. TEST #135 Internal Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Therefore, it cannot be reset without major system disruption. 1. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: ■ Issue the **disable synchronization-switch** command. ■ Next, issue the **set synchronization UUCSS** command. ■ Lastly, issue the **enable synchronization-switch** command.
2000	ABORT	The test was aborted. Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as Test 139 and Test 140) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-245. TEST #135 Internal Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	DS1 Interface circuit pack failed in the Internal Looparound Test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the DS1 Interface circuit pack is TN767, enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. Otherwise, skip this step. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the physical connectivity of DS1 Interface circuit packs and cable. 5. Contact T1 Network Service to diagnose remote DS1 endpoint. 6. If all of the above are OK, escalate this problem.
	PASS	All administered trunks of DS1 Interface circuit pack pass the Internal Looparound Test. The bit pattern consistency test is executed successfully over the path that covers a DS1 port, cable, and the external NCTE device.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Loss of Signal Alarm Inquiry Test (#138)

This test verifies the synchronization status and continuity of the DS1 link. The Loss of Signal alarm indicates that the DS1 Interface circuit pack is unable to derive the synchronization clock from the DS1 facility. When the DS1 Interface circuit pack detects a Loss of Signal alarm, it stops providing the synchronization clock for the system if it is administered as a timing source and transmits a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, the maintenance software places all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored. The DS1 Interface circuit pack raises a Loss of Signal alarm after the signal has been lost for about 1second. It will not retire the alarm until the signal has returned for about 10 seconds.

This test is also used to maintain the new 120A CSU Module and the 401A T1 Sync Splitter. The CSU Module, when combined with the functionality provided by the TN767E circuit pack, provides functionality equivalent to an external standalone ESF T1 CSU. The 401A T1 Sync Splitter, when combined with the functionality provided by the TN767E circuit pack, allows an ATM switch to derive its timing from a T1 connected to the DS1 in the DEFINITY.

If a TN767E circuit pack detects certain I-CSU/T1 Sync Splitter hardware errors, it will notify maintenance. When the maintenance subsystem receives notification of the error, it will execute this Loss of Signal Inquiry test. The test, in addition to querying for a Loss Of Signal alarm condition, will also query the TN767E board to confirm the error. A Minor or Warning alarm will be raised depending on the severity of the error. The trunks on the board may be taken out of service if the error is deemed serious.

If a Loss Of Signal alarm and an I-CSU/T1 Sync Splitter error co-exist, the Loss Of Signal alarm condition will take priority and the board and all trunks on the board will be put in the out-of-service state. Errors will be logged, however, for both.

When the maintenance subsystem receives notification that the ICSU/T1 Sync Splitter hardware error condition no longer exists, maintenance will restore the board and all trunks to their previous service state if the alarm can be cleared (no other errors or Loss Of Signal alarm exist).

Table 9-246. TEST #138 Loss of Signal Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.

Table 9-246. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	DS1 Interface circuit pack detects a Loss of Signal alarm. The physical link is broken or the remote DS1 endpoint is down. All trunks or ports of this DS1 interface circuit pack are out-of-service. If the DS1 Interface circuit pack is designated as the supplier of the system synchronization source, then the system synchronization maintenance will adopt a source elsewhere. Refer to "SYNC (Synchronization)" section for details. 1. If the DS1 Interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 Interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 2. Check the physical connection of the DS1 Interface circuit pack and the cable. If a 120A1 CSU Module/T1 Sync Splitter is physically connected to a TN767E board on the back of the port carrier, check the physical connection of the CSU Module/T1 Sync Splitter and make sure the Network Interface cable is plugged into the CSU Module's/T1 Sync Splitter's NETWORK jack.
1300	FAIL	The CSU Module or the T1 Sync Splitter is missing. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the 120A1 CSU Module/T1 Sync Splitter is not physically connected to the TN767E board on the back of the port carrier. 1. If using the 120A1 CSU Module/T1 Sync Splitter, plug the CSU Module/T1 Sync Splitter into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *Near-End CSU Type* field using the *change ds1* form to *other*. 2. Run the test again.
1301	FAIL	The 120A1 CSU Module or the T1 Sync Splitter is physically connected to the TN767E board on the back of the port carrier but the *Near-End CSU Type* field on the *add ds1* form has not been administered as *integrated*. 1. If the 120A1 CSU Module/T1 Sync Splitter is to be used, use the *change ds1* command to change the *Near-End CSU Type* field to *integrated*. Otherwise, physically remove the 120A1 CSU Module/T1 Sync Splitter from the back of the port carrier. 2. Run the test again.
1302	FAIL	Attempting to use the 120A1 CSU Module with a TN767E circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America. 1. If the 120A1 CSU Module is to be used, physically remove the TN767E circuit pack and reconfigure for 24-channel (1.544 Mbps) operation. 2. Reinsert the circuit pack and run the test again.

Continued on next page

Table 9-246. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1303	FAIL	The DS1 circuit pack Suffix is incorrect for CSU Module/T1 Sync Splitter administration. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the DS1 circuit pack is not a TN767E or later suffix DS1 board. 1. If the CSU Module or the T1 Sync Splitter is to be used, and the *Near-End CSU* Type field is set to *integrated* to allow for CSU Module/T1 Sync Splitter administration, remove the circuit pack and replace it with a TN767E or later suffix board. Otherwise use the *change ds1* command to change the *Near-End CSU Type* field to *other*.
1310	FAIL	The DS1 Board Loopback (BLB) demand test (#1209) failed. 1. Repeat the test using the *test ds1-loop UUCSS ds1/csu-loopback-tests* command. 2. If the BLB test continues to fail, then replace the TN767E circuit pack. 3. Run this test again.
1311	FAIL	The Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test (#1210) failed. This test is executedduring ICSU/T1 Sync Splitter power-up/reset (the TN767E board is physically inserted and the CSU Module/T1 Sync Splitter is already installed) or when the 120A CSU Module/T1 Sync Splitter is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command **test ds1-loop UUCSS ds1/csu-loopback-tests**. 1. Execute **test ds1-loop UUCSS ds1/csu-loopback-tests**. 2. If the ELB test continues to fail, then either the TN767E board, the CSU Module/T1 Sync Splitter, or the I/O cable between the backplane and the CSU Module/T1 Sync Splitter (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module/T1 Sync Splitter and running the *t***est ds1-loop UUCSS ds1/csu-loopback-tests** command again. 3. If the ELB test continues to fail, then replace the TN767E board and run **test ds1-loop UUCSS ds1/csu-loopback-tests** again. 4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU Module/T1 Sync Splitter.

Continued on next page

Table 9-246. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1312	FAIL	The Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test (#1211) failed. This test is executed during ICSU/T1 Sync Splitter power-up/reset (the TN767E board is physically inserted and the CSU Module/T1 Sync Splitter is already installed), or when the 120A1 CSU Module/T1 Sync Splitter is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command **test ds1-loop UUCSS ds1/csu-loopback-tests**. 1. Execute **test ds1-loop UUCSS ds1/csu-loopback-tests**. 2. If the RLB test continues to fail, then replace the CSU Module/T1 Sync Splitter. 3. Run this test again.
1313	FAIL	The TN767E circuit pack could not deactivate a CPE Loopback Jack loopback. 1. Execute **test ds1-loop UUCSS end-loopback/span-test**. 2. If the attempt to deactivate the CPE Loopback Jack is not successful, check the cabling and investigate the problem at the CPE Loopback Jack. 3. Run the test again.
1314	FAIL	The TN767E circuit pack could not deactivate a far-end CSU loopback. 1. Execute **test ds1-loop UUCSS end-loopback/span-test**.
1320	FAIL	A CSU Module/T1 Sync Splitter hardware failure or an ICSU/T1 Sync Splitter serial interface audit failure was detected by the TN767E DS1 circuit pack. 1. Replace the CSU Module/T1 Sync Splitter, and then run the test again. 2. If the test continues to fail with this error code, replace the TN767E and run the test again. 3. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU Module/T1 Sync Splitter.
1321	FAIL	DTE LOS (loss of signal) was detected between the TN767E DS1 board and the 120A1 CSU Module or the T1 Sync Splitter. Either the TN767E board, the 120A1 CSU Module/T1 Sync Splitter, or the I/O cable between the backplane and the 120A1 CSU Module or the 401A T1 Sync Splitter (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. 1. Replace the CSU Module/T1 Sync Splitter and run the test again. 2. If the test continues to fail with this error code, then replace the TN767E board and run the test again. 3. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the 120A1 CSU Module or the 401A T1 Sync Splitter.

Continued on next page

Table 9-246. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1322	FAIL	No 5 volts power detected from the TN767E circuit pack to the 120A1 CSU Module/T1 Sync Splitter. Problem probably due to an open fuse on the DS1 board or a faulty ICSU/T1 Sync Splitter. **NOTE** *Do not swap DS1 boards as this may open the fuse on the new board*. 1. Remove the TN767E from the system and reinsert. 2. Run the test again once the board has finished its reset. 3. If the test continues to fail with this error code, then replace the CSU Module/T1 Sync Splitter and run the test again. 4. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the 120A1 CSU Module or the 401A T1 Sync Splitter. 5. If the test continues to fail with this error code, escalate this problem.
1323	FAIL	A service-affecting CSU Module/T1 Sync Splitter audit failure was detected by the TN767E DS1 circuit pack. All administered ports on the DS1 circuit pack are affected and maintenance software will place the ports into the out-of-service state. 1. Replace the 120A1 CSU Module/T1 Sync Splitter.
1324	FAIL	A non-service-affecting CSU Module/T1 Sync Splitter audit failure was detected by the TN767E DS1 circuit pack. No ports should be affected. No immediate action is required. These errors indicate that the CSU Module/T1 Sync Splitter hardware may have a problem, and that it should be replaced when practical to avoid further deterioration.
	PASS	DS1 signal is present and the physical link is healthy. In addition, no Integrated CSU errors are detected.

Continued on next page

Table 9-246. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Blue Alarm Inquiry Test (#139)

The Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the blue alarm status of the remote DS1 endpoint.

When the DS1 Interface circuit pack detects a Blue Alarm signal from the remote DS1 endpoint, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a BLUE ALARM message to the maintenance software. When the Blue alarm is confirmed, the maintenance software places all trunks of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Blue alarm is cleared.

The DS1 Interface circuit pack takes 2 seconds to recognize and report a Blue alarm and 16 seconds to recognize and report the resolution of a Blue alarm. When the Blue alarm is cleared, the DS1 Interface circuit pack stops transmitting the Yellow alarm and places the trunks back into the service state before the Blue alarm occurs.

Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the ICSU or DS1 into a loopback mode. When the ICSU or DS1 Board is in the LLB mode, the arriving bit pattern is regenerated and sent back. Line Loopback (LLB) Alarm is activated when the in-band activate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line. LLB is deactivated when the in-band deactivate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line.

Since LLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. PLB Alarm is activated when a network protocol activate bit pattern arrives over the 4-Kbps ESF data link on the DS1 line. PLB is deactivated when a network protocol deactivate bit pattern arrives over the 4-Kbps ESF data link on the DS1 line.

Since PLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Table 9-247. TEST #139 Blue Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.
	FAIL	The remote DS1 endpoint is out-of-service. 1. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote endpoint. 2. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint.

Continued on next page

Table 9-247. TEST #139 Blue Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1794	FAIL	The DS1 Interface circuit pack detects a Line Loopback Alarm (LLB). 1. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. 2. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. If the DS1 interface circuit pack connects directly to a line-side terminating device (for example, a PRI terminal adapter), call the vendor of the terminating device to diagnose the equipment.
1795	FAIL	The DS1 Interface circuit pack detects a Payload Loopback Alarm (PLB). If the DS1 Interface circuit pack connects to a leased T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 Interface circuit pack connects directly to another DS1 board, call the system technician of the remote switch to diagnose the DS1 endpoint.
	PASS	Remote DS1 endpoint is in-service. Neither a Blue alarm nor a Line Loopback alarm nor a Payload Loopback alarm is detected in the DS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Red Alarm Inquiry Test (#140)

DS1 Interface circuit pack raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry Test checks the framing status of a DS1 Interface circuit pack. DS1 Interface circuit pack takes 3 seconds to recognize and report a Red alarm and 10 seconds to recognize and report the resolution of a Red alarm.

When the DS1 Interface circuit pack detects a Red alarm, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a RED ALARM message to the maintenance software. After the Red alarm is confirmed, the maintenance software places all trunks of the circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Red alarm is cleared.

When the Red alarm is cleared, the DS1 Interface circuit pack will stop transmitting the Yellow alarm to the remote DS1 endpoint. The maintenance software restores all trunks of the DS1 Interface circuit pack to the service state before the Red alarm occurs.

Loss of Multiframe Alarm: If the DS1 Interface circuit pack is administered using DMI-BOS signaling, the DS1 Interface circuit pack raises a Loss of Multiframe Alarm (LMA) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24th channel. Once DS1 Interface circuit pack detects an LMA, the circuit pack will transmit a Remote Multiframe Alarm (RMA) to the remote DS1 endpoint. Maintenance software handles both Red alarm and LMA alarm(s) using the same mechanism.

Table 9-248. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The DS1 Interface circuit pack detects a Red alarm. An out-of-frame condition occurs on the DS1 Interface circuit pack. DS1 Interface circuit pack will transmit a Yellow alarm to the remote DS1 endpoint until the Red alarm is retired. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSU's are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. If this continues to fail, escalate this problem.
1	FAIL	The DS1 interface circuit pack detected a loss of multiframe alarm (LMA). An out of frame condition occurred on the DS1 interface circuit pack. The DS1 interface circuit pack will transmit a remote multiframe alarm (RMA) to the remote DS1 endpoint until the LMA is retired. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSU's are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. If this continues to fail, escalate this problem.
	PASS	No Red alarm is detected on DS1 Interface circuit pack.

Table 9-248. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Yellow Alarm Inquiry Test (#141)

Receiving a Yellow alarm from remote DS1 endpoint indicates that the remote DS1 endpoint has an out-of-frame condition. The Yellow Alarm Inquiry Test is used to determine whether the remote DS1 endpoint is transmitting a Yellow alarm. The DS1 Interface circuit pack takes 500 msec to recognize and report a Yellow alarm and 500 msec to recognize and report that a Yellow alarm condition is cleared.

When the DS1 Interface circuit pack detects a Yellow alarm from the remote DS1 endpoint, it will send a YELLOW-ALARM uplink message to the maintenance software. After the maintenance software receives the YELLOW-ALARM message, the Yellow Alarm Inquiry Test is run to confirm the Yellow alarm. Once the Yellow alarm is confirmed, the maintenance software places all trunks on the circuit pack into the out-of-service state. The Inquiry Test will be run every 10 minutes until the Yellow alarm is cleared.

When the Yellow alarm is cleared, the maintenance software restores all trunks on the DS1 Interface circuit pack back to their previous service state before the Yellow alarm is raised.

This Yellow Alarm corresponds to the yellow F2 state documented in CCITT recommendation I.431.

Remote Multiframe Alarm: Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition while the DS1 Interface circuit pack is administered using the DMI-BOS common channel signaling. The RMA is handled as a Yellow alarm.

Yellow F5 State Alarm: For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431

Table 9-249. TEST #141 Yellow Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The DS1 interface circuit pack detected a yellow alarm sent by the remote DS1 endpoint. An out of frame condition occurred at the DS1 endpoint.
1	FAIL	The DS1 Interface circuit pack detects a Remote Multiframe Alarm sent by the remote DS1 endpoint. An out-of-frame condition occurs on the remote DS1 endpoint.
2	FAIL	The DS1 Interface circuit pack is reporting a yellow F5 State alarm. There is a fault in the user-network interface from the user (PBX) to the network. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSUs are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. If this continues to fail, escalate this problem.
	PASS	No Yellow alarm nor Remote Multiframe Alarm nor F5 State Alarm is received from the remote DS1 endpoint.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Major Alarm Inquiry Test (#142)

The Major alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1000. The Major Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 16 seconds to recognize and report a Major alarm and 16 seconds to recognize and report that a Major alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 seconds to recognize and report a Major alarm and 10 seconds to recognize and report that a Major alarm condition is cleared.

When the DS1 Interface circuit pack detects a Major alarm, it will send a MAJOR-ALARM message to the maintenance software. After the maintenance software receives a MAJOR-ALARM message, the Major Alarm Inquiry Test is initiated to confirm the Major alarm on the DS1 Interface circuit pack. The Inquiry Test will be run every 10 minutes until the Major alarm is cleared. The maintenance software places all trunks on the circuit pack in the out-of-service state if the Major alarm persists for more than 20 minutes.

When the Major alarm is cleared, the maintenance software restores all trunks on the circuit pack to their previous service state before a Major alarm occurs.

Table 9-250. TEST #142 Major Alarm Inquiry Test

Table 9-250. TEST #142 Major Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Minor Alarm Inquiry Test (#143)

The Minor alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1,000,000, but less than 1/1000. The Minor Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 41 minutes to recognize and report a Minor alarm and 41 minutes to recognize and report that a Minor alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 minutes to recognize and report a Minor alarm and 10 minutes to recognize and report that a Minor alarm condition is cleared.

When the DS1 Interface circuit pack detects a Minor alarm condition, it will send a MINOR-ALARM message to the maintenance software. After the maintenance software receives a MINOR-ALARM message, the Minor Alarm Inquiry Test is initiated to confirm the Minor alarm. All trunks on the circuit pack are kept in the in-service state after the Minor alarm is confirmed. The Minor Alarm Inquiry Test is run every 10 minutes until the Minor alarm is cleared.

Table 9-251. TEST #143 Minor Alarm Inquiry Test

Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Slip Alarm Inquiry Test (144)

Slips occur when transmitter and receiver are not running at precisely the same clock rate. The DS1 Interface circuit pack can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test is used to acquire the total number of slips occurred on a DS1 link.

When the DS1 Interface circuit pack detects a slip condition, the circuit pack will increase the on-board slip counter by 1. A SLIP-COUNT message is spontaneously sent to the system software after the counter reaches a threshold (for example, 88). When the maintenance software receives the SLIP-COUNT message, the Slip Alarm Inquiry Test is initiated to query the slip counters on DS1 Interface circuit pack and total the slip counts in the maintenance software.

If the count of slips is over the threshold, a Minor alarm is raised against the DS1 Interface circuit pack. All trunks of the DS1 Interface circuit pack are still in the in-service state. If the DS1 Interface circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See “TDM-BUS” and "SYNC (Synchronization)" for details.

Table 9-252. TEST #144 Slip Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 to 88	FAIL	The DS1 interface circuit pack detected a slip alarm. The error code equals the number of slips detected by the DS1 interface circuit pack since the last slip alarm inquiry test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the DS1 interface circuit pack is a TN767, enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that both endpoints and all intermediate equipment of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 5. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors. 6. Check the physical connectivity of the DS1 pack and of the cable. 7. If this continues to fail, escalate this problem.
	PASS	No Slip alarm is detected on the DS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Misframe Alarm Inquiry Test (#145)

Misframe Alarm indicates that framing bits observed on a DS1 Interface circuit pack are in error. Misframe Alarm Inquiry Test queries the total number of misframes that occurred on a DS1 Interface circuit pack since the last inquiry.

When the DS1 Interface circuit pack detects a misframe error, it will increase its misframe counter by 1. If the counter reaches the threshold, a MISFRAME-COUNT message is automatically sent to the switch maintenance software. After the maintenance software receives the MISFRAME-COUNT message, the Misframe Alarm Inquiry Test is initiated to collect the misframe counts from the DS1 Interface circuit pack.

When the threshold of misframes is reached, if the DS1 Interface circuit pack is supplying the system synchronization source, then a switching synchronization source message is sent to the TDM Bus Clock. See TDM-BUS (TDM Bus) Maintenance documentation for details. A Minor alarm against the DS1 Interface circuit pack is raised, but all trunks of the DS1 Interface circuit pack are still in the in-service state.

Table 9-253. TEST #145 Misframe Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 9-253. TEST #145 Misframe Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may appear. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.

Continued on next page

Table 9-253. TEST #145 Misframe Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The test failed because the DS1 interface circuit pack detected errors in the received framing bits pattern. The error code equals the number of misframes detected by the DS1 interface circuit pack since the last misframe alarm inquiry test. Major bit and minor bit error rate (error types 2561 and 2817) error logs often accompany misframe alarms. Clearing the cause of these error logs may clear the misframes which are occurring. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the DS1 interface circuit pack is a TN767, enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that both endpoints and all intermediate equipment of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 5. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors. 6. Check the physical connection of the DS1 pack and of the cable. 7. If this continues to fail, escalate this problem.
	PASS	No Misframe alarm is detected on the DS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information specified by System Administration to the DS1 Interface circuit pack. Translation includes the following data administered for a DS1 Interface circuit pack (see output of **display ds1 UUCSS** command): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

If a TN767E or later DS1 circuit pack is combined with a 120A CSU Module or a T1 Sync Splitter to form an Integrated CSU Module, this test will also send the administration for this Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU Module is done using the DS1 circuit pack administration form. Translation for the CSU Module includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power?, and so forth.

Table 9-254. TEST #146 Translation Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system software error. 1. Enter the **display ds1 UUCSS** command to verify the DS1 Interface circuit pack translation.
	PASS	Translation data has been downloaded to the DS1 Interface circuit pack successfully.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

DS1 Board Loopback Test (#1209)

This test is destructive.

The DS1 Board Loopback (BLB) Test causes a loopback at the TN767E DS1 board edge and tests DS1 board internal circuitry.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop UUCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the BLB Test.

When the BLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the BLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

Table 9-255. TEST #1209 DS1 Board Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry **test ds1-loop UUCSS ds1/csu-loopback-tests** at 1-minute intervals a maximum of 5 times.
1005	ABORT	DS1 Board Loopback Test cannot be executed in the current configuration. To run this Test, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter **busyout board UUCSS** to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.

Continued on next page

Table 9-255. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop UUCSS end-loopback/span-test* command in order to execute this test.
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-255. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.
	FAIL	DS1 Interface circuit pack failed the DS1 Board Loopback Test. 1. Retry **test ds1-loop UUCSS ds1/csu-loopback-tests**. 2. If the BLB test continues to fail, then replace the DS1 circuit pack.
	PASS	The BLB test executed successfully. The test pattern was transmitted and received successfully up to the TN767E DS1 board edge.

Table 9-255. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

CSU Equipment Loopback Test (#1210)

This test is destructive.

The CSU Equipment Loopback (ELB) Test causes a loopback at the near-edge of the local 120A CSU Module or T1 Sync Spilitter, and tests the connection from the TN767E DS1 board to the CSU Module/T1 Sync Splitter (DS1 board edge interconnecting cable, and CSU Module/T1 Sync Splitter edge). This test will only be performed if the 120A CSU Module/T1 Sync Splitter is present, administered, and connected to a 1.544Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop UUCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the ELB Test.

When the ELB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board sets up the ELB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 9-256. TEST #1210 CSU Equipment Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry *t***est ds1-loop UUCSS ds1/csu-loopback-tests** at 1-minute intervals a maximum of 5 times.
1005	ABORT	CSU Equipment Loopback Test cannot be executed in the current configuration. To run this test, the *Near-End CSU Type* field on the DS1 circuit pack administration form must be set to *integrated* and the "Bit Rate" field must be set to "1.544" (24-channel operation). 1. Use the **change ds1 UUCSS** command to set the *Near-End CSU Type* field on the DS1 circuit pack administration form to *integrated*, and/or change the "Bit Rate" field to "1.544" if the board is to be used in the 24-channel configuration. 2. Retry **test ds1-loop UUCSS ds1/csu-loopback-tests**.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.

Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

CSU Repeater Loopback Test (#1211)

This test is destructive.

The CSU Repeater Loopback (RLB) Test causes a loopback at the far-edge of the local 120A CSU Module or T1 Sync Splitter, and tests the connection from the TN767E DS1 board to and including the CSU Module/T1 Sync Splitter circuitry. This test will only be performed if the 120A CSU Module/T1 Sync Splitter is present, administered, and connected to a 1.544 Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop UUCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the RLB Test.

When the RLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the RLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

CPE Loopback Jack Test (#1212)

This test is destructive.

The CPE Loopback Jack (CLJ-LB) Test causes a loopback at the CPE Loopback Jack and tests the building wiring connection between the TN767E DS1 board and the CPE Loopback Jack.

The test is highly destructive and can only be initiated by a system technician demanded **test ds1-loop UUCSS cpe-loopback-jack-test-begin [number-of-bits bit-pattern]** command. The System technician has the choice of entering a loopback activation code on the command line or using the default code (0x47F).

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the CPE Loopback Jack Test.

The CPE Loopback Jack Test has the TN767E DS1 Interface circuit pack transmit a loopback activation code to the CPE Loopback Jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully sent. If the loopback is not established within the 10 seconds, the test returns FAIL.

The status of the CPE Loopback Jack test will be available in the hardware error log via error type 3900. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (*3-in-24 Pattern*) is synchronized (*Synchronized Field*).

To terminate the test, enter **test ds1-loop UUCSS end-loopback/span-test** command or the **release board**. Using the **release board** command restores all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 9-258. TEST #1212 CPE Loopback Jack Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry **test ds1-loop UUCSS cpe-loopback-jack-test-begin** at 1-minute intervals a maximum of 5 times.
1005	ABORT	CPE Loopback Jack Test cannot be executed in the current configuration. To run this Test, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.

Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop UUCSS end-loopback/span-test* command in order to execute this test.
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-258. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.
2	FAIL	The CLJ-LB test failed because it was not set up properly. The DS1 interface pack could not successfully put the CPE loopback jack into loopback mode. 1. Rerun the **test ds1-loop UUCSS cpe-loopback-jack-test-begin** command. 2. If the test continues to fail, the problem could be with the TN767E board, the CPE loopback jack equipment, or somewhere between. Run the **test ds1-loop UUCSS ds1/csu-loopback-tests** command to determine if the loopback tests that are closer to the TN767E board are successful. If any of these tests fail, follow the maintenance strategy that is associated with the test that fails.

Continued on next page

Table 9-258. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The CPE Loopback Jack Test was not set up properly. The framed 3-in-24 test pattern, generated by the DS1 Interface circuit pack and looped back through the CPE Loopback Jack, could not be detected properly by the DS1 circuit pack. 1. Retry **test ds1-loop UUCSS cpe-loopback-jack-test-begin**. 2. If the CPE Loopback test continues to fail, the problem could be with the TN767E board, the CPE Loopback Jack equipment, or somewhere in between. Run **test ds1-loop UUCSS ds1/csu-loopback-tests** to see if the loopback tests closer to the TN767E board are successful. If any of those loopback tests fail, follow the maintenance strategy associated with those loopbacks.
	PASS	The CPE Loopback Jack test has successfully began executing. The test will continue to run until the system technician enters the **test ds1-loop UUCSS end-loopback/span-test** command or the **release board UUCSS** command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Far CSU Loopback Test (#1213)

This test is destructive.

The Far CSU Loopback (R-LLB) Test causes a loopback at the far-end CSU and tests all circuitry and facilities from the local TN767E DS1 board to the far-end CSU.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop UUCSS far-csu-loopback-test-begin** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Far CSU Loopback Test.

If the far-end CSU is not a 120A CSU Module or a 401A T1 Sync Splitter, and the DS1 is administered for ami-zcs line coding, one’s density protection must be disabled on the CSU during the test due to the large number of zero’s in the 3-in-24 test pattern.

The Far CSU Loopback Test has the TN767E DS1 Interface circuit pack transmit a loopback activation code to the remote CSU, waits up to 15 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result. If the loopback is not established within the 15 seconds, the test fails.

The status of the Far CSU Loopback test will be available in the hardware error log via error type 3901. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (*i.e. 3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter *t***est ds1-loop UUCSS end-loopback/span-test** or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 9-259. TEST #1213 Far CSU Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry *t***est ds1-loop UUCSS far-csu-loopback-test-begin** at 1-minute intervals a maximum of 5 times.
1005	ABORT	Far CSU Loopback Test cannot be executed in the current configuration. To run this, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop UUCSS end-loopback/span-test* command in order to execute this test.
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-259. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.

Table 9-259. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The far CSU Loopback Test was not set up properly. The DS1 Interface circuit pack could not put the far-end CSU into loopback mode.
3	FAIL	The far CSU Loopback Test was not set up properly. The framed 3-in-24 test pattern, generated by the DS1 Interface circuit pack and looped back through the far-end CSU, could not be detected by the DS1 circuit pack. 1. Retry *t***est ds1-loop UUCSS far-csu-loopback-test-begin**. 2. If the Far CSU Loopback test continues to fail with this error code, the problem could be with the TN767E board, the far-end CSU equipment, or somewhere in between. Run **test ds1-loop UUCSS cpe-loopback-jack-test-begin** to see if the CPE Loopback Jack test which is closer to the TN767E board is successful. (If a CPE Loopback Jack device is not being used, then run **test ds1-loop UUCSS ds1/csu-loopback-tests** to see if these even closer loopback tests succeed). If the closer loopback test fails, follow the maintenance strategy associated with that loopback
	PASS	The Far CSU Loopback test has successfully began executing. The test will continue to run until the system technician enters **test ds1-loop UUCSS end-loopback/span-test** or the **release board UUCSS**.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

One-Way Span Test (#1214)

This test is destructive.

The One-Way Span Test allows one-way span testing to and from remote test equipment or another DEFINITY communications system. This will test all circuitry and facilities from the local TN767E DS1 board to the remote test equipment or other DEFINITY communications system.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS one-way-span-test-begin* command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the One-Way Span Test.

The One-Way Span Test has the TN767E DS1 Interface circuit pack transmit a framed 3-in-24 test pattern and attempt to receive and verify the pattern. If the TN767E board receives a framed 3-in-24 test pattern sent from another DEFINITY G3V3 or test equipment at the far-end of the DS1, it will begin counting bit errors within the received pattern.

The status of the One-Way Span test will be available in the hardware error log via error type 3902. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being sent cleanly over the span from the far-end, the number of bit errors should be very low. The *Test Duration* field will show *0* until the test pattern is received from the far-end. Upon receiving the test pattern, the board will begin calculating the test duration and number of bit errors. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (*i.e. 3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop UUCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 9-260. TEST #1214 One-Way Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the **test ds1-loop UUCSS one-way-span-test-begin** command at 1-minute intervals a maximum of 5 times.
1005	ABORT	One-Way Span Test cannot be executed in the current configuration. To run this, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the **test ds1-loop UUCSS end-loopback/span-test** command in order to execute this test.
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.
	PASS	The One-Way Span test has successfully began transmitting a framed 3-in-24 test pattern. The test will continue to run until the system technician enters the *test ds1-loop UUCSS end-loopback/span-test* command or the *release board UUCSS* command.

Continued on next page

Table 9-260. TEST #1214 One-Way Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

Inject Single Bit Error Test (#1215)

This test is destructive.

The Inject Single Bit Error Test will cause a single bit error to be sent within an active framed 3-in-24 test pattern.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS inject-single-bit-error* command. An attempt to use this command will be rejected if none of the three long-duration DS1 loopback/span tests (CPE Loopback Jack Test, Far CSU Loopback Test, One-Way Span Test) are active on a TN767E circuit pack.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Inject Single Bit Error Test.

The *list measurements ds1 summary* command displays the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). Injecting this single bit error should increment the bit error count of the loopback/span test by one.

Table 9-261. TEST #1215 Inject Single Bit Error Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS inject-single-bit-error* command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.
	PASS	A single bit error has been successfully injected into an active framed 3-in-24 test pattern.

Continued on next page

Table 9-261. TEST #1215 Inject Single Bit Error Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

End Loopback/Span Test (#1216)

This test is destructive.

The End Loopback/Span Test will terminate an active loopback or span test on a TN767E DS1 circuit pack. Bit error counting against the received test pattern stream is terminated and sending of the framed 3-in-24 test pattern is halted. If either the CPE Loopback Jack or the far-end CSU is looped, the appropriate loopback deactivate code is sent. If the loopback could not be deactivated, then the test will FAIL and a MINOR alarm will be noted in the alarm log until the loopback is cleared.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS end-loopback/span-test* command. Since only one of these three different long-duration loopback/span tests can be active at a time, the TN767E circuit pack knows which loopback/span test to terminate.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running this End Loopback/Span Test.

The *list measurements ds1 summary* command will display the length of time the test ran (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field).

To restore the trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state, execute the **release board** command.

Table 9-262. TEST #1216 End Loopback/Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS end-loopback/span-test* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	End Loopback/Span Test cannot be executed in the current configuration. To run this, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-262. TEST #1216 End Loopback/Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, escalate this problem.
1313	FAIL	The TN767E DS1 circuit pack could not deactivate the loopback through the Customer Loopback Jack. 1. Retry the *test ds1-loop UUCSS end-loopback/span-test* command at 1-minute intervals for a maximum of 5 times.
1314	FAIL	The TN767E DS1 circuit pack could not deactivate the loopback through the far-end CSU. 1. Make sure that the far-end DS1 is installed if the far-end CSU is a 120A CSU Module/T1 Sync Splitter. 2. Retry the *test ds1-loop UUCSS end-loopback/span-test* command at 1-minute intervals for a maximum of 5 times.
	PASS	The active long-duration loopback or span test on the TN767E circuit pack was successfully terminated.

Continued on next page

Table 9-262. TEST #1216 End Loopback/Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the link between the internal ID and the port.

ICSU Status LEDs Test (#1227)

The TN767E DS1 circuit pack has four status LEDs on the faceplate in addition to the three standard faceplate LEDs. These four status LEDs are associated with the 120A1 Channel Service Unit (CSU) Module that can be connected to the TN767E board via the I/O connector panel on the back of the port carrier.

This test is a visual test. It will light the four status LEDs red for 5 seconds, then light them green for 5 seconds, then light them yellow for 5 seconds, then turn the LEDs off and returns control of the status LEDs to the circuit pack.

This test will only be executed on TN767E or later suffix DS1 circuit packs administered for 24-channel operation (1.544 bit rate).

If the 1201 CSU Module/T1 Sync Splitter is not installed, the status LEDs are always off and this test aborts.

Table 9-263. TEST #1227 ICSU Status LEDs Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	The ICSU Status LEDs test can not be executed for the current configuration. The test applies only to TN767E or later DS1 circuit packs administered for 24-channel operation (1.544 bit rate). 1. If the circuit pack is a TN767E or later suffix DS1 circuit pack, then retry the command.
1951	ABORT	The ICSU Status LEDs Test can not be executed because a 120A1 or later suffix CSU Module or a 401A or later suffix T1 Sync Splitter is not physically installed. If using a 120A1 CSU Module/T1 Sync Splitter, physically connect it to the TN767E board on the back of the port carrier otherwise, ignore this abort.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command.
	PASS	The ICSU Status LEDs test executed successfully. A PASS result, however, does not necessarily mean that the status LEDs behaved properly. It only means that the software successfully attempted to light the status LEDs. This is a visual test. The service technician must visually exam the behavior of the LEDs while the test is running. The LEDs are functioning properly if the four status LEDs are lit red for 5 seconds, then lit green for 5 seconds, then lit yellow for 5 seconds. If the LEDs behave differently, escalate this problem.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 UUCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Continued on next page

DS1-FAC (DS1 Facility)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DS1-FAC	MAJOR	test board UUCSS sh r 1	DS1 Facility
DS1-FAC	MINOR	test board UUCSS sh r 1	DS1 Facility
DS1-FAC	WARNING	test board UUCSS sh r 1	DS1 Facility

1. UU is the universal cabinet number (1 for PPN, 2-44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). f is the DS1 facility (a, b, c, or d). See Chapter 7, or the DS1C-BD section, for identification of DS1 facility LEDs.

The DS1-FAC is a part of the DS1 Converter (DS1 CONV) Complex. The DS1 CONV Complex consists of two TN574 DS1 CONV circuit packs or two TN1654 DS1 CONV circuit packs connected by one to four DS1 facilities. The maintenance object name for the DS1 CONV circuit pack is DS1C-BD, and the maintenance object name for the connected DS1 facilities is DS1-FAC.

The TN1654 DS1 Converter Circuit pack is a redesign of the TN574 DS1 Converter board. The TN1654 provides functionality equivalent to the TN574 but also adds a 32-Channel E1 interface for international support as well as circuit-switched wideband connections (NxDS0).

The TN1654 DS1 CONV circuit pack is not compatible with the TN574 DS1 CONV board or the Y-cable used to interface to the TN574 DS1 CONV. A TN573B or later suffix SNI board must also be used when connecting to the TN1654 DS1 CONV board. See section DS1C-BD for information on both DS1 CONV circuit packs.

The DS1 CONV Complex is a part of the Port Network Connectivity (PNC). The DS1 CONV Complex is used to extend the range of the 32 Mbps fiber links that connect EPNs to either the PPN or the Center Stage Switch, allowing EPNs to be located at remote sites.

The DS1 CONV circuit pack contains on-board firmware that detects DS1 facility alarms and errors, communicates status to maintenance software, and runs tests in the background or on demand from maintenance software. The overall maintenance software strategy includes demand tests, recovery strategies, error logging and alarm logging, and periodic audits.

Every error condition reported by the firmware is associated with the background tests that the firmware runs autonomously. Demand tests that are executed by the maintenance software do not have any functionality that would effect any additional error manipulation by the firmware. However, the Failure Audit test #949 effects auditing of the software error log by forcing the firmware to report the pending errors again.

DS1 CONV circuit packs are connected to the Expansion Interface (EI) circuit packs (TN570) and the Switch Node Interface (SNI) circuit packs (TN573) as shown in Figure 9-25.

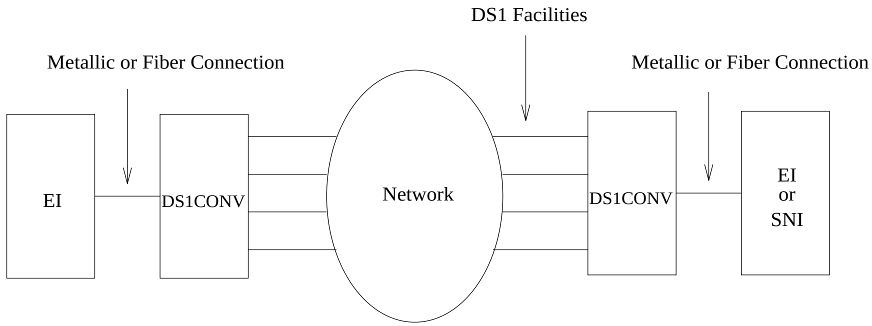

Figure 9-25. DS1 CONV Complex and the DS1 Facilities

The DS1 CONV Complex can replace fiber links between two EIs and fiber links between an EPN EI and an SNI. Fiber links between two SNIs and fiber links between the Processor Port Network (PPN) and the Center Stage Switch (CSS) cannot be replaced by a DS1 CONV Complex.

On the TN574 DS1 CONV circuit pack, one of the four DS1 facilities is used as the primary facility (or packet facility), and it is the only facility that can carry packet traffic besides providing circuit connections. The primary facility has 22 channels available for circuit and packet connections. Other facilities each have 24 channels available for circuit connections. On the TN574 primary facility, channels 1and 24 are not available for packet or for circuit connections. Channel 1 is used for excess packets traffic to prevent packet overflow that might result from zero code substitutions. Channel 24 is the DS1 Control Channel that carries control link data between the two DS1 CONV circuit packs.

The primary facility on the TN1654 DS1 CONV circuit pack is restricted to facility A or facility B. The TN1654 provides fixed packet bandwidth of 192 Kbps while the TN574 provides packet bandwidth of up to 1408 Kbps with a dynamic allocation mechanism that could change packet/circuit use of individual channels. The first three 64 Kbps channels on the primary facility of the TN1654 are reserved as the packet channels. The DS1 Control Channel will be Channel 24 in T1 mode and Channel 31 in E1 mode. In T1 format the TN1654 provides 24 circuit channels for use on non-primary facilities and 20 circuit channels on the primary facility. E1 format provides 31 circuit channels for use on non-primary facilities and 27 circuit channels on the primary facility.

When there are alarms on the packet facility, DS1 CONV circuit pack firmware changes the mapping of the DS1 channels to move the packet traffic to another facility. On TN574 DS1 CONV boards, the packet traffic will be moved to another ‘‘Digital Data Compatible’’ facility (as indicated on the fiber link administration screen). On TN1654 DS1 CONV boards, the packet traffic will be moved to either facility A or B if available. This mapping is done to keep the packet service operational at all times as the system control links are carried on these packet connections. When packet traffic is moved to another facility, circuit connections on the new facility are torn down and circuit connections on the old (faulty) facility are re-mapped to the new packet facility.

After firmware initialization, facility A, the first facility, is chosen as the default primary facility for both DS1 CONV boards.

The TN574 DS1 CONV has seven LEDs which provide an indication of the state of the DS1 CONV circuit pack and the DS1 facilities. There is a yellow, a green, and a red LED under software and/or firmware control. There are four Green LEDs under hardware control that indicate, for each DS1 facility, whether a receive signal is present for the DS1 facility. From top to bottom these green LEDs correspond to DS1 facilities A, B, C, and D respectively. If one of the four green LED is on, it indicates a signal is present, but it does not imply that the signal is using the correct framing format (ESF or D4) or line coding (ZCS or B8ZS). See section DS1C-BD for the description of the red, the green, and the yellow LEDs on the DS1 CONV circuit pack.

The TN1654 DS1 CONV board has eleven LEDs on its faceplate. The top three system standard LEDs (yellow, green and red) are used to provide an indication of the state of the DS1 CONV board. The bottom four LEDs on the TN1654 board are labeled SPAN LEDs. These LEDs are under firmware control. If the facility is not administered, then the LED is not lit. The LED is lit amber if the facility is running alarm free. If the facility is detecting either a red alarm (loss-of-signal or loss-of-frame), a yellow alarm (remote frame alarm) or a blue alarm (AIS signal) then the LED is lit red. See section DS1C-BD for a complete description off all the LEDs.

The TN1654 DS1 CONV circuit pack supports the Wideband Switching feature. The TN574 DS1 CONV does not.

DS1 Facility Busyout

Busying out a maintenance object allows service to be disconnected gracefully. Busyout puts the object out-of-service until the repair procedures are completed.

DS1 facilities are busied out via the **busyout ds1-facility** command. When an attempt is made to busyout the packet facility (or primary facility), system will print a warning message indicating that the **override** option must be used to busyout the packet facility. Busying out the packet facility will result in moving the packet traffic to another facility and disconnecting circuit connections on that new facility.

The system will not allow the last packet DS1 facility to be busied out. In this case, the DS1 CONV circuit pack must be busied out instead.

When the **busyout ds1-facility** command is executed, software communicates with both DS1 CONV circuit packs in the DS1 CONV Complex. If the board at which the facility is being busied out is not accessible, then the abort code 2100 will be returned, if the board at the other end of the DS1 CONV Complex is not accessible, then the abort code 105 will be returned.

DS1 Facility Administration

DS1 facility administration is a part of the fiber link administration. DS1 options are set on the second page of the fiber link administration screen. In Critical Reliability systems, the third page of the fiber link administration screen contains the DS1 facility options for the B side of the PNC.

DS1 facility administration is explained in the following sections. Descriptions given here do not provide complete coverage of fiber link administration. See the DEFINITY ECS Release 5 Implementation Manual (555-230-302).

Replacing a DS1 Facility

Disconnecting a DS1 facility is service disrupting except on Critical Reliability Systems since they have PNC duplication.

On a Standard Reliability or High Reliability System (no PNC Duplication):

This procedure is destructive.

1. Busyout the DS1 facility via the **busyout ds1-facility** command.
2. Replace the DS1 facility.
3. Release the DS1 facility via the **release ds1-facility** command.

On a Critical Reliability System (PNC Duplication):

This procedure is non-destructive.

1. If the DS1 facility to be replaced is on the active PNC (its yellow LED will be on solid), first do a PNC demand interchange via the **reset pnc interchange** command. (The **status pnc** command can also be used to determine the active PNC.)
2. When the DS1 facility to be replaced is on the standby PNC (if the DS1 facility was originally on the standby PNC or after the PNC interchange has finished), busyout the DS1 facility via the **busyout ds1-facility** command.
3. Replace the DS1 facility.
4. Release the DS1 facility via the **release ds1-facility** command.

Installing a DS1 Facility

Installing a DS1 facility is done in the following sequence:

1. Connect the facility.
2. Check the fiber link number via the **list fibers** command. Administer the DS1 facility via the **change fiber-link** command. Change the **Facility Installed** field from "no" to "yes" for the facility that is being installed.
3. Busyout the DS1 CONV circuit pack via the **busyout board** command.
4. Run the DS1 Facilities Connectivity test #790 via the **test board UUCSS long** command to make sure that the facilities are connected correctly.
5. Release the DS1 CONV circuit pack via the **release board** command.

Removing a DS1 Facility

Removing a DS1 facility is service disrupting in any system configuration (because the DS1 facility administration is similar on both sides of the PNC on Critical Reliability Systems).

This procedure is destructive.

1. Busyout the DS1 facility via the **busyout ds1-facility** command.
2. Check the fiber link number via the **list fibers** command. De-administer the DS1 facility via the **change fiber-link** command. Change the **Facility Installed** field from "yes" to "no" for the facility that is being removed.
3. Disconnect the DS1 facility (or facilities in Critical Reliability System configuration).

DS1 Interface Options

The following DS1 Interface options must be set with fiber link administration. To set the values, check the number of the fiber link via the **list fibers** command. Execute the **change fiber-link** command and set the following fields:

Facility Installed

This field determines if the DS1 facility is installed. The field is set to *yes* if the facility is installed.

For TN574 DS1 CONV boards, facility A must be installed before the others. Facilities B, C and D can then be installed in any order desired since the primary facility can reside on any of the four facilities.

For TN1654 DS1 CONV boards, facility A must be installed first, then B, then C or D. This is required since the primary facility can only reside on facilities A or B.

Passes Far-end Clock

This field determines if the DS1 facility can be used as a clock reference for the receive fiber signal. The field is set to *yes* unless the DS1 facility cannot be used as clock reference signal.

This field appears on the fiber-link form only for TN574 DS1 CONV circuit packs. On the TN1654 DS1 CONV board, none of the facilities can be used as a clock reference for the receive fiber signal thus administration of this field is not applicable.

DS1 facilities cannot be used as system synchronization sources.

Digital Data Compatible

This field determines if the DS1 facility is suitable for carrying packet traffic. The field is set to *yes* unless the DS1 facility is not digital data compatible.

This field appears on the fiber-link form only for TN574 DS1 CONV circuit packs. The TN574 circuit pack allows any of the four facilities to be used as the primary facility which carries the packet traffic. The TN1654 DS1 CONV board, however, allows packet traffic only on facilities A and B. Thus there is no need to administer this information as it is already predetermined.

Bit Rate

This field is used to select domestic T1 operation or international E1 operation for all facilities in the TN1654 DS1 CONV Complex. The field is set to *1.544* Mbps for T1 operation and *2.048* Mbps for E1 operation.

This field appears on the fiber-link form only for TN1654 DS1 CONV circuit packs.

NOTE:
The TN1654 DS1 CONV circuit pack is also field configurable for T1 or E1 operation. All four DS1 facilities are configured to either T1 or E1 as a group via an option switch located on the component side of the circuit pack. An error will be logged and an alarm will be raised if there is a T1/E1 inconsistency between the administered bit rate and the board option switch setting.

Idle Code

This field is used to set the idle code for all facilities on the TN1654 DS1 CONV board. This field can accept any combination of ones (1) and zeros (0) with the exception that the second left-most digit must be set to one (1) at all times.

This field appears on the fiber-link form only for TN1654 DS1 CONV circuit packs.

CRC

This field determines if CRC is enabled for all facilities on the TN1654 circuit pack. The field is set to *yes* if a cyclic redundancy check (CRC) is to be performed on transmissions that the board receives.

CRC is applicable only to E1 operation. Thus, this field appears on the fiber-link form only for TN1654 DS1 CONV circuit packs whose bit rate is administered to 2.048 Mbps.

DS1 CONV-1 and DS1 CONV-2 Line Compensation

The DS1 facility line signal is pre-equalized at the transmitter on the DS1 CONV circuit pack so that DS1 line pulses have correct amplitude and shape when they reach the Network Interface (see Figure 9-26). The amount of equalization necessary is determined by the distance to the Network Interface and also by the type of wiring used to connect to the Network Interface. If the equalization is not set to the correct value, potentially high error rates (errored seconds) will be observed on the DS1 facility. Equalization values are determined as follows:

Equalizer Setting	Distance to Network Interface (feet)	
	Cable type 22 AWG ABAM & 24 AWG PDS	Cable type 26 AWG PDS
1	1 to 133	0 to 90
2	133 to 266	90 to 180

Equalizer Setting	Distance to Network Interface (feet)	
	Cable type 22 AWG ABAM & 24 AWG PDS	Cable type 26 AWG PDS
3	266 to 399	180 to 270
4	399 to 533	270 to 360
5	533 to 655	360 to 450

Line compensation is applicable only to T1 operation, thus these fields will not appear on the fiber-link form if the TN1654 DS1 CONV is administered for a bit rate of 2.048 Mbps.

Line Coding

This field is used to administer the line coding for the DS1 facility. For the TN574 board and the TN1654 board in T1 mode, the field may be set to *ami-zcs* or *b8zs*. If the TN1654 board is set for E1 operation, the line coding may be set to either *ami-basic* or *hdb3*. The line coding must be the same at each end of the DS1 CONV Complex.

Framing Mode

Either *esf* or *d4* framing mode can be selected for the DS1 facility. The same framing mode must be used at each end of the DS1 CONV Complex

For TN574 DS1 CONV boards, the framing mode field is administrable.

For TN1654 DS1 CONV boards, this field is display only. It can not be administered. The TN1654 has option switches located on the component side of the circuit pack. If T1 operation is selected via the first switch, four additional switches are used to select the framing mode for each facility. Each facility can be set to either D4 or ESF framing. The framing mode field will display what the switch is set to for the DS1 facility.

Framing Mode is applicable only to T1 operation, thus this field will not appear on the fiber-link form if the TN1654 DS1 CONV is administered for a bit rate of 2.048 Mbps.

Line Termination

This field displays the line termination for the DS1 facility on the TN1654 DS1 Converter circuit pack. This field is display only. It can not be administered. The TN1654 has option switches located on the component side of the circuit pack. If E1 operation is selected via the first switch, four additional switches are used to select the line termination for each facility. Each facility can be set to either CEPT 75 ohm coaxial or 120 ohm CEPT twisted pair. This line termination field will display what the switch is set to for the DS1 facility.

Line Termination is applicable only to E1 operation, thus this field will not appear on the fiber-link form if the TN1654 DS1 CONV is administered for a bit rate of 1.544 Mbps

Facility Circuit ID

These fields are used to specify a unique alpha-numeric name up to 40 characters long for each DS1 facility. This field will be displayed for each facility whose *Facility Installed?* field is set to *yes*.

DS1 Converter Performance Measurements Report

The DS1 Converter Performance Measurements provide link performance measurements for the DS1 facilities.

When no facility alarms exist on the DS1 facility, events that indicate a degradation in the performance of the DS1 facility are monitored and recorded. These events will generate appropriate alarms when performance of the DS1 facility has degraded below acceptable levels. These measurements include errored seconds, bursty seconds, severely errored seconds, and failed seconds.

There are two DS1 Converter Performance Measurements Sub-reports. The first sub-report, DS1 Converter Performance Measurements Summary Report, provides information on the worst 15 minute interval of data, the total for 24 hours of data and the current 15 minute counter for each of the above mentioned counters.

The second sub-report, DS1 Converter Performance Measurements Detailed Report displays a detailed log for the last 96 15-minute intervals for each of the above mentioned counters.

The DS1 Converter Performance Measurements Summary Report can be accessed with **list measurements ds1-facility summary UUCSSf [print/schedule]**. A more detailed version of the report is accessed with **list measurements ds1-facility log UUCSSf [print/schedule]**.

The user can reset all hardware and software measurement counters for a given facility with **clear measurements ds1-facility UUCSSf**. The *Counted Since* time is also reset and the *Number of Valid Intervals* count is set to zero.

The reports are printed on the screen or, by using the *print* option, on a printer attached to the terminal.

Clearing Firmware Errors

DS1 CONV error reports are generated by firmware autonomously, they are not associated with system technician demanded tests. Therefore, **test board clear** command does not affect the error status known by the DS1 CONV firmware. To clear all the on-board firmware-detected errors unconditionally, execute the **clear firmware-counters** command.

Error Log Entries and Test to Clear Values

Table 9-264. DS1 Facility Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test ds1-facility UUCSSf sh r 1
1(a)		Failure Audit #949	MAJOR	ON	test board UUCSS sh r 1
18(b)	0	busyout ds1-facility UUCSSf	WARNING	OFF	release ds1-facility UUCSS
257(c)		Failure Audit #949	MINOR	ON	test board UUCSS sh r 1
513(d)	1	Failure Audit #949	MINOR	OFF	test board UUCSS sh r 1
513(d)	2	Failure Audit #949	MINOR	OFF	test board UUCSS sh r 1
856(e)		DS1 Facility Query for Slips/Misframes #972	MINOR	OFF	none
1025(f)		Failure Audit #949	MAJOR[2]	OFF	test board UUCSS sh r 1
1281(g)	None	Failure Audit #949	MAJOR[2]	OFF	test board UUCSS sh r 1
1281(g)	1	Failure Audit #949	MAJOR[2]	OFF	test board UUCSS sh r 1
1281(g)	2	Failure Audit #949	MAJOR[2]	OFF	test board UUCSS sh r 1
1537(h)		Failure Audit #949	MAJOR[2]	OFF	test board UUCSS sh r 1
1793(i)		Failure Audit #949	MAJOR[2]	OFF	test board UUCSS sh r 1
2065(j)		DS1 Facility Query for Slips/Misframes #972	MINOR	OFF	none
2305(k)		Failure Audit #949	MAJOR	OFF	test board UUCSS sh r 1
2561(l)		Failure Audit #949	MINOR[3]	OFF	test board UUCSS sh r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. These failures are logged as a WARNING alarm when the error is first reported. The alarm severity is raised to a MAJOR in 15 minutes if the problem persists.
3. This failure is logged as a WARNING alarm when the error is first reported. The alarm severity is raised to a MINOR in 15 minutes if the problem persists.

Notes:

When problems persist, resetting the DS1 CONV circuit pack via the **reset board** command may temporarily resolve the error condition and restore service until further assistance is provided.

a. A major failure occurred on the DS1 interface hardware on the DS1 CONV circuit pack associated with this DS1 facility. Replace the DS1 CONV circuit pack.

b. This error indicates that the DS1 facility has been busied out via the **busyout ds1-facility** command. To resolve this error, release the DS1 facility via the **release ds1-facility** command.

c. A minor failure occurred on the DS1 interface hardware on the DS1 CONV circuit pack associated with this DS1 facility. Replace the DS1 CONV circuit pack.

d. DS1 CONV circuit packs in this DS1 CONV Complex do not match in their framing formats or line coding formats.

   Aux Data 1 indicates that the framing formats (ESF or D4) do not match. For TN574 DS1 CONV boards, the framing mode is administered on the fiber-link form. The TN1654 DS1 CONV has option switches located on the component side of the circuit pack. If T1 operation is selected via the first switch, four additional switches are used to select the framing mode for each facility. The Framing Mode field on the fiber-link form is display-only for the TN1654 boards. It displays what the switch is set to for the DS1 facility. It can not be administered.

   Aux Data 2 indicates that the line coding formats do not match. Line Coding is an administrable value on the fiber-link form. The line coding options are *ami-zcs* or *b8zs* for TN574 boards and TN1654 boards in T1 mode. For TN1654 boards in E1 mode, the line coding options are *ami-basic* or *hdb3*.

   This error should clear in 15 minutes.

   1. Verify that DS1 facility and the network is using the same line coding (ami-zcs, b8zs, ami-basic, hdb3) and framing mode (ESF, D4). Use **list fibers** and **display fiber**-link commands to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network.

      If the framing mode format differs on boards in a TN1654 DS1 CONV Complex, the DS1 CONV board that has its option switch set incorrectly will have to be physically removed from the system in order to set the facility framing mode switch properly.

   2. If the problem persists, reset both DS1 CONV circuit packs via the **reset board** command.

   3. If the problem still persists, replace this DS1 CONV circuit pack.

   4. If the problem still persists, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.

e. More than 88 negative and/or positive slip errors occurred. This error will clear when there are no slips for 1 hour.

   1. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
   2. Verify that the DS1 facility and the network are using the same Line Coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. Use **list fibers** and **display fiber**-link commands to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network. See the above sections, “Line Coding” and “Framing Mode” for details on how these options apply to the TN574 and TN1654 DS1 CONV boards.
   3. For TN574 boards and TN1654 boards in T1 mode, check line equalization settings as described in the above section, ‘‘DS1 CONV-1 and DS1 CONV-2 Line Compensation.’’
   4. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints. Enter **display errors** and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
   5. If the problem still persists, replace this DS1 CONV circuit pack.
   6. If the problem still persists, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.

f. Loss of Frame Alignment (LFA) Alarm, the RED alarm: This alarm indicates that the DS1 interface associated with the DS1 facility cannot frame up on the received data.

   For the following repair procedure, refer to Figure 9-26 and the diagrams in the related test descriptions.

   1. If the network is used instead of private T1 lines, check that the DS1 facility and the network are using the same line coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. For TN1654 boards, verify that the two boards in the DS1 CONV Complex are using the same bit rate. Use **list fibers** and **display fiber-link** commands to check the values for this DS1 facility. Contact T1 Network Service to verify the modes set for the network. See the above sections, “Line Coding”, “Framing Mode” and “Bit Rate” for details on how these options apply to the TN574 and TN1654 DS1 CONV boards
   2. Run the Near-end External Loopback test #799 via the **test ds1-facility UUCSSf external-loopback** command by setting up a loopback at CPE side of CSU towards DS1 CONV circuit pack shown as loopback point **LB 1** in the test description diagram. If the test fails, replace connectors and the cables between CSU and the DS1 CONV circuit pack.

3. If the test passes, run the Near-end External Loopback test #799 via the **test ds1-facility UUCSSf external-loopback** command by setting up a loopback at DS1 facility side of CSU towards the DS1 CONV circuit pack shown as loopback point **LB 2** in the test description diagram. If the test fails, replace the CSU.
4. If the test #799 passes, run the Far-end Internal Loopback test #797 via the **test ds1-facility UUCSSf long** command. If the test #797 passes, go to step 6. If the test fails, then run the Near-end External Loopback test #799 via the **test ds1-facility UUCSSf external-loopback** command at the other end of the DS1 CONV Complex, and repeat steps 2 and 3 for the other end-point.

   If the system is not configured as a Critical Reliability System and if there is only one DS1 facility, then the test #799 can only be executed at the end which is closer to the SPE relative to the DS1 CONV circuit pack at the end of the DS1 CONV Complex. If the test cannot be executed for this reason, then replace the cables, connectors and the CSU at the other end of the DS1 CONV Complex.
5. If the problem could not be isolated by the near-end external loopback tests, then the fault should be between CSU A and CSU B. Contact T1 Network Service to resolve the problem(*).
6. If the problem still persists, check for excessive slips and synchronization problems. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, or SNC-BD errors. For TN574 boards and TN1654 boards in T1 mode, check line equalization settings as described in the above section, *DS1 CONV-1 and DS1 CONV-2 Line Compensation*.
7. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints. Enter **display errors** and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
8. If the problem still persists, replace this DS1 CONV circuit pack.
9. If the problem still persists, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.

If D4 framing mode is used, an in-band alarm signal (RFA) will be transmitted that will corrupt the transmit data on this facility.

g. *Aux Data None* This entry in the DS1 Facility Error Log will only occur prior to release V5. The DS1 CONV circuit pack's neighbor (the DS1 CONV circuit pack at the other end of the DS1 CONV complex) is unable to frame up on the signal being sent to it by this DS1 CONV circuit pack on this DS1 facility. The far-end facility will be in LFA state. To isolate faults for this case, follow the repair procedure for error type 1025 for the other end of the DS1 facility. Note that references to the near-end and far-end are reversed, for example, the neighbor is now the near-end. If D4 framing is used, received data will be corrupted as well as transmitted data.

Aux Data 1 indicates that the facility is detecting a Remote Frame Alarm (RFA), also known as the YELLOW alarm, being sent by the remote DS1 endpoint. This Yellow alarm corresponds to the yellow F2 state documented in CCITT Recommendation I.431. If D4 framing is used, received data will be corrupted in addition to transmitted data.

Aux Data 2 indicates that the facility is detecting a yellow F5 state alarm. This error only applies to TN1654 DS1 CONV boards in 32-channel E1 operation with CRC enabled via the fiber-link form. The F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431.

The far-end facility will be in LFA state. To isolate faults for this case, follow the same repair procedure as in error type #1025 (Loss of Frame Alignment) for the other end of the DS1 facility.

h. Alarm Indication Signal (AIS), the BLUE alarm. This alarm indicates that the far end of the facility is out of service. This means that the other end of the DS1 facility is undergoing maintenance testing or has a LOS condition and the CSU is providing a **Keep Alive** signal. If the **Keep Alive** signal is not supplied by the CSU, a LOS condition will exist on the facility instead of the AIS. If a LOS condition exists on the facility, the green LED on the TN574 DS1 CONV circuit pack that is associated with the facility will be off; if an AIS condition exists on the facility, the green LED that is associated with the facility that has the AIS will be on. For TN1654 DS1 CONV boards, the LED associated with the facility will be lit red if either the LOS or AIS conditions exist.

   To isolate faults for this case, follow the same repair procedure as in error type #1793 (Loss of Signal) for the other end of this DS1 facility.

   An RFA alarm indication (YELLOW alarm) is transmitted in response to this BLUE alarm. If D4 framing is used, transmitted data is corrupted.

i. Loss of Signal (LOS) alarm. This alarm indicates that no signal is present at the DS1 interface associated with the facility. On TN574 DS1 CONV boards, the green LED that is associated with the facility will be off. For TN1654 DS1 CONV boards, the LED that is associated with the facility will be lit red. If the LED behavior differs, replace the DS1 CONV circuit pack.

   Fault isolation for this problem may be different depending on the capabilities of the CSU device that is being used. Typically, CSUs provides an LED that is useful for fault isolation (see Figure 9-27). This is the "16 Zeros" LED. This LED is momentarily lit when a string of 16 consecutive zeros is detected in the DS1 signal from the DS1 CONV. Zeros on a DS1 link are represented by an absence of a pulse. Thus, an active 16 Zeros LED indicates a LOS alarm from the DS1 CONV.

For the following repair procedure, refer to Figure 9-26 and the diagrams in the related test descriptions.

1. If the DS1 facility side LOS indication on CSU A is off (inactive), check for a problem between the DS1 CONV A circuit pack and the CPE side of CSU A. Connectors, cables, and the CSU may need to be replaced.
2. If the DS1 facility side LOS indication on CSU A is on (active), check for a problem between the CSU A and the CSU B. Contact T1 Network Service to resolve the problem. [1]
3. If the CPE side LOS indication on CSU B is on (active), check for a problem between the CPE side of CSU B and the DS1 CONV B circuit pack. Connectors, cables, and the CSU B may need to be replaced.
4. If the CSU A and the CSU B do not provide visual CPE side and DS1 facility side LOS indications, follow the repair procedure that is given for error type #1025 (Loss of Frame Alignment). Apply the procedure first to the DS1 CONV B side instead of the DS1 CONV A where the error is reported (external loopback test is not expected to pass if we execute it at this end as long as we have the LOS indication).

   Repair procedure for error type #1025 (Loss of Frame Alignment) includes execution of Near-end External Loopback test #799. If the system is not configured as a Critical Reliability System and if there is only one DS1 facility, then the test #799 can only be executed at the end which is closer to the SPE relative to the DS1 CONV circuit pack at the end of the DS1 CONV Complex. If the test cannot be executed for that reason, then still make the external loopback as if the test was going to be executed, but instead of executing the test, check the green LED at the face plate of the DS1 CONV B that is associated with this DS1 facility. If the green LED is off, then replace the connectors, cables, and the CSU B.
5. If the problem still persists, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.
6. If the problem still persists, replace this DS1 CONV circuit pack.

If D4 framing is used, an in-band alarm signal (RFA) is transmitted that corrupts transmit data in response to this alarm.

1. ;DS1 facility may be a private line or it may be connected to the Network. Network Interface (NI) point is where the customer's maintenance responsibility ends and the DS1 facility vendor's maintenance responsibility begins. This point ideally is the T, R, T1, and R1 terminals on the rear of the CSU to which the wires of the DS1 facility vendor's DS1 facility is attached. If the NI does not occur at this point, then any cabling between the CSU terminals and the NI is also considered to be part of the CPE. This cable typically runs between the DS1 facility terminals of the CSU and a cross-connect field where the DS1 facility vendor has terminated the DS1 facility. Maintenance responsibility for this portion of the DS1 facility resides with the customer unless other arrangements are made.

j. More than 17 misframe errors occurred. This error will clear when there are no misframes for 1 hour.

1. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, or SNC-BD errors.
2. Verify that the DS1 facility and the network are using the same Line Coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. Use **list fibers** and **display fiber**-link commands to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network. See the above sections, “Line Coding” and “Framing Mode” for details on how these options apply to the TN574 and TN1654 DS1 CONV boards.
3. For TN574 boards and TN1654 boards in T1 mode, check line equalization settings as described in the above section *DS1 CONV-1 and DS1 CONV-2 Line Compensation*.
4. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints. Enter **display errors** and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
5. If the problem still persists, replace this DS1 CONV circuit pack.
6. If the problem still persists, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.

k. Facility Packet Channel Loopback Error. This error indicates that the DS1 CONV primary facility which carries the packet timeslots and DS1 control channel is looped to itself. This error applies only to facilities A and B on TN1654 DS1 CONV boards. If both facilities A and B are being used and firmware detects a loopback condition an attempt will be made to switch the primary facility to the other facility. If the other facility is looped, down or not being used, the EPN will be down until this loopback is removed.

1. Check the loopback LEDs on both CSU A and CSU B as shown in Figure 9-26 to see if a CSU is in a loopback mode. Also check to see if the CSUs have been manually hard-wired into a loopback mode. Remove detected loopbacks.
2. If the CSUs are not in loopback mode, reset both DS1 CONV boards via the **reset board** command.

l. Facility Jitter Alarm. This alarm indicates excessive receive jitter on the DS1 facility. This error only applies to TN1654 DS1 CONV boards. The problem is external to the DS1 CONV board. It could be caused by bad wiring, a bad device (CSU or repeater) or a bad signal coming in at the Network Interface.

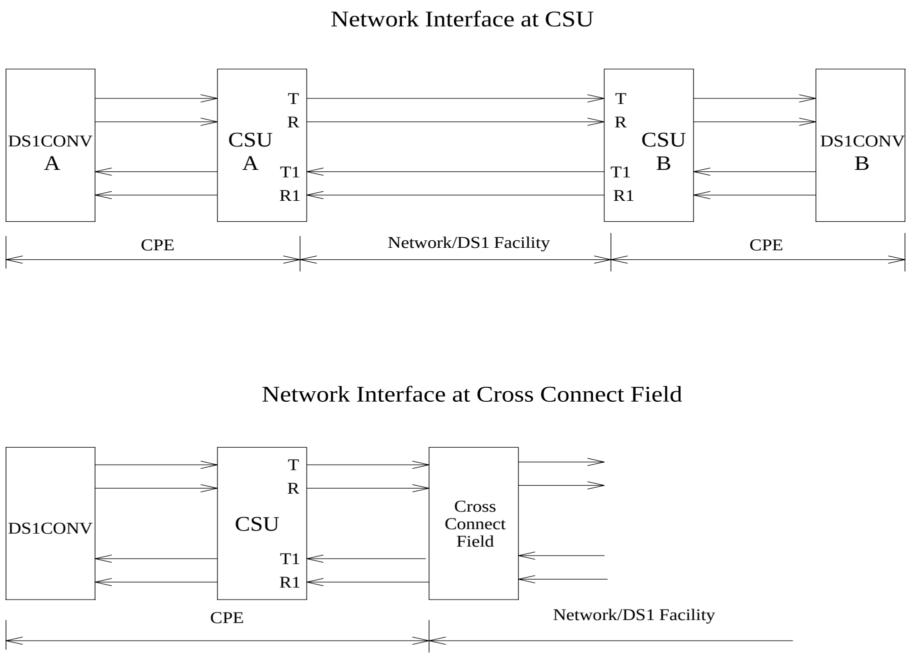

Figure 9-26. DS1 Facility Connections

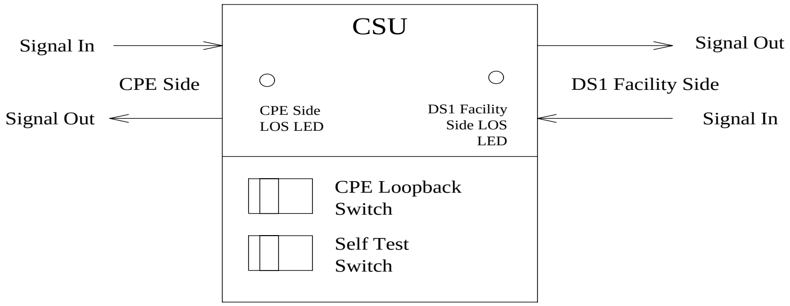

Figure 9-27. Typical CSU Maintenance Capabilities

System Technician-Demanded Tests: Descriptions And Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Failure Audit* for example, you may also clear errors generated from other tests in the testing sequence. The *Failure Audit* test is executed via the test board command.

Order of Investigation	Short Test Sequence	Long Test Sequence	External Loopback	Reset Sequence	D/ND[1]
Failure Audit (#949)					ND
DS1 Interface Options Audit (#798)	X	X			ND
Far-End Internal Loopback Test (#797)		X			D
Near-end External Loopback Test (#799)			X		D

1. D = Destructive; ND = Nondestructive

Far-End Internal Loopback Test (#797)

This test is destructive.

This test starts at the DS1 CONV circuit pack whose equipment location was entered and traverses over the specified facility and loops at the internal facility interface on the other DS1 CONV circuit pack in the DS1 CONV Complex. See diagram below.

Every part of this test is executed under firmware control and the result is sent back to the maintenance software. The test is executed by sending digital data through every DS1 channel on this facility. For TN574 DS1 Converter facilities, test patterns are sent through all DS1 channels. For TN1654 DS1 Converter facilities, test patterns are sent through one DS1 channel.

If there is only one DS1 facility available, the system will not allow that last facility to be busied out. In that case, the DS1 CONV circuit pack must be busied out before executing this test.

On a Standard Reliability and High Reliability System (no PNC duplication), if there is only one DS1 facility available, then this test can only be executed at the end-point which is closer to the SPE relative to the neighbor DS1 CONV circuit pack because of its impacts on the system control links. For TN574 DS1 CONV boards, the completion of the test will be delayed in this configuration to wait for the recovery of the system control links. On a Critical Reliability System (PNC Duplication), or when there are multiple DS1 facilities, the test can be executed at any DS1 CONV circuit pack.

If the test passes on a TN1654 DS1 facility, the *round trip delay time* will be displayed in milliseconds in the *Error Code* field. The round trip delay time is defined as the length of time in milliseconds it takes for the firmware to receive the test pattern after it has been sent.

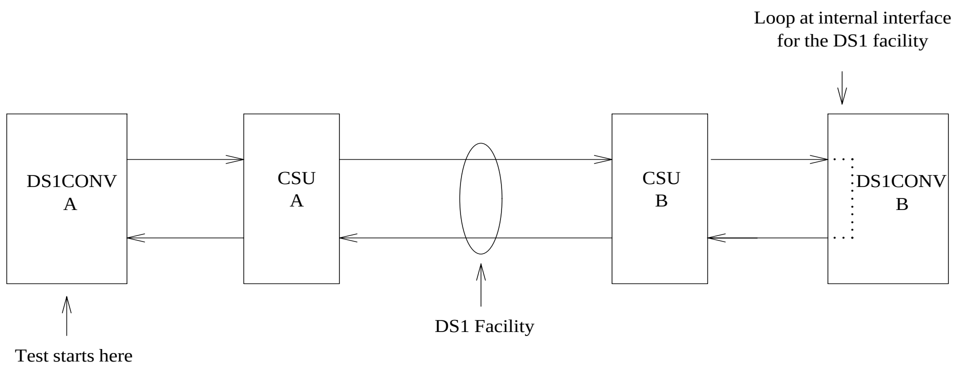

Figure 9-28. Far-End Internal Loopback Test (#797)

Table 9-265. TEST #797 Far-End Internal Loopback Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2321	ABORT	DS1 facility is not busied out. Busyout the DS1 facility via the **busyout ds1-facility** command. If there is only one DS1 facility, then busyout the DS1 CONV circuit pack via the **busyout board** command.
2332	ABORT	Test is not allowed to execute at the far end with this system configuration when there is only one DS1 facility available. Execute the test at the other end of the DS1 CONV Complex.

Continued on next page

Table 9-265. TEST #797 Far-End Internal Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	Far-End Internal loopback failed. A problem exists between DS1 CONV A and the internal interface for DS1 facility on the DS1 CONV B (see diagram above). 1. If the test is executed as a part of an error analysis, then return back to the related section. 2. Enter **display errors** and follow the associated repair procedures for any on-board DS1 CONV-BD errors on this DS1 CONV circuit pack and the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. 3. If the network is used instead of private T1 lines, verify that the DS1 facility and the network are using the same Line Coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. Use **list fibers** and **display fiber**-link commands to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network. See the above sections, “Line Coding” and “Framing Mode” for details on how these options apply to the TN574 and TN1654 DS1 CONV boards. 4. Isolate the problem by running the Near-end External Loopback test #799 via the **test ds1-facility UUCSSf external-loopback** command, first at this end and then at the other end of the DS1 CONV Complex. Setup loopbacks at different points as shown in the description diagram for test #799, and follow repair procedures described for test #799. 5. If the problem could not be found by near-end external loopback tests, then the fault should be between the CSU A and the CSU B. Contact T1 Network Service to resolve the problem, also see the repair procedures for error type #1025 (Loss of Frame Alignment).
Any	PASS	Transmission through the path of the loopback is successful. TN1654 DS1 facilities will display the round trip delay time in milliseconds in the Error Code field. The round trip delay time is defined as the length of time in milliseconds it takes for the firmware to receive the test pattern after it has been sent.

DS1 Interface Options Audit Test (#798)

This test is non-destructive.

This test sends the administered DS1 Interface options to the DS1 CONV circuit pack. Options are sent to both DS1 CONV circuit packs at the same time to prevent any transitional mismatch of options.

The following DS1 facility options are sent to the TN574 DS1 CONV circuit pack: Framing Mode, Line Coding and DS1 CONV-1 and DS1 CONV-2 Line Compensation.

The following DS1 facility options are sent to the TN1654 DS1 CONV circuit pack: Line Coding and DS1 CONV-1 and DS1 CONV-2 Line Compensation (T1 only). These option fields are given in the fiber link administration screen.

Table 9-266. TEST #798 DS1 Interface Options Audit

Error Code	Test Result	Description/ Recommendation
105	ABORT	The neighbor DS1 CONV circuit pack at the other end of the DS1 CONV Complex is not accessible.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	The DS1 Interface options are sent to the circuit pack.

Near-end External Loopback Test (#799)

This test is destructive

This test starts at the DS1 CONV circuit pack whose equipment location was entered and traverses over the specified facility and loops back at the manually hard-wired external loopback device. Depending on the type of physical connectivity of the DS1 facility, special tools, cables or connectors may be required to make the hard-wired loopbacks.

To isolate a problem, set the loopback first at the loopback point **LB 1**, and then at the loopback point **LB 2**, see Figure 9-29 and *Figure 9-26*. Place the loopbacks at as many points as your CSU capabilities will allow. Hard-wired loopbacks at the far end are not desirable, because the equalization level adjustments may cause problems.

Every part of this test is executed under firmware control and the result is sent back to the maintenance software. The test is executed by sending digital data through every DS1 channel on this DS1 facility.

This test is executed via the **test ds1-facility UUCSSf external-loopback** command. It is not part of the Long Test Sequence because it requires modifications to the physical connectivity of the DS1 facility.

If there is only one DS1 facility available, system will not allow the last facility to be busied out. In that case, the DS1 CONV circuit pack must be busied out before executing this test.

On a Standard Reliability and High Reliability System (no PNC duplication), if there is only one DS1 facility available, then this test can only be executed at the end-point which is closer to the SPE relative to the neighbor DS1 CONV circuit pack because of its impacts on the system control links. On a Critical Reliability System (PNC Duplication), or when there are multiple DS1 facilities, the test can be executed at any DS1 CONV circuit pack.

If the test passes on a TN1654 DS1 facility, the *round trip delay time* will be displayed in milliseconds in the *Error Code* field. The round trip delay time is defined as the length of time in milliseconds it takes for the firmware to receive the test pattern after it has been sent. This measurement is taken on the last DS1 channel tested.

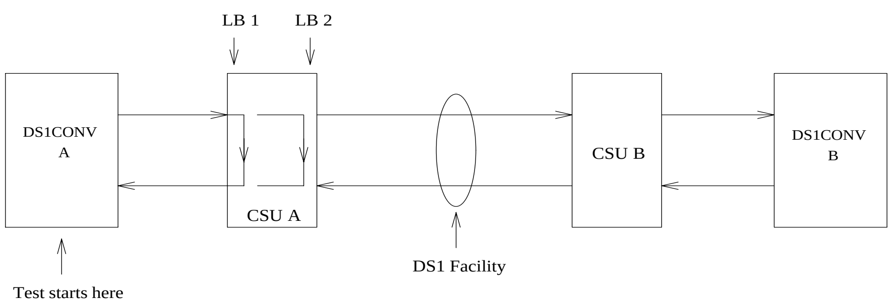

Figure 9-29. Loopback Points for Test #799

Table 9-267. TEST #799 Near-end External Loopback Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test.
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2321	ABORT	DS1 facility is not busied out. Busyout the DS1 facility via the **busyout ds1-facility** command. If there is only one DS1 facility, then busyout the DS1 CONV circuit pack via the **busyout board** command.
2332	ABORT	Test is not allowed to execute at the far end with this system configuration when there is only one DS1 facility available. Check the green LED at the face plate of the DS1 CONV circuit pack. The green LED should be on if the loop is complete.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	Near-end external loopback failed. A problem exists in the path of the loopback. 1. If the test is executed as a part of an error analysis, then return back to the related section. 2. Enter **display errors** and follow the associated repair procedures for any on-board DS1C-BD errors. 3. If the loopback point is **LB 1**, replace connectors and cables between the DS1 CONV A and the CSU A. If the loopback point is **LB 2**, replace CSU A. Also see the repair procedure for error type #1025 (Loss of Frame Alignment). 4. If the test still fails, replace DS1 CONV A circuit pack.
Any	PASS	Transmission through the path of the loopback is successful. TN1654 DS1 facilities will display the round trip delay time in milliseconds in the Error Code field. The round trip delay time is defined as the length of time in milliseconds it takes for the firmware to receive the test pattern after it has been sent. This measurement is taken on the last DS1 channel tested.

Failure Audit (#949)

This test is non-destructive.

This test queries the DS1 CONV circuit pack for any existing circuit pack or facility failures and any unacknowledged cleared failure messages. Upon receiving the query request, DS1 CONV firmware sends failure reports to the maintenance software for every error in its failure database.

This test operates on both maintenance objects DS1C-BD and DS1-FAC. Error counts of both MOs (DS1C-BD and DS1-FAC) that are displayed in the error log will be incremented when this test is executed. This test is executed via the **test board** command. The test is also executed internally by the maintenance software when an alarm is resolved

Table 9-268. TEST #949 Failure Audit

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test.
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The DS1 CONV circuit pack reported failures or retransmitted a cleared failure message. 1. Enter **display errors** and follow the associated repair procedures for any DS1C-BD and DS1-FAC errors.
	PASS	The DS1 CONV circuit pack has no failures.

DS1 CONV-BD

DS1 Converter (Also called DS1 CONV)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DS1 CONV-BD	MAJOR	test board UUCSS sh r 1	DS1 CONV Circuit Pack
DS1 CONV-BD	MINOR	test board UUCSS sh r 1	DS1 CONV Circuit Pack
DS1 CONV-BD	WARNING	test board UUCSS sh r 1	DS1 CONV Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2-44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The DS1 CONV Complex is part of the Port Network Connectivity (PNC) consisting of two TN574 DS1 Converter or two TN1654 DS1 Converter circuit packs connected by one to four DS1 facilities. It is used to extend the range of the 32 Mbps fiber links that connect EPNs to either the PPN or the Center Stage Switch, allowing EPNs to be located at remote sites.

The TN1654 DS1 Converter Circuit pack is a redesign of the TN574 DS1 Converter board. The TN1654 provides functionality equivalent to the TN574 but also adds a 32-Channel E1 interface for international support as well as circuit-switched wideband connections (NxDS0). The TN1654 is supported beginning with DEFINITY Release 5r.

Every error condition reported by the firmware is associated with background tests that the firmware runs autonomously. Demand tests that are executed by the maintenance software do not cause any new error generation by the firmware. However, the Failure Audit test #949 effects auditing of the software error log by forcing the firmware to report the pending errors again.

Maintenance of the DS1 facilities themselves is covered under the “DS1-FAC” maintenance object.

The DS1 CONV Complex can extend a fiber link between two EIs or between an EPN EI and an SNI. Fiber links between two SNIs or between the Processor Port Network (PPN) and the Center Stage Switch (CSS) cannot be extended.

The TN1654 board is not compatible with the TN574 board. A DS1 CONV Complex may consist of two TN574 boards or two TN1654 boards but a TN574 cannot be combined with a TN1654 in the same complex. A system with multiple DS1 CONV-remoted EPNs may contain DS1 CONV Complexes of both types, TN1654 board-pairs and TN574 board-pairs. Critical reliability configurations with a pair of DS1 CONV Complexes serving an EPN require identical board pairs and facilities. For example, a TN574 Complex and a TN1654 Complex may not be used together to serve the same EPN in a critical reliability configuration.

DS1 CONV circuit packs connect to TN570 Expansion Interface (EI) circuit packs and TN573 Switch Node Interface (SNI) circuit packs via metallic cables as shown in Figure 9-30. A fiber link cable can be used instead of the metallic cable if it is necessary to locate the DS1 CONV far from the connected EI or SNI circuit pack, for example, in an adjacent cabinet.

The DS1 CONV circuit pack can be placed in any regular slot in a PN carrier. However, the DS1 CONV circuit pack can only be placed in slots 1 and 21 in a Switch Node (SN) carrier. The DS1 CONV circuit pack is not connected to the TDM bus or the SN backplane. Communication to the circuit pack is done through the connected EI or the SNI circuit packs. Therefore, there is considerable interaction between the DS1 CONVs and the connected EIs and the SNIs. A special "Y" cable connects the DS1 CONV circuit pack to the Fiber Endpoint and to the facilities.

NOTE:
The two DS1 CONV boards, TN1654 and TN574, use unique “Y” cables that are incompatible with each other.

The TN573 SNI circuit pack is incompatible with the TN1654 board. A TN573B or later suffix SNI board must be used when connecting to a TN1654 board. The TN573B SNI board is fully backward compatible with the TN573 board and can be connected to either TN1654 or TN574 boards.

NOTE:
A TN573B or later suffix board must be used when connecting a SNI board to a TN1654 board. Error 125 will be logged and an on-board minor alarm will be generated against the SNI board if it is incompatible with the TN1654 circuit pack.

Figure 9-31 and Figure 9-32 show DS1 CONV connections in a direct connect PNC configuration and between the CSS and an EPN in a Critical Reliability System configuration (duplicated PNC).

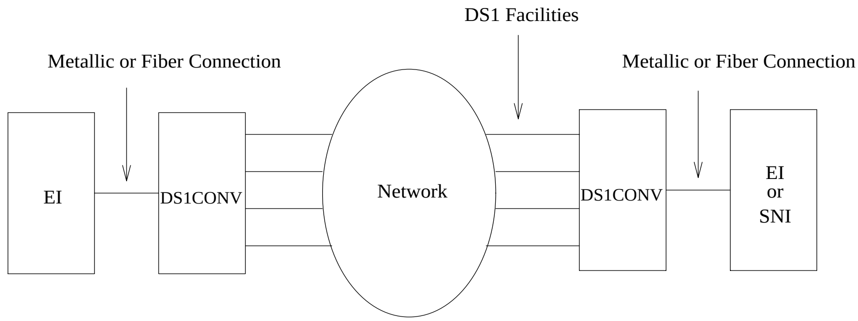

Figure 9-30. DS1 CONV connection to EIs and SNIs

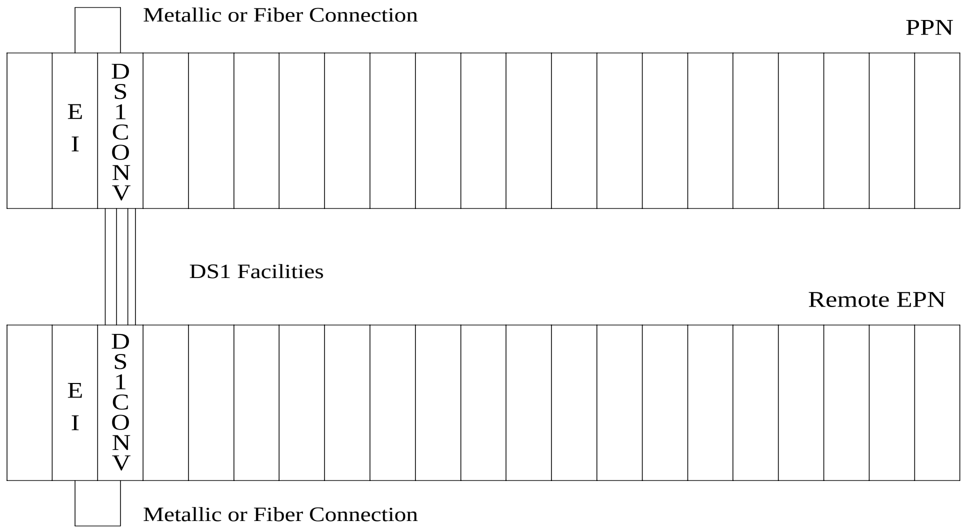

Figure 9-31. DS1 CONV Complex in Direct Connect PNC

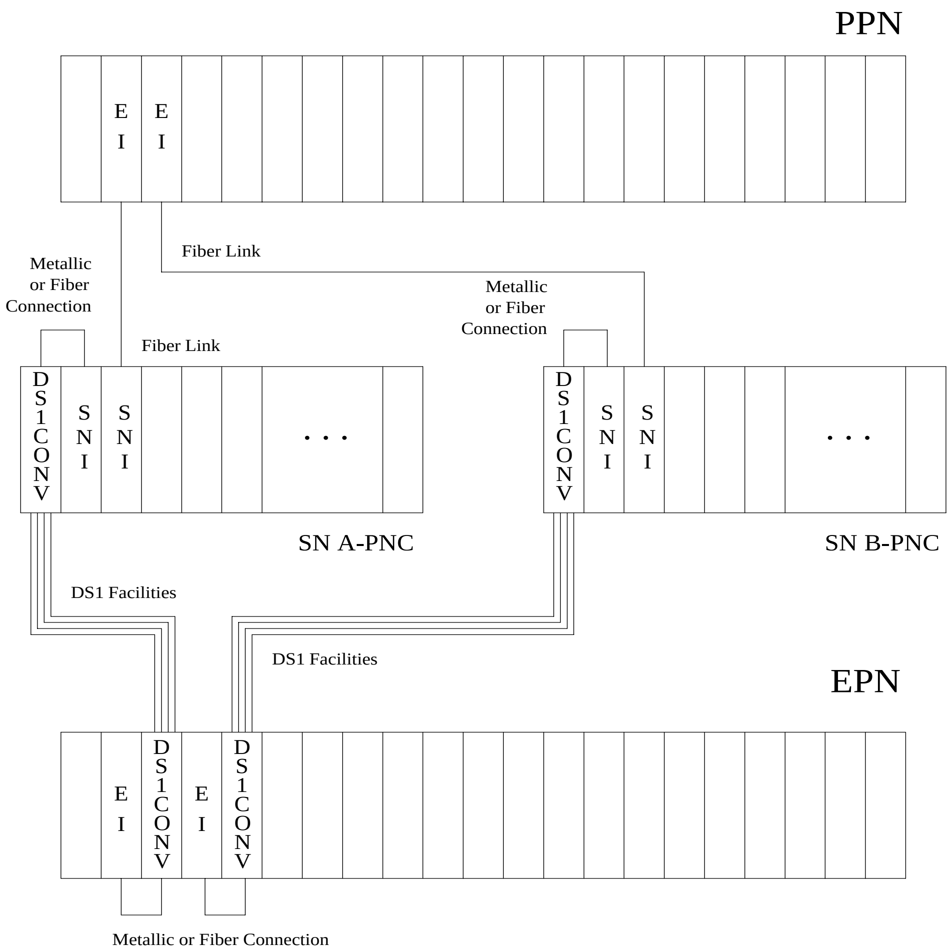

Figure 9-32. DS1 CONV Complex in Duplicated PNC with 1 SN

DS1 CONV Administration and Board Insertion

Board insertion is the detection of a circuit pack by the system. The DS1 CONV circuit pack will not be inserted unless the circuit pack type, TN574 or TN1654, is entered into the associated field in circuit pack administration screen. The Fiber Endpoint (the EI or the SNI) must also be inserted and be operational for the DS1 CONV circuit pack to function.

Fiber link administration must be completed before the DS1 CONV maintenance can be operational. Fiber links are administered via the **add fiber-link** command. Fiber Endpoints, DS1 CONV circuit pack locations and DS1 facility options are entered as a part of the fiber link administration.

Administration steps for a Standard Reliability and High Reliability System (no PNC Duplication) are as follows:

1. Administer carriers via the **add/change cabinet** command
2. Administer circuit packs via the **change circuit-pack** command
3. Administer connectivity and the facility options of the DS1 CONV Complex via the **add/change fiber-link** command

Administration steps for a Critical Reliability System (PNC duplication) are as follows:

1. Enable PNC duplication feature using **change system-parameter customer-option** command
2. Administer carriers via the **add/change cabinet** command
3. Administer circuit packs via the **change circuit-pack** command
4. Administer connectivity and the DS1 facility options of each DS1 CONV Complex via the **add/change fiber-link** command
5. Turn on PNC duplication via the **change system-parameter duplication** command

TN1654 Board Configuration Switch Settings

The TN1654 DS1 CONV circuit pack is field configurable for T1 or E1 operation so that a single board serves worldwide application. All four DS1 facilities are configured to either T1 or E1 as a group via an option switch located on the component side of the circuit pack. If T1 operation is selected, four additional switches are used to select the framing mode for each facility. Each facility can be set to either D4 or ESF framing. If E1 operation is selected, the same four switches are used to select the E1 facility line termination impedance. The E1 line termination impedance for each facility can be set to either 120Ω for twisted-pair or 75Ω for coaxial wiring.

T1 or E1 operation must also be administered for the TN1654 DS1 CONV board on the fiber-link form via the Bit Rate field. An error will be logged and an alarm will be raised if there is a T1/E1 inconsistency between the administered bit rate and the board option switch setting.

The T1 facility framing mode and the E1 facility line termination impedance are defined by the option switch settings only. Administration of these values is not allowed. The fiber-link form will display the selected option switch settings for each facility.

DS1 CONV LEDs

The TN574 board has seven LEDs on its faceplate. The TN1654 board has eleven LEDs on its faceplate. The top three system standard LEDs are used to provide an indication of the state of the DS1 CONV board. These LEDs are under firmware control until the board has established a link to the SPE via the EI or SNI. Once the link is established, software controls the three LEDs. If the link breaks, the LEDs are again under firmware control.

The red and green LEDs have the traditional use where red means an alarm condition and green indicates that maintenance testing is in progress. The red and green LED is also turned on during circuit pack initialization by firmware. When the control link to the circuit pack is lost, firmware controls the red LED to indicate an alarm condition.

The yellow LED under firmware control is used to indicate the state of the physical Fiber Interface, the Fiber Channel (link to EI or SNI), the DS1 Control Channel (link to opposite DS1 CONV board) and the SPE communications link in the following manner and order of priority. (The yellow LED remains on for longer periods of time as the DS1 CONV Complex becomes closer to being fully operational.)

1. If the Fiber is Out of Frame or if a Fiber Loss of Signal condition exists, the yellow LED will flicker at a 5 Hz rate (on for 100 mS, off for 100 mS).
2. If the Fiber Channel is down (DS1 Converter circuit pack/fiber endpoint communications), the yellow LED will flash at a 1 Hz rate (on for 500 mS, off for 500 mS).
3. If the DS1 Control Channel is down between the two DS1 CONVs in the DS1 CONV Complex, the yellow LED will pulse at a 1/2 Hz rate (on for 1 second, off for 1 second).
4. If the SPE communications link is down, the yellow LED will wink off every 2 seconds for 200 ms (2 seconds on, 200 mS off).
5. If all is well with the Fiber Interface and all communications channels, the yellow LED will remain on continuously in a Standard Reliability and High Reliability System configuration. In Critical Reliability systems (duplicated PNC), an active DS1 CONV circuit pack will have its yellow LED on continuously, and a standby DS1 CONV circuit pack will have its yellow LED off. The LED will then be under software control.

The bottom four green LEDs on the TN574 DS1 CONV board are under hardware control. The four green LEDs indicate, for each DS1 CONV facility, whether a receive signal is present for the DS1 facility

The next four LEDs on the TN1654 DS1 CONV board are labeled STATUS LEDs and are for future use. These LEDs will not be lit.

The bottom four LEDs on the TN1654 board are labeled SPAN LEDs. These LEDs are under firmware control. If the facility is not administered, then the LED is not lit. The LED is lit amber if the facility is running alarm free. If the facility is detecting either a red alarm (loss-of-signal or loss-of-frame), a yellow alarm (remote frame alarm) or a blue alarm (AIS signal) then the LED is lit red. The SPAN SELECT Switch on the TN1654 faceplate is for future use. Pushing the switch will have no affect on the board.

Clear Firmware-Counters Command

DS1 CONV firmware generates error reports autonomously. This takes place independently of technician-demanded tests. Therefore, the **test board** UUCSS clear command will not affect the error status reported by firmware. The **clear firmware-counters command will clear all on-board firmware-detected errors unconditionally.**

The **clear firmware-counters** UUCSS command sends a downlink message to the DS1 CONV circuit packs, causing them to clear out their firmware error counters and failure databases. Once the firmware failure database is cleared, the failure audit test (#949) will pass. If problems still exist, the firmware will increment its error counters and the failure audit test will begin failing again.

This command should not be used as a replacement for the repair procedures associated with the hardware error log entries. This command may be useful if a problem has been fixed and off-board alarms associated with the problem are still active.

Downtime required when upgrading to TN1654 DS1 CONV Circuit Packs

WARNING:

Upgrading from TN574 DS1 CONV circuit packs to TN1654 DS1 CONV circuit packs will require down time for the affected EPN.

The TN1654 DS1 Converter circuit pack is not compatible with the TN573 SNI circuit pack, the TN574 DS1 CONV board, the Y-cable used to connect to the TN574 DS1 CONV board or pre-G3V5 software. All DS1 CONV boards and Y-cables must be upgraded. If the EPN is remoted via a Center-Stage Switch, the connected SNI must also be upgraded. A TN573B or later suffix SNI board must be used when connecting to a TN1654 DS1 CONV board.

The fiber-link administration for the TN574 DS1 CONV Complex must be removed via the remove fiber-link command. The change circuit-pack form must be updated to reflect that TN1654 boards are now being used. The TN1654 DS1 CONV Complex can then be administered via the add fiber-link command.

Replacing a DS1 CONV Circuit Pack with the same type DS1 CONV circuit pack—Simplex PNC

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack.

WARNING:
Replacing a Switch Node Interface, Switch Node Clock, Expansion Interface or DS1 Converter circuit pack on a simplex system disrupts service. The service effect can range from outage of a single EPN to outage of the entire system.

WARNING:
A DS1 Converter Complex must consist of two TN574 boards or two TN1654 boards. A TN574 cannot be combined with a TN1654 in the same DS1 CONV Complex.

Steps	Comments
Enter **busyout board** UUCSS	UUCSS represents the cabinet-carrier-slot address of the circuit pack to be replaced. A G3-MT logged in at the EPN Maintenance circuit pack will remain active in spite of the busyout.
Replace the circuit pack with the same DS1 CONV board type.	
Wait for the circuit pack to reset	Red and green LEDs will light and then go out.
Enter **release board** UUCSS	**CAUTION:** *Do not busyout any Expansion Interface circuit pack after this point.*
Enter **test alarms long clear** for category **exp-intf**.	
Wait 5 minutes for SNI-BD, FIBER-LK AND DS1C-BD alarms to clear, or enter **clear firmware counters a-pnc**	

Replacing a DS1 CONV Circuit Pack with the same type DS1 CONV circuit pack—Duplicated PNC

WARNING:
On a system with duplicated PNC, synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WARNING alarm against TDM-CLK with error type 2305. Repairs to standby PNC in this state may disrupt service. Otherwise, if the active PNC is functional, replacement of a standby component will not disrupt service.

Steps	Comments
Enter **status pnc**	Verify that the component to be replaced is on the standby PNC.
Enter **busyout pnc**	
Enter **busyout board** UUCSS	UUCSS represents the cabinet-carrier-slot address of the circuit pack to be replaced.
Replace the circuit pack with the same DS1 CONV board type.	
Enter **release board** UUCSS	**CAUTION:** *Do not busyout any Expansion Interface circuit pack after this point.*
Enter **test alarms long clear** for category **exp-intf**	
Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C-BD alarms to clear, or enter **clear firmware counters <a-pnc or b-pnc>**	Use the letter designation of the pnc which holds the replaced component (the standby pnc).
Enter **status pnc**	If either PNC state-of-health is not "functional", consult the PNC-DUP section of the Maintenance Manual.
Enter **release pnc**	

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack.

WARNING:
Replacing a Switch Node Interface, Switch Node Clock, Expansion Interface or DS1 Converter circuit pack on a simplex system disrupts service. The service effect can range from outage of a single EPN to outage of the entire system.

WARNING:
A DS1 Converter Complex must consist of two TN574 boards or two TN1654 boards. A TN574 cannot be combined with a TN1654 in the same DS1 CONV Complex.

WARNING:
The two DS1 CONV boards, TN1654 and TN574, use unique “Y” cables that are incompatible with each other.

WARNING:
A TN573B or later suffix board must be used when connecting a SNI board to a TN1654 DS1 Converter board.

Steps	Comments
Enter **list fiber-link**	Determine the fiber-link number associated with the two TN574 circuit packs to be upgraded.
Enter **busyout fiber-link** <fiber #>	fiber # represents the fiber-link number associated with the TN574 DS1 CONV Complex that is being upgraded to a TN1654 DS1 CONV Complex.
Enter **remove fiber-link** <fiber #>	
Remove the TN574 DS1 CONV circuit packs from the system.	
Replace the TN574 Y-cables with appropriate TN1654 Y-cables.	
Replace the removed TN574 DS1 CONV circuit packs with TN1654 DS1 CONV circuit packs. Prior to installing the TN1654 boards, review the prior section, *TN1654 Board Configuration Switch Settings*.	
If a TN1654 DS1 CONV board is connected to an SNI board, upgrade the SNI to a TN573B or greater.	
Wait for the circuit packs to reset	Red and green LEDs will light and then go out.

Steps	Comments
Enter **change circuit-packs <cabinet #>**. Update the form to show that TN1654 boards are now being used instead of TN574 boards. Also update the connected SNI, if applicable, to suffix B.	cabinet # represents the cabinet associated with a DS1 CONV board. The appropriate *change circuit-packs* form needs to be updated for both DS1 CONV boards. Also, if needed, re-add translations for connected EI boards.
Enter **add fiber-link** <fiber #> to re-add the fiber-link using TN1654 DS1 CONV circuit packs. See the *Definity Enterprise Communications Server, Release 5, Implementation Manual*, 555-230-302, for details on TN1654 administration.	fiber # represents the fiber-link number associated with the TN574 DS1 CONV Complex that is being upgraded to a TN1654 DS1 CONV Complex
Enter **test alarms long clear** for category **exp-intf**.	
Wait 5 minutes for SNI-BD, FIBER-LK AND DS1C-BD alarms to clear, or enter **clear firmware-counters a-pnc**	

Upgrading TN574 DS1 CONV Circuit Packs in a fiber-link to TN1654s—Duplicated PNC

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack.

WARNING:
In duplicated PNC configurations, one DS1 CONV complex in the fiber-link serves as the active and the second DS1 CONV complex serves as the standby. Each DS1 Converter Complex consists of two TN574 boards or two TN1654 boards. A TN574 cannot be combined with a TN1654 in the same DS1 CONV Complex. It is also required that all four DS1 CONV boards and interconnecting facilities that serve an EPN be of the same type. Note, however, that TN574 and TN1654 boards can coexist within the same system, they just cannot be in the same fiber-link.

WARNING:
The two DS1 CONV boards, TN1654 and TN574, use unique "Y" cables that are incompatible with each other.

WARNING:
A TN573B or later suffix board must be used when connecting a SNI board to a TN1654 DS1 Converter board.

Table 9-269. Upgrading TN574 DS1 CONV Circuit Packs in a fiber-link to TN1654s—Duplicated PNC

Steps	Comments
Enter **status pnc**	Verify that the A-PNC is active. If the B-PNC is active, enter the reset pnc interchange command to cause the A-PNC to go active.
Enter **busyout pnc-standby**	Fiber link can not be removed if PNC duplication is operational. Must busyout the standby PNC first.
Enter change system-parameters duplication. Change the `Enable Operation of PNC Duplication?` field to n.	Disable PNC duplication.
Enter **list fiber-link**	Determine the fiber-link number that the four TN574 circuit packs to be upgraded are associated with.
Enter **busyout fiber-link** <fiber #>	fiber # represents the fiber-link number associated with the TN574 DS1 CONV Complexes that are being upgraded to TN1654 DS1 CONV Complexes.
Enter **remove fiber-link <fiber #>**	
Remove the four TN574 DS1 CONV circuit packs from the system.	
Replace the TN574 Y-cables with appropriate TN1654 Y-cables.	
Replace the removed TN574 DS1 CONV circuit packs with TN1654 DS1 CONV circuit packs. Prior to installing the TN1654 boards, review the prior section, *TN1654 Board Configuration Switch Settings*.	
If a TN1654 DS1 CONV board is connected to an SNI board, upgrade the SNI to a TN573B or greater.	

Continued on next page

Table 9-269. Upgrading TN574 DS1 CONV Circuit Packs in a fiber-link to TN1654s—Duplicated PNC — *Continued*

Steps	Comments
Wait for the circuit packs to reset	Red and green LEDs will light and then go out.
Enter **change circuit-packs <cabinet #>**. Update the form to show that TN1654 boards are now being used instead of TN574 boards. Also update the connected SNI, if applicable, to suffix B.	cabinet # represents the cabinet associated with a DS1 CONV board. The appropriate *change circuit-packs* form needs to be updated for all four DS1 CONV boards. Also, if needed, re-add translations for connected EI boards.
Enter **change system-parameters duplication**. Change the `Enable Operation of PNC Duplication?` field to y.	Enable PNC duplication.
Enter **add fiber-link** <fiber #> to re-add the fiber-link using TN1654 DS1 CONV circuit packs. See the *Definity Enterprise Communications Server, Release 5, Implementation Manual*, 555-230-302, for details on TN1654 administration.	fiber # represents the fiber-link number associated with the TN574 DS1 CONV Complexes that are being upgraded to TN1654 DS1 CONV Complexes.
Enter **test alarms long clear** for category **exp-intf**.	
Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK and DS1C-BD alarms to clear, or enter **clear-firmware counters <a-pnc or b-pnc>**	
Enter **status pnc**	If either PNC State of Health is not "functional", consult the PNC-DUP section of the Maintenance Manual.

Converting DS1-CONV complex to direct-connect fiber (duplicated PNC)

NOTE:
The procedure below is generic in its scope. Check the customer's switch configuration for EI/SNI structures.

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack.

WARNING:
In duplicated PNC configurations, one DS1-CONV complex in the fiber-link serves as the active and the second DS1-CONV complex serves as the standby. Each DS1 Converter Complex consists of two TN574 or TN1654 circuit packs.

Table 9-270. Convert from DS1-CONV to direct-connect fiber in a duplicated PNC

√	#	Command/Step	Description
	1.	**status pnc**	Verify that the A-side is active. 1. If the B-PNC is active, enter **reset pnc-interchange** and press Enter. 2. Then verify that the A-side is active (**status pnc**).
	2.	**busyout pnc-standby**	Busyout the duplicated switch side.
	3.	**change system-parameters duplication**	Disable PNC duplication by changing the `Enable Operation of PNC Duplication?` field to **n**.
	4.	**list fiber-link**	Lists administered fiber connections by number. Select the link number associated with the appropriate DS1-CONV complex that you are removing.
	5.	**busyout fiber link *n***	Busyout the fiber link of interest. The fiber link number (Step 6) is **n** for this command.
	6.	**remove fiber link *n***	Remove the link administration for this link.
	7.	**change circuit-pack *cabinet***	Remove the DS1-CONV administration for the four designated circuit packs (***cabinet*** is the cabinet number where these DS1-CONV complexes reside). Press Enter.

Continued on next page

Table 9-270. Convert from DS1-CONV to direct-connect fiber in a duplicated PNC — *Continued*

√	#	Command/Step	Description
	8.	Remove the DS1- CONV hardware	Remove the 4 TN574 or TN1654 DS1-CONV circuit packs and Y-cables. **NOTE:** The TN1654 and TN574 DS1-CONV boards use unique "Y" cables that are incompatible with each other. Reuse these cables only with the proper circuit pack.
	9.	Install Fiber-Optic Cable	Add the lightwave transceivers (multi-mode 9823A or single-mode 300A) to match the lightguide fiber. Add these to the EI's and SNI's formerly connected to the DS1 CONV circuit packs. Connect the lightwave transceivers with appropriate lightguide fiber.
	10.	Check fiberoptic cable connections	Ensure that the fiberoptic cables are securely connected to the lightwave transceivers that are attached to the designated circuit packs through the connections on the back of the cabinet.
	11.	**add fiber-link *n***	Administer the new EI/SNI fiber connection
	12.	**change system-parameters duplication**	Enable PNC duplication by changing the `Enable Operation of PNC Duplication?` field to **y**.
	13.	Enter **test alarms long clear** for category **exp-intf**.	
	14.	Wait 5 minutes	SNI-BD, SNI-PEER, FIBER-LK and EXP-INTF maintenance objects need time to clear (or enter **clear firmware-counters *a-pnc*** or ***b-pnc*)**
	15.	Enter **status pnc**	If the A-PNC or B-PNC State of Health is not `functional`, consult the PNC-DUP maintenance object.

Removing Fiber Connectivity to an EPN

This procedure covers removing the connectivity to an EPN or between SN's. Removing an EPN and its associated carrier and circuit packs can be handled on a board-type basis.

If this system is duplicated, start with Step 1; otherwise, start with Step 6.

NOTE:
The procedure below is generic in its scope. Check the customer's switch configuration for EI/SNI structures.

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack.

WARNING:
In duplicated PNC configurations, one DS1-CONV complex in the fiber-link serves as the active and the second DS1-CONV complex serves as the standby. Each DS1Converter Complex consists of two TN574 or TN1654 circuit packs.

Table 9-271. Removing Fiber Connectivity to an EPN

√	#	Command/Step	Description
	1.	**status pnc**	Verify that the A-side is active. a. If the B-PNC is active, enter **reset pnc-interchange** and press Enter. b. Then verify that the A-side is active (**status pnc**).
	2.	**busyout pnc standby**	Busyout the duplicated switch side.
	3.	**change system-parameters duplication**	Disable PNC duplication by changing the `Enable Operation of PNC Duplication?` field to **n**.
	4.	**list fiber link**	List administered fiber connections by number. Record the end points (EI's, SNI's, and DS1C's), and fiber link numbers that you are removing.
	5.	**busyout fiber link *n***	Busyout the fiber link of interest. The fiber link number (Step 4) is ***n*** for this command.
	6.	**remove fiber link *n***	Remove the link administeration for this link.

Continued on next page

Table 9-271. Removing Fiber Connectivity to an EPN — *Continued*

√	#	Command/Step	Description
	7.	**change system-parameters duplication**	Enable PNC duplication by changing the `Enable Operation of PNC Duplication?` field to **y**.
	8.	Physically remove the a-pnc and b-pnc fiber end-point circuit packs	Physically remove EI, SNI, and DS1C circuit packs associated with the **b-pnc**.
	9.	**change circuit-pack**	Un-administer the PNC circuit packs.
	10.	**clear firmware**	Clear any alarms or errors against those circuit packs.
	11.	**status pnc**	Use the **status pnc** command to ensure that the PNC is in good health.

Downgrade Procedure to Go from Critical to High Reliability

The strategy this downgrade follows is to change from Critical Reliability to Standard Reliability and then follow the normal up-grade path for Standard Reliability to High Reliability. High Reliability is actually a Processor (SPE) duplication with multiple paths from PPN to CSS (both paths are active).

Table 9-272. Downgrade Procedure to Go from Critical to High Reliability

√	#	Command/Step	Description
	1.	**status pnc**	Check to see if A-side is active. If not: a. Resolve any alarms against **a-pnc**. b. **reset pnc-interchange** to activate **a-pnc**.
	2.	**busyout pnc-standby**	Busyout the duplicated switch side.
	3.	**change system-parameters duplication**	Disable PNC duplication by changing the `Enable Operation of PNC Duplication?` field to **n**.
	4.	**list fiber**	Lists administered fiber connections by number.

Continued on next page

Table 9-272. Downgrade Procedure to Go from Critical to High Reliability — *Continued*

√	#	Command/Step	Description
	5.	**change fiber *n***	Change fiber removes the b-pnc end points (EI, DS1Cs, if equipped). ***n*** is the number of the fiber from Step 4. Repeat this step for all fibers from Step 4.
	6.	Physically remove the b-pnc end-point circuit packs	Start with the switch carrier most distant from the SPE. Physically remove EI, SNI, and SNC circuit packs associated with the **b-pnc**. Remove fiber cable not used for b-pnc carriers.
	7.	**change circuit pack**	Up-date the translations for the removed circuit packs using the **change circuit pack** command for the: ■ Cabinet with b-pnc SN carrier — SNI's — SNC's — EI's and DS1C's, if any ■ Cabinet with b-pnc SN carrier — DS1C's from port carrier ■ Cabinet with b-pnc EI's in all EPN's (also DS1C's, if equipped)
	8.	**change cabinet UUC**	Remove the b-pnc SN carrier. **See the following CAUTION.**
	9.	**change system-parameters customer options disable duplication**	Disable PNC duplication by changing the `Enable Operation of PNC Duplication?` field to **n**.

CAUTION:
The removal of hardware and fiber cable will interrupt service.

NOTE:
At this point in the down-grade procedure, the system is in Simplex mode and is operational. The physical removal of the SN carriers may be done at a time that is convenient for the customer. The next step in the down-grade is to follow the normal up-grade procedures for Simplex to High Reliability.

Error Log Entries and Test to Clear Values

Table 9-273. DS1 CONV Board Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS sh r 1
1(a)		Failure Audit Test #949	MAJOR	ON/OFF	test board UUCSS sh r 1
18(b)	0	busyout board UCSS	WNG	OFF	release board UCSS
125(c)	3	None	MINOR	ON	
218(d)	any	None	MAJOR	ON	
257(e)		Failure Audit Test #949	MINOR	ON	test board UUCSS sh r 1
513(f)	1	Failure Audit Test #949	MAJOR	ON	test board UUCSS sh r 1
513(g)	2	Failure Audit Test #949	MAJOR	ON	test board UUCSS sh r 1
513(h)	3	Failure Audit Test #949	MAJOR	ON	test board UUCSS sh r 1
513(i)	4	Failure Audit Test #949	MAJOR	ON	test board UUCSS sh r 1
513(j)	5	Failure Audit Test #949	MAJOR	ON	test board UUCSS sh r 1
769(k)	1	Failure Audit Test #949	MINOR	ON/OFF	test board UUCSS sh r 1
769(l)	2	Failure Audit Test #949	MINOR	ON/OFF	test board UUCSS sh r 1
769(m)	3	Failure Audit Test #949	MINOR	ON/OFF	test board UUCSS sh r 1
769(n)	5	Failure Audit Test #949	MINOR	ON/OFF	test board UUCSS sh r 1
769(o)	6	Failure Audit Test #949	MINOR	ON	test board UUCSS sh r 1
769(p)	7	Failure Audit Test #949	MINOR	ON	test board UUCSS sh r 1
1281(q)		Failure Audit Test #949	MINOR	OFF	test board UUCSS sh r 1
1537(r)		Failure Audit Test #949	MAJOR	OFF	test board UUCSS sh r 1
1793(s)		Failure Audit Test #949	MAJOR	OFF	test board UUCSS sh r 1

Continued on next page

Table 9-273. DS1 CONV Board Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
2049(t)		Failure Audit Test #949	MAJOR	OFF	test board UUCSS sh r 1
3329(u)		Failure Audit Test #949	WNG	OFF	test board UUCSS sh r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

When problems persist, resetting the DS1 CONV circuit pack via the **reset board** command may temporarily resolve the error condition and restore service until further assistance is provided.

a. If the alarm is on board, then a major hardware error has occurred in a common part of the circuit pack, not circuit or packet specific. Replace the DS1 CONV circuit pack.

   If the alarm is off board, then either a major hardware error has occurred in a common part of the circuit pack, or a good clock signal cannot be recovered from the synchronization source. The synchronization source can be the fiber link or any one of the DS1 facilities.

   1. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
   2. Enter **display errors** and follow the associated repair procedures for any FIBER-LK and DS1-FAC errors.
   3. If the problem persists, replace the DS1 CONV circuit pack.

b. This error indicates that the DS1 CONV circuit pack has been busied out via the **busyout board** command. To resolve this error, release the DS1 CONV circuit pack via the **release board** command.

c. The 24/32-channel option switch setting on the TN1654 circuit pack does not match the administered Bit Rate on the fiber-link form. If the on-board switch setting is wrong, the circuit pack must be physically removed to change the setting of the board option switch. If the administered bit rate is wrong, use the change fiber-link command to correct it.

d. The DS1 CONV board is physically installed in a slot different than its administered slot. Remove the DS1 CONV board and install it in its administered slot or execute the remove fiber-link command followed by the add fiber-link command to re-add the fiber-link setting the DS1 CONV board's administered location to the physically installed slot.

e. A minor hardware error has occurred in a common part of the circuit pack, not circuit or packet specific. Replace the DS1 CONV circuit pack.

f. A major hardware problem has occurred that affects only circuit data being received from the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

g. A major hardware problem has occurred that affects only circuit data being transmitted from the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

h. A major hardware problem has occurred that affects only packet data being received from the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

i. A major hardware problem has occurred that affects only packet data being transmitted from the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

j. A major lightwave transceiver transmit error occurred that affects data transmitted from the fiber link to the DS1 facility. Replace the DS1 CONV circuit pack.

k. *This error only applies to TN574 DS1 CONV circuit packs*.

If the alarm is on board, then a minor hardware problem has occurred that affects only circuit data being received from the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

If the alarm is off board, then either a minor hardware problem has occurred that affects only circuit data being received into the DS1 CONV circuit pack or a good clock signal cannot be recovered from one of the DS1 facilities.

1. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
2. Enter **display errors** and follow the associated repair procedures for any DS1-FAC errors.
3. If the problem persists, replace the DS1 CONV circuit pack.

l. *This error only applies to TN574 DS1 CONV circuit packs*.

If the alarm is on board, then a minor hardware problem has occurred that affects only circuit data being transmitted from the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

If the alarm is off board, then either a minor hardware problem has occurred that affects only circuit data being transmitted from the DS1 CONV circuit pack or a good clock signal cannot be recovered from the fiber channel.

1. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
2. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, SNI-BD, and FIBER-LK errors.
3. If the problem persists, replace the DS1 CONV circuit pack.

m. *This error only applies to TN574 DS1 CONV circuit packs*.

If the alarm is on board, then a minor hardware problem has occurred that affects only packet data being received from the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

If the alarm is off board, then either a minor hardware problem has occurred that affects only packet data being received from the DS1 CONV circuit pack or corrupted packets are being received from the packet facility.

1. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, SNI-BD, and DS1-FAC errors.
2. If the problem persists enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
3. If the problem still persists, replace the DS1 CONV circuit pack.

n. If the alarm is on board, then a minor FOI transmit error occurred that affects data transmitted from the fiber link to the DS1 facility. Replace the DS1 CONV circuit pack.

If the alarm is off board, then either a minor FOI transmit error occurred that affects data transmitted from the fiber link to the DS1 facility. or corrupted packets are being received from the packet facility.

1. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, SNI-BD, and DS1-FAC errors.
2. If the problem persists enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
3. If the problem still persists, replace the DS1 CONV circuit pack.

o. A minor FOI receive error occurred that affects data received from the DS1 facility and transmitted to the fiber link. Replace the DS1 CONV circuit pack.

p. A minor on-board hardware failure exists on the processor/control hardware on the DS1 CONV circuit pack. Replace the DS1 CONV circuit pack.

q. For TN574 DS1 CONV boards, this error indicates that the facility masks or the clock reference masks do not match between the two DS1 CONV circuit packs in the DS1 CONV Complex.

For TN1654 DS1 CONV boards, this error indicates that the facility masks do not match between the two DS1 CONV circuit packs in the DS1 CONV Complex.

Alarm should clear in 15 minutes.

1. If the problem persists, reset both DS1 CONV circuit packs in the DS1 CONV Complex via the **reset board** command.
2. If the problem persists, replace this DS1 CONV circuit pack.
3. If the problem persists, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.

r. The two TN574 DS1 CONV circuit packs in the DS1 CONV complex do not have the same firmware vintage. The TN574 DS1 CONV with the older vintage should be replaced. This error does not apply to TN1654 boards.

s. Fiber Loss of Frame Alignment (LFA) alarm occurred at the other end of the DS1 CONV Complex. The DS1 CONV circuit pack at the other end of the DS1 CONV Complex cannot frame up on the signal coming into the circuit pack from the fiber. (The neighbor DS1 CONV circuit pack detected the LFA and relayed this information to this DS1 CONV circuit pack via the DS1 Control Channel.) The yellow LED will flicker at a 5 Hz rate (on for 100 mS, off for 100 mS).

1. Execute the **list fibers** command to determine the Fiber Endpoint that is connected to the DS1 CONV circuit pack. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints. Enter **display errors** and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
2. If the problem still persists, check for excessive slips and synchronization problems. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
3. If the problem still persists, run the Far-end DS1 CONV Circuit Pack Loopback test #788 on this DS1 CONV circuit pack via the **test board UUCSS long** command. This test will indicate if the neighbor DS1 CONV circuit pack hardware is functioning. If this test fails, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.

4. If the problem still persists, run the Far-end Fiber Optic Terminator (lightwave transceiver) Loopback test #789 on this DS1 CONV circuit pack via the **test board UUCSS long** command. If this test fails, replace the lightwave transceiver that is connected to the neighbor DS1 CONV circuit pack at the other end of the DS1 CONV Complex. (If the neighbor board is connected to the Fiber Endpoint via metallic cable, then this test will abort.)
5. If the problem still persists, replace connectors and the cable between the neighbor DS1 CONV circuit pack and the Fiber Endpoint at the other end of the DS1 CONV Complex. The cable may be a fiber or a metallic cable.

t. Fiber Loss of Signal (LOS) alarm occurred at the other end of the DS1 CONV Complex. The DS1 CONV circuit pack at the other end of the DS1 CONV Complex does not detect a signal coming into the circuit pack from the fiber. (The neighbor DS1 CONV circuit pack detected the LOS and relayed this information to this DS1 CONV circuit pack via the DS1 Channel.) The yellow LED will flicker at a 5 Hz rate (on for 100 mS, off for 100 mS).

1. Execute the **list fibers** command to determine the Fiber Endpoints that are connected to both ends of this DS1 CONV Complex. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints that are administered on this fiber link, and Enter **display errors** and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
2. If the problem still persists, run the Far-end DS1 CONV Circuit Pack Loopback test #788 on this DS1 CONV circuit pack via the **test board UUCSS long** command. This test will show if the neighbor DS1 CONV circuit pack hardware is functioning. If this test fails, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex.
3. If the problem still persists, run the Far-end Fiber Optic Terminator (lightwave transceiver) Loopback test #789 on this DS1 CONV circuit pack via the **test board UUCSS long** command. If this test fails, replace the lightwave transceiver that is connected to the neighbor DS1 CONV circuit pack. (If the neighbor board is connected to the Fiber Endpoint via metallic cable, then this test will abort.)
4. If the problem persists, replace connectors and the cable between the neighbor DS1 CONV circuit pack and the Fiber Endpoint at the other end of the DS1 CONV Complex. The cable may be fiber or metallic.

u. This error indicates that excessive slips have occurred on the fiber link between the DS1 CONV board and the Fiber Endpoint. See MO SYNC for diagnosing slip problems.

System Technician-Demanded Tests: Descriptions And Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Failure Audit* for example, you may also clear errors generated from other tests in the testing sequence. Tests 788 and 789 are executed by the TN574 DS1 Converter circuit pack only.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Failure Audit (#949)	X	X		ND
DS1 Facilities Connectivity Test (#790)		X		D
Far-end DS1 CONV Circuit Pack Loopback Test (#788) (Executed by TN574 only)		X		D
Far-end Lightwave Transceiver Loopback Test (#789) (Executed by TN574 only)		X		D
Board Options Audit (#795)	X	X		ND
Reset Test (#787)			X	D

1. D = Destructive; ND = Nondestructive

NOTE:
Test #984 is not an actual demand maintenance test. This test number is used to report results of the **clear firmware-counters** command. Refer to the table for Test #949 to interpret ABORT codes for Test #984.

Reset Test (#787)

This test is destructive.

DS1 CONV circuit pack is reset via the **reset board** command. When the circuit pack is reset, firmware executes a series of diagnostic tests on the circuit pack. The results of these tests are queried from the board when the board is inserted after completion of the reset sequence. If any one of the diagnostic test fails, the error log will have an entry of error type 1 for this circuit pack location, and the alarm log will have an entry of ON-BOARD MAJOR alarm.

The reset sequence will take about one minute to complete.

Table 9-274. TEST #787 Reset Board

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2321	ABORT	DS1 CONV circuit pack is not busied out. Busyout the DS1 CONV circuit pack via the **busyout board** command.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	Reset sequence was executed successfully. This test result does not indicate if the firmware diagnostic tests have passed. Display error log via the **display errors** command to see if any one of the diagnostic firmware test have failed, this will be indicated by an entry of error type 1 for this circuit pack location, and the alarm log will have an entry of ON-BOARD MAJOR alarm, display the alarm log via the **display alarms** command.
0	NO BOARD	The system software found no board. 1. Reset the board. 2. Remotely retry the command.

Far-end DS1 Converter Circuit Pack Loopback Test (#788)

This test is destructive.

This test is executed by the TN574 DS1 Converter circuit pack only. Test #790 covers this testing for the TN1654 DS1 Converter.

This test starts at the DS1 CONV circuit pack whose equipment location was entered and loops all fiber timeslots at the far edge Fiber Optic Interface of the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. See diagram below.

Every part of this test is executed under firmware control and the result is sent back to the maintenance software. Test is executed by sending digital data through every administered DS1 facility channel. Two different test patterns are used, these are hexadecimal values 55 and AA.

On a Standard Reliability and High Reliability System (no PNC duplication), this test can only be executed at the end-point which is closer to the SPE relative to the neighbor DS1 CONV circuit pack because of its impacts on the system control links, also the completion of the test will be delayed in this configuration to wait for the recovery of the system control links. On a Critical Reliability System (PNC Duplication), test can be executed at any DS1 CONV circuit pack.

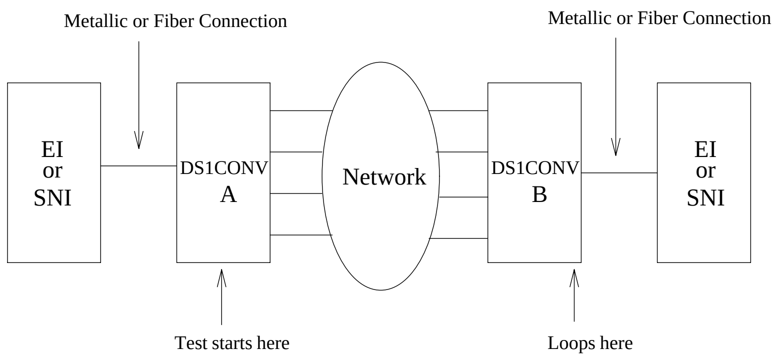

Figure 9-33. Far-end DS1 CONV Loopback Test (#788)

Table 9-275. TEST #788 Far-end DS1 Converter Board Loopback Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent to the selected DS1C board.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-275. TEST #788 Far-end DS1 Converter Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2321	ABORT	DS1 CONV circuit pack is not busied out. Busyout the DS1 CONV circuit pack via the **busyout board** command.
2332	ABORT	The test was aborted because it cannot be run at the far-end with this system configuration (PNC simplex) when there is only one DS1-FAC available (the link would be lost and no test results would be seen at the SPE). Run the test at the other end of the DS1C complex.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	Far-end DS1 CONV loopback failed. A problem exists between the DS1 CONV A and the DS1 CONV B (see diagram above). 1. If there are facilities that are not **digital data compatible**, then busyout those facilities via the **busyout ds1-facility** command. 2. If the test is executed as a part of an error analysis, then return back to the related section. 3. Enter **display errors** and follow the associated repair procedures for any on-board DS1C-BD errors on this DS1 CONV circuit pack and the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. Enter **display errors** and follow the associated repair procedures for any DS1-FAC errors on the DS1 facilities. 4. Check the DS1 Converter Measurements Report to see if there are facilities with excessive errors, execute command **list measurements ds1-facility summary**. If there are facilities with excessive errors, execute Far-end Internal Loopback test #797 on those facilities, and follow repair procedures described for the test. 5. If the test still fails, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. 6. If the test still fails, replace this DS1 CONV circuit pack.
	PASS	Transmission through the path of the loopback is successful.
0	NO BOARD	The system software found no board. 1. Reset the board. 2. Remotely retry the command.

Far-end Lightwave Transceiver Loopback Test (#789)

This test is destructive.

This test is executed by the TN574 DS1 Converter circuit pack only. Test #790 covers this testing for the TN1654 DS1 Converter.

This test starts at the DS1 CONV circuit pack whose equipment location was entered and loops at the Fiber Optic Terminator (lightwave transceiver) that is connected to the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. See diagram below.

Every part of this test is executed under firmware control and the result is sent back to the maintenance software. Test is executed by sending digital data through every DS1 facility channel. Two different test patterns are used, these are hexadecimal values 55 and AA.

On a Standard and High Reliability System (no PNC duplication), this test can only be executed at the end-point which is closer to the SPE relative to the neighbor DS1 CONV circuit pack because of its impacts on the system control links, also the completion of the test will be delayed in this configuration to wait for the recovery of the system control links. On a Critical Reliability System (PNC Duplication), test can be executed at any DS1 CONV circuit pack.

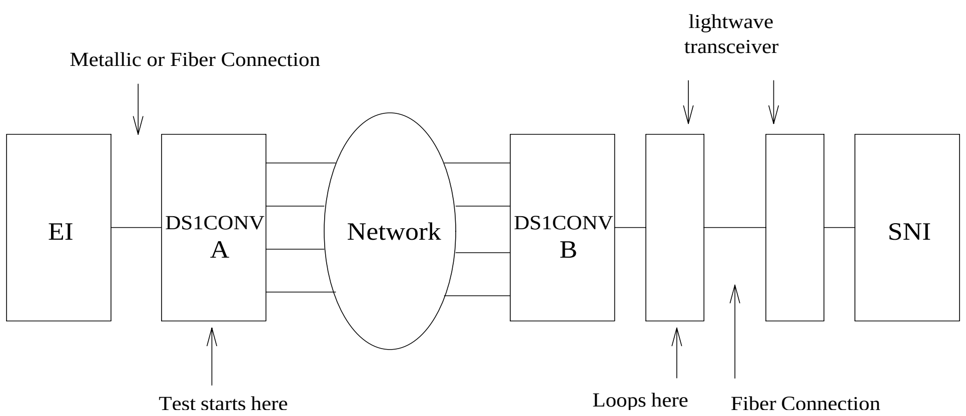

Figure 9-34. Far-end Lightwave Transceiver Loopback Test

Table 9-276. TEST #789 Far-end FOT (Lightwave Transceiver) Loopback Test

Error Code	Test Result	Description/ Recommendation
1410	ABORT	The test aborted because no lightwave transceiver is present. The neighbor DS1 CONV circuit pack and the fiber endpoint are connected via metallic cable. This abort may be ignored.
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2321	ABORT	DS1 CONV circuit pack is not busied out. Busyout the DS1 CONV circuit pack via the **busyout board** command.
2332	ABORT	The test was aborted because it cannot be run at the far-end with this system configuration (PNC simplex) when there is only one DS1-FAC available (the link would be lost and no test results would be seen at the SPE). Run the test at the other end of the DS1C complex.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-276. TEST #789 Far-end FOT (Lightwave Transceiver) Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Far-end lightwave transceiver loopback failed. A problem exists between the DS1 CONV A and the lightwave transceiver connected to the DS1 CONV B (see diagram above). 1. If there are facilities that are not **digital data compatible**, then busyout those facilities via the **busyout ds1-facility** command. 2. If the test is executed as a part of an error analysis, then return back to the related section. 3. Enter **display errors** and follow the associated repair procedures for any on-board DS1 CONV-BD errors on this DS1 CONV circuit pack and the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. Enter **display errors** and follow the associated repair procedures for any DS1-FAC errors on the DS1 facilities. 4. Check the DS1 Converter Measurements Report to see if there are facilities with excessive errors, execute command **list measurements ds1-facility summary**. If there are facilities with excessive errors, execute Far-end Internal Loopback test #797 on those facilities, and follow repair procedures described for the test. 5. If the test still fails, replace the lightwave transceiver device that is connected to the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. 6. If the test still fails, replace the DS1 CONV circuit pack at the other end of the DS1 CONV Complex. 7. If the test still fails, replace this DS1 CONV circuit pack.
	PASS	Transmission through the path of the loopback is successful.
0	NO BOARD	The system software found no board. 1. Reset the board. 2. Remotely retry the command.

DS1 Facilities Connectivity Test (#790)

This test is destructive.

The DS1 facilities connectivity test will check the correct connectivity of the DS1 facilities at opposite ends of the DS1 CONV Complex. Every part of this test is executed under firmware control and the result is sent back to the maintenance software.

For TN574 DS1 Converter circuit packs, this test is executed by sending digital data through each timeslot of every DS1 facility channel. Two different test patterns are used, these are hexadecimal values 55 and AA.

For TN1654 DS1 Converter circuit packs, this test has been enhanced to provide error codes that point to the exact fault. Rather than simply reporting a failure of the connectivity test, the TN1654 test specifically identifies the two DS1 facilities that are cross-connected at the near and far ends of the DS1 converter complex. In addition, a fault code will indicate the condition of not being able to loop-up the far-end as required to run the test due to the packet DS1 facility being down.

The TN1654 connectivity test sends digital data through only one timeslot. Instead of looping back the facility to itself, the TN1654 version of the test loops-up the other three facilities. If the test pattern comes back, the firmware fails the test due to an incorrect connection between DS1 facilities. It should be noted that this test will pass and give no indication of problems if the non-packet facilities are down.

On a Standard and High Reliability System (no PNC duplication), this test can only be executed at the end-point which is closer to the SPE relative to the neighbor DS1 CONV circuit pack because of its impacts on the system control links. In addition, for TN574 DS1 CONV boards, the completion of the test will be delayed in this configuration to wait for the recovery of the system control links. On a Critical Reliability System (PNC Duplication), test can be executed at any DS1 CONV circuit pack.

Table 9-277. TEST #790 DS1 Facilities Connectivity Loopback Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.
2321	ABORT	DS1 CONV circuit pack is not busied out. Busyout the DS1 CONV circuit pack via the **busyout board** command.
2332	ABORT	The test was aborted because it cannot be run at the far-end with this system configuration (PNC simplex) when there is only one DS1-FAC available (the link would be lost and no test results would be seen at the SPE). Run the test at the other end of the DS1C complex.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-277. TEST #790 DS1 Facilities Connectivity Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	TN574 DS1 facilities connectivity loopback test failed.
1	FAIL	TN1654 Near-end DS1 facility A is connected to far-end DS1 facility B.
2	FAIL	TN1654 Near-end DS1 facility A is connected to far-end DS1 facility C.
3	FAIL	TN1654 Near-end DS1 facility A is connected to far-end DS1 facility D.
10	FAIL	TN1654 Near-end DS1 facility B is connected to far-end DS1 facility A.
12	FAIL	TN1654 Near-end DS1 facility B is connected to far-end DS1 facility C.
13	FAIL	TN1654 Near-end DS1 facility B is connected to far-end DS1 facility D.
20	FAIL	TN1654 Near-end DS1 facility C is connected to far-end DS1 facility A.
21	FAIL	TN1654 Near-end DS1 facility C is connected to far-end DS1 facility B.
23	FAIL	TN1654 Near-end DS1 facility C is connected to far-end DS1 facility D.
30	FAIL	TN1654 Near-end DS1 facility D is connected to far-end DS1 facility A.
31	FAIL	TN1654 Near-end DS1 facility D is connected to far-end DS1 facility B.
32	FAIL	TN1654 Near-end DS1 facility D is connected to far-end DS1 facility C.
55	FAIL	TN1654 DS1 CONV packet facility is down and can’t send loop-up message to the far-end. 1. Enter **display errors** and follow the associated repair procedures for any DS1-FAC errors on the DS1 facilities at both ends of the DS1 CONV Complex. If an alarm exists on a DS1 facility, then this test will fail. 2. Check the DS1 connections, both circuit packs should have their DS1 facilities connected identically. 3. Check the DS1 Converter Measurements Report to see if there are facilities with excessive errors, execute command **list measurements ds1-facility summary**. If there are facilities with excessive errors, execute Far-end Internal Loopback test #797 via the **test ds1-facility UUCSSf long** command on those facilities, and follow repair procedures described for the test. 4. Both circuit packs may not have the same translation information. Run the Board Options Audit test #795 via the **test board UUCSS short** command for both circuit packs in the DS1 CONV Complex to send the options, and check the results of this audit test. This test will not pass until the audit test problems are resolved.
	PASS	DS1 facility connections are correct.
0	NO BOARD	The system software found no board. 1. Reset the board. 2. Remotely retry the command.

Board Options Audit (#795)

This test is non-destructive.

This test sends the administered circuit pack options to the DS1 CONV circuit pack. Options are sent to both DS1 CONV circuit packs at the same time to prevent any transitional mismatch of options.

The following data is sent to the TN574 DS1 CONV circuit pack: system reliability configuration, master and slave end-points for framing (this is determined by the relative position of the circuit pack to the SPE), the facility mask (if each facility is installed), clock reference mask (whether each facility can be used as a clock reference source and whether the board is being used as a Network Timing Source), packet compatible mask (whether each facility is packet compatible) and facility information for line coding, framing mode, and line compensation.

The following data is sent to the TN1654 DS1 CONV circuit pack: system reliability configuration, master and slave end-points for framing (this is determined by the relative position of the circuit pack to the SPE), the facility mask (whether each facility is installed), idle code, CRC enabled/disabled flag (sent in E1 mode only) and facility information for line coding and line compensation (sent in T1 mode only).

Table 9-278. TEST #795 Board Options Audit

Error Code	Test Result	Description/ Recommendation
105	ABORT	The neighbor DS1 CONV circuit pack at the other end of the DS1 CONV Complex is not accessible (only applies to TN574 boards with vintage less than 7). 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. The link to the other end of the DS1 CONV Complex may be down. Enter **display errors** and follow the associated repair procedures for any DS1C-BD and DS1-FAC errors.
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.

Continued on next page

Table 9-278. TEST #795 Board Options Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	The options are sent to the circuit pack.
0	NO BOARD	The system software found no board. 1. Reset the board. 2. Remotely retry the command.

Failure Audit (#949)

This test is non-destructive.

This test queries the DS1 CONV circuit pack for any existing circuit pack or facility failures and any unacknowledged cleared failure messages for auditing purposes. Upon receiving the query request, DS1 CONV firmware sends failure reports to the maintenance software for every error in its failure database.

This test operates on both maintenance objects DS1C-BD and DS1-FAC. Error counts of both maintenance objects (DS1C-BD and DS1-FAC) that are displayed in the error log will be incremented when this test is executed. This test is also executed internally by the maintenance software when an alarm is resolved

Table 9-279. TEST #949 Failure Audit

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Timed out while waiting for a response from the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2316	ABORT	Fiber link is not administered. Administer the DS1 CONV fiber link via the **add fiber-link** command.

Continued on next page

Table 9-279. TEST #949 Failure Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The DS1 CONV circuit pack reported failures or retransmitted a cleared failure message. 1. Enter **display errors** and follow the associated repair procedures for any DS1C-BD and DS1-FAC errors.
	PASS	The DS1 CONV circuit pack has no failures.
0	NO BOARD	The system software found no board. 1. Reset the board. 2. Remotely retry the command.

DT-LN-BD (Data Line Circuit Pack)

MO Name (In Alarm Log	Alarm Level	Initial Command to Run[1]	Full Name of MO
DT-LN-BD	MIN	test board UUCSS sh	Data Line Circuit Pack
DT-LN-BD	WRN	test board UUCSS sh	Data Line Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Refer to "XXX-BD (Common Port Circuit Pack)" for circuit pack level errors. See also DAT-LINE (Data Line Circuit Port) for related line information.

DTMR-PT (Dual Tone Multi-Frequency Receiver Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DTMR-PT	MAJOR	test port UUCSSpp sh	Dual Tone Multi-Frequency Receiver Port (TTR)
DTMR-PT	MINOR	test port UUCSSpp sh	Dual Tone Multi-Frequency Receiver Port (TTR)
DTMR-PT	WARNING	release port UUCSSpp	Dual Tone Multi-Frequency Receiver Port (TTR)

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

Dual Tone Multi-Frequency Receiver Ports (DTMR), also known as Touch-Tone Receivers (TTR), reside on the following circuit packs:

- TN748 (mu-law companding)
- TN420 (A-law companding) [G3r V2]

There are four Dual Tone Multi-Frequency Receiver (DTMR-PT) ports and two General Purpose Tone Detector (GPTD-PT) ports on each Tone Detector circuit pack. The DTMR port is used to detect touch-tone digits that are placed on the Time Division Multiplex (TDM) bus. Examples of touch-tone digits are digits 0 through 9, digit #, and digit *. The ability of the DTMR port to detect touch-tone digits is essential for maintenance of other circuit packs (for example, Tone-Clock circuit pack) and in placing a station-to-station call. Calls originating from a hybrid station *do not* require a DTMR port.

The DTMR-PT maintenance object implements a set of tests to ensure that detection of touch tone digits by the DTMR port is functioning properly. For all Tone Detector circuit pack level errors (DETR-BD), refer to the "XXX-BD (Common Port Circuit Pack)".

Error Log Entries and Test to Clear Values

Table 9-280. Dual Tone Multi-Frequency Receiver Port (TTR) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1	17664	Tone Detector Audit/ Update Test (#43)	MAJOR/ MINOR(a)	ON	test port UUCSSpp r 2
18	0	busyout port UUCSSpp	WARNING	ON	release port UUCSSpp
130 (d)		None	WARNING	ON	test port *UUCSSpp* sh r 2
257 (b)	17666	Tone Detector Audit/ Update Test (#43	MAJOR/ MINOR(a)	ON	test port UUCSSpp r 3
513 (c)	Any	Tone Detection Verification Test (#42	MAJOR/ MINOR(a)	ON	test port UUCSSpp r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. There are two possible alarm levels for this error: Major alarm and Minor alarm. A Major alarm is raised if the total number of DTMR ports currently in service is less than or equal to 1/2 of the administered threshold number. Otherwise, a Minor alarm is raised. In either case, run the Short Test Sequence against the DTMR port and follow the error code procedures for the individual tests.

   The threshold number of DTMR ports for service is administered using the **change system-parameters maintenance** command.

b. The DTMR port lost its translation. Testing the DTMR port is sufficient to reload its translation. If testing the DTMR port does not clear the error, then the Tone Detector circuit pack containing the defective DTMR port should be replaced.

c. This error indicates the DTMR port is having problems detecting touch-tone digits. If this error is being constantly logged, then the Tone Detector circuit pack containing the defective DTMR port should be replaced.

d. This error type indicates that the circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Tone Detection Verification Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test (#42)	X	X	ND
Tone Detector Audit/Update Test (#43)	X	X	ND

1. D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test checks the touch-tone digits detection capability of the DTMR port.

Table 9-281. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system was not able to allocate all the resources needed for this test or there was an Internal system error.
1	ABORT	The system could not allocate all the resources needed to test the DTMR port.
1001	ABORT	The system was unable to put the DTMR port in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This could happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM Bus via the **test tdm [a|b]** command. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a Tone Generator for the test connection. This may be caused by a heavy load on the system or by a faulted Tone-Clock. 1. Check to see if there are any alarms against the Tone-Clock in the port network where the test aborted. If so refer to the recommended procedures for TONE-BD or TONE-PT. 2. If a new Tone-Clock has been inserted, allow about 1 minute for maintenance to run on the newly inserted circuit pack. 3. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-281. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test 1. Retry the command at one-minute intervals a maximum of five times.
2006	ABORT	DTMF detection failed. Make sure that the companding mode administered for the system matches that of the Tone Detector: mu-law for TN748, A-law for TN420.
1-3	FAIL	DTMF digits were not correctly detected. 1. Run the Short Test Sequence: **test port UUCSSpp sh r 1**. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore the system performance to normal, replace the Tone Detector circuit pack containing the defective DTMR port.
	PASS	The DTMR port is able to detect all the touch-tone digits.

Tone Detector Audit/Update Test (#43)

The DTMR port is refreshed with all time slot information and sanity audit is performed on the DTMR port.

Table 9-282. TEST #43 Tone Detector Audit/Update Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	The system was not able to allocate all the resources needed for this test. 1. Wait 1 minute and try again.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Hardware audit failed. 1. Run the Short Test Sequence: **test port UUCSSpp sh r 1**. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore the system performance to normal, replace the Tone Detector circuit pack containing the defective DTMR port.
	PASS	The DTMR port has been successfully refreshed with its translation.

DUP-CHL (Duplication Interface)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DUP-CHL	MAJOR	test duplication-interface l c	Duplication-Interface
DUP-CHL	MINOR	test duplication-interface l c	Duplication-Interface

The Duplication Channel (DUP-CHL) maintenance object tests both UN330B Duplication Interface circuit packs and the interconnecting cable. These tests, as a group, test end-to-end functionality. That is to say, software on the standby and the active as well as both duplication circuit packs and their cabling must be operational to some degree for these tests to PASS or FAIL. Otherwise, they will ABORT. Tests that fail are recorded in the error and alarm log as errors/alarms against the standby SPE. No errors/alarms are recorded against the active SPE for this maintenance object.

Duplication Interface Functions

The Duplication Interface is comprised of two UN330B circuit packs, one in each of the duplicate SPE carriers, connected by a single Duplication Interface cable. The circuit packs and cable provide the following functions to support SPE duplication.

- Memory Shadowing

  Every write to memory made by the active SPE is also written into the standby SPE memory. Only those memory writes to addresses that lie within certain address boundaries, as defined by memory bounds registers on the Duplication Interface circuit packs, and other qualified writes are shadowed.

- SPE Communication

  Software running on the active SPE communicates with software on the standby SPE by sending and receiving information via the two way, general purpose mailbox mechanism provided by the circuit packs.

- Manual SPE Locking

  The Duplication Interface Circuit packs monitor the relative states-of-health of the two SPEs, and control selection of active/standby status for them.

- SPE Selection

  The SPE-Select switches on the Duplication Interface circuit packs can be used to lock the active SPE and prevent interchanges. See STBY-SPE for instructions.

Three Maintenance Objects are involved in the maintenance of the Duplication Interface circuit packs and their cabling: DUPINT, DUP-CHL, and SPE-SELE. DUPINT runs tests that check the operation of the active Duplication Interface circuit pack. DUP-CHL tests overall functionality of the circuit packs. This utilizes both circuit packs, their cabling, and communication with the standby software. SPE-SELE monitors the position of the select switches located on the front of the Duplication Interface circuit packs.

Testing is directional from the active Duplication Interface circuit pack to the standby Duplication Interface circuit pack. If an interchange has occurred with alarms raised against DUPINT or DUP-CHL, testing cannot resolve or clear these alarms because they are against the wrong circuit packs in the active to standby directional configuration. An interchange is needed to allow testing to resolve or clear these directional alarms.

DUP-CHL tests

Eight tests run under this MO. Four of these (Status Register Comparison, SMM Channel, Remote SPE Error, and Memory Shadowing) are run at system initialization, during short and long demand testing, and during periodic and scheduled testing. Three other tests (Remote Loop-Around, State-of-Health, and Memory Shadowing Disable) are run only at initialization time (reset system 2 or higher) and during long demand testing. The FIFO Full destructive test is run only as a long demand test.

For long demand testing use **test duplication-interface long clear**. The clear option is needed to clear alarms for error types that don't have an associated test. Since these tests require the turning on and off of memory shadowing, you must enter the command **busyout spe** before the long sequence can be run. Busying out the SPE turns off memory shadowing but handshake communication continues between the SPEs. After testing of DUP-CHL is complete, **release spe** must be entered before memory shadowing is turned on and refresh completes. Memory shadowing is not turned back on if DUPINT, DUP-CHL or other MAJOR alarms pertinent to memory shadowing are not retired. See Chapter 1 and STBY-SPE for details.

test dup and **test dup long** run DUPINT *and* DUP-CHL tests. This is the only command that runs short and long test sequences for these maintenance objects.

Replacement procedures for the standby Duplication Interface circuit pack, the active Duplication Interface circuit pack, and the interconnecting cable appear at the end of this section (DUP-CHL). These procedures are designed to prevent disruption of customer service (except when the active Duplication Interface circuit pack must be replaced due to shadowing failure). Each procedure also describes testing after replacement to verify duplication operation when either SPE carrier is active. Test failures in a procedure may direct you to another maintenance object for repairs.

Administration

No **add** or **remove** commands are associated with the Duplication Interface circuit packs.

In-line errors

If standby SPE software detects problems with the standby Duplication Interface circuit pack, it will report these via the handshake to the active. The report will indicate one of the following:

- — An error in reading or writing one or more of the registers on the circuit pack
- — A problem with local loop around test
- — A problem with the HFAIL bit being set

The last error is a bit set by the Duplication Interface circuit pack's hardware indicating a possible problem with the multiplexing of address and data during memory shadowing. No tests can retire these alarms reported by standby software. If the software stops reporting the errors, the alarms will be retired in about 15 minutes.

Other types of in-line errors are catastrophic ones resulting from FIFO overflow or Remote SPE Error interrupts. If these errors cause an alarm, shadowing will be turned off until the alarm is resolved. Alarms from these errors and the other in-line errors can be resolved by executing **test duplication-interface long clear** with no tests failing.

MAJOR vs. MINOR alarms

DUP-CHL may have MAJOR or MINOR alarms. MAJOR alarms cause memory shadowing to be turned off. MINOR Alarms do not. DUP-CHL alarms do not lower the Standby State of Health and do not cause an SPE interchange.

Tests run by DUP-CHL are directional in nature: they are run by the active SPE on the standby SPE. Failures of these tests are logged against the standby Duplication Interface circuit pack. Consequently, should an interchange occur, alarms logged against DUP-CHL associated with the formerly standby, now active SPE can not be resolved. An interchange is required to allow testing to resolve or clear these directional alarms.

MO interactions

test duplication-interface runs DUPINT and DUP-CHL non-destructive tests. **test duplication-interface long clear** runs DUPINT and DUP-CHL destructive and non-destructive tests, and requires that the standby SPE be busied out. Busying out the standby SPE turns off memory shadowing and lowers the health of the standby to *partially-functional*. This prevents an SPE interchange.

Once all DUPINT, DUP-CHL and any other alarms pertinent to shadowing are retired, a release of the standby will allow shadowing to be turned back on and refresh to complete. See STBY-SPE for more details.

DUP-CHL tests can also fail because shadowing is prevented by of a fault with MO: PKT-INT or MEM-BD. Use the command **status spe** to observe the presence of active alarms and display the alarm log to determine if alarms exist against these related maintenance objects that could cause memory shadowing to fail. MAJOR alarms from these other maintenance objects that cause memory shadowing failures must be resolved before attempting to resolve DUP-CHL alarms. A memory shadowing failure that is caused by another maintenance object such as PKT-INT can also cause a DUP-CHL alarm due to a test failure or in-line errors. Executing the **test duplication-interface long clear** command after repairing the underlying cause of the memory shadowing failure can also resolve a DUP-CHL alarm.

Error Log Entries and Test to Clear Values

Table 9-283. Duplication Channel Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level[1]	On/Off Board	Test to Clear Value
0[2]		Any	Any	Any	
001		State-of-Health (#873)	MINOR	ON	test dupl l
257		Memory Shadow Disable Interrupt test (#872)	MINOR	ON	test dupl l
513	any	SMM Channel test (#874)	MINOR	ON	test dupl l
769		Remote Error Interrupt test (#875)	MAJOR	ON	test dupl l
1025		Memory Shadowing test (#876)	MAJOR	ON	test dupl l
1281(a)		none	MAJOR	ON	test dupl l c
1537(b)		none	MINOR	ON	test dupl l c
1793(c)		none	MAJOR	ON	test dupl l c

Continued on next page

Table 9-283. Duplication Channel Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level[1]	On/Off Board	Test to Clear Value
2049		Remote Loop-Around test (#869)	MAJOR	ON	test dupl l
2305		FIFO Full Interrupt test (#871)	MINOR	ON	test dupl l
2561(d)	any	Status Register Comparison Test (#980)	MAJOR	ON	test dupl l
2817(e)	any	none	MAJOR	OFF	test dupl l c

1. DUP-CHL alarms can be resolved only when the alarmed Duplication Interface circuit pack is in the standby SPE carrier.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Reported by software on the standby via the handshake mechanism. This error indicates that software on the standby has seen the HFAIL bit become set on the standby Duplication Interface circuit pack. The setting of the HFAIL bit is an indication that an error in the multiplexing of the address and data by the Duplication Interface circuit packs has occurred. Three reports of this bit being set will result in a MAJOR alarm that can only be cleared over time (i.e. within 15 minutes of the final report) or by using **test duplication interface long clear**. Recommendation for repair (only if an alarm is raised): Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.

b. Reported by the software on the standby via the handshake. This error indicates that the software on the standby failed tests with one or more of the registers located on the standby Duplication Interface circuit pack. The following Error Types are used to specify the register tests that failed:

1	Control Register Test
2	Shadowing Bounds Register Test
4	Type/Suffix/Vintage Register Test
3, 5, 6, 7	Additive combinations of the above

Three reports of this error will result in a MINOR alarm that can only be cleared over time (within 15 minutes of the final report) or by using **test duplication interface long clear**. Follow the repair procedures listed in note a above.

c. Reported by the software on the standby the handshake mechanism. This error indicates that the software on the standby failed the Local Loop-Around test on the standby Duplication Interface circuit pack. Three reports of this error will result in a MAJOR alarm that can only be cleared over time (within 15 minutes of the final report) or by using **test duplication interface long clear**. Follow the repair procedures listed in note a above.

d. Error Type 2561

- Aux Data 1032 or 2032 (SPE A); Aux Data 1016 or 2016 (SPE B): indicates a discrepancy between the SPE select switch settings and the **status spe** command screen display. Do not replace any circuit packs. Call Tier 3.

e. Catastrophic in-line error failure.

- Aux Data 1: Remote SPE shadowing bus error

  Possible false alarms can be caused by pulling a standby SPE circuit pack (other than R-MEDIA or DISK) while carrier power is on. Use the following repair procedure for this off circuit pack alarm.

  1. Use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL, should be repaired first.
  2. Execute the **test duplication-interface long clear** command to clear this alarm. If any DUPINT or DUP-CHL test fails or aborts, use the repair strategy for that test.
  3. If no DUPINT nor DUP-CHL tests failed, the DUPINT and DUP-CHL alarms are resolved or cleared in this active to standby direction so release the standby SPE from the busyout condition using the **release spe-standby** command and wait (about 10 minutes) for the standby SPE to be refreshed as observed with the **status spe** command.
  4. If the standby SPE is refreshed, and fully functional, with no DUPINT or DUP-CHL alarms in the other active to standby direction, this procedure is finished.
  5. If the standby SPE is refreshed, and fully functional, with DUPINT or DUP-CHL alarms in the other active to standby direction, use the **reset system interchange** command. Go to step 8.

6. If the standby SPE is not refreshed, and fully functional, with DUPINT or DUP-CHL alarms in the other active to standby direction, arrange a time with the customer to interchange the SPE carriers because this interchange will disrupt service. If the standby SPE is not cycling as indicated by the flashing yellow LED on the standby Processor circuit pack, use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE. If the standby SPE is still not cycling, escalate the problem.
7. Hard switch into the standby SPE by moving both SPE Select switches to the position that selects the standby SPE as active.
8. After the interchange, use the **busyout spe-standby** command. If the SPE Select switches are not in the auto position, move the switches to the auto position. Use the **test duplication-interface long clear** command to resolve the DUPINT and DUP-CHL alarms. If any DUPINT or DUP-CHL test fails, use the repair strategy for that test.
9. If no DUPINT nor DUP-CHL tests fail, the DUPINT and DUP-CHL alarms are resolved or cleared in both directions so release the standby SPE from the busyout condition using the **release spe-standby** command and wait (about 10 minutes) for the standby SPE to be refreshed as observed with the **status spe** command.

- Aux Data 3: Remote Duplication Interface circuit pack FIFO overflow

  Execute the **test duplication-interface long clear** command to resolve this alarm. If any DUPINT or DUP-CHL test fails, use the repair strategy for that test.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *SMM Channel test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Status Register Comparison Test (#980)	X	X		ND
Remote Loop-Around Test (#869)		X		D
Dup Mailbox Test (#874)	X	X		ND
Remote Error Interrupt Test (#875)	X	X		ND

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Memory Shadowing Test (#876)	X	X		ND
State-of-Health Test (#873)		X		D
Memory Shadowing Disable Test (#872)		X		D
FIFO Full Interrupt Test (#871)		X		D

1. D = Destructive; ND = Nondestructive

Remote Loop-Around Test (#869)

This test is destructive.

This test writes a word to a memory address on the active SPE that is inverted and is looped back by the standby Duplication Interface circuit.

Table 9-284. TEST #869 Remote Loop-Around Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby 3. Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1405	ABORT	This test did not run because the Duplication Channel was busy. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-284. TEST #869 Remote Loop-Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Remote Loop-Around Test has failed to loop a data word from the active to the standby and back to the active Duplication Interface circuit pack. 1. The standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs. 2. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
55	FAIL	The attempt to turn off memory shadowing in this DUPINT circuit pack could not be verified in the DUPINT hardware status register. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
	PASS	A data word was successfully looped around from the active to the standby and back to the active Duplication Interface circuit pack.

FIFO Full Interrupt Test (#871)

This test is destructive.

This test effectively checks the correct operation of the FIFO located on the standby Duplication Interface circuit pack.

Table 9-285. TEST #871 FIFO Full Interrupt Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1325	ABORT	Memory shadowing is inhibited from the standby SPE. 1. Shadowing may not be turned on yet, so wait 5 minutes and run the test again. 2. Rerun the test; if the same 1325 abort occurs again, use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 3. Rerun the test; if the same 1325 abort occurs again, look for other DUPINT or DUP-CHL test failures by using the **busyout spe-standby** if not already busied out and the **test duplication-interface long clear** commands. Fix these problems according to the service documentation for these packs. 4. If this 1325 abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.

Continued on next page

Table 9-285. TEST #871 FIFO Full Interrupt Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1418	ABORT	The HFAIL bit being set in the active Duplication Interface circuit pack prevented this test from running. 1. Run this long demand test sequence and verify that test #870 passes or follow the repair strategy for test #870 until it passes.
2000	ABORT	This test did not run because communication with the standby timed out while waiting for a reply to a maintenance message. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2334	ABORT	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The expected interrupt was not received from the standby Duplication Interface circuit pack when the FIFO was filled to overflowing with test data. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
53	FAIL	The Duplication Interface circuit pack FIFO flow control flag was not set during this FIFO Full Interrupt Test. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
54	FAIL	The attempt to turn on memory shadowing in this DUPINT circuit pack could not be verified in the DUPINT hardware status register. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
	PASS	The FIFO full interrupt was received from the standby Duplication Interface circuit pack when the FIFO was filled to overflowing with test data.

Memory Shadowing Disable Test (#872)

This test is destructive.

This test verifies the correct operation of the interrupt that indicate when shadowing has been turned off (disallowed) by the standby Processor

Table 9-286. Test #872 Memory Shadowing Disable Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.

Continued on next page

Table 9-286. Test #872 Memory Shadowing Disable Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1322	ABORT	Memory shadowing is off, but not inhibited by the standby SPE. 1. Shadowing may not be turned on yet, so use **release spe-standby** if the standby is busied out, wait 5 minutes and run the test again. If the long duplication-interface demand test was being used, investigate any failure or abort from test #872 because this test is expected to turn on shadowing. 2. Rerun the test; if the same 1322 abort occurs again, use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 3. Rerun the test; if the same 1322 abort occurs again, look for other DUPINT or DUP-CHL test failures by using the **busyout spe-standby** if not already busied out and the **test duplication-interface long clear** commands. Fix these problems according to the service documentation for these packs. 4. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
1325	ABORT	Memory shadowing is inhibited from the standby SPE. 1. Shadowing may not be turned on yet, so wait 5 minutes and run the test again. 2. Rerun the test; if the same 1325 abort occurs again, use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 3. Rerun the test; if the same 1325 abort occurs again, look for other DUPINT or DUP-CHL test failures by using the **busyout spe-standby** if not already busied out and the **test duplication-interface long clear** commands. Fix these problems according to the service documentation for these packs. 4. If this 1325 abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
1405	ABORT	This test did not run because the Duplication Channel was busy. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-286. Test #872 Memory Shadowing Disable Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
2000	ABORT	This test did not run because communication with the standby timed out while waiting for a reply to a maintenance message instructing it to disallow memory shadowing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
2334	ABORT	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5. to power down and power up the standby SPE, but don't replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The expected interrupt that indicates shadowing has been turned off in the standby SPE was not received after this test had instructed the standby SPE to turn off shadowing. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
54	FAIL	The attempt to turn on memory shadowing in this DUPINT circuit pack could not be verified in the DUPINT hardware status register. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
	PASS	The interrupt that indicates shadowing has been turned off in the standby SPE was received after this test had instructed the standby SPE to turn off shadowing.

State-of-Health (#873)

This test is destructive.

This test verifies the correct operation of the State-of-Health interrupt

Table 9-287. TEST #873 State-Of-Health Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1405	ABORT	This test did not run because the Duplication Channel was busy. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.

Continued on next page

Table 9-287. TEST #873 State-Of-Health Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1420	ABORT	The state-of-health of the active SPE is **partially functional.** 1. Use the **display alarms** command selecting the SPE category to determine which alarms have caused the active SPE to have a lower state-of-health. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs. Try this test again.
2000	FAIL	This test did not run because communication with the standby timed out while waiting for a reply to a maintenance message instructing it to lower it's state-of-health. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this section.
2334	ABORT	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The standby state-of-health was lowered but no interrupt was received after the test had instructed the standby SPE to lower its state of health. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
	PASS	The test successfully received the lowered state-of-health interrupt from the standby Duplication Interface circuit pack.

Duplication Channel Test (#874)

This test verifies the correct transmission of a message sent from the active SPE to the standby SPE via the Duplication Interface circuit pack mailbox.

Table 9-288. TEST #874 Duplication Channel Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don’t replace any circuit packs.
2000	ABORT	This test did not run because communication with the standby timed out while waiting for a reply to a maintenance message. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The standby software did not return the test message sent from the active SPE to the standby SPE via the Duplication Interface circuit pack mailbox. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.

Continued on next page

Table 9-288. TEST #874 Duplication Channel Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2334	FAIL	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this failure continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs. 3. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this section.
	PASS	The standby software returned the test message sent from the active SPE to the standby SPE via the Duplication Interface circuit pack mailbox.

Remote SPE Error Interrupt Test (#875)

This test is used to check for the correct operation of the Remote SPE Error interrupt.

Table 9-289. TEST #875 Remote SPE Error Interrupt Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1322	ABORT	Memory shadowing is off, but not inhibited by the standby SPE. 1. Shadowing may not be turned on yet, so use **release spe-standby** if the standby is busied out, wait 5 minutes and run the test again. If the long duplication-interface demand test was being used, investigate any failure or abort from test #872 because this test is expected to turn on shadowing. 2. Rerun the test; if the same 1322 abort occurs again, use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 3. Rerun the test; if the same 1322 abort occurs again, look for other DUPINT or DUP-CHL test failures by using the **busyout spe-standby** if not already busied out and the **test duplication-interface long clear** commands. Fix these problems according to the service documentation for these packs. 4. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.

Continued on next page

Table 9-289. TEST #875 Remote SPE Error Interrupt Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1325	ABORT	Memory shadowing is inhibited from the standby SPE. 1. Shadowing may not be turned on yet, so wait 5 minutes and run the test again. 2. Rerun the test; if the same 1325 abort occurs again, use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 3. Rerun the test; if the same 1325 abort occurs again, look for other DUPINT or DUP-CHL test failures by using the **busyout spe-standby** if not already busied out and the **test duplication-interface long clear** commands. Fix these problems according to the service documentation for these packs. 4. If this 1325 abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
2000	ABORT	This test did not run because communication with the standby timed out while waiting for a reply to a maintenance message. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2334	ABORT	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-289. TEST #875 Remote SPE Error Interrupt Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	This test attempted to shadow a word with bad parity from the active SPE into the standby SPE memory, but the expected remote SPE error interrupt from detecting this bad parity word was not received in the active SPE. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
54	FAIL	The attempt to turn on memory shadowing in this DUPINT circuit pack could not be verified in the DUPINT hardware status register. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
	PASS	The test successfully created an Remote SPE Error interrupt.

Memory Shadowing Test (#876)

This test checks to see if memory writes in the active SPE that occur within shadowed address space, can be successfully shadowed into the standby SPEs memory.

Table 9-290. TEST #876 Memory Shadowing Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1322	ABORT	Memory shadowing is off, but not inhibited by the standby SPE. 1. Shadowing may not be turned on yet, so use **release spe-standby** if the standby is busied out, wait 5 minutes and run the test again. If the long duplication-interface demand test was being used, investigate any failure or abort from test #872 because this test is expected to turn on shadowing. 2. Rerun the test; if the same 1322 abort occurs again, use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 3. Rerun the test; if the same 1322 abort occurs again, look for other DUPINT or DUP-CHL test failures by using the **busyout spe-standby** if not already busied out and the **test duplication-interface long clear** commands. Fix these problems according to the service documentation for these packs. 4. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.

Continued on next page

Table 9-290. TEST #876 Memory Shadowing Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1325	ABORT	Memory shadowing is inhibited from the standby SPE. 1. Shadowing may not be turned on yet, so wait 5 minutes and run the test again. 2. Rerun the test; if the same 1325 abort occurs again, use the **display alarms** command and select Category **spe**. If any maintenance objects other than DUPINT or DUP-CHL have MAJOR alarms, fix these problems. Problems causing MAJOR alarms for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, and SW-CTL should be repaired first. 3. Rerun the test; if the same 1325 abort occurs again, look for other DUPINT or DUP-CHL test failures by using the **busyout spe-standby** if not already busied out and the **test duplication-interface long clear** commands. Fix these problems according to the service documentation for these packs. 4. If this 1325 abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but don't replace any circuit packs.
2000	ABORT	This test did not run because communication with the standby timed out while waiting for a reply to a maintenance message. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Test data retrieved from the standby SPE memory didn't match test data written into the active SPE memory and shadowed to the standby SPE memory. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this section.

Continued on next page

Table 9-290. TEST #876 Memory Shadowing Test — *Continued*

Error Code	Test Result	Description/ Recommendation
54	FAIL	The attempt to turn on memory shadowing in this DUPINT circuit pack could not be verified in the DUPINT hardware status register. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section.
	PASS	The test was able to successfully shadow, within shadowed address space, writes in the active SPE into the standby SPE memory.

Status Register Comparison Test (#980)

The Status Register Comparison Test compares active Duplication Interface circuit pack remote status with standby Duplication Interface circuit pack local status.

Table 9-291. TEST #980 Status Register Comparison Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of this DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.

Continued on next page

Table 9-291. TEST #980 Status Register Comparison Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1411	ABORT	This test did not run because the standby Duplication Interface circuit pack cannot be detected as being plugged in by the software. 1. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2000	ABORT	This test did not run because communication with the standby timed out while waiting for a reply to a maintenance message requesting the standby status. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2334	ABORT	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this abort continues to occur, the standby SPE may not have initialized properly. Use the lock-and-power-down procedure described in Chapter 5 to power down and power up the standby SPE, but do not replace any circuit packs.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The remote status in the active did not match the local status in the standby Duplication Interface circuit pack, or the remote status in the standby did not match the local status in the active Duplication Interface circuit pack. 1. Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this section.
	PASS	The comparison of remote with local status matched in both directions for the pair of Duplication Interface circuit packs.

Replacing Duplication Channel Components

The SPE Duplication Channel consists of a Duplication Interface circuit pack (DUPINT) in the active SPE, a DUPINT in the standby SPE, and an interconnecting cable. The following sections contain step-by-step procedures for replacing each of these components. DUPINT replacement must be done on the standby SPE to prevent loss of service.

If replacement of standby DUPINT circuit pack does not repair the Duplication Channel, replace the DUPINT circuit pack on the active SPE. If replacement of both of these circuit packs does not repair the Duplication Channel, replace the interconnecting cable.

Replacing the STANDBY Duplication Interface (DUPINT) Circuit Pack

This procedure is used after a **test duplication-interface long** displays a failure for at least one of the tests that indict the standby DUPINT. The procedure to interchange the active DUPINT to the standby mode also uses this procedure.

1. Use the **busyout spe-standby** command to lower the standby State of Health to **partially functional** to prevent an unwanted interchange during replacement and testing of the standby DUPINT.
2. Manually lock the active SPE. by moving the SPE select switches located on the front of the DUPINT circuit packs to positions where they are both selecting the current active SPE.
3. Whenever locking the SPE, *always* verify that the active PPN Tone/Clock is in the active SPE carrier *before* doing any repair activity on the standby SPE carrier such as powering down. Enter **status port-network 1** to check which clock is active. Remove power from the standby SPE carrier by pulling the power cords located on both sides of the carrier. *Power must be removed from the standby carrier in order for the replacement DUPINT to initialize properly.*
4. Set the SPE-select switch on the new DUPINT circuit pack to the same position as the circuit pack you are going to replace. Then remove and replace the defective circuit pack.

CAUTION:

The new standby DUPINT must have its SPE Select switch set to lock the currently active carrier. The switch should be in the same position as the removed circuit pack.

5. Apply power to the standby SPE carrier.

6. Verify that the standby is up. Regular flashing of the yellow LED on the Processor circuit pack indicates that the standby SPE is up and cycling. If the yellow LED is not flashing after 5 minutes test the standby SPE by using the lock-and-power-down procedure described in Chapter 5.
7. With the standby SPE still busied out to prevent an interchange, unlock the active SPE by moving the SPE Select Switches back to the Auto position.
8. Use the **status spe** command to verify that handshake is up. Wait up to 10 minutes for handshake to come up.
9. If **status spe** shows MAJOR alarms, enter the **display alarms** command for category **spe**. Resolve alarms for maintenance objects other than STBY-SPE, DUPINT and DUP-CHL first.
10. Execute the **test duplication-interface long clear** command to resolve the DUPINT and DUP-CHL alarms. If any test aborts, but none fail, run this test again at 1-minute intervals up to a maximum of 5 times, until all tests pass.
    - If no DUPINT or DUP-CHL tests failed, the DUPINT and DUP-CHL alarms are resolved or cleared in this active to standby direction. Continue with step 11.
    - If any DUPINT or DUP-CHL tests failed, and the standby DUPINT has been replaced, but the active DUPINT pack has *not* been replaced, replace the active DUPINT using the procedure in the following section.
    - If any DUPINT or DUP-CHL tests failed, and *both* DUPINTs have been replaced, but the DUPINT interconnecting cable has not been replaced, replace the DUPINT interconnecting cable using the replacement procedure for the DUPINT interconnecting cable.
    - If any DUPINT or DUP-CHL tests failed, and both DUPINT circuit packs and the interconnecting cable have been replaced, escalate the problem.
11. Release the standby SPE from the busyout using the **release spe-standby** command and wait about 10 minutes for the standby SPE to be refreshed. If the standby SPE fails to refresh, as observed with **status spe**, follow normal escalation procedures.
12. If the SPE Standby State-of-Health is functional as observed with **status spe**, enter the **reset system interchange** command. With this SPE now active, execute **busyout spe-standby** and use **test duplication-interface long clear** to test the Duplication Channel in the other direction.
    - If all tests pass, continue with step 13.
    - If any test fails, and the currently *standby* DUPINT circuit pack has not already been replaced, replace it now by starting at the beginning of this procedure. This circuit pack has passed tests while on the active carrier, but is still the most likely circuit pack to be faulted, especially if DUP-CHL tests are failing.

- If any test fails, and the currently *active* DUPINT circuit pack has not already been replaced, replace it now by starting at the beginning of the replacement procedure for the *active* DUPINT. This circuit pack has passed tests while on the standby carrier, but failed when on the active carrier, especially if DUPINT tests are failing.
- If any test fails, and *both* DUPINTs have been replaced, replace the DUPINT interconnecting cable by using the procedure on the following pages.

13. Execute the **release spe-standby** command and wait for memory shadowing and standby refreshed to occur as verified with the **status spe** command.
    - If the standby is refreshed within 10 minutes, this replacement procedure is successfully finished.
    - If the standby is not refreshed within 10 minutes, continue with step 14.
14. Use the **status spe** command. If the status shows MAJOR alarms, use the **display alarms** command with the **spe** category selection. Resolve alarms for maintenance objects other than DUPINT and DUP-CHL.
    - If the standby is refreshed within 10 minutes, and the DUPINT and DUP-CHL alarms are resolved, this replacement procedure is successfully finished.
    - If the DUPINT and DUP-CHL alarms are not resolved, and the standby DUPINT has been replaced, but the *active* DUPINT has *not* been replaced, replace the active DUPINT using the procedure in the following section.
    - If the DUPINT and DUP-CHL alarms are not resolved, and both DUPINTs have been replaced, but the DUPINT interconnecting cable has *not* been replaced during this repair activity, replace the DUPINT interconnecting cable using the procedure for interconnecting cable.

Replacing the ACTIVE Duplication Interface (DUPINT) Circuit Pack

This procedure is used after a **test duplication-interface (long)** displays a failure for at least one of the tests that indict the active DUPINT, or when replacement of the active DUPINT is otherwise recommended. The active SPE must be interchanged to the standby mode before replacing this DUPINT to minimize disruption of customer service. Replacement of the DUPINT in the standby SPE carrier is described in the previous section.

1. If the **status spe** command displays `Standby Busied? yes`, release the standby SPE by using the **release spe-standby** command. If the System was recently interchanged, or if the standby SPE was busied out and released, or if some other recent maintenance was performed on the standby SPE, it may take up to 10 minutes for the standby SPE to be refreshed. Use **status spe** to determine if `State of Health: functional` for the `Mode: standby` side is displayed.
   - If handshake is down, continue with step 5.
   - If the Standby State of Health is other than functional, continue with step 2.
   - If the Standby State of Health is functional, enter the command **reset system interchange**.
     - *If the SPE interchange occurred,* replace the standby DUPINT using the replacement procedure for the standby DUPINT.
     - *If the SPE interchange did not occur* continue with step 2.
2. If there are no major alarms against MEM-BD, PKT-INT, SYSAM, H-ADAPTR, or SW-CTL, continue with step 5 in this procedure.
3. If MAJOR alarms cannot be resolved for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, or SW-CTL using their associated maintenance procedures, escalate the problem. These MAJOR alarms must be resolved before continuing with DUPINT and DUP-CHL Maintenance.
4. If any MAJOR alarms were resolved for MEM-BD, PKT-INT, SYSAM, H-ADAPTR, or SW-CTL using their associated maintenance procedures, test DUPINT and DUP-CHL again: use **busyout spe-standby** followed by **test duplication-interface long clear** and see if any tests fail. Enter **release spe-standby.**
   - If any test fails, continue with step 5 in this procedure.
   - If all tests pass, wait up to 10 minutes and enter **status spe** to determine whether `Standby Refreshed? yes` and `State of Health: functional` are displayed for the standby SPE.

     If the above are not displayed, go to Step 5 of this procedure.

     If the above are displayed, enter the command **reset system interchange**.

- If this interchange was not successful, continue with step 5 in this procedure.
- If this interchange was successful, use the **busyout spe-standby** command followed by the **test duplication-interface long clear** command and see if any tests fail. Execute **release spe-standby**.

  If all tests pass, the duplication channel has been successfully tested in both directions and this procedure is finished.

  If any test fails, replace the standby DUPINT using the previous replacement procedure for the standby DUPINT.

5. Use the **status spe** command to determine if `Standby Refreshed?` `yes` for `Mode: standby` is displayed.
   - *If the standby is refreshed,* a hard switch will not affect customer service. Continue with step 6.
   - *If the standby is not refreshed,* you will need to execute a hard switch that *will* affect customer service (by at least dropping current calls). Notify the customer and establish a time to perform this disruptive maintenance.
6. Hard switch into the standby SPE by moving both SPE Select switches to the position that selects the standby SPE as active.
   - If the interchange was successful, replace the standby DUPINT using the replacement procedure for the standby DUPINT.

Replacing the Duplication Interface Interconnecting Cable

This procedure is used after replacing both DUPINT circuit packs has failed to resolve the duplication channel failure.

1. Use the **busyout spe-standby** command to lower the standby State of Health to partially functional to prevent an unwanted interchange during the Duplication Interconnecting cable replacement and testing.
2. Manually lock the active SPE. This is done by moving the SPE select switches located on the front of the DUPINTs to positions where they are both selecting the current active SPE.
3. Whenever locking the SPE, *always* verify that the active PPN Tone/Clock is in the active SPE carrier *before* doing any repair activity on the standby SPE carrier such as powering down. Enter **status port-network 1** to check which clock is active. Remove power from the standby SPE carrier by pulling the power cords located on both sides of the carrier. **Power must be removed from the standby carrier. If power is not removed from the standby SPE carrier before the interconnecting cable is disconnected, an interchange to the standby SPE will occur, causing disruption of customer service.**

4. Examine the cable and associated connectors for obvious problems. Check for broken or bent pins, and repair or replace before installing the new cable.

CAUTION:
This cable interconnects the powered down standby and the active carriers. Use extreme caution. Shorting pins can cause the active SPE to fail. Consider replacing this cable during periods of light traffic or, ideally, when both carriers are powered down (system out of service).

   Replace the cable observing proper connector location and orientation.

5. Apply power to the standby SPE carrier.
6. Verify that the standby is up. Regular flashing of the yellow LED on the Processor circuit pack indicates that the standby SPE is up and cycling. If the yellow LED is not flashing after 5 minutes test the standby SPE by using the lock-and-power-down procedure described in Chapter 5.
7. With the standby SPE still busied out to prevent an interchange, unlock the active SPE by moving the SPE Select Switches back to the Auto position.
8. Use the **status spe** command to verify that handshake is up. Wait up to 10 minutes for handshake to come up.
9. If the status shows MAJOR alarms, use the **display alarms** command for category **spe**. Resolve alarms for maintenance objects other than DUPINT and DUP-CHL first.
10. Execute the **test duplication-interface long clear** command to resolve the DUPINT and DUP-CHL alarms. If any tests abort, but no tests fail, run the test again at 1-minute intervals up to a maximum of 5 times with the goal of observing all tests passing.
    - If no DUPINT nor DUP-CHL tests fail, the DUPINT and DUP-CHL alarms are resolved or cleared in this active to standby direction. Continue with step 11.
    - You should by now have replaced both DUPINT circuit packs and the interconnecting cable.
11. Release the standby SPE from the busyout condition using the **release spe-standby** command and wait (about 10 minutes) for the standby SPE to be refreshed as observed with the **status spe** command.

12. If the SPE Standby State-of-Health is functional as observed with the **status spe** command, use the **reset system interchange** command. With the other SPE now active, execute the **busyout spe-standby** command and use the **test duplication-interface long clear** command to test the Duplication Channel in the other direction, resolving any outstanding alarms against DUPINT and DUP-CHL.
    - If these tests pass, continue with step 13.
13. Execute the **release spe-standby** command and wait for memory shadowing and standby refreshed to complete as verified with the **status spe** command.
    - If the standby is not refreshed within 10 minutes, continue with step 14.
    - If the standby is refreshed within 10 minutes, this replacement procedure is successfully finished.
14. Use the **status spe** command. If the status shows MAJOR alarms, use the **display alarms** command with the **spe** category selection. Resolve alarms for maintenance objects other than DUPINT and DUP-CHL.
    - If the standby is not refreshed within 10 minutes, or the DUPINT and DUP-CHL alarms are not resolved, escalate the problem.
    - If the standby is refreshed within 10 minutes, and the DUPINT and DUP-CHL alarms are resolved, this replacement procedure is successfully finished.

DUPINT (Duplication Interface Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DUPINT	MAJOR	test duplication-interface l c	Duplication Interface circuit pack
DUPINT	MINOR	test duplication-interface l c	Duplication Interface circuit pack

The Duplication Interface (DUPINT) maintenance object tests the active UN330B Duplication Interface circuit pack. Tests that fail are recorded in the error and alarm log as errors/alarms against the active Duplication Interface circuit pack. No errors/alarms are recorded against the standby Duplication Interface circuit pack by this maintenance object.

Three Maintenance Objects are utilized in the maintenance of the Duplication Interface circuit pack and their cabling. These are DUPINT, DUP-CHL, and SPE-SELE. The first of these, DUPINT, is composed of tests that check the operation of the active Duplication Interface circuit pack. The second maintenance object, DUP-CHL, test overall functionality of the circuit pack. This requires both circuit pack, their cabling, and communication with the standby software. The third and final MO is SPE-SELE. SPE-SELE monitors the position of the select switches located on the front of the Duplication Interface circuit pack.

Testing is directional from the active Duplication Interface circuit pack to the standby Duplication Interface circuit pack. If an interchange has occurred with alarms raised against DUPINT or DUP-CHL, testing cannot resolve or clear these alarms because they are against the wrong circuit pack in the active to standby directional configuration. An interchange is needed to allow testing to resolve or clear these directional alarms.

Duplication Interface Maintenance Operation

There are six tests that comprise DUPINT. The not-destructive Active DUPINT HFAIL test is run as scheduled, periodic and demand short. The Active DUPINT Reset test is the destructive version of the HFAIL test and is only run at initialization time and on demand long. They are not run as part of periodic or scheduled maintenance. Test failures or in-line errors for this maintenance object are logged against the active Duplication Interface circuit pack.

The five destructive tests run by DUPINT are only run during initialization (reset system 2 or worse) and on demand with the command line of **test duplication-interface long**. The clear option is needed to clear alarms for error types that don't have an associated test when all of the tests pass or abort. Since these tests require the turning on and off of memory shadowing, you must enter the command **busyout spe** before the long sequence may be run. The busying out of the SPE turns off memory shadowing but handshaking continues between the active and standby SPEs. After testing of DUPINT is complete, the command **release spe** must be entered before memory shadowing is allowed to be turned on and memory refresh to complete. Memory shadowing is not turned back on if DUPINT, DUP-CHL or other MAJOR alarms pertinent to memory shadowing are not retired. See STBY-SPE for more details as to how the turning on/off of shadowing is controlled.

The **test duplication-interface and test duplication-interface long** commands run DUPINT and DUP-CHL tests. This is the only command that can run short and long test sequences for these maintenance objects.

Replacement procedures are provided for the standby Duplication Interface circuit pack, the active Duplication Interface circuit pack, and the interconnecting cable. These procedures are designed to prevent disruption of customer service except when the active Duplication Interface circuit pack must be replaced because of a failure that prevents memory shadowing. Each procedure also describes testing after replacement to verify duplication operation when SPE carrier A is active and when SPE carrier B is active. Test failures in a procedure can direct you to another procedure for the replacement and testing of a related component.

Administration

No **add** or **remove** commands are associated with the Duplication Interface circuit pack.

In-line Errors

The Local FIFO Full Failure and DUPINT Driver Failure error types can raise alarms when in-line errors are received. There are no tests that can retire these reported alarms. The command line option of **test duplication-interface long clear** with the long test sequence and the clear option is needed to clear alarms for these in-line errors. The in-line error types are cleared by this command only if no tests fail.

MAJOR vs. MINOR Alarms

DUPINT may have MAJOR or MINOR alarms. Whenever a MAJOR alarm is raised, memory shadowing to the standby is turned off. A MINOR alarm does not turn off shadowing. Neither type of alarm causes an SPE interchange.

Maintenance Object Interactions

The command **test duplication-interface** runs both DUPINT and DUP-CHL non-destructive tests. The command **test duplication-interface long** runs both DUPINT and DUP-CHL destructive and non-destructive tests. The second command can only be run if the standby SPE is busied out. This busy out of the standby SPE turns off memory shadowing, and lowers the health of the standby to partially-functional; thereby preventing a possible interchange between the active and standby SPE carriers. Then, if all DUPINT and DUP-CHL alarms are retired, a release of the standby SPE will allow memory shadowing to be turned back on (if no further alarms pertinent to memory shadowing are present) and refresh to complete. See STBY-SPE for more details as to how the turning on/off of shadowing is controlled.

Error Log Entries and Test to Clear Values

Table 9-292. Duplication Interface Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level[1]	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	
1		Control Register test (#865)	MAJOR	ON	test dupl l
257	Any	Mailbox Loop-around test (#866)	MAJOR	ON	test dupl l
513	Any	Local Loop-around test (#867)	MAJOR	ON	test dupl l
769	Any	Memory Shadowing Bounds Test (#868)	MAJOR	ON	test dupl l
2049 (a)	Any	Active DUPINT Reset Test (#870) Active DUPINT STDONE/ HFAIL Check Test (#979)	MINOR	ON	test dupl l
3073 (b)	2	None	MINOR	ON	test dupl l c
3329 (c)	Any	None	MAJOR	ON	test dupl l c

1. DUPINT alarms can be resolved only when the alarmed Duplication Interface circuit pack is in the active SPE carrier.

Notes:

a. Indicates either a failure during a reset of the Duplication Interface circuit pack, or a report that either or both of the HFAIL and STDONE bits are in the wrong state. These errors cause a MINOR alarm that does not affect memory shadowing. The Aux Data indicates which error occurred.

Aux Data	Cause of Error
None	The active DUPINT Reset Test failed because the reset was unsuccessful.
1	The STDONE bit is in the wrong state.
2	The HFAIL bit is in the wrong state.
3	The STDONE and HFAIL bits are both in the wrong state.
51	The Active DUPINT Reset Test failed because the HFAIL bit stayed set after reset.
52	The Active DUPINT Reset Test failed because the state of health could not be restored after the reset.
55	The Active DUPINT Reset Test failed because shadowing could not be turned off after the board was successfully reset.

b. A local DUPINT FIFO overflow condition has been reported. If this alarm cannot be cleared by replacing the active Duplication Interface circuit pack, escalate the problem.

c. In-line errors have been reported from the DUPINT driver. If this alarm cannot be cleared by replacing the active Duplication Interface circuit pack, escalate the problem.

Aux Data	Cause of Error
23	DUPINT driver suicide
24	DUPINT driver loss of interrupt path
27	DUPINT driver no handshake path for processes
28	DUPINT driver no handshake path for drivers
29	DUPINT driver no control path
30	DUPINT driver main receive failed

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Control Register Test* for example, you may also clear errors generated from other tests in the testing sequence.

Tests listed as *destructive* are so designated because they require shadowing to be turned off. For testing to resolve DUPINT alarms, the alarmed circuit pack must be on the Active SPE carrier.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Active DUPINT HFAIL Check Test (#979)	X	X	ND
Active DUPINT Reset Test (#870)		X	D
Control Register Test (#865)		X	ND
Mailbox Loop-around Test (#866)		X	D
Local Loop-around Test (#867)		X	D
Memory Shadow Bounds Test (#868)		X	D

1. D = Destructive, ND = Non-destructive

Control Register Test (#865)

This test checks the operation of the control register located on the Duplication Interface circuit pack.

Table 9-293. Test #865 Control Register Test

Error Code	Test Result	Description/ Recommendation
1418	ABORT	The HFAIL bit and/or the STDONE bit is in the wrong state. The active Duplication Interface circuit pack needs to be reset. 1. Run the **test duplication-interface long** command and follow instructions for the Active DUPINT Reset Test (#870). 2. If test #870 passes and this test still aborts, escalate the problem.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Control Register test bit was not set in the Status Register and the Type/Suffix/Vintage Register after this bit was written into the Control Register. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of this section.
	PASS	The Control Register test bit was set in the Status Register and the Type/Suffix/Vintage Register after this bit was written into the Control Register.

Mailbox Loop-around Test (#866)

This test is destructive.

This test checks the functionality of the mailbox mechanism provided by the Duplication Interface circuit pack

Table 9-294. TEST #866 Mailbox Loop-around Test

Error Code	Test Result	Description/ Recommendation
1405	ABORT	This test did not run because the Duplication Channel was busy. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-294. TEST #866 Mailbox Loop-around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1418	ABORT	The HFAIL bit and/or the STDONE bit is in the wrong state. The active Duplication Interface circuit pack needs to be reset. 1. Run the **test duplication-interface long** command and follow instructions for the Active DUPINT Reset Test (#870). 2. If test #870 passes and this test still aborts, escalate the problem.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The test message written into the active Duplication Interface circuit pack mailbox did not cause an interrupt to notify the software to retrieve it from the receive mailbox; or if retrieved, the looped back message did not match the message written into the mailbox. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
55	FAIL	The attempt to turn off memory shadowing in this Duplication Interface circuit pack could not be verified in the Duplication Interface circuit pack hardware status register. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
	PASS	The test message written into the active Duplication Interface circuit pack mailbox successfully caused an interrupt to notify the software to retrieve it from the receive mailbox and the retrieved looped back message matched the message written into the mailbox.

Local Loop-around Test (#867)

This test is destructive.

This test checks the ability of the active Duplication Interface circuit pack to shadow writes that are within the shadowed address boundaries

Table 9-295. TEST #867 Local Loop-around Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of the DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1405	ABORT	This test did not run because the Duplication Channel was busy. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1418	ABORT	The HFAIL bit and/or the STDONE bit is in the wrong state. The active Duplication Interface circuit pack needs to be reset. 1. Run the **test duplication-interface long** command and follow instructions for the Active DUPINT Reset Test (#870). 2. If test #870 passes and this test still aborts, escalate the problem.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-295. TEST #867 Local Loop-around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The retrieved test data word that was looped around in the active Duplication Interface circuit pack did not match the inversion of the written test data word. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
55	FAIL	The attempt to turn off memory shadowing in this Duplication Interface circuit pack could not be verified in the hardware status register. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
	PASS	The retrieved test data word that was looped around in the active Duplication Interface circuit pack matched the inversion of the written test data word.

Memory Shadowing Bounds Test (#868)

This test is destructive.

This test is used to check the memory shadowing bounds register located on the Duplication Interface circuit pack.

Table 9-296. TEST #868 Memory Shadowing Bounds Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	The faceplate switches on the Duplication Interface circuit packs are not set to **auto**. 1. If the switches are locked because you are using a replacement procedure, continue with this procedure to the step that directs you to unlock the active SPE by moving both switches to **auto**. The next step using the **test duplication-interface long clear** should not abort with this error code. 2. If the switches are locked and a replacement procedure is not being used, start with step 6 of the SPE Duplication Channel Component Replacement procedure for the standby Duplication Interface Circuit pack at the end of the DUP-CHL section to avoid an undesired interchange when unlocking the active SPE. 3. If this same abort is received with both switches in auto, Replace Duplication Interface components starting with the standby Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section. In addition to looking for failures, also check for the absence of this 1321 abort code when testing after the procedure directs setting the switches to **auto** after a component replacement.
1405	ABORT	This test did not run because the Duplication Channel was busy. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1418	ABORT	The HFAIL bit and/or the STDONE bit is in the wrong state. The active Duplication Interface circuit pack needs to be reset. 1. Run the **test duplication-interface long** command and follow instructions for the Active DUPINT Reset Test (#870). 2. If test #870 passes and this test still aborts, escalate the problem.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The looped around test word within the shadowing bounds did not match the inversion of the written test word or the looped around test word outside the shadowing bounds matched the inversion of the written test word. The test words are looped within the active Duplication Interface circuit pack. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.

Continued on next page

Table 9-296. TEST #868 Memory Shadowing Bounds Test — *Continued*

Error Code	Test Result	Description/ Recommendation
55	FAIL	The attempt to turn off memory shadowing in this Duplication Interface circuit pack could not be verified in the hardware status register. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
	PASS	The looped around test word within the shadowing bounds matched the inversion of the written test word and the retrieved test word outside the shadowing bounds did not match the inversion of the written test word. The test words are looped within the active Duplication Interface circuit pack.

Active DUPINT Reset Test (#870)

This test is destructive.

This test checks the HFAIL bit in the active Duplication Interface circuit pack and attempts to reset the circuit pack if the HFAIL bit is set. The state-of-health of the standby SPE must be *partially functional* for this test to run.

Table 9-297. Test #870 Active DUPINT Reset Test

Error Code	Test Result	Description/ Recommendation
1419	ABORT	A standby state-of-health of *functional* or *not refreshed* prevented the test from running. 1. Manually lock the active SPE by moving the SPE-select switches located on the front of the DUPINT circuit pack to positions where they are both selecting the currently active SPE. 2. Rerun the test. 3. If the test passes, then unlock the active SPE by moving both SPE select switches to the Auto position and rerun the **test duplication-interface long** command. 4. If the test fails or aborts, replace the active DUPINT circuit pack. Use procedures described in *Replacing Duplication Channel Components* in the DUP-CHL section.

Continued on next page

Table 9-297. Test #870 Active DUPINT Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1321 2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Active Duplication Interface circuit pack hardware did not initialize. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
51	FAIL	After the active Duplication Interface circuit pack reset attempt, the HFAIL was still set. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
52	FAIL	After the active Duplication Interface circuit pack was reset, an attempt to set the software state-of-health to its value that existed before running this reset test failed. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
55	FAIL	The attempt to turn off memory shadowing in this Duplication Interface circuit pack could not be verified in the Duplication Interface hardware status register. 1. Replace Duplication Interface components starting with the active Duplication Interface circuit pack. Use SPE Duplication Channel Component Replacement procedures at the end of the DUP-CHL section.
	PASS	The Active Duplication Interface circuit pack HFAIL bit was not set, or the HFAIL bit was set and successfully cleared by this test.

Continued on next page

Active DUPINT HFAIL/STDONE Check Test (#979)

This test checks the HFAIL and STDONE bits on the active Duplication Interface circuit pack. This test is used only for periodic or scheduled testing

Table 9-298. Test #979 Active DUPINT HFAIL/STDONE Check Test

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	The STDONE bit on the active Duplication Interface circuit pack is in the wrong state.
2	FAIL	The STDONE bit on the active Duplication Interface circuit pack is in the wrong state.
3	FAIL	The STDONE and HFAIL bits on the active Duplication Interface circuit pack are in the wrong state. 1. Run the **test duplication-interface long** command and follow instructions for the Active DUPINT Reset Test (#870).
	PASS	The STDONE and HFAIL bits on the active Duplication Interface circuit pack are in the correct state.

E-DIG-BD (Multi Application Platform Board)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DIG800-BD	MIN	test board UUCSS sh	MO800DIG-BD
DIG800-BD	WRN	test board UUCSS sh	MO800DIG-BD

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).

The maintenance strategy for DIG800-BD is the same as the one described for MO-COMBD (MO-XXX-BD). Maintenance testing of the common circuit pack is handled by on-board firmware and SPE controlled tests. Maintenance software queries the firmware for error and alarm information, status, and test results. The firmware automatically reports error conditions that will result in SPE-controlled testing.

Board Insertion

The switch makes an additional board query if any of the following circuit packs are inserted:

Circuit Pack	Vintage
TN754	49
TN556	49, 80 or greater
TN800	any

For any of the above initial board up-links, the switch sends queries requesting additional data from the board for administration purposes, while also telling the board the switch software release and the system type.

For the native mode, the response to the board query downlink messages consists of several CCMS uplink messages that identify the true board code, vintage, suffix, emulation type, and the number of reserved slots it needs.

Hyperactivity

The common circuit pack is considered “hyperactive” if the service dispatcher receives 200 up-link messages from the circuit pack in a 10-second period. Since MAPD has 32 ports, the hyperactivity limit is increased to 500 up-link messages per 10seconds. An alarm is issued and the board taken out of service when the limit reaches 400 or when it hits 500 up-link messages in 10 seconds.

LED Use

The LED Control message 038x requests the Angel to drive the Red, Yellow, and Green LEDs on the face plate of typical port board on or off. On the MAPD, only the Red LED is controlled by this message. Yellow and Green change requests received from the switch by the MAPD drive LCD behavior rather than LED behavior. The switch continues to send the same LED control messages to the MAPD that it currently sends to all other port boards. The MAPD handles proper interpretation of these messages. You should note that the PC on the MAPD, as well as the switch itself, can control the LEDs and the LCD on the MAPD.

Port Administration

In administration without hardware, the switch allows administration of up to 32 MAPD ports of any port type. If the port type later reported by the board does not match the existing type, the switch assumes the board is a MAPD board with a different configuration and rejects the board. MAPD_DCP_STA and MAPD_ASAI_STA are the only two types of terminals are allowed on a MAPD board. Therefore, while administering ports on MAPD using **add station form**, it will allow only the terminals mentioned above.

NOTE:
Refer to XXX-BD (Common Port Circuit Pack) maintenance documentation for circuit pack level errors. See also DIG-LINE maintenance documentation for related line information.

E-DIG-RES (TN800 reserve slot)

See ASAI-RES.

E-DIG-STA (Emulated Digital Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1] (a) (b)	Full Name of MO
E-DIG-STA	MINOR	test port UUCSSpp l	Emulated Digital St.
E-DIG-STA	WARNING	test port UUCSSpp sh	Emulated Digital St.

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).

There are 4 tests in the Emulated Digital Line station maintenance test sequence and only one test path in the test sequence. Once the test sequence is started, all tests in the test sequence are executed.

E-DIG-ST maintenance monitors and tests ports on the TN800 MAPD circuit pack and the hardware connected to those ports for lines administered as a digital station. These include stations with an emulated digital voice terminal and stations with an emulated digital voice terminal and a linked data module. Stand-alone data modules and data adaptors in stand-alone mode are not supported by the TN800 circuit pack. Circuit pack maintenance is covered by E-DIG-BD.

Hardware Error Log Entries and Test to Clear Values

Table 9-299. Digital Line Error Log Entries - E-DIG-STA

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
18 (a)	0	busyout port UUCSSpp	WNG	OFF	rel port UUCSSpp
130 (b)		None	WNG	ON	test port UUCSSpp sh
257 (c)	40971	None			
1537 (d)	40968	None	WNG	OFF	
1793 (e)		Voice and Control Local Loop Test (#13)	MIN/ WNG[2]	ON	test port UUCSSpp l r 3
2049 (f)		NPE Crosstalk Test (#9)	MIN/ WNG[2]	ON	test port UUCSSpp l r 3

Continued on next page

Table 9-299. Digital Line Error Log Entries - E-DIG-STA — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
2305 (g)	32770	None			
3840 (h)	40965	None			
3841 (i)	41029	None			
2304 (j)		None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. Maintenance personnel have busied out the port in question. Make sure that the port is released from busyout by using the **release port UUCSSpp** command.

b. The circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.

c. Problems transmitting to the voice terminal. This problem can be caused by defective wiring, which can cause varying degrees of problems on different types of sets. Sets such as the 7410 appear to be more susceptible to wiring problems than others.

d. An in-link maintenance error has generated an off-board warning due to some problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal to a jack that is closer to the switch (number of feet of wiring between the jack and the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired after a predetermined amount of time.

e. The local loop test failed. Each failure increments the counter by 1 when the local loop test fails. The counter is decremented when the loop test passes. When the counter reaches a threshold of 3, an on-board MINOR alarm is raised.

f. The NPE Crosstalk test failed. The counter is incremented by 1 when the NPE Crosstalk test fails. The counter is decremented by 1 when the NPE Crosstalk test passes. When the counter reaches a threshold of 3, an on-board MINOR alarm is raised and the board is taken out of service.

g. The station went off-hook while it was in the ready-for-service state. Use the **status station** command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No technician action is necessary.

h. No terminal is connected to the Digital Line board. No maintenance action is required.

i. The circuit pack's message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack. No action is necessary.

j. Internal system error; no action is necessary. The error counters 1, 2, 3, 4, 5, 6, 10, 11, 12, 13, 14, 15, and 16 do not have any significance for this MO.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the Voice and Control Channel Local Loop Around Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Voice and Control Channel Local Loop Around Test (#13)		X	D
NPE Crosstalk Test (#9)		X	ND
Station Lamp Updates Test (#16)		X	ND

1. D = Destructive; ND = Nondestructive

Digital Line NPE Crosstalk Test (#9)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port’s NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port’s Long Test Sequence and takes about 20 to 30 seconds to complete. Crosstalk testing occurs on both the primary information channel (voice) and the secondary information channel (data) associated with each digital station port. If this test fails on either channel, the station and the DTDM are taken out-of-service.

Table 9-300. TEST #9 Digital Line NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available or the port was busy during the test. 1. Check the port status. 2. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before retesting. 3. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
2	ABORT	During testing of DTDM, system resources may not have been available or he port was busy during the test. 1. Check if port is being used. If possible, disconnect by toggling the disconnect button on DTDM. Retry the command after 1 minute. **CAUTION:** *This action drops the call in progress.*
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until it is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-300. TEST #9 Digital Line NPE Crosstalk Test — ***Continued***

Error Code	Test Result	Description/Recommendation
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system is under heavy traffic conditions or has time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system is oversized for the number of Tone Detectors present, or some Tone Detectors are out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. 2. Use **status station** or **status attendant** to determine the service state of the port. 3. If the service state indicates that the port is in use, then the port is unavailable for certain tests. Wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out.
1020	ABORT	Test disabled by background testing. Use the **status station** command to determine when the station is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1 2	FAIL	The Network Processing Element (NPE) of the tested port is transmitting in error. This causes noisy and unreliable connections. Error code 1 = Crosstalk test failed on the primary channel. Error code 2 = Crosstalk test failed on the secondary channel. 1. Replace the circuit pack.

Continued on next page

Table 9-300. TEST #9 Digital Line NPE Crosstalk Test — ***Continued***

Error Code	Test Result	Description/Recommendation
	PASS	The port is correctly using its allocated time slots. 1. To ensure that this is not an intermittent problem, repeat this test a maximum of 10 times. 2. If complaints persist, examine the station, connections, and wiring.

Voice and Control Channel Local Loop Test (#13)

These tests check the information and control channels between the Switch Processing Element (SPE) and the Digital Line port circuit. The SPE sends a message to loop around both the information and control channels for the port. First, the primary information (voice) channel loopback test sends a digital count from the Tone-Clock circuit pack on the primary information channel time slot and receives the same digital count with a general purpose tone detector.

While the primary information channel is still looped around, the Control Channel Loop Around Test sends four different transparent patterns to the on-board microprocessor, receives them back, and compares them.

The Loop Around Test for the secondary information (data) channel is the same as the primary information channel loop around test and is performed only if a DTDM is administered.

Next, a Conference Test checks the primary information channel. This test is the same as Conference Test #6.

The four tests generate only one result: Pass, Fail, or Abort. If any test fails or aborts, the test sequence stops.

Table 9-301. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-301. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until it is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system is under heavy traffic conditions or it has time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system is oversized for the number of Tone Detectors present, or some Tone Detectors are out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. 2. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until it is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 3. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Rerun the test at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-301. TEST #13 Voice and Control Channel Local Loop Test — ***Continued***

Error Code	Test Result	Description/ Recommendation
7	FAIL	Conference Test failed on primary channel. In some cases, users may not notice disruption in service. In extreme cases, conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port.
15	FAIL	The control channel between the processor and digital circuit pack is not transmitting properly. User impact may range from noticing nothing to not being able to use the port. This could disrupt other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using the **test board UUCSSpp** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the test still fails, replace the Digital Line circuit pack.
	PASS	The test passed, and all channels are transmitting properly. 1. To ensure that this is not an intermittent problem, repeat this test up to 10 times. 2. If noisy connections for voice or corrupted data for data transfer persist, examine the station, connections, and wiring.

Station Lamp Updates Test (#16)

This test lights all lamps on the terminal as specified. The lamp updates will run only if the station is in-service. The status of the station is checked and the lamp updates are blocked from taking place if the station is not in the in-service state. This test does not affect the status of the Message Waiting lamp.

Table 9-302. TEST #16 DIG-LINE Station Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	ABORT	System technician may have busied out the port. 1. Look for Error Type 18 (port busied out) for this port. If this error type is present, then release the port (**release station *extension***) and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
3	ABORT	Station may be in ready-for-service or out-of-service state. 1. Use the **status station** command to verify state of station. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port is busy with a valid call. 1. Use **display port UUCSSpp** to determine the station extension or attendant number of the port. 2. Use **status station** or **status attendant** to determine the service state of the port. If the port is in use, wait until it is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 3. Retry the command at 1-minute intervals a maximum of 5 times

Continued on next page

Table 9-302. TEST #16 DIG-LINE Station Lamp Updates Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1392	ABORT	This is currently a TTI port, and the test cannot execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicates that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
	FAIL	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The message to light all of the station lamps was sent successfully to the port. 1. Observe the station lamps being lit when running the test. If all lamps do not light successfully, the other Digital Line test results may indicate related problems that will not allow the lamps to light. 2. Investigate by using other Digital Line port tests and by examining the station, wiring, and connections.

EMG-XFER (Emergency Transfer)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
EMG-XFER	MAJOR	test environment UU	Emergency Transfer
EMG-XFER	WARNING	test environment UU	Emergency Transfer

1. UU is the universal cabinet number as listed in the PORT field of the Alarm or Error Log.

The Emergency Transfer maintenance object monitors the position of the Emergency Transfer switch(es) on the SYSAM circuit pack(s) in a PPN and the EPN Maintenance circuit packs in an EPN. It does not monitor whether or not the system is actually in Emergency Transfer.

Emergency Transfer (ET) provides the ability to connect designated analog phones to CO trunks when the switch cannot provide minimal phone service. Each cabinet (PPN and EPNs) has its own ET capability, and there is one EMG-XFER maintenance object for each cabinet or stack of single-carrier cabinets.

ET is controlled either automatically by the system, or manually, depending on the setting of the ET switches as described below.

Emergency Transfer Switches: EPNs and Simplex SPE

In a simplex SPE PPN cabinet, or in an EPN cabinet, if the ET switch is in the “on” position, ET is manually invoked and the system has no control of ET. This will generate a major alarm. In a simplex SPE PPN cabinet or in an EPN cabinet, if the ET switch is in the “off” position, ET cannot be invoked even if the system requests it. This will generate a warning alarm. Unless a technician is currently working on the cabinet, the switches should be left in the auto position, giving control of ET to the system.

Emergency Transfer Switches: Duplicated SPEs

On a system with duplicated SPE, the switches on both SYSAMs must be in the manual “on” position to manually invoke ET, generating a major alarm. If the switch on either SYSAM is in the manual “off” position, ET cannot be invoked, generating a warning alarm. Other settings give control to the system.

Emergency Transfer Status

The **status cabinet** UU command shows the location of the ET switches and the current status of ET in the designated cabinet as follows:

`on`	ET is manually invoked.
`off`	ET is manually prevented.
`auto+`	ET is invoked and under system control.
`auto-`	ET is not in effect and is under system control (normal operating state).
`unavailable`	The switch setting(s) is not available.

Error Log Entries and Test to Clear Values

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment UU
1	0	Emergency Transfer Query (#124)	MAJOR	ON	test environment UU r 3
257	0	Emergency Transfer Query (#124)	WARNING	ON	test environment UU r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes (Multi-Carrier)

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Battery & Battery Charger Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-303. System Technician-Demanded Tests: EMG-XFER (Multi-Carrier Cabinets)

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
OLS Query Test (Carrier E) (#127) (c)	X	X	ND
OLS Query Test (Carrier D) (#127) (c)	X	X	ND
OLS Query Test (Carrier A) (#127) (c)	X	X	ND
OLS Query Test (Carrier B) (#127) (c)	X	X	ND
OLS Query Test (Carrier C) (#127) (c)	X	X	ND
Emergency Transfer Query Test (#124)	X	X	ND
Cabinet Sensors Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test			
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1. D = Destructive, ND = Non-destructive

Notes:

a. Refer to "POWER" section for a description of this test.

b. Refer to AC-POWER section for a description of this test.

c. Refer to CARR-POW section for a description of this test.

d. Refer to CABINET section for a description of this test.

e. Refer to "EXT-DEV ADMIN? Y (External Device Alarm)" section for a description of this test.

f. Refer to "RING-GEN" section for a description of this test. These tests show up in the test sequence only if there is a TN768 or TN780 Tone/Clock circuit pack in the port network being tested.

System Technician-Demanded Tests: Descriptions and Error Codes (Single-Carrier)

Always investigate tests in the order presented in the following table. By clearing error codes associated with the *Battery & Battery Charger Query Test,* for example, you may also clear errors generated from other tests in the testing sequence. For example, you may also clear errors generated from other tests in the testing sequence.

Single-Carrier System

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Power Query Test (#79) (a)	X	X	ND
Emergency Transfer Query Test (#124)	X	X	ND
External Alarm Lead Query Test (#120) (b)	X	X	ND
Analog Ring Generator Initialization Test (#117) (c)	X	X	ND
Analog Ring Generator Query Test (#118) (c)	X	X	ND

1. D = Destructive; ND = Nondestructive

Notes:

a. Refer to "DC-POWER" for a description of this test.

b. Refer to "EXT-DEV ADMIN? Y (External Device Alarm)" for a description of this test.

c. Refer to "RING-GEN" for a description of this test.

NOTE:
These tests only show up in the test sequence if there is a TN768 Tone-Clock Board in the port network being tested.

Emergency Transfer Query Test (#124)

The Emergency Transfer Query Test queries the hardware for the state of the Emergency Transfer switch (or switches in a duplicated SPE system) and reports the result. If the position of the switch in a single SPE cabinet or EPN cabinet, or switches in a duplicated SPE cabinet, is such that the system software can control Emergency Transfer (auto), then the test passes. If the position of the switch or switches is such that the system software cannot control Emergency Transfer (manual "on" or manual "off"), then the test fails. In the PPN the SYSAM controls Emergency Transfer, and in the EPN, the EPN Maintenance circuit pack controls Emergency Transfer

Table 9-304. TEST #124 Emergency Transfer Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to ABORT with Error Code 2000, check for system powering problems with the A carrier (PPN or EPN). Resolve all AC-POWER and CARR-POW alarms in a multi-carrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Then, repeat the test. 3. If the test continues to ABORT with a 2000 Error Code, resolve all SYSAM errors in a PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test.
2029 2319 2320 2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
17 18 20 33 65 289	FAIL	Emergency Transfer is manually turned OFF (Emergency Transfer switch off). 1. Place the switch (or switches in a PPN with duplicated SPE) in the AUTO position.
34 290	FAIL	Emergency Transfer is manually turned ON (Emergency Transfer switch on). 1. Place the switch (or switches in a PPN with duplicated SPE) in the AUTO position.
	PASS	System software has control of Emergency Transfer within this cabinet. If Emergency Transfer is currently invoked (the emergency transfer LED is on), the cause could be a major alarm. 1. The following list shows the error types that can cause Emergency Transfer. If any of these errors appear in the log, then refer to the appropriate section and resolve those problems first. R-MEDIA SW-CTL TONE-BD, Error Type 3585 Aux Data 121; Error Type 2305, Aux Data 40800 2. If none of the above errors appear in the log, then check the Emergency Transfer hardware. 3. On an EPN, if Emergency Transfer is invoked while call processing is permitted, verify that the current limiter card (982LS) is in the correct slot on the backplane. If the current limiter card is not in the correct slot, move it to the correct location and rerun Test #124.

EPN-SNTY (EPN Sanity Audit)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
EPN-SNTY	None	None	EPN Sanity Audit

The EPN Sanity Audit feature enhances the system’s ability to recover from failure conditions that disable an entire EPN. In such situations, not only is the affected EPN unable to provide service to the system, but the system itself has not detected the condition. The EPN Sanity Audit feature recognizes an EPN as unable to provide service when the software cannot receive control messages from EPN circuit packs. When such a failure is detected by the EPN Sanity Audit, a sequence of recovery actions is triggered to restore the EPN to service.

For a Standard Reliability system (simplex SPE), the recovery sequence is:

1. TDM Bus Switch
2. EPN WARM Reset
3. EPN COLD Reset

For a High or Critical Reliability system (duplicated SPE), the recovery sequence is:

1. TDM Bus Switch
2. Tone/Clock Switch within the EPN
3. PNC Interchange
4. EPN WARM Reset
5. EPN COLD Reset

The EPN Sanity Audit feature activates only when all existing maintenance operations have failed to detect the EPN problem. The EPN Sanity Audit serves as a safety net for the EPN.

NOTE:
It is not clear why certain types of EPN problems activate this feature. Thus, error log entries related to these problems do not specify which hardware to replace. The error log entries only indicate that some drastic recovery action occurred due to an unknown problem. However, clues as to the root cause of the EPN outage may be present in the Error Logs and the Alarm Logs of the following MOs: Switch Control (SW-CTL), TDM Bus (TDM-BUS), Expansion Interface (EXP-INTF), TDM Bus Clock (TDM-CLK), EXP-PN, and PNC-DUP. You should refer to these maintenance sections during troubleshooting operations.

Error Log Entries and Test to Clear Values

Table 9-305. EPN-SNTY Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any			None
8801 (a)	Any	None			
8803 (b)	Any	None			
9901 (c)	Any	None			
9902 (d)	Any	None			
9903 (e)	Any	None			
9904 (f)	Any	None			
9905 (g)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Error 8801 occurs whenever the EPN is unable to send up-link control messages and the control channel of the TDM Bus in the EPN has been switched as part of the recovery procedure.

b. Error 8803 occurs each time whenever the EPN is unable to send up-link control messages and the EPN Tone-Clock has been switched as part of the recovery procedure.

c. Error 9901 occurs whenever the EPN is unable to send up-link control messages, but recovers after the control channels of the TDM Bus in the EPN are switched.

d. Error 9902 occurs whenever the EPN is unable to send up-link control messages, but recovers after the active Tone-Clock in the EPN is switched.

e. Error 9903 occurs whenever the EPN is unable to send up-link control messages, but recovers after a PNC interchange has taken place.

f. Error 9904 occurs whenever the EPN is unable to send up-link control messages, but recovers after an EPN WARM reset.

g. Error 9905 occurs whenever the EPN is unable to send up-link control messages, but recovers after an EPN COLD reset.

ERR-LOG (Error Log)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ERR-LOG	none	none	Error Log

The ERR-LOG maintenance object (MO) is responsible for the sanity of the Alarm Log, the Hardware Error Log, and the Software Error Log. If an inconsistency is detected in any one of these logs, all logs will be re-initialized and a hardware error will be logged against ERR-LOG indicating the time of inconsistency. There are no tests and no alarms for the Error Log MO. This MO exists solely for the purpose of allowing errors to be logged against it.

Hardware Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
510 (a)	See below	none	none	none	none

Notes:

a. Indicates that an inconsistency was detected in either the Alarm Log, the Hardware Error Log, or the Software Error Log. The system attempts to recover the logs but, depending on the extent of the corruption, some or all entries in the logs may be lost. Any alarms that were active at the time of this error have been cleared. There is no associated test for this error.

   The Aux Data value indicates when the inconsistency was found:

0	During a periodic audit of the Error Log
1	After an extended reboot
2	After a reboot
4	After a Level-3 System Reset (COLD_1)
8	After a Level-2 System Reset (COLD_2)
16	After a Level-1 System Reset (Warm Start)
100	After an internal software audit
2500	After a single-process (MDM) restart

ETH-PT (Control LAN Ethernet)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ETH-PT	MAJOR	test port UUCSSpp long	MO_ETH_PT
ETH-PT	MINOR	test port UUCSSpp long	MO_ETH_PT
ETH-PT	WARNING	test port UUCSSpp	MO_ETH_PT

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The TN799 Control LAN (CLAN) packet port circuit pack provides TCP/IP connection to adjuncts applications such as CMS, Intuity, and DCS Networking. The CLAN circuit pack has one 10baseT Ethernet connection and up to 16 DS0 physical interfaces for PPP connections. Multiple CLAN circuit packs in a system gives additional TCP/IP capacity.

A remote socket control link (RSCL) links the CLAN and the SPE to pass call control and other management information. Since one link serves all the ports on the circuit pack, maintenance of the RSCL is part of the CLAN circuit pack maintenance.

NOTE:
The CLAN TN799 circuit pack replaces the PGATE and PI circuit packs in the G3r and G3si/G3vs systems, respectively. The PGATE or PI can be used with the CLAN to create an X.25-to-TCP/IP bridge for adjunct and DCS connections.

Control LAN Congestion Controls

The switch activates congestion controls on CLAN when it detects buffers exceeding the threshold. The switch releases the congestion controls when the CLAN reports that its buffer level has returned to normal levels.

If congestion:	Then the switch:
Persists for a 14-minute interval,	Raises MINOR alarm.
Exhausts buffers,	Raises MINOR alarm.
Ceases for 12 minutes,	Retires MINOR alarm.

Error Log Entries and Test to Clear Value

Table 9-306. ETH-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp s
1 (a)	0	Ethernet Local Looparound Test (#1278)	MINOR	ON	test port UUCSSpp l r 3
513 (b)	0	Link Integrity Inquiry (#1282)	MINOR	OFF	test port UUCSSpp r 2
769 (c)	0		WNG	OFF	
1281 (d)	0				
1537, 1538 (e)		Session Status Test (#1286)	MINOR	OFF	
1793-1920 (f)					
2305-2560 (g)					
2561-2816 (g)					
3329 (h)		TCP/IP Ping Test (#1281)	WNG	OFF	

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. **Error Type 1**: Ethernet Local Looparound Test (#1278) failed.

1. Test the port (**test port UUCSSpp long**).
2. Refer to repair procedures for Test #1278.

b. **Error Type 513**: Link Integrity Inquiry Test (#1282) failed or CLAN port detected loss of Ethernet link integrity.

Possible causes:

- Cabling
- Ethernet transceiver

1. Test the port (**test port UUCSSpp long**).
2. If the Link Integrity Inquiry Test (#1282) fils, refer to its repair procedure.

c. **Error Type 769**: Port received invalid frame.

Invalid Ethernet frame errors occur when the frame

- Contains a bad Cyclic Redundancy Check (CRC)
- Is misaligned

1. Isolate the problem with the Ethernet Local Looparound Test (#1278).
2. Test the port (**test port UUCSSpp long**).
3. Verify the repair with the Ethernet Local Looparound Test (#1278).
4. Clear the alarm (**test port UUCSSpp long clear**).

d. **Error Type 1281**: System software received an indication that the far-end has requested a disconnect of a session on this link. This is a log-only error.

e. **Error Type 1537-1538**: Some or all sessions on a port are down.

If:	Then the switch:
Some sessions are down	Raises WARNING alarm on circuit pack
All sessions are down	Raises MINOR alarm on circuit pack

1. Test the port (**test port UUCSSpp short**).
2. Refer to Session Status Test (#1286) repair procedure to verify repair.

f. **Error Type 1793-1920**: system software received an indication that a socket was closed due to an error. Error Type indicates the application associated with this socket.

Error Type	Application
1793	Unused
1794	DCS
1795	AUDIX
1796	CMS
1797	ISDN Gateway
1798-1920	Reserved for future

Aux Data indicates the internal application number.

g. **Error Type 2305-2816**: System software detected a session is down. Aux Data indicates the session number. These are log only errors. Error types 2305-2560 are for session numbers 1-256. Error types 2561-2816 are for session numbers 257-512.

h. **Error Type 3329**: TCP/IP Ping Test failed.

1. Test port (**test port UUCSSpp short**).
2. Refer to TCP/IP Ping Test (#1281) repair procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Investigate errors in the order they appear in the table below.

Table 9-307. System Technician-Demanded Tests: ETH-PT

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Ethernet Local Loop-Around Test (#1278)		X	D
TCP/IP Ping Test (#1281)	X	X	ND
Session Status Test (#1286)	X	X	ND
Link Integrity Inquiry Test (#1282)	X	X	ND

1. D = Destructive, ND = Non-destructive

Ethernet Local Looparound Test (#1278)

This test is destructive.

Use this test to check circuitry in the data path for an Ethernet call (from the on-board processor to the Ethernet Transceiver). This test fails if the data it receives does not match the data it transmits.

Table 9-308. TEST #1278 Ethernet Local Looparound Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port is in use. 1. Determine status of port (**status clan-port UUCSSpp**). 2. Retry the command when the port is idle. The post may be forced to the idle state by executing a **busyout port UUCSS** command. **NOTE:** The busyout port command is destructive, causing all calls and links associated with the port to be torn down.
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. If the problem persists, reset the circuit pack (**busyout board UUCSS, reset board UUCSS,** and **release board UUCSS**). 2. If the problem persists, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. If the problem persists, escalate the problem.
2100	ABORT	Could not allocate the necessary resources to run test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
1	FAIL	Circuit pack detected failure in the Ethernet Local Looparound Test (#1278). 1. If the problem persists, reset the circuit pack (**busyout board UUCSS, reset board UUCSS,** and **reset board UUCSS**). 2. If the problem persists, replace the circuit pack.
	PASS	The circuitry tests properly.

TCP/IP PING Test (#1281)

This non-destructive test fails if all the endpoints fail to respond. Use this test to check the circuitry in the data path for a peer-to-peer IP layer connection.

Table 9-309. TEST #1281 TCP/IP PING Test

Error Code	Test Result	Description/ Recommendation
1, 2, 11	ABORT	Internal error 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the problem persists, escalate the problem.
7	ABORT	Destination unreachable. 1. Verify that there is a destination to ping in the routing table (list ip-route and look for destinations reachable through this ethernet port). 2. If there are no reachable destinations from this port (i.e., no routes administered on ethernet), administer a route and retry. 3. Escalate if the problem persists.
1005	ABORT	Incorrect test configuration. 1. Verify Ethernet link is in service (**status port UUCSSpp** or **status link n**). 2. Verify that Ethernet link is enabled (**status port UUCSSpp** or **status link *n*** or **display data-module**). 3. Verify routing table has reachable destinations. 4. Repeat the test. 5. If problem persists while the Ethernet link is in service and enabled, escalate the problem.
1124	ABORT	Ethernet link is not enabled. 1. Verify that the Ethernet link is enabled (**status port UUCSSpp**, **status link *n***, or **display data-module**). 2. If the link is not enabled, enable the link (**change data-module**). 3. Repeat the test. 4. Escalate if the problem persists.
1125	ABORT	Ethernet link not in service. 1. Verify Ethernet link is in service (**status port UUCSSpp** or **status link n**). 2. If the link is not in service, release the link using (**release link n** or **release port UUCSSpp**). 3. Repeat the test. 4. Escalate if the problem persists.

Continued on next page

Table 9-309. TEST #1281 TCP/IP PING Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. Reset the circuit pack (**busyout board UUCSS, reset board UUCSS,** and **release board UUCSS**). 2. If the test fails again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
1003	FAIL	Ping to the destination failed due to on-board problem. 1. Retry the command at 1-minute intervals, up to 3 times. 2. If the problem persists, reset the circuit pack (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). 3. If the problem persists, re-administer the ehternet connection through a different ethernet port, if available. 4. If the problem still persists, or if there are no other available ethernet ports, replace the circuit pack.
1007	FAIL	Ping to the destination failed due to the destination down. 1. Verify that at least one destination reachable through this port is up. Ping this destination (ping ip-address xxx.xxx.xxx.xxx). 2. If the ping to any destination is successful through this port, the link is up, although some destinations are unreachable. Ignore the failure. 3. If ping to all destinations fail, test this port (**test port UUCSSpp short**) and follow repair procedures for Session Status Test (#1286) failures.
	PASS	TCP/IP Ping Test (#1281) is successful.

Link Integrity Inquiry Test (#1282)

This non-destructive test queries the CLAN Ethernet port's physical connections.

If:	Then the test:
CLAN connection is present,	Passes.
CLAN connection is absent,	Fails.
There is no response,	Aborts.

Table 9-310. TEST #1282 Link Integrity Inquiry Test

Error Code	Test Result	Description/ Recommendation
1124	ABORT	Ethernet link is not enabled. 1. Verify that the Ethernet link is enabled (**status port UUCSSpp**, **status link *n***, or **display data-module**). 2. If the link is not enabled, enable the link (**change data-module**). 3. Repeat the test. 4. Escalate if the problem persists.
1125	ABORT	Ethernet link not in service. 1. Verify whether Ethernet link is in service (**status port UUCSSpp** or **status link n**). 2. If the Ethernet link is not in service, release the link (**release link n** or **release port UUCSSpp**). 3. Repeat the test. 4. Escalate if the problem persists.
1959	ABORT	Downlink message error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.

Continued on next page

Table 9-310. TEST #1282 Link Integrity Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
	FAIL	Link integrity lost due to problem with attachment of Ethernet cable to the port. 1. Repeat the test. 2. If the test fails, verify that the cable properly is secured to Ethernet port and to the bus. 3. Verify the CLAN circuit pack link integrity LED is glowing. 4. Retry the test. 5. If problem persists, refer to Ethernet Local Looparound Test (#1278) repair procedures.
	PASS	The Ethernet Link Integrity Test (#1282) detects good connections.

Session Status Test (#1286)

This non-destructive test determines the status of all Ethernet port sessions. This test queries the system software on port session status.

If the system software indicates that:	Then the switch:
All port sessions are up (ALL UP)	Raises no alarm, or retires alarm
Some port sessions are up (SOME UP)	Raises WARNING alarm
All port sessions are down (ALL DOWN)	Raises MINOR alarm

Table 9-311. TEST #1286 Session Status Test

Error Code	Test Result	Description/ Recommendation
1124	ABORT	Ethernet link is not enabled. 1. Verify that the Ethernet link is enabled (**status port UUCSSpp**, **status link *n***, or **display data-module**). 2. If the link is not enabled, enable the link (**change data-module**). 3. Repeat the test. 4. Escalate if the problem persists.
1125	ABORT	Ethernet link not in service. 1. Verify whether Ethernet link is in service (**status port UUCSSpp** or **status link n**). 2. If the Ethernet link is not in service, release the link (**release link n** or **release port UUCSSpp**). 3. Repeat the test. 4. Escalate if the problem persists.
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. If the problem persists, reset the circuit pack (**busyout board UUCSSpp**, **reset board UUCSS**, and **release board UUCSS**). 2. If the problem persists, replace the circuit pack.
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
1	FAIL	System software indicates at least one Ethernet link session is down (SOME UP). 1. Isolate downed sessions (**status port UUCSSpp** or **status link n**). 2. Follow actions based on session information.

Continued on next page

Table 9-311. TEST #1286 Session Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	System software indicates all Ethernet sessions are down (ALL DOWN). 1. Test the port (**test port UUCSSpp**) to verify the Ethernet Local Looparound Test (#1278) result. 2. If test passes, wait for system software to indicate ALL UP. 3. If the test fails, check the destination and other components in the path. 4. If the destination and other components in the path are in-service, take action based on session information.
	PASS	All sessions are up.

ETR-PT (Enhanced Tone Receiver Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ETR-PT	MAJOR	test port UUCSSpp sh	Enhanced Tone Receiver Port
ETR-PT	MINOR	test port UUCSSpp sh	Enhanced Tone Receiver Port
ETR-PT	WARNING	test port UUCSSpp sh	Enhanced Tone Receiver Port

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

NOTE:
Replacing the tone/clock circuit pack requires a special procedure which is described in “TONE-BD (Tone-Clock Circuit Pack)”. That section also describes the LED display for this board.

The TN2182 is a combined Tone Generator/Tone Detector board. It provides 8 Enhanced Tone receiver (ETR) ports. Each of these ports provides the functions previously found individually on DTMR-PTs, GPTD-PTs and CLAS-PTs ports. Thus each port on the TN2182 may be used for any tone detection function that was previously done by TN748, TN420 or TN744 Tone detection boards.

The TN2182 provides Mu-law or A-law tone detection capability.

Since the TN2182 also provides Tone/Clock function only one (or two if your system is duplicated) TN2182 circuit packs may be present in a port network. Thus if more tone detection resources are needed, the additional resources must be provided by TN748, TN420 or TN744 circuit packs.

Error Log Entries and Test to Clear Values

Table 9-312. ETR-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1 (a)	any	Tone Detector Audit/Update Test (#43)	MAJ/ MIN	ON	test port UUCSSpp r 2
18		busyout port	WARNING	OFF	release port UUCSSpp
257 (a)(b)	17666	Tone Detection Audit Update Test (#43	MAJ/ MIN	ON	test port UUCSSpp r 3
513 (a)(c)	any	Tone Detection Verification Test (#42)	MAJ/ MIN	ON	test port UUCSSpp r 3

Notes:

a. There are two possible alarm levels for this error type: major alarm and minor alarm. These alarm levels are dependent on the administered thresholds for TTR, CPTR and CCTR. Each ETR port is capable of operating an any of these.

A major alarm is raised if the total number of ports capable of TTR, CPTR or CCTR detection currently in-service is less than or equal to 1/2 of the administered TTR, CPTR or CCTR threshold number.

Otherwise, a minor alarm is raised. In either case, run the short test sequence against the port (ETR-PT) and follow the error code procedures for the individual tests.

The threshold number of ports for service is administered using the **change system-parameters maintenance** command.

1. Use **list configuration carrier** to get the board type and location. If the board is TN744, then do Steps 2-4; if it is TN2182, do Steps 5-12.
2. Execute 3 commands: **busyout board UUCSS**, **reset board UUCS**S, and **release board UUCSS**. Reset is required to reload RAM associated with the TN744's DSPs. This will take all 8 tone detector ports out of service for a few seconds. Only 4 of the 8 would be out of service due to the alarm. (There are 4 tone detectors on each of the two DSPs.) Other than the unlikely potential of running out of tone detector resources in the switch, there is no other effect when the board is reset.
3. Test the board (**test board UUCSS long**).

4. If the test passes, terminate the repair process. If the test fails, replace the board.
5. Check to see if the board is duplicated (**list cabine**t and **status port-network** on the affected port network.)
6. If the board is not duplicated, use test tone UUCSS long to resolve the error. The long test resets the board and is required to reload on-board RAM associated with the TN2182"s DSPs. The effect is that tone detectors are taken out of service momentarily and tones are removed from the TDM bus for about 10 seconds. This means no dial or touch tones during this interval, which probably will not affect calls in progress, but could cause a call origination to abort or cause a user to not get dial tone when going off hook.
7. If all tests pass and the alarm does not resolve, retest (**test tone UUCSS long clear**).
8. If the test passes, terminate the repair process. If it fails, replace the circuit pack at the customer's convenience.
9. If the board is duplicated, switch to the standby side (**set tone**).
10. Test the alarmed board (test tone UUCSS long). This resets the board and is required to reload on-board RAM associated with the TN2182's DSPs.
11. If all tests pass and the alarm does not resolve, retest with **test tone UUCSS long clear**.
12. If the test passes, terminate the repair process. If it fails, replace the board.

b. The ETR-PT lost its translation. Testing the ETR-PT is sufficient to reload its translation. If testing the ETR port does not clear the error, then the circuit pack containing the defective ETR port should be replaced at a time when it is convenient to remove a clock board from the system. Follow the procedures described in "TONE-BD (Tone-Clock Circuit Pack)" for replacing a tone/clock circuit pack.

c. This error indicates the (ETR-PT) Enhanced Tone Receiver is having problems detecting touch tones, call progress or MFC tones. If this error type is persistently logged, then the circuit pack containing the defective ETR-PT should be replaced at a time it is convenient to remove a clock board from the board from the system. Follow the procedures described in the "TONE-BD (Tone-Clock Circuit Pack)" section for replacing a tone/clock circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test(#42)	X	X	ND
Tone Detection Audit/Update Test(#43)	X	X	ND

1. D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test checks out a single ETR port in the touch-tone receiver mode MFC tone detection/generation mode and general purpose tone detection mode. During the first portion of the test, the touch-tone receiver mode is tested. Then general purpose call progress and maintenance tones are tested and lastly MFC tones are tested

Table 9-313. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test OR there was an Internal system error.
1	ABORT	The system could not allocate all the resources needed to test the tones.
1001	ABORT	The system was unable to put the ETR-PT in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This situation could occur when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS with the **test tdm** command. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a Tone-Clock for the test connection. This may be caused by a heavy load on the system or by a faulted Tone-Clock. 1. Check to see if there are any alarms against the TONE-BD or TONE-PT in the port network where the test aborted. 2. If a new Tone-Clock has been inserted, allow about 1 minute for maintenance to run on the newly inserted circuit pack. 3. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Circuit Pack’s response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-313. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2006	ABORT	This abort code indicates that the active Tone-Clock circuit pack or a Tone Detector circuit pack may not be functioning properly. 1. Test the *active* Tone-Clock circuit pack in the port network with the **test tone-clock UUC** command. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1-122	FAIL	DTMF digits were not detected correctly. 1. Run the short test sequence wth the **test port UUCSSpp sh r 1** command. 2. If the problem persists, the system is still operating properly but capacity is reduced. To restore performance to normal, replace the circuit pack with the defective ETR-PT.
102	FAIL	2225-Hz Modem Answer Tone was not detected correctly. This impacts call-classification operation. 1. Run the short test sequence via the **test port UUCSSpp sh r 1** command. 2. If the problem persists, the system can still operate properly but capacity is reduced. In order to restore performance to normal, replace the circuit pack containing the defective port. Follow the procedures described in the "TONE-BD (Tone-Clock Circuit Pack)" section for replacing a tone/clock circuit pack.
130	FAIL	Forward or Backward MFC signals were not correctly generated or detected. This will impact MFC calls. 1. Run the short test sequence via **test port UUCSSpp sh r 1**. 2. If the problem persists, the system can still operate properly but capacity will be reduced. In order to restore performance to normal, replace the TN2182 circuit pack containing the defective ETR-PT. Follow the procedures described in the "TONE-BD (Tone-Clock Circuit Pack)" section for replacing a tone/clock circuit pack.
	PASS	Tone Detection Verification is successful. The ETR Port is able to detect/generate all necessary tones.

Tone Detector Audit/Update Test (#43)

A Digital Signal Processor sanity audit is performed on the ETR-PT.

Table 9-314. TEST #43 Tone Detector Audit/Update Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system could not allocate all the resources needed for this test.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-314. TEST #43 Tone Detector Audit/Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Hardware audit failed. 1. Use **list configuration carrier** to get the board type and location. If the board is TN744, then do Steps 2-4; if it is TN2182, do Steps 5-12. 2. Execute 3 commands: **busyout board UUCSS**, **reset board UUCS**S, and **release board UUCSS**. Reset is required to reload RAM associated with the TN744's DSPs. This will take all 8 tone detector ports out of service for a few seconds. Only 4 of the 8 would be out of service due to the alarm. (There are 4 tone detectors on each of the two DSPs.) Other than the unlikely potential of running out of tone detector resources in the switch, there is no other effect when the board is reset. 3. Test the board (**test board UUCSS long**). 4. If the test passes, terminate the repair process. If the test fails, replace the board. Follow the procedures in TONE-BD. 5. Check to see if the board is duplicated (**list cabine**t and **status port-network** on the affected port network.) 6. If the board is not duplicated, use test tone UUCSS long to resolve the error. The long test resets the board and is required to reload on-board RAM associated with the TN2182"s DSPs. The effect is that tone detectors are taken out of service momentarily and tones are removed from the TDM bus for about 10 seconds. This means no dial or touch tones during this interval, which probably will not affect calls in progress, but could cause a call origination to abort or cause a user to not get dial tone when going off hook. 7. If all tests pass and the alarm does not resolve, retest (**test tone UUCSS long clear**). 8. If the test passes, terminate the repair process. If it fails, replace the circuit pack at the customer's convenience. Follow the procedures in TONE-BD. 9. If the board is duplicated, switch to the standby side (**set tone**). 10. Test the alarmed board (test tone UUCSS long). This resets the board and is required to reload on-board RAM associated with the TN2182's DSPs. 11. If all tests pass and the alarm does not resolve, retest with **test tone UUCSS long clear**. 12. If the test passes, terminate the repair process. If it fails, replace the board. Follow the procedures in TONE-BD.
	PASS	The ETR Port has passed the sanity inquiry.

EXP-INTF (Expansion Interface Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
EXP-INTF	MAJOR	test board UUCSS s	Expansion Interface Circuit Pack
EXP-INTF	MINOR	test board UUCSS s	Expansion Interface Circuit Pack
EXP-INTF	WARNING	test board UUCSS s	Expansion Interface Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

WARNING:

If the Expansion Interface (EI) circuit pack you are troubleshooting is associated with a Survivable Remote EPN (SREPN), before the SREPN can be returned to normal service, all LAPD EI link problems must be cleared, and the SREPN slide switch on the TN2301 (located in the SRPPN carrier) must be ***manually*** *set to the normal position. See* *"Restoring Normal Service to the SREPN" on page 9-825* *in this section.*

Refer also to *DEFINITY ECS Installation and Maintenance for Survivable Remote EPN, Issue 1*, 555-230-102.

Following this introductory description of the Expansion Interface (EI) circuit pack are sections on the following topics:

- "EI In-Service Mechanism"
- "Survivable Remote EPN"
- "LEDs"
- "EI and Tone-Clock Interactions"
- "Replacing an EI Circuit Pack—Simplex PNC"
- "Replacing an EI Circuit Pack— Duplicated PNC"
- "Expansion Interface Manual Loopback Procedure"

The TN570 or the TN776 Expansion Interface (EI) Circuit Pack provides a TDM and Packet bus to fiber interface for the communication of signaling information, circuit switched connections, and packet switch connections between endpoints residing in separate port networks. EI Circuit Packs are located in the Processor Port Network (PPN) or in Expansion Port Networks (EPNs) and are connected via optical fiber links. An EI can be connected to:

- Another EI (direct-connect configuration)
- A DS1 Converter in a DS1 CONV Complex used to remote an EPN
- A Switch Node Interface (center stage switch configuration)
- A SREPN (Survivable Remote EPN)

In a Center Stage Switch configuration with duplicated Port Network Connectivity, the PPN Expansion Interface circuit pack may be located in the Switch Node Carrier (see Figure 9-38). In these cases, the Expansion Interface circuit pack and Switch Node Interface circuit pack may be connected via a metallic cable instead of an optical fiber link. Metallic cable should be tested and replaced in the same manner as the optical fiber.

A PPN-EPN connection can be extended through a DS1 CONV Complex. (See Figure 9-39). When discussing problems that may be related to fiber link problems, the DS1 CONV will be considered part of the fiber link. If diagnosis of the problem points to the fiber connectivity, and a DS1 CONV circuit pack is part of this connectivity, problems with the DS1 CONV circuit pack should be investigated (See DS1 CONV-BD Maintenance documentation). The DS1 CONV circuit pack enters into diagnostics for the Expansion Interface circuit pack via such tests as the Neighbor Query Test (#237), the Fiber Out-of-frame Test (#238), the Two-way Transmission Test (#241), and the Packet Transmission Test (#589).

In critical reliability systems, the fiber link connections are duplicated as part of Port Network Connectivity (PNC) duplication. In high reliability systems with a Center Stage Switch and simplex Port Network Connectivity, a single point of failure between the PPN and the Center Stage Switch is eliminated by duplicating PPN EIs, the SNI s to which they connect in the Center Stage Switch, and the fiber or metallic connections between them. These two connections normally share the call processing load. In the event of the failure of one of these connections, the load can be shifted to the operational link.

Figure 9-35 shows the location of the EI circuit packs in a typical simplex PNC, direct connect configuration.

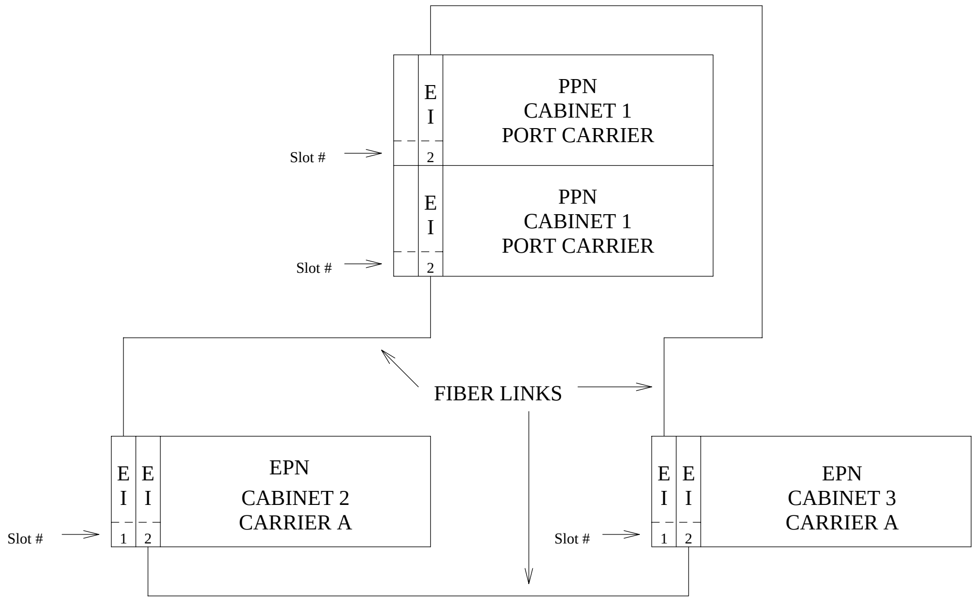

Figure 9-35. Direct Connect Configuration with Simplex PNC

Each Port Network in direct connect configurations must be connected to each other port network through a fiber link. Each EPN has one EI that functions as an archangel. This EI must be connected with fiber to an EI located in the PPN. If an EI is functioning as an archangel (bus master), its yellow led will be flashing at a rate of 2 seconds on and 200 ms off.

Figure 9-36 shows the location of EI circuit packs in a typical duplicated PNC, direct-connect configuration.

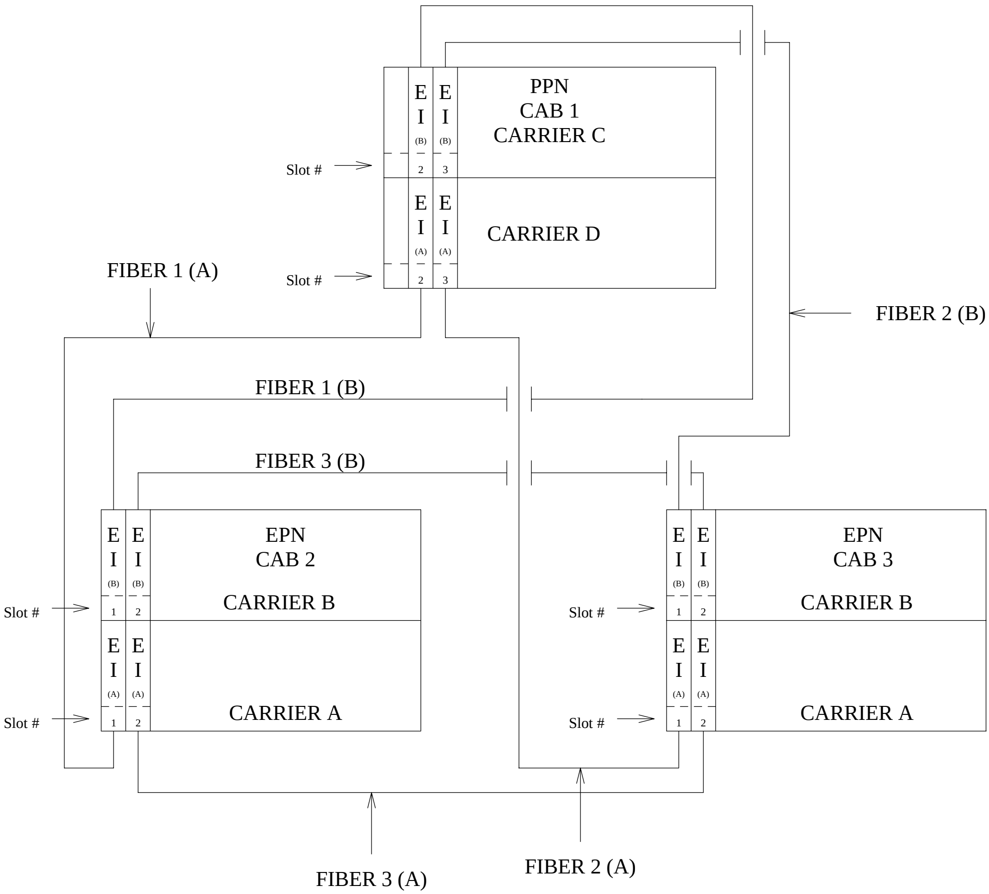

Figure 9-36. Direct Connect Configuration with Duplicated PNC

In a duplicated PNC there is an A-side PNC and a B-side PNC. All EIs in this diagram are labeled with an A or a B to designate which PNC they are a part of. Note that the PNC designation (A or B) does not relate directly to carrier location. Again, only one of the EIs in an EPN can function as an archangel (TDM Bus Master). The EI that is on the active PNC and that is connected to the PPN is the only one that can function in this mode. In normal operation, its yellow LED should be blinking at a rate of 2 seconds on and 200 ms. off.

Figure 9-37 shows the location of EIs in a typical center stage switch configuration with simplex PNC.

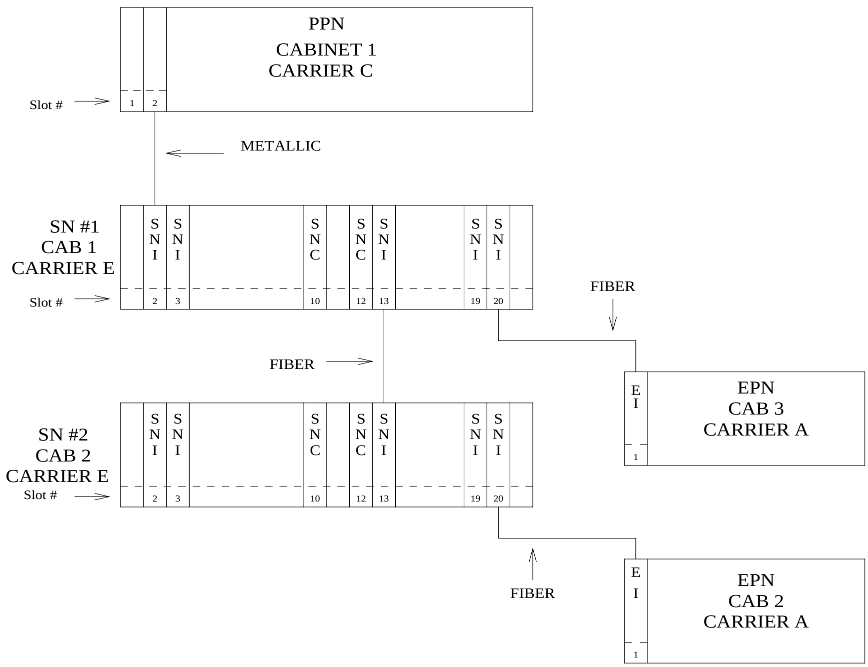

Figure 9-37. Center Stage Switch Configuration with Simplex PNC

In a simplex stage switch configuration, only one EI is needed in each port network. Notice that there is no direct connection between the EPNs, rather all inter-EPN connections are made through the stage switch. Each SNI in the switch node carriers can be connected to an EPN through an EI circuit pack.

Figure 9-38 shows the location of EIs in a typical two Switch Node Center Stage Switch configuration with duplicated PNC.

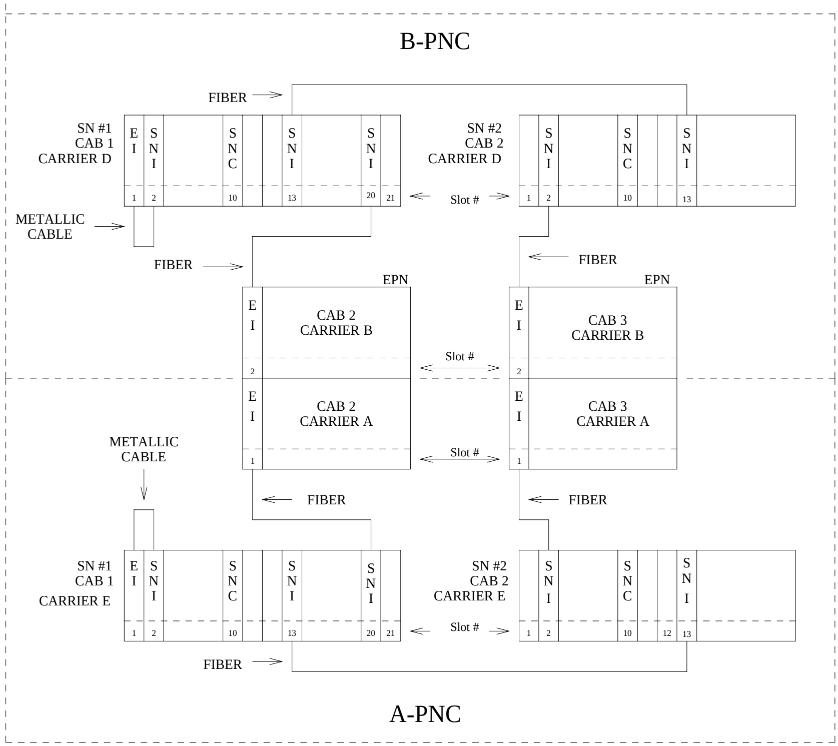

Figure 9-38. Center Stage Switch Configuration with Duplicated PNC

In a duplicated center stage switch configuration, two EIs are needed in each port network. One is located on the A-side PNC and the second one is located on the B-side PNC. Note that PNC designation (A or B) does not relate directly to carrier location. The EI that is on the active PNC is the one that is acting as the Archangel (TDM Bus Master) for the EPN. This is the EI that should have its yellow led blinking at a rate of 2 seconds on and 200 ms. off. The standby PNC EI should have its yellow led off. The PPN EI circuit packs are located in the first slot of the switch node carriers, although they may be located in port carriers.

An EPN (and thus, the EIs contained in that EPN) can be remoted via a DS1 converter complex. This requires that the associated fiber link which provides connectivity to the remoted EPN, be administered with a DS1 converter complex. The DS1 converter complex consists of two TN574 DS1 converter (DS1 CONV) circuit packs connected by from 1 to 4 DS1 facilities. Figure 9-39 shows where the DS1 converter complex fits into an EI to SNI, or EI to EI fiber link. For more information, refer to the DS1 CONV circuit pack Maintenance documentation.

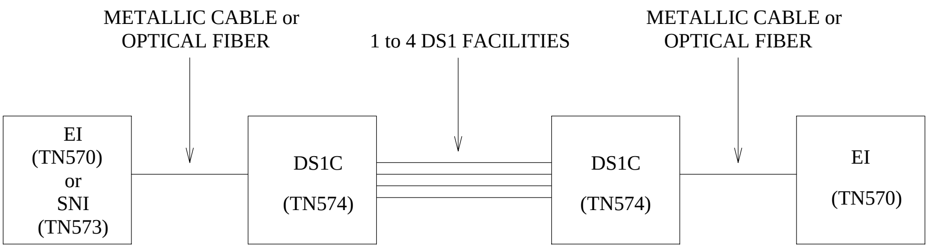

Figure 9-39. Fiber Link with DS1 Converter Complex

EI In-Service Mechanism

In order for calls to be routed through a given EPN, the EI that is part of the connectivity to that EPN must be put into service. In order for an EI to be put into service, the following criteria must be met:

1. The EI must be recognized by software (inserted). Use the **list config carrier** command to determine if the board is recognized by software.
2. The EI must have a fiber link administered to it. Use the **list fiber-link** command to determine if this EI circuit pack has a fiber administered to it.
3. The EI must have established a LAPD link to its neighbor (the circuit pack on the "other end" of the fiber link). This neighbor can be another EI or an SNI (Switch Node Interface).

CAUTION:
If requirements 1 and 2, above, have been met, and the yellow LED s are flashing in a manner that appears to confirm that the Expansion Interface circuit pack has established a LAPD link to its neighbor, the circuit pack still may not be "in-service". The requirement is that it must have the CORRECT neighbor on the other end of the fiber. Care must be taken when connecting the fibers to the back of the carriers so that fibers are connected to the correct circuit packs. In a Center Stage Switch configuration, run the "configuration audit" test against the Switch Node Interface circuit pack that is the neighbor of the Expansion Interface circuit pack in question (see SNI-BD Maintenance Documentation for more details).

Once an EI has been put into service, if any of the above listed "in-service" criteria become untrue, the EI is taken out of service, and service to that port network is not available.

In a system that is configured with PNC duplication active, taking an EI out of service that is on the active PNC will, if all other things on the active and standby PNC are equal (i.e. both PNCs are equally healthy, the standby PNC is not busied out, the PNC is not locked by software), result in a PNC interchange.

Survivable Remote EPN

The Survivable Remote EPN (SREPN) feature allows a DEFINITY R6r EPN (either MCC or SCC) to provide service to the customer when:

- The fiber (or T1/E1 Expansion Interface link to the main R6r processor) fails or is severed
- The R6r processor or center stage fails.

NOTE:
This feature is viewed as a “disaster recovery operation” capability rather than as an additional reliability option.

The SREPN requires remote EPN cabinet to provide processor (SPE) capabilities to the EPN in the event of a failure. A logic switch circuit pack (TN2301) located in the SRPPN detects when the link to the R6r is down and switches to a link from the local SRPPN (TN790-based processor). When the links to the R6r are restored and verified to be stable, the logic switch is ***manually reset***, and the EPN is reconnected to the links from the R6r.

NOTE:
The SREPN feature is not available when an ATM-PNC/EI circuit pack is used to replace the TN570 EI circuit pack in a direct-connect configuration, or an ATM Switch is providing the Center Stage (PNC) connectivity.

NOTE:
If you suspect a problem with the TN790B-based R6si SRPPN use the R6si maintenance documentation supplied with the SREPN feature to resolve any alarms/errors associated with the SRPPN carrier.

SREPN Feature Active

WARNING:
All calls within the SREPN are terminated when the SREPN feature is activated, and the R6si *SRPPN takes control of the SREPN.*

The SREPN feature is activated when the maintenance circuit pack (TN775C or later and located in the SREPN) detects a problem with the SREPN's EI (TN570B) LAPD link to its counterpart in the R6r PPN. The TN775C maintenance circuit pack notifies the co-located SRPPN of the problem, and the TN2301 SRSwitch circuit pack in the SRPPN carrier switches the EI LAPD link connection from the R6r PPN to its new counterpart in the R6si SRPPN. The SREPN is now in the Survivable Remote mode and has the capabilities of an R6si EPN that has been pre-translated with a *Disaster Recovery* configuration.

NOTE:
When SREPN feature is active, the EI circuit pack that is assigned to the SREPN and located in the R6r PPN is put in loopback mode.

Restoring Normal Service to the SREPN

WARNING:
All calls within the SREPN are terminated when the SREPN feature is returned to normal service.

To restore normal connections to the SREPN Expansion Interface (EI) circuit pack in the R6r PPN you must:

1. Clear all errors logged against the R6r SREPN Expansion Interface (EI) circuit pack by using the suggested repair procedures outlined in this maintenance object.
2. At the SRP flip the 3-position switch on the TN2301 to the RSTR (restore) or top position for at least 1 second and return the switch to the AUTO, or middle position.
3. After the SREPN slide switch has been restored to the normal position, test the connectivity to R6r EI LAPD link, by using the suggested procedures outlined in this maintenance object.
4. After normal service is returned to the SREPN, the R6si SRPPN will be in an *alarmed state*. This is *normal* for a R6si SRPPN and indicates the SRSwitch (TN2301) has disconnected it from its neighbor (EI in the SREPN), and the R6si SRPPN is no longer in control. Connectivity has been reestablished between the EI in the SREPN and its counterpart EI circuit pack in the R6r PPN. The system is now in a normal R6r EI configuration.

LEDs

SREPN Expansion Interface

The Expansion Interface circuit pack has red, green, and yellow LEDs. The red and green LEDs show the standard conditions:

- Red indicates an alarm condition
- Green indicates maintenance testing in progress

The yellow LED is used to provide useful visual status information:

- Active EI circuit packs:
  - Have their yellow LED on solid (for an inter-EPN EI in a direct connect system) o
  - Blink a pattern of 2 seconds on and 200 ms off.
- The standby PNC EI circuit packs should have their yellow LEDs off.

Another way to determine which PNC (and therefore, which EI(s) in a port network) is active and which is standby, use the **status port-network** and **status PNC** commands.

See Table 9-315 for the possible EI yellow LED states.

Table 9-315. Expansion Interface Circuit Pack Yellow LED Flashing States

Condition	LED On	LED Off
Fiber Out-of-Frame (a)	0.1 second	0.1 second
In frame-No Neighbor (b)	0.5 second	0.5 second
Expansion Interface Active (c)	2 second	0.2 second
Expansion Interface Active (d)	solid on	never off
Expansion Interface Standby (e)	never on	solid off

Notes:

a. This flashing state corresponds to error codes 769 and 770 from the Hardware Error Log and indicates a failure of Test #238. These error codes are usually accompanied by error code 1281 (no Expansion Interface or Switch Node Interface detected on opposite end of fiber). This condition may be caused by the absence of the neighbor Expansion Interface or Switch Node Interface circuit pack, a broken or missing fiber, or a missing lightwave transceiver on either endpoint (Expansion Interface or Switch Node Interface circuit packs).

b. This corresponds to error code 1281 from the Hardware Error Log and indicates a failure of Test #237. This condition is usually due to the failure of this Expansion Interface circuit pack or a failed Expansion Interface or Switch Node Interface circuit pack counterpart.

c. This is the normal state for an Active EPN Expansion Interface circuit pack that is also the bus master (Expansion Archangel) in the EPN.

d. This is the normal state for an Active Expansion Interface circuit pack that is not the bus master (Expansion Archangel) for an EPN. This applies only in the direct-connect configuration where the Expansion Interface circuit pack in an EPN is connected via a fiber link to an Expansion Interface circuit pack in the other EPN. This state also applies for an active Expansion Interface circuit pack located in the PPN.

e. This is the normal state for a Standby Expansion Interface circuit pack in both the PPN and EPNs.

NOTE:
In an EPN the TN775C EPN Maintenance (MAINT) circuit pack monitors the sanity of the Expansion Interface circuit pack. If the Expansion Interface circuit pack should cycle between sane and insane several times, the Maintenance circuit pack will hold the Expansion Interface circuit pack reset. If a new Expansion Interface circuit pack is installed in the EPN, and the red LED remains lit, the EPN Maintenance circuit pack should be removed because it may be holding the new Expansion Interface circuit pack reset. This condition could present itself if there is a link problem to the EPN, and the EPN experiences several EPN restarts. The Maintenance circuit pack may be reinstalled after the Expansion Interface circuit pack has been physically inserted and the Expansion Interface circuit pack's red LED has gone off.

The link between two Active Expansion Interface circuit packs or between an Active Expansion Interface circuit pack and an Active Switch Node Interface circuit pack is involved in synchronization. The Expansion Interface circuit pack reports slip errors if synchronization is not operating properly. When diagnosing synchronization problems, the Expansion Interface circuit packs should be examined as a possible cause.

Expansion Interface LEDs

The Expansion Interface circuit pack has the standard red, green, and yellow LEDs. The red and green LEDs have the traditional uses: red means some alarm condition and green indicates maintenance testing in progress. The yellow LED is used to provide useful visual status information. The state of the yellow LED is very important when executing the Expansion Interface Manual Loopback Procedure. The possible yellow LED states are shown in Table 9-316.

Upon power-up, the red and green LEDs turn on and off. The yellow LED goes to its appropriate state.

To determine which PNC (and which EI(s) in a port network) is active and which is standby, use the **status port-network** and **status PNC** commands. Alternately, visual inspection will show that the active EI circuit packs will have their yellow LED on solid (for an inter-EPN EI in a direct connect system) or blink a pattern of 2 seconds on and 200 ms off. The standby PNC EI circuit packs will have their yellow LED s off. See Table 9-316 for the possible EI yellow LED states.

Table 9-316. Expansion Interface Circuit Pack Yellow LED Flashing States

Condition	LED On	LED Off
Fiber Out-of-Frame (a)	0.1 second	0.1 second
In frame-No Neighbor (b)	0.5 second	0.5 second
Expansion Interface Active (c)	2 second	0.2 second
Expansion Interface Active (d)	solid on	never off
Expansion Interface Standby (e)	never on	solid off

Notes:

a. This flashing state corresponds to error codes 769 and 770 from the Hardware Error Log and indicates a failure of Test #238. These error codes will usually be accompanied by error code 1281 (no Expansion Interface or Switch Node Interface detected on opposite end of fiber). This condition may be caused by the absence of the neighbor Expansion Interface or Switch Node Interface circuit pack, a broken or missing fiber, or a missing lightwave transceiver on either endpoint (Expansion Interface or Switch Node Interface circuit pack).

b. This flashing state corresponds to error code 1281 from the Hardware Error Log and indicates a failure of Test #237. This condition is usually due to the failure of this Expansion Interface circuit pack or a failed Expansion Interface or Switch Node Interface circuit pack neighbor.

c. This is the normal state for an Active EPN Expansion Interface circuit pack that is also the bus master (Expansion Archangel) in the EPN.

d. This is the normal state for an Active Expansion Interface circuit pack that is not the bus master (Expansion Archangel) for an EPN. This applies only in the Direct Connect Configuration where the Expansion Interface circuit pack in an EPN is connected via a fiber link to an Expansion Interface circuit pack in the other EPN. This state also applies for an active Expansion Interface circuit pack located in the PPN.

e. This is the normal state for a Standby Expansion Interface circuit pack in both the PPN and EPNs.

NOTE:
In an EPN the TN775 EPN Maintenance (MAINT) circuit pack monitors the sanity of the Expansion Interface circuit pack. If the Expansion Interface circuit pack should cycle between sane and insane several times, the Maintenance circuit pack will hold the Expansion Interface circuit pack reset. If a new Expansion Interface circuit pack is installed in the EPN, and the red LED remains lit, the EPN Maintenance circuit pack should be removed because it may be holding the new Expansion Interface circuit pack reset. This condition could present itself if there is a link problem to the EPN, and the EPN experiences several EPN restarts. The Maintenance circuit pack may be reinstalled after the Expansion Interface circuit pack has been physically inserted and the Expansion Interface circuit pack's red LED has gone off.

The link between two Active Expansion Interface circuit packs or between an Active Expansion Interface circuit pack and an Active Switch Node Interface circuit pack is involved in synchronization. The Expansion Interface circuit pack will report slip errors if synchronization is not operating properly. When diagnosing synchronization problems, the Expansion Interface circuit packs should be examined as a possible cause.

EI and Tone-Clock Interactions

The viability of the EI fiber link depends upon the system clock that is provided by the active Tone-Clock circuit pack on each network (see “TDM-CLK” and “TONE-BD” documentation). Each Expansion Interface circuit pack transmits over the fiber at a rate derived from the system clock on its network. If the Active Tone-Clock is defective in such a way that the frequency of system clock it produces is out of the specified range (“out of spec”), an Expansion Interface fiber link might go down. This affects an Expansion Archangel Link (EAL), a Remote Neighbor Link (RNL), and/or a Local Neighbor Link (LNL), even though the Expansion Interface circuit packs are healthy. When the PNC is duplicated, both fiber links could go down if there is a defective Active Tone-Clock. Whether or not a fiber link goes down, depends on certain characteristics of the Expansion Interface circuit packs. An Expansion Interface circuit pack should not be replaced if the fiber link on which it resides goes down because of a defective Active Tone-Clock circuit pack. The defective Tone-Clock circuit pack should be replaced instead. The Expansion Interface circuit packs are more sensitive to a defective system clock than the rest of the components of the system. Therefore, testing of the Tone-Clock circuit pack might not reveal a problem.

The symptoms of the problem in which an invalid system clock causes an Expansion Link to go down are as follows:

- If the Tone-Clock in the PPN, or in an EPN that provides the current on-line synchronization reference (see **status synchronization**), is providing an invalid system clock:

  Any Expansion Interface or SNI circuit pack has a Fiber Out-of-Frame condition or a No Neighbor condition.

  An Expansion Interface circuit pack yellow LED blinks quickly when a Fiber Out-of-Frame condition exists (0.1 seconds on, 0.1 seconds off) and Test #238 fails on the Expansion Interface circuit pack that is out-of-frame.

  An SNI circuit pack with a Fiber Out-of-Frame condition blinks its yellow LED quickly (0.1 seconds on, 0.1 seconds off) and Test #989 fails on the SNI circuit pack that is out-of-frame.

  An Expansion Interface circuit pack yellow LED blinks slowly when a No Neighbor condition exists (0.5 seconds on, 0.5 seconds off) and Test #237 fails on this Expansion Interface circuit pack, but Test #238 passes.

  An SNI circuit pack with a no neighbor condition blinks its yellow LED slowly (0.5 seconds on, 0.5 seconds off) and Test #759 fails on this SNI circuit pack, but Test #989 passes.

- If a Tone-Clock in an EPN that does not provide the current on-line synchronization reference (see **status synchronization**) is providing an invalid system clock:

  In a direct connect configuration, the PPN Expansion Interface circuit pack yellow LED will blink quickly (Fiber Out-of-Frame condition - 0.1 seconds on, 0.1 seconds off).

  Test #238 fails on this Expansion Interface circuit pack.

  In a CSS configuration, the SNI connected to the EPN Expansion Interface circuit pack blinks its yellow LED quickly (Fiber Out-of-Frame condition - 0.1 seconds on, 0.1 seconds off).

  The EPN Expansion Interface circuit pack yellow LED blinks slowly (In-frame, No Neighbor condition - 0.5 seconds on, 0.5 seconds off).

  If the EPN is in-service, Test #237 fails on this Expansion Interface circuit pack, but Test #238 passes.

These symptoms can also be the result of other problems (for example, one half of the fiber being unable to transmit data). If the system exhibits these symptoms, execute the following procedure:

1. Verify that the EPN stays down for at least 1 minute.

   If the EAL comes back in service after a short time, without switching the Active Tone-Clock, the problem was probably that the on-line synchronization source became invalid (See SYNC Maintenance documentation for more information).

   However, if the EAL (s) have not come back into service after a minute, the synchronization source is not the cause of the problem. Proceed to Step 2.

2. Check for errors via the **display errors** command with the `Category` field set to **tone** and the Active alarms field set to **n**. Some of the alarms on EPN objects might have been resolved if the EPN went down. Refer to the appropriate MO Maintenance documentation for descriptions of any of the errors occurring at about the same time as the EXP-PN errors, SYS-LINK errors against EAL s, RNLs, or LNLs, or FIBER-LK (769, 1025, or 1281) errors. Resolve any active alarms. Also, if Error Type 18 was logged against the SYNC MO when the EPN went down, the problem was probably that the synchronization on-line reference became invalid. Since reference switching was disabled, the Tone-Clock did not switch from the invalid reference. Therefore, the Tone-Clock circuit pack put out a system clock that was “out of spec.” Issue the **enable synchronization-switch** command. If the EPN is down, reseat the Tone-Clock circuit packs on the EPN. This action should restore the EPN to service.

   Execute Steps 3 and 4 in the order most convenient to you and least destructive to the customer.

3. Check to see if the fiber optic cable is transmitting properly via the following procedure on one of the out-of-service links, or use the “Fiber Fault Isolation Procedure” in Chapter 5.

   a. Carefully record the symptoms (yellow LED pattern and test failing) that were occurring on the PPN Expansion Interface circuit pack and the EPN Expansion Interface circuit pack or the connected Switch Node Interface circuit pack in the case of a Center Stage system. Clearly indicate which symptoms are occurring on which Expansion Interface/Switch Node Interface circuit pack.

      CAUTION:
      Before proceeding, note which is the current transmit fiber and which is the current receive fiber for proper reconnection.

   b. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of one of the Expansion Interface circuit pack slots that is exhibiting symptoms.

   c. Connect what was formerly the transmit fiber to the receive jack.

d. Connect what was formerly the receive fiber to the transmit jack.

e. Perform Steps b, c, and d on the opposite end of the fiber and the lightwave transceiver on the back of the connected Expansion Interface or Switch Node Interface circuit pack slot.

f. If the symptoms which were formerly occurring on the Expansion Interface circuit pack that was exhibiting these symptoms are now occurring on the connected Expansion Interface or Switch Node Interface circuit pack and vice versa, the fiber is defective and should be replaced.

4. Determine if the problem is due to a defective Active Tone-Clock circuit pack. Refer to the preceding list of symptoms to decide which network contains the suspect Active Tone-Clock.

CAUTION:

If you remove the EPN Expansion Interface circuit pack that is active or that was active when the EPN was last in-service, the Tone-Clock lead will revert to the default value which will cause the Tone-Clock circuit pack located in the A carrier to become the Active Tone-Clock. This characteristic can be deceiving. Replacing or reseating the Active EPN Expansion Interface circuit pack might restore the link(s) temporarily. However, if the Tone-Clock circuit pack located in the B carrier was really the source of the problem and not the Expansion Interface circuit pack, then the link(s) will go down again the next time a Tone-Clock switch to the Tone-Clock in the B carrier is attempted (probably when the scheduled Tone-Clock switch occurs).

CAUTION:

If, after all the links are restored, you suspect the problem might have been due to a defective Tone-Clock circuit pack, switch to this Tone-Clock at an appropriate time. If the Tone-Clock circuit pack was the cause of the problem and the same Expansion Interface circuit packs are in place, the same link(s) will go down again.

a. On a system in which the network containing the suspect Tone-Clock circuit pack has duplicated Tone-Clock circuit packs and the network is in-service:

   Switch to the Standby Tone-Clock on this network. If the suspect Tone-Clock circuit pack is defective, link(s) should be restored at this point. Switching back to the defective Tone-Clock should make the same link(s) go out-of-service. Such a Tone-Clock is defective and should be replaced as soon as possible. If switching

Tone-Clocks does not bring up the EPN, then this Tone-Clock is not the source of the problem. Make sure to switch back to the original Tone-Clock.

CAUTION:

If the defective Tone-Clock circuit pack is left as the Standby Tone-Clock, then a scheduled Tone-Clock switch will cause the same link(s) go out-of-service again.

b. On a system in which the EPN containing the suspect Tone-Clock circuit pack is out-of-service:

Replace the Active Tone-Clock circuit pack on this network. In a network with duplicated Tone-Clock circuit packs, the Active Tone-Clock will be the Tone-Clock circuit pack whose yellow LED is flashing: if both are flashing, it is the one that is blinking slower. If the link(s) comes up after replacing this Tone-Clock circuit pack, then this Tone-Clock circuit pack should be replaced as soon as possible.

CAUTION:

If the defective Tone-Clock circuit pack is left as the Standby Tone-Clock, then a scheduled Tone-Clock switch will cause the same EPN to go out-of-service again.

If replacing the Active Tone-Clock did not bring up the link(s), then this Tone-Clock circuit pack is not the source of the problem.

c. On a Standard Reliability system in which the PPN contains the suspect Tone-Clock circuit pack:

Replace the PPN Tone-Clock circuit pack at a time when bringing down the system is most convenient to the customer.

CAUTION:

Replacing the PPN Tone-Clock circuit pack will stop call processing on that network and also bring down stable calls. This action will eventually cause a Reset System 2 (Cold_2 restart).

If replacing the Tone-Clock circuit pack restores the link(s), then the Tone-Clock circuit pack is defective and should be replaced. Otherwise, the problem is not with the PPN Tone-Clock circuit pack.

Replacing an EI Circuit Pack—Simplex PNC

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack.

WARNING:
Replacing a Switch Node Interface, Switch Node Clock, Expansion Interface or DS1 Converter circuit pack on a simplex system disrupts service. The service effect can range from outage of a single EPN to outage of the entire system.

Step	Action	Explanation/Caution
1.	Enter **busyout board UUCSS**	UUCSS = cabinet-carrier-slot address of the circuit pack to be replaced.
2.	Replace the circuit pack	
3.	Wait for the circuit pack to reset	Red and green LEDs light and then go out. If the red LED remains lit, see the Note under "Expansion Interface LEDs" above.
4.	Enter **release board UUCSS**	**CAUTION:** *Do not busyout any Expansion Interface circuit pack after this point.*
5.	Enter **test alarms long clear** for category **exp-intf**	
6.	Wait 5 minutes for SNI-BD, FIBER-LK AND DS1 CONV-BD alarms to clear, or enter **clear firmware counters a-pnc**	

Replacing an EI Circuit Pack— Duplicated PNC

WARNING:
On a system with duplicated PNC, synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WARNING alarm against TDM-CLK with error type 2305. Repairs to standby PNC in this state may disrupt service. Otherwise, if the active PNC is functional, replacement of a standby component will not disrupt service.

Step	Action	Explanation/Caution
1.	Enter **status pnc**	Verify that the component to be replaced is on the standby PNC.
2.	Enter **busyout pnc**	
3.	Enter **busyout board UUCSS**	UUCSS represents the cabinet-carrier-slot address of the circuit pack to be replaced.
4.	Replace the circuit pack	
5.	Enter **release board UUCSS**	**CAUTION:** *Do not busyout any Expansion Interface circuit pack after this point.*
6.	Enter **test alarms long clear** for category **exp-intf**	
7.	Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1 CONV alarms to clear, or enter **clear firmware counters <a-pnc or b-pnc>**	Use the letter designation of the pnc that holds the replaced component (the standby pnc).
8.	Enter status pnc	If either PNC state-of-health is not “functional,” consult the “PNC-DUP (PNC Duplication)” section.
9.	Enter **release pnc**	

If the red LED remains lit, see the Note under “Expansion Interface LEDs” above.

Expansion Interface Manual Loopback Procedure

This procedure is to be used when an Expansion Interface circuit pack cannot be tested by software. This is usually when the Expansion Interface circuit pack is in the EPN and the EPN is down. When the connection to the Expansion Interface circuit pack is via fiber, a short length of optical fiber is required for this procedure. If a metallic cable is used in the connection, the metallic connector must be removed from the back of the carrier, and a lightwave transceiver connected in its place. The short length of optical fiber can then be used.

If this procedure is run on both endpoints of a fiber link (Expansion Interface circuit packs or Switch Node Interface circuit packs), and both check out fine, then the failure is most likely in the fiber itself, assuming neither endpoint circuit pack is busied out and the link remains inactive.

1. Busyout the circuit pack (Expansion Interface or Switch Node Interface) using the **busyout board UUCSS** command.
2. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the circuit pack (Expansion Interface or Switch Node Interface) slot.

NOTE:
The fiber connected to the transmit side of the lightwave transceiver on one Expansion Interface circuit pack should be connected to the receive side of the lightwave transceiver on the circuit pack on the opposite end of the fiber.

3. Using a fiber jumper cable, interconnect the transmit and receive jacks of the lightwave transceiver as shown in Figure 9-40.

NOTE:
Make sure that the total length of the fiber jumper cable does not exceed the maximum length recommended for the fiber link connections between cabinets. Using cable lengths not within connectivity guidelines can adversely affect test results.

4. Go to the front of the cabinet and inspect the yellow LED.
   - If the yellow LED flashes on at a rate of once per second, the (Expansion Interface or Switch Node Interface) circuit pack or transceiver should be replaced.
   - If the yellow LED flashes on at a rate of five times per second, the circuit pack (Expansion Interface or Switch Node Interface) or the lightwave transceiver may need replacement. This condition may also be due to a faulty system clock on the network containing this Expansion Interface circuit pack.
   - If the yellow LED is not blinking, this circuit pack (Expansion Interface or Switch Node Interface) and the lightwave transceiver are functioning properly.
5. Replace faulty components and reconnect the original fiber. Be sure to reconnect the fibers properly as noted in Step 3. If there is a problem with the port network after re-connecting the fiber, and the port network is connected to a Center Stage Switch, run the Configuration Audit via the **test board** command on the Switch Node Interface circuit pack to which the intervening fiber is connected. See the SNI-BD section for instructions on interpreting results.
6. Release Expansion Interface circuit pack or Switch Node Interface circuit pack with the **release board UUCSS** command.

1. Aux Data 32767 for any error log entry indicates that an alarmed EI was busied out and then released. When this occurs, existing service affecting alarms must be preserved. As is typical, when the EI is released all alarms are resolved. Therefore the alarm and error logs must be repopulated with the alarms present at time of busy out. This error code is an indication that existing aux data and error log time stamps are no longer valid because they were lost when the alarms were resolved upon release of the circuit pack.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates that the Expansion Interface circuit pack has been busied out via the **busyout board UCSS** command. To resolve this error, release the Expansion Interface circuit pack via the **release board UCSS** command.

b. Expansion Interface circuit pack has been administered on the Circuit Pack form, but has not been physically inserted into the system. Insert the circuit pack.

c. A wrong circuit pack is located in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack that is physically inserted in this slot. If a fiber is administered to this circuit pack the fiber must be removed via administration before the circuit pack can be removed from administration.

d. This alarm is raised after an Expansion Interface circuit pack has been removed from a slot for 5 minutes. The alarm will be resolved when the Expansion Interface circuit pack is physically inserted into this slot and becomes recognized by software.

   Another way to resolve or prevent this alarm is to use the **change circuit pack** command to remove the Expansion Interface circuit pack administrative entry for this slot after the Expansion Interface circuit pack has been removed from the slot.

   It is also possible that the EI could be held in reset by the EPN Maintenance Board (MAINT) and is not inserted in the system. Try issuing the **test maint P long** command on the maintenance board in the same port network.

e. Error Type 257 indicates that this Expansion Interface circuit pack is detecting incorrect data on the incoming fiber bit stream. The data is originating at the connected circuit pack (DS1 CONV circuit pack, Expansion Interface circuit pack, or Switch Node Interface circuit pack).

   1. Enter **display errors** and save a copy of the error log for use in later steps. Intervening repair procedures are likely to alter the contents of the error log and this information may be needed in later steps.
   2. Perform the “Fiber Fault Isolation Procedure” described in Chapter 5.
   3. If errors are still present or if this error occurs intermittently, replace the Expansion Interface circuit packs, Switch Node Interface circuit packs, DS1 CONV circuit packs, or the transceivers on this link.
   4. These errors could result from a bad timing reference on the network or switch node which contains the DS1 CONV circuit pack, the Expansion Interface circuit pack or Switch Node Interface circuit pack on the opposite end of the fiber. Refer to the error log that was saved in step 1 and follow the associated repair procedure for EXP-INTF error 2305 to resolve this error. If there are any TONE-BD, TDM-CLK, or SYNC errors, resolve these errors as well.

f. Error Type 513 with Aux Data 5-7 indicates an ON BOARD hardware failure of the circuit packs RAM or ROM.

   1. Replace the Expansion Interface circuit pack.

g. Besides running the test sequence and following procedures outlined for test #238, perform the “Fiber Fault Isolation Procedure” described in Chapter 5.

h. Error type 1281 means that the link to the neighbor circuit pack is broken or that the fibers have been connected incorrectly. Enter **test board UUCSS** and follow repair procedures for the tests.

i. Error Type 1538 indicates a hyperactive Expansion Interface circuit pack that is generating an abnormal amount of control messages to the Processor. When this error was generated, the Expansion Interface was automatically reset by the system. If this system does not have duplicated

Port Network Connectivity, service to the EPN will have been disrupted. If this system does have duplicated Port Network Connectivity, the system should have switched to the Standby Port Network Connectivity.

1. Enter the **reset board UUCSS** command for this Expansion Interface circuit pack.
2. If error 1538 is detected again, replace the Expansion Interface circuit pack.

j. Error Type 2305 with Aux Data 118 indicates that the Expansion Interface circuit pack has detected slips on the incoming fiber data stream. That is, an EPN and the PPN in a Direct Connect configuration, or a Port Network and a Switch Node in a Center Stage Switch configuration, are not synchronized.

1. Enter **display errors** and follow the repair procedures for *non-slip* errors against any SYNC , TDM-CLK, TONE-BD, DS1 CONV-BD, EXP-INTF, SNC-BD, and SNI-BD. Non-slip errors are those *not* listed below:

Circuit Pack Name	Error Log Name	Error Log Entry for Slips
DS1 Interface	DS1-BD	3073 to 3160
Expansion Interface	EXP-INTF	2305
Switch Node Interface	SNI-BD	1537
Tone-Clock	TDM-CLK	1025
UDS1 Interface	UDS1-BD	3073 to 3160
DS1 CONV Circuit Pack	DS1 CONV-BD	3329

2. For slip errors, refer to the SYNC section.

Error type 2306 indicates on-board failures related to system timing and synchronization. Perform the ''Fiber Fault Isolation Procedure'' described in Chapter 5, ''Alarms, Errors, and Troubleshooting''.

k. Error Type 2561 indicates an on-board failure of Expansion Interface circuitry related to handling packet data from the fiber interface and from the Packet bus interface.

1. If this error has generated a minor alarm, the Expansion Interface circuit pack should be replaced.

l. Error type 2817 indicates an on-board failure of Expansion Interface circuitry related to transmission of data to the fiber interface.

1. If this error has generated a minor alarm, the Expansion Interface circuit pack or transceiver should be replaced.

m. Perform the following steps for error type 3073:

   1. Execute the **display errors** command and resolve any errors on the following: PKT-BUS, PKTINT, PDATA-BD, PGATE-BD, BRI-BD, BRI-PT, BRI-SET/ASAI, UDS1-BD.

   2. Enter the **test board UUCSS r3** command for this circuit pack. If this error continues to appear, replace the EI circuit pack.

n. Error Types 3074 and 3075 indicate failures of the Expansion Interface Circuit Pack Packet Path Test. This packet path test exercises circuitry on the Expansion Interface circuit pack, the neighbor Expansion Interface or Switch Node Interface circuit pack, and any intervening DS1 CONV circuit packs (if the EPN is remoted).

   1. Certain packet bus faults can cause these errors without the EI being defective. Check to see of PKT-BUS errors are also present. If they are, use the PKT-BUS section of this chapter and *Packet Bus Fault Isolation and Repair* in Chapter 6 to diagnose the problem.

   2. If Error Type 3075 is present without Error Type 3074, replace the Expansion Interface circuit pack.

   3. If Error Type 3074 exists with or without 3075, run **test board UUCSS** on the EI and follow the repair procedures for any test that does not pass.

   4. If PKT-BUS errors are not present, and replacing the Expansion Interface does not resolve the problem, there is still the possibility of a packet bus fault. See *Packet Bus Fault Isolation and Repair* in Chapter 6.

o. Error Type 3330 indicates a failure of a diagnostic component on the Expansion Interface circuit pack. The failed component will not impair service, but it may leave the Expansion Interface circuit pack in a state where the Expansion Interface circuit pack cannot detect errors.

   1. Replace the Expansion Interface circuit pack at a time when it is most convenient for the customer (this may cause service outages).

p. Error Type 3585 indicates that the Expansion Interface circuit pack experienced a series of very short out of frame conditions within several minutes. This may indicate transmission difficulties over the fiber link. If this condition ceases, the warning alarm should be resolved within 15 minutes.

   1. Enter **display errors** and resolve any SNC-BD, TDM-BUS, TDM-CLK or SYNC errors.

   2. Perform the “Fiber Fault Isolation Procedure” described in Chapter 5.

3. If the alarm is not resolved within the next 15 minutes, replace the lightwave transceiver on the Expansion Interface circuit pack reporting the problem and on the connected Expansion Interface circuit pack, Switch Node Interface circuit pack, or DS1 CONV circuit pack.
4. If the alarm is not resolved within the next 15 minutes, replace the Expansion Interface circuit pack reporting the alarm.
5. If the alarm is not resolved within the next 15 minutes, replace the connected Expansion Interface circuit pack, Switch Node Interface circuit pack or DS1 CONV circuit pack.

q. Error Type 3841 indicates the EI has reported a loss of lock with the backplane system clock.

r. Error Type 3842 indicates that the test that queries the EI for the state of the lock to the system clock has failed. This means that a loss of lock condition is present.

s. The counter associated with Error Types 3841 and 3842 is cleared when the query for the state of the clock-to-system-clock passes. Once the alarm is raised, this test is run every five minutes. However, the test is not part of any sequence that can be run on demand. See Note “p” above for repair procedure.

t. Error type 10001 is a report that the Expansion Interface circuit pack dropped one control message to the EPN. This condition may have been observed as a call that did not complete correctly. No system technician action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in Table 9-318 below. By clearing error codes associated with the *Expansion Interface Reset Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-318. System Technician-Demanded Tests: EXP-INTF

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Expansion Interface Reset Test (#336)			X	D
Expansion Interface Fiber Out-of-Frame Query Test (#238)	X	X		ND
Expansion Interface Lightwave Transceiver Looparound Test (#242)		X		D
Expansion Interface Control Channel Test (#316)	X	X		ND
Expansion Interface Neighbor Query Test (#237)	X	X		ND
Expansion Interface Local Looparound Test (#240)	X	X		ND
Expansion Interface 2-way Transmission Test (#241)	X	X		ND
Expansion Interface Packet Interface Test (#589)	X	X		ND

1. D = Destructive, ND = Non-destructive

When testing Expansion Interface circuit packs to investigate problems, tests should always be run on both circuit packs on the associated fiber link, whether the circuit packs are both Expansion Interface circuit packs, or one is a Switch Node Interface circuit pack. This will provide a better indication of where a problem is located.

When testing of the EI is not possible, (for example, when the EPN is down), see the EI Manual Loopback Procedure above.

Expansion Interface Neighbor Query Test (#237)

This test is non-destructive.

The Expansion Interface Neighbor Query Test is a request to an Expansion Interface circuit pack to determine if it has established communication with its neighbor Expansion Interface or Switch Node Interface circuit pack.

Table 9-319. TEST #237 Expansion Interface Neighbor Query Test

Error Code	Test Result	Description/ Recommendation
1033	ABORT	The Expansion Interface circuit pack does not have a fiber link administered to it. There is not sufficient data to run test. 1. Issue the **list fiber-link** command to verify that there is no fiber link administered to this circuit pack. 2. If there is no fiber administered to this circuit pack, but there should be add the correct fiber using the **add fiber-link** command. 3. Retry the command.
2000	ABORT	Response to the test was not received within the allowable time period.
2031	ABORT	The attempt to send the message to the Expansion Interface circuit pack, asking it who it’s neighbor is, was not successful.
2100	ABORT	System resources required to run this test are not available. Someone may be doing something on this Port Network Interface.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
1033	FAIL	The EI circuit pack under test cannot make contact with its neighbor EI or Switch Node Interface circuit pack. Perform the ‘‘Fiber Fault Isolation Procedure’’ in ‘‘Alarms, Errors, and Troubleshooting’’.
2027	FAIL	The EI circuit pack has contact with the neighboring EI or Switch Node Interface circuit pack, but it is the incorrect EI or Switch Node Interface circuit pack. 1. Enter **list fiber-links** and verify that all fiber link cables are installed as they are administered. 2. Repeat the command.
	PASS	The EI circuit pack has successfully established a link with the neighbor EI or Switch Node Interface circuit pack. If the **status port-network** command still indicates that this link is down, it is possible that one or both of the EI and/or Switch Node Interface circuit packs have been busied out. 1. If the link still does not come up, reset one or both EI and/or Switch Node Interface circuit packs on the link.

Continued on next page

Table 9-319. TEST #237 Expansion Interface Neighbor Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (Error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Fiber Out-of-Frame (FOOF) Query Test (#238)

This test is nondestructive. This test is a request to an Expansion Interface circuit pack to determine if it is currently detecting the framing sequence on the incoming fiber data stream. If it cannot detect this framing signal, the Expansion Interface circuit pack will not be able to establish a link with the neighbor Expansion Interface or Switch Node Interface circuit pack.

Table 9-320. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test

Error Code	Test Result	Description/ Recommendation
1033	ABORT	The EI circuit pack does not have a fiber link administered to it. There is not sufficient data to run test. 1. Issue the **list fiber-link** command to verify that there is no fiber link administered to this circuit pack. 2. If there is no fiber administered to this circuit pack, but there should be add the correct fiber using the **add fiber-link** command. 3. Retry the command.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-320. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Expansion Interface circuit pack could not detect framing sequence. 1. If the Expansion Interface circuit pack that is failing Test #238 is in the EPN, and the red LEDs are ON on a large number of circuit packs, then reseat any Tone-Clock circuit packs in the EPN. 2. Perform the ''Fiber Fault Isolation Procedure'' in ''Alarms, Errors, and Troubleshooting''. 3. Enter **display errors** and resolve any SNC-BD, TDM-BUS, TDM-CLK, or SYNC errors.
	PASS	The Expansion Interface circuit pack has detected the valid framing signal on the fiber. 1. Refer to errors from other Expansion Interface circuit pack, Switch Node Interface tests, or DS1 CONV tests (if present) if the link is still not functioning.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Local Looparound (#240)

This test is nondestructive. The EI local looparound is similar to the Lightwave Transceiver looparound described in test #242. A test tone is received by the EI being tested, but is not transmitted out to the fiber interface before being looped back. The loopback is internal to the circuit pack. Thus, this test does not interfere with the normal fiber data stream.

Table 9-321. TEST #240 Expansion Interface Local Looparound

Error Code	Test Result	Description/ Recommendation
1	ABORT	Could not allocate time slot on TDM Bus A. Loopback passed on TDM Bus B.
2	ABORT	Could not allocate time slot on TDM Bus B. Loopback passed on TDM Bus A. 1. If there is no reason to doubt that the EI circuit pack can transfer data to or from a TDM Bus, then since the test passed on one bus, assume that the test passes on the other bus. 2. If this test continues to abort with the same error, rerun test at 1-minute intervals a maximum of 3 times. 3. If the test still does not pass on the other TDM Bus, follow the procedure for ABORT Error Code 3.
3	ABORT	The system could not allocate time slots for the test on either TDM Bus. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 3 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out of service. 1. Enter **display errors** and follow associated repair procedures for TTR-LEV errors in the error log. Even if there are not TTR-LEV errors, there may not be a tone detector available on the network that contains the circuit pack being tested. Verify that there is at least one tone detector on the network. If not, this test always aborts for this EI circuit pack. This does not harm the system. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
1031	ABORT	A query of the EI circuit pack aborted. The purpose of this query was to see if the EI circuit pack could detect the framing signal. 1. If Test #238 aborted, follow the procedure associated with this abort code. 2. If Test #238 did not abort, rerun Test #240 at 1-minute intervals a maximum of 3 times.
1032	ABORT	The EI cannot detect the framing signal and cannot run the test. 1. Refer to the errors for Test #238 to determine why the EI circuit pack is out of frame.

Continued on next page

Table 9-321. TEST #240 Expansion Interface Local Looparound — *Continued*

Error Code	Test Result	Description/ Recommendation
1033	ABORT	The EI circuit pack does not have a fiber link administered to it. There is not sufficient data to run test. 1. Issue the **list fiber-link** command to verify that there is no fiber link administered to this circuit pack. 2. If there is no fiber administered to this circuit pack, but there should be add the correct fiber using the **add fiber-link** command. 3. Retry the command.
1394	ABORT	The EI circuit pack is out of service and the test cannot be run. This condition is due to a change in the EI circuit pack's ability to communicate with the EI or Switch Node Interface circuit pack on the other end of the fiber. 1. Run Test #237 and check the Error Log for EXP-INTF error type 1281. If error type 1281 is present or if Test #237 does not pass, refer to repair procedures for Test #237.
1395	ABORT	This test cannot be run on an EI circuit pack if it is part of the B-side PNC and Duplicated PNC is not enabled. 1. If this test needs to run on this EI circuit pack, enable PNC with the **change system-parameters duplication** command. 2. Prevent the system from doing a PNC interchange by executing the **set PNC lock** command. 3. Repeat this test.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-321. TEST #240 Expansion Interface Local Looparound — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Loopback on TDM Bus A failed. Loopback on TDM Bus B passed.
2	FAIL	Loopback on TDM Bus B failed. Loopback on TDM Bus A passed.
3	FAIL	Loopback on both TDM Buses failed.
12	FAIL	Loopback on TDM Bus B failed. Loopback on TDM Bus A aborted because the system could not allocate time slots.
21	FAIL	Loopback on TDM Bus A failed. Loopback on TDM Bus B aborted because the system could not allocate time slots.
None	FAIL	The test tone was not detected correctly after being looped through the EI circuit pack. 1. If Error Type 2305 has been logged against the EI circuit pack in the last 5 minutes, this test could have failed due to the associated slips. If so, first resolve the 2305 error, and then repeat the test. 2. Run the tests for the Active Tone-Clock on the PN that contains the indicted EI circuit pack to verify that dial-tone is supplied. 3. If the tone-clock is healthy, repeat the short test on the EI board. 4. If this test continues to fail, replace the EI circuit pack.
	PASS	Test tone was correctly detected after internal EI loopback on both TDM Busses. 1. Refer to other EI circuit pack tests if the links between this EI circuit pack and the EI or Switch Node Interface circuit pack on the other end of the fiber is not functioning correctly.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface 2-way Transmission Test (#241)

This test is nondestructive. The EI 2-way transmission test is a basic connectivity test between two PNs. The test first sends dialtone from the cabinet of the EI circuit pack under test through the Center Stage Switch, through the DS1 CONV circuit packs, and through another EI circuit pack to a tone detector in the other cabinet. The connections are then reversed and the tone is passed in the opposite direction. If the system is equipped with a Center Stage Switch, and this test either fails or aborts with the above connection, a second PN is chosen (if one is available and the EI circuit pack is In-Service) and the same test is run on this new connection. This helps in the isolation of the fault. Since two EI circuit packs are involved in the connection, either one of them could be at fault and this repeated test can help determine which is actually at fault.

The path used in this test is represented in Figure 9-41.

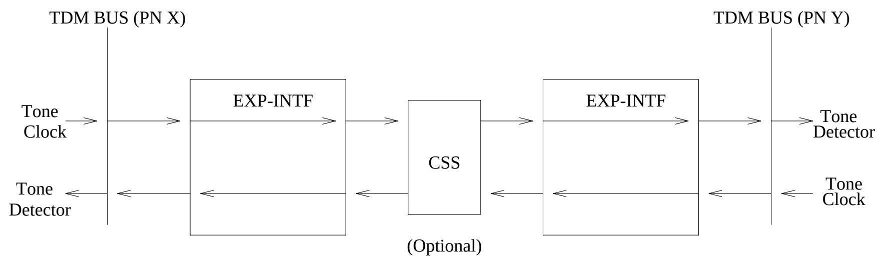

Figure 9-41. Two-Way Circuit Switch Transmission Test

Table 9-322. TEST #241 Expansion Interface 2-way Transmission Test

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out of service due to TDM-BUS errors. Enter **display errors** and follow associated repair procedures for TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 3 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out of service. 1. Enter **display errors** and follow associated repair procedures for TTR-LEV errors in the error log. Even if there are not TTR-LEV errors, there may not be a tone detector available on the network that contains the circuit pack being tested. Verify that there is at least one tone detector on this network. If not, this test will always abort for this EI circuit pack. This will not harm the system in any way. **NOTE:** DEFINITY Systems require that Tone Detector circuit packs (TN768) must be of vintage “B” or newer. If older Tone Detector circuit packs are installed in the system, this test will always abort with this code. 2. Enter **display errors** and follow associated repair procedures for TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
1033	ABORT	The test cannot run because either the EI board does not have a fiber link administered to it and there is not sufficient data to run the test, or there were no other PNs administered that had its EI board In-Service. 1. Check fiber administration to insure that there is a fiber link administered to this Expansion Interface circuit pack. 2. If there is a fiber administered to this EI circuit pack, then some change in the status of the ability of the EI circuit pack in the other PNs to communicate with the EI or Switch Node Interface circuit pack on the other end of its fiber has occurred. 3. Test #237 and check for EXP-INTF circuit pack Error Type 1281 in the Error Log for the EI circuit packs in these other PNs. If Error Type 1281 is present and/or Test #237 does not pass, refer to repair procedures for Test #237. 4. If Test #237 passes, reseat the EI circuit pack. This is not destructive since the circuit pack cannot be serving as the Expansion Archangel if it is not in service.

Continued on next page

Table 9-322. TEST #241 Expansion Interface 2-way Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1394	ABORT	The Expansion Interface circuit pack is out of service and the test cannot be run. This condition is due to a change in the EI circuit pack's ability to communicate with the EI or Switch Node Interface circuit pack on the other end of the fiber. 1. Run Test #237 and check the Error Log for EXP-INTF Error Type 1281. If Error Type 1281 is present or if Test #237 does not pass, refer to repair procedures for Test #237.
1395	ABORT	This test cannot be run on an EI circuit pack if it is part of the B-side PNC and Duplicated PNC is not enabled. 1. If this test needs to run on this EI circuit pack, enable PNC with the **change system-parameters duplication** command. 2. Prevent the system from doing a PNC interchange by executing the **set PNC lock** command. 3. Repeat this test.
1413	ABORT	This test requires the use of a Tone/Clock circuit pack in each of the port networks used in this test. This abort code indicates that there are none of these circuit packs located in one of the PNs. 1. Make sure that there is a Tone/Clock circuit pack located in the PN in which the Expansion Interface circuit pack under test is located. 2. In Direct Connect configurations, make sure that there is a Tone/Clock circuit pack located in the PN where the neighbor Expansion Interface circuit pack is located. 3. In Center Stage Switch configurations, make sure that there is at least one other PN, besides the PN where the EI circuit pack under test resides, that contains a Tone/Clock circuit pack.
1414	ABORT	This test requires the use of an active Tone/Clock circuit pack in each of the port networks used in this test that does not have a MAJOR or MINOR alarm logged against it. This abort code indicates that the active Tone/Clock circuit pack in one of the port networks being used for the test has a MAJOR or MINOR alarm logged against it. 1. Enter **display alarms** and resolve all TONE-BD and TONE-PT alarms.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-322. TEST #241 Expansion Interface 2-way Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The test tone was not detected correctly in either direction. 1. Run the test for the Active Tone-Clocks on the Port Networks for which the Expansion Interface circuit pack under test provides a link. This will determine if the dial tone is being supplied. 2. Perform the "Fiber Fault Isolation Procedure" in Chapter 5, "Alarms, Errors, and Troubleshooting".
1 or 2	FAIL	The test tone was detected correctly in one direction, but not the opposite direction. 1. Test for the Active Tone-Clocks on the PNs for which the defective EI board provides a link. This determines if the dial tone is supplied. 2. Perform the "Fiber Fault Isolation Procedure" in Chapter 5, "Alarms, Errors, and Troubleshooting". **Center Stage:** These failure codes are possible on a Center Stage Switch configuration only when there is just one other PN available for looping back the test tone. 1. Perform the "Fiber Fault Isolation Procedure" in Chapter 5, "Alarms, Errors, and Troubleshooting".
3 or 4	FAIL	The failure codes only apply to a system equipped with a Center Stage Switch. They indicate that the test aborted or failed for the first connection from the EI board under test to another EPN, and that the test tone was detected correctly in one direction, but not the opposite direction when the connection was between the EI board under test and a different EPN than was used in the first connection. 1. Run the test for the Active Tone-Clocks on the PNs for which the defective EI board provides a link. This determines if the dial tone is being supplied. 2. Perform the "Fiber Fault Isolation Procedure" in Chapter 5, "Alarms, Errors, and Troubleshooting".
	PASS	The tone was successfully transmitted in both directions. Both EI boards, Switch Node Interface boards, DS1 CONV circuit packs, and their lightwave transceivers are functioning properly.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Lightwave Transceiver Looparound Test (#242)

This test is destructive.

This test requires that the Expansion Interface circuit pack first be busied out. If the system has a duplicated Port Network Connectivity, this test cannot be run on an Expansion Interface circuit pack that resides on the current active PNC due to restrictions that prohibit the busying-out of certain components that are part of the active PNC. If this test is run on an Expansion Interface circuit pack that is part of the Standby PNC, this test is not destructive and no service outages will take place.

In a system without duplicated Port Network Connectivity, where this Expansion Interface circuit pack supports a PPN to EPN link, this test will disrupt service to one EPN (Direct Connect) or all EPN s (Center Stage). If the Expansion Interface circuit pack is part of an EPN to EPN link in a Direct Connect system, service between the two EPN s will be disrupted.

This is a two part connectivity test. In the first part of the test, a digital count is transmitted from the cabinet of the Expansion Interface circuit pack under test, through the Expansion Interface circuit pack under test, out to its lightwave transceiver. The connection then loops back into the lightwave transceiver through the same Expansion Interface circuit pack again and into the originating cabinet. If the test tone is detected by a tone detector, the first part of the test passes. The path used for this part of the test is represented in Figure 9-42.

In the second part of the test, a data packet is sent from the TN1655 Packet Interface circuit pack to the Expansion Interface circuit pack under test, the packet is looped back through the lightwave transceiver and is sent back to the Packet Interface circuit pack. If the Packet Interface circuit pack receives the same packet it transmitted, the second part of the test passes. If the entire test has passed, the Expansion Interface circuit pack, its backplane wiring and the electrical portion of the lightwave transceiver are healthy.

The path used for this test if the Expansion Interface is located in the PPN is represented in Figure 9-43. The path used for this test if the Expansion Interface is located in an EPN is represented in Figure 9-44.

When the Expansion Interface circuit pack under test is in an EPN, the data packet must also pass through the Active Expansion Interface circuit packs and the Active DS1 CONV circuit packs (and the Active Switch Node Interface circuit pack(s) in a Center Stage Switch system) of the Active PNC link connecting the EPN to the PPN.

This test requires the Expansion Interface circuit pack to ignore incoming data from its neighbor Expansion Interface circuit pack or Switch Node Interface circuit pack. Thus this test will disturb any inter-port network connections that currently exist over the link provided by the Expansion Interface under test and its neighbor and disrupt signaling between the two circuit packs.

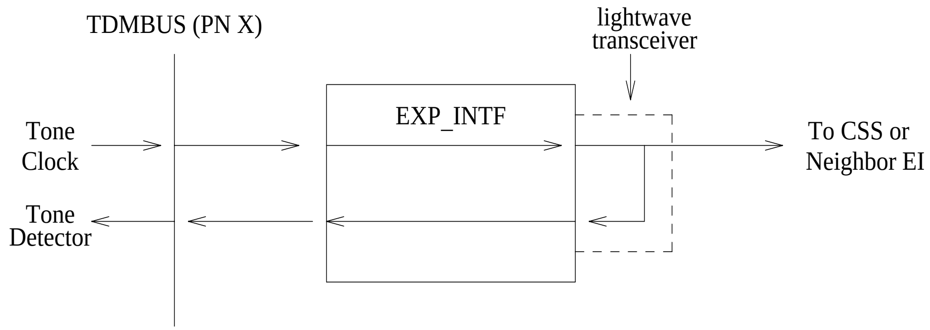

Figure 9-42. TDM BUS Lightwave Transceiver Looparound

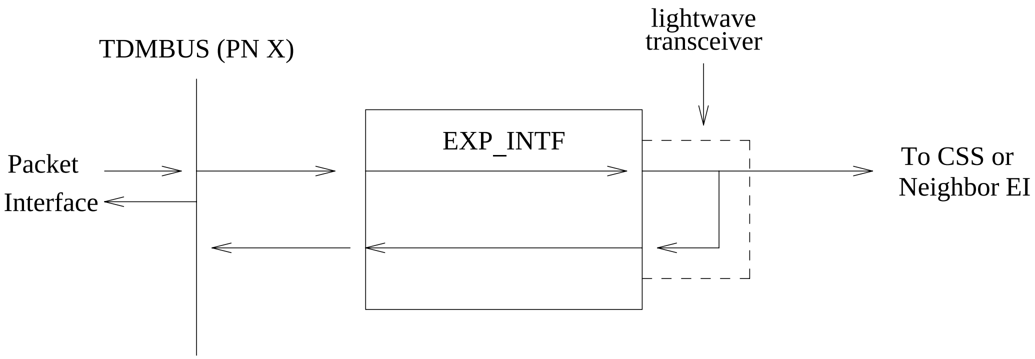

Figure 9-43. Packet BUS Lightwave Transceiver Looparound—PPN only

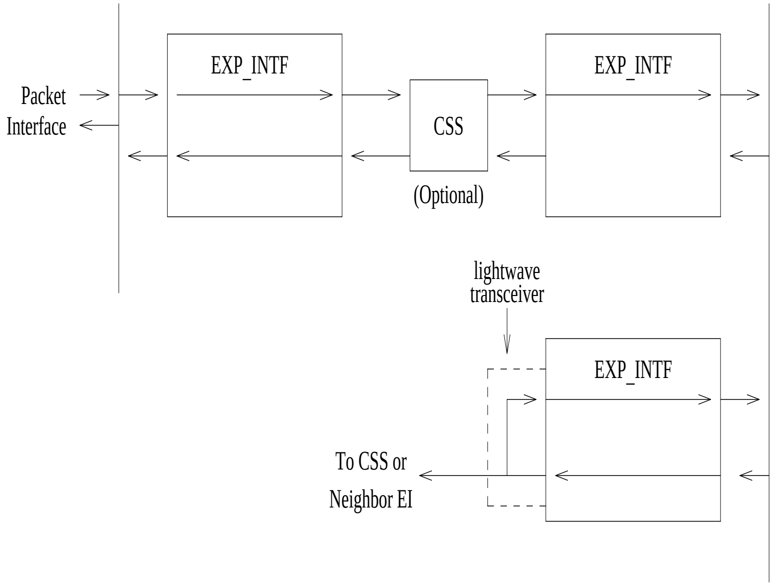

Figure 9-44. Packet BUS Lightwave Transceiver Looparound—EPN only

Table 9-323. TEST #242 Expansion Interface Lightwave Transceiver Looparound

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM-BUS errors. Enter **display errors** and resolve any TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 3 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out of service. 1. Enter **display errors** and follow associated repair procedures for TTR-LEV. Even if there are no TTR-LEV errors, there may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. If there is not at least one Tone Detector, this test always aborts for this EI board. This will not harm the system. 2. Enter **display errors** and follow associated repair procedures for TONE-PT. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
1015	ABORT	The system will not allow this test to be run because the EI circuit pack has not been busied out. 1. Busyout the Expansion Interface circuit pack. Then, repeat the **test board UUCSS long** command.
1031	ABORT	If the Expansion Interface circuit pack is in an EPN and is on the active PNC, and is not part of an EPN to EPN link, this test *cannot* be executed. If the lightwave transceiver looparound is activated, it is impossible to deactivate it. 1. If PNC Duplication is enabled, attempt to make the Standby PNC active through the **reset pnc interchange** command. 2. If the PNC Interchange is successful, the lightwave transceiver looparound test may now be executed on the original Expansion Interface circuit pack.
1033	ABORT	The test cannot run because the EI circuit pack does not have a fiber link administered to it and there is not sufficient data to run the test. 1. Issue the **list fiber-link** command to verify that there is no fiber link administered to this circuit pack. 2. If there is no fiber administered to this circuit pack (but should be), add the correct fiber using the **add fiber-link** command. 3. Retry the command.

Continued on next page

Table 9-323. TEST #242 Expansion Interface Lightwave Transceiver Looparound — *Continued*

Error Code	Test Result	Description/ Recommendation
1139	ABORT	The packet bus in the EPN where this EI board is located has a major alarm against it. This test needs to use the alarmed PN's packet bus. 1. Enter **display alarms** and **display errors** and resolve any PKT-BUS alarms. 2. Retry the command.
1141	ABORT	The Packet Interface circuit pack is out of service. 1. Refer to "PKT-INT (Packet Interface Circuit Pack)".
1144	ABORT	The packet bus in the PPN has a major alarm against it. This test needs to use the alarmed PPN packet bus. 1. Enter **display alarms** and **display errors** and resolve any PKT-BUS alarms. 2. Retry the command.
1394	ABORT	The EI board is out of service and the test cannot be run. This condition is due to a change in the EI board's ability to communicate with the EI or Switch Node Interface circuit pack on the other end of the fiber. 1. Run Test #237 and check the Error Log for EXP-INTF Error Type 1281. If Error Type 1281 is present or if Test #237 does not pass, refer to repair procedures for Test #237.
1395	ABORT	This test cannot be run on an EI circuit pack if it is part of the B-side PNC and Duplicated PNC is not enabled. 1. If this test needs to run on this EI circuit pack, enable PNC with the **change system-parameters duplication** command. 2. Prevent the system from doing a PNC interchange by executing the **set PNC lock** command. 3. Repeat this test.
1407	ABORT	This test cannot be run on an EI board that is on the active PNC because it cannot be busied out. This error code indicates that PNC duplication is enabled. 1. Attempt to perform a PNC interchange via the **reset pnc interchange** command. 2. If the PNC interchange is successful, busy out the original Expansion Interface circuit pack via the **busyout board UUCSS** (address of the original EI board). 3. Retry the command.
2000	ABORT	Response to the test was not received in the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-323. TEST #242 Expansion Interface Lightwave Transceiver Looparound — *Continued*

Error Code	Test Result	Description/ Recommendation
2060	ABORT	The link on the packet bus being used to perform the test has failed. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continue to abort, enter **display errors** and resolve any PKTINT errors.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
1	FAIL	The test did not detect the test tone through the looparound connection. **NOTE:** The packet portion of this test was not run since the circuit portion failed. 1. Test the Active Tone-Clock on the PN that contains the defective EI circuit pack to verify that dial tone is being supplied. 2. If the Tone-Clock is healthy, issue the **test board UUCSS long** on the EI circuit pack. 3. If this test continues to fail, replace the EI circuit pack or transceiver. Then reissue the **test board UUCSS long** on the new EI circuit pack.
2	FAIL	The test tone was transmitted and detected correctly, but the correct data packet was not detected by the TN1655 Packet Interface circuit pack. 1. Test the TN1655 Packet Interface circuit pack to verify that it is functioning properly. If any tests fail, investigate those tests and repair the Packet Interface circuit pack. 2. If the Packet Interface circuit pack checks out OK, enter **display errors** and **display alarms** and resolve any SNI-BD and FIBER-LK alarms or errors (Center Stage Switch only) and DS1 CONV-BD alarms or errors (if present). 3. Issue the **test board UUCSS long** command on the EI board. 4. If test #242 continues to fail, replace the EI board. Then issue the **test board UUCSS long** command on the new EI board. 5. If test #242 continues to fail, replace the lightwave transceiver, reset the circuit pack and issue the **test board UUCSS long** command on the EI circuit pack.

Continued on next page

Table 9-323. TEST #242 Expansion Interface Lightwave Transceiver Looparound — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	When this test (#242) and the EI Local Looparound Test #240 pass, this indicates that the EI board is functioning properly, but it does not verify that the optical portion of the lightwave transceiver is functioning. 1. Issue the **test board UUCSS** command on the EI board on both ends of fiber. If this test passes from both sides, but other tests fail, such as #241, this condition indicates either a faulty lightwave transceiver or the fiber itself has failed. To determine if either a lightwave transceiver or the fiber itself has failed, execute the EI Manual Loopback procedure described in a previous section. **NOTE:** Test #242 can only be run from both EI s if they are the standby pair and the active pair is working properly. 2. If this EI board is failing other tests, execute the EI Manual Loopback Test. 3. If problems still exist after the EI Manual Loopback Procedure indicates both EI boards and both lightwave transceivers are healthy, manually check out the building fiber. Verify that each optical fiber connects to a transmitter at one end and a receiver at the other.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (Error 125) or no board (Error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Control Channel Test (#316)

This test is nondestructive. If an Expansion Interface circuit pack is a standby Expansion Interface circuit pack (yellow LED off) or if the Expansion Interface is active in the PPN (yellow LED on), this test queries the Expansion Interface circuit pack for its circuit pack type and vintage information. If the Expansion Interface circuit pack is an active Expansion Interface circuit pack in the EPN (yellow LED on long off short) the Expansion Interface Control Channel test checks to see if the Expansion Interface circuit pack can communicate with other circuit packs in the EPN using the EPN TDM bus.

Table 9-324. TEST #316 Expansion Interface Control Channel Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
Any	FAIL	The EI circuit pack responded incorrectly or if it is the EPN active EI circuit pack, it could not talk to EPN circuit packs. 1. If the active EI circuit pack in the EPN is failing and duplicated Port Network Connectivity is enabled, attempt to switch to the standby PNC using the **reset PNC interchange** command. 2. Repeat the short test sequence. 3. If test continues to fail, reset the EI circuit pack via the **reset board UUCSS** command. 4. If the EI circuit pack in the EPN is failing, enter **display errors** and **display alarms** and resolve anyTDM-CLK, TONE-BD, or SYNC alarms or errors and repeat the Short Test Sequence. 5. If test continues to fail, replace the circuit pack or transceiver.
	PASS	The EI circuit pack did respond correctly to test. Communication from software to the EI circuit pack is functioning. 1. Refer to other EI circuit pack tests if the link is not functioning correctly.
0	NO BOARD	No board was detected by the test. 1. Resolve either wrong board (Error 125) or no board (Error 131) issues. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Reset Test (#336)

This test is destructive.

This test is potentially very destructive and requires the Expansion Interface circuit pack to be busied out prior to execution of this test.

The Expansion Interface Reset test, which is not part of either the Short or the Long test sequences test is executed via the **reset board UUCSS** command where UUCSS is the address of the Expansion Interface circuit pack to be reset.

If the system does not have Duplicated Port Network Connectivity, and is a Direct Connect system, and one of the Expansion Interface circuit packs must be reset, the action of busying out the desired Expansion Interface circuit pack will deny calls to the EPN until the Expansion Interface circuit pack is released from the busyout state. If the Expansion Interface circuit pack is part of a PPN to EPN link, new connections to the EPN will be denied. If the Expansion Interface circuit pack is part of an EPN to EPN link, calls between the two EPN s will be denied.

In a non-duplicated PNC system with a Center Stage Switch, if the Expansion Interface circuit pack in the EPN is busied out, new service to that EPN only will be denied. However, if the Expansion Interface circuit pack is located in the PPN, new service to all EPN s will be denied until the Expansion Interface circuit pack is released from the busyout state.

If the system does not have duplicated PNC, the reset of any EI is allowed, but it will result in the resetting of all EPN boards and loss of service to the EPN (s) for a few minutes.

If the system does have duplicated PNC, and the Expansion Interface circuit pack to be reset is part of the Active PNC, the system will not allow the busyout and the system technician will be required to interchange the PNCs via the **reset PNC interchange** command. After executing the PNC interchange, it will be possible to busyout and then reset the original Expansion Interface circuit pack.

If the EPN Maintenance (MAINT) circuit pack determines that the Expansion Interface (EXP-INTF) circuit pack is cycling between sane and insane several times within several minutes, MAINT may inhibit operation of the EXP-INTF by holding the Expansion Interface circuit pack in a reset state. This condition may result in an unsuccessful reset of the Expansion Interface circuit pack.

If the reset command returns “EPN is unavailable,” execute the following steps:

1. Use the **change circuit-pack P** (port network number of the EPN) command.
2. For the Expansion Interface circuit pack you wish to reset, add an entry to the Circuit Pack form for the TN570 Expansion Interface circuit pack. Be sure to enter the appropriate carrier and slot.
3. Enter the form.
4. Issue the **busyout board UUCSS** command.
5. Repeat the **reset board** command

Table 9-325. TEST #336 Expansion Interface Reset Test

Error Code	Test Result	Description/ Recommendation
4	ABORT	Could not reset the EPN Expansion Interface circuit pack over the optical fiber since the neighbor Expansion Interface circuit pack or Switch Node Interface circuit pack is not recognized by software (inserted). 1. Insert neighbor Expansion Interface circuit pack or Switch Node Interface circuit pack and perform reset again.
1015	ABORT	The system will not allow this test to be run because the EI circuit pack has not been busied out. Busyout the EI circuit pack. Repeat the **reset board UUCSS** command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
1	FAIL	The Expansion Interface did not successfully reset. 1. If the EI circuit pack is in the EPN, the EPN Maintenance Board may be holding the EI circuit pack reset. Attempt to rectify this condition by executing the **test maint P long** command on the maintenance board in the same EPN. 2. If Step #1 was not successful in releasing the Expansion Interface circuit pack, temporarily remove the EPN maintenance circuit pack. 3. Repeat the **reset board UUCSS** command. 4. If reset continues to fail, replace circuit pack. 5. Insert EPN maintenance circuit pack if it was removed.

Continued on next page

Table 9-325. TEST #336 Expansion Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The Expansion Interface circuit pack was successfully reset, but it did not begin running after the reset. 1. If the Expansion Interface circuit pack is in the EPN, temporarily remove the EPN maintenance circuit pack. 2. Repeat the **reset board UUCSS** command. 3. Reinsert the EPN maintenance circuit pack if it was removed.
3	FAIL	The reset over the optical fiber failed. 1. Execute the **test board UUCSS** command on the PPN neighbor EI circuit pack located on the opposite end of the fiber from this EI circuit pack. If Test #238 does not pass, follow the maintenance procedure associated with this test result. Then perform the reset again. 2. If the EI circuit pack is in the EPN, temporarily remove the EPN Maintenance circuit pack. 3. Repeat the **reset board UUCSS** command. 4. Reinsert EPN Maintenance circuit pack if it was removed. 5. If the symptoms match those described in the "EI and Tone-Clock Interactions" section, follow those guidelines. 6. Check the Error Log for the EPN Tone-Clock errors that were resolved when the EPN went down. These errors may have been resolved BECAUSE the EPN went down. When there is no Tone-Clock generating the system clock on an EPN, then an Expansion Interface (EI) circuit pack can only be reset once. All subsequent reset attempts fail. It is also possible that the system itself may have already tried to reset the EI circuit pack. Refer to "TONE-BD (Tone-Clock Circuit Pack)" for Tone-Clock problems. 7. If the reset still fails, execute the Manual Loop Back Procedure on the opposite PPN EI circuit pack. This procedure is described in the section preceding the Error Log Entries and Test to Clear Values table for this MO. If the EI circuit pack and the lightwave transceiver are healthy, the problem is the EI circuit pack and its lightwave transceiver on the EPN end of the fiber or the fiber itself. Test the EPN EI circuit pack with the manual loop back procedure and investigate the test results.

Continued on next page

Table 9-325. TEST #336 Expansion Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The EI was successfully reset. Remove the Expansion Interface circuit pack from the busyout state by using the **release board UUCSS** command. 1. Execute **test board UUCSS short** command. Refer to errors for each test.
0	NO BOARD	No board was detected by the test. 1. Resolve either wrong board (error 125) or no board (error 131) issues. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Packet Interface Test (#589)

This test is nondestructive. This test attempts to send a data packet from the TN1655 Packet Interface circuit pack through any intervening Expansion Interface circuit packs and/or Switch Node Interface circuit packs and through the Expansion Interface circuit pack to be tested. The path the data packet takes is dependent on the location of the Expansion Interface circuit pack to be tested and whether the system has duplicate Port Network Connectivity. The following diagrams and short discussion of each describe the different paths the test uses.

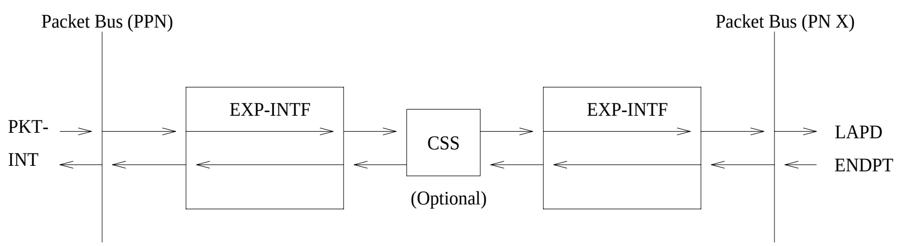

Figure 9-45. Expansion Interface Packet Interface Test—Packet Endpoint Loop

The path shown in Figure 9-45 is used when testing an EPN EI that is on the active PNC.

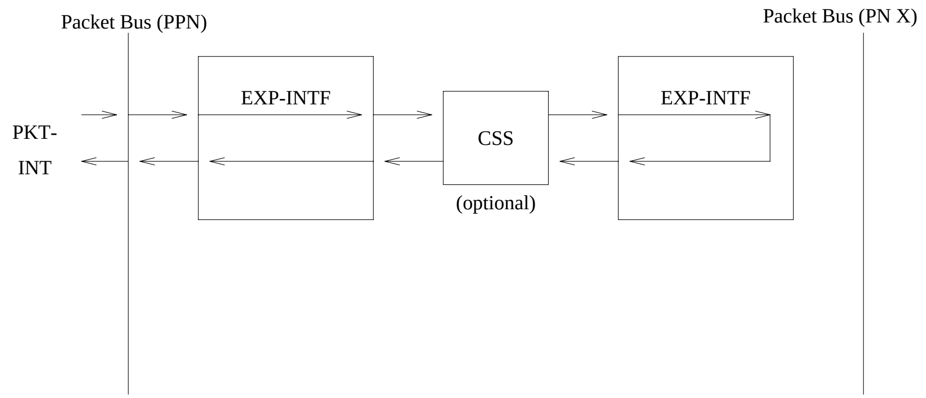

Figure 9-46. Expansion Interface Packet Interface Test—PPN to EPN loop

In a Center Stage configuration the path shown in Figure 9-46 is used when testing an EPN EI that is on the standby PNC. In a Direct Connect configuration, this path is used on any PPN EI or on an EPN EI that is on the standby PNC.

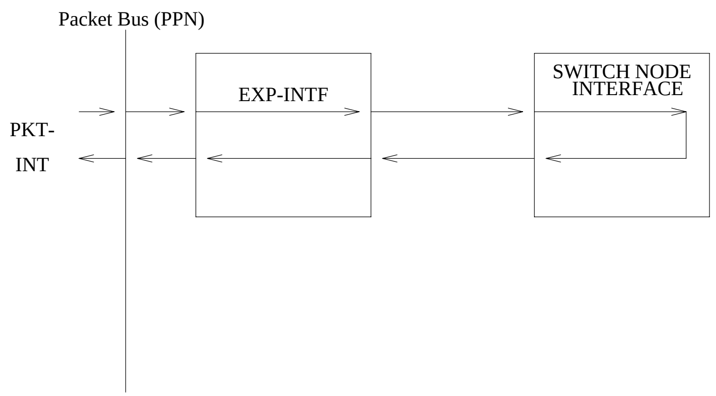

Figure 9-47. Expansion Interface Packet Interface Test—PPN to CSS Loop

The path shown in Figure 9-47 is used when running the test on a PPN EI in a Center Stage configuration.

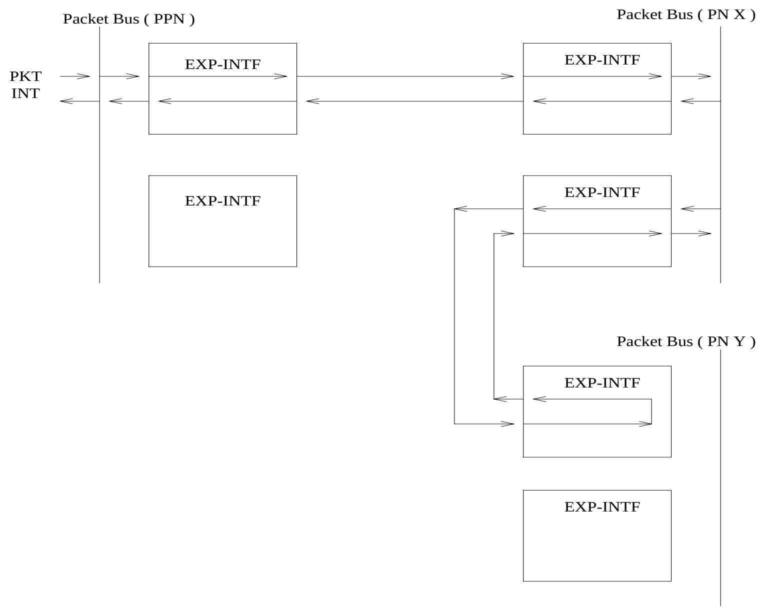

Figure 9-48. Expansion Interface Packet Interface Test-EPN to EPN link

The path shown in Figure 9-48 is used when the EI under test is one that provides connectivity between the two EPN s in a Direct Connect configuration.

Table 9-326. TEST #589 Expansion Interface Packet Interface Test

Error Code	Test Result	Description/ Recommendation
1033	ABORT	The test cannot run because the Expansion Interface circuit pack does not have a fiber link administered to it and there is not sufficient data to run the test or because Expansion Interface circuit packs on other port networks needed for this test are out of service. 1. Execute the **list fiber-link** command and determine if the Expansion Interface circuit pack under test is an endpoint of one of the administered fiber links. If it is one of the administered endpoints of a fiber link, proceed to Step 2. If it is not an administered endpoint, then this is considered to be a spare board and the test should not be attempted on this Expansion Interface circuit pack. 2. Follow procedures for applicable configuration: **DIRECT CONNECT** 1. Issue the **list config** command for the cabinet and carrier where the neighbor EI circuit pack is located. If the results reveal that the board is not recognized by software, the board is out of service because of this condition. Perform the following steps: a. If this test is being executed on an Expansion Interface circuit pack located in the PPN, enter **display errors** and resolve any EXP-PN errors for the port network where the neighbor Expansion Interface circuit pack is located. Re-execute this test. b. If this test continues to abort with this abort code reset the DS1 CONV circuit pack (if so equipped) or the neighbor Expansion Interface circuit pack. This will not be destructive since the circuit pack cannot be serving as the Expansion Archangel if it is not in service. 2. Run Test #237 and check for EXP-INTF circuit pack Error Type 1281 in the Error Log. If Error Type 1281 is present and/or Test #237 does not pass, refer to repair procedures for Test #237.

Continued on next page

Table 9-326. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1033 *(cont'd.)*	ABORT *(cont'd.)*	3. If Test #237 passes, reseat the Expansion Interface circuit pack. This will not be destructive since the circuit pack cannot be serving as the Expansion Archangel if it is not in service. 4. Repeat test #237. **CENTER STAGE** *If the Expansion Interface circuit pack under test is located in the PPN:* None of the Expansion Interface circuit packs located in the EPNs (on the same PNC side) are in service (for EPN EIs see the next case). 1. Issue the **list fiber-link** command and determine if any of the Expansion Interface circuit packs located in the EPNs are administered as endpoints of a fiber link. If none of them are then ignore the results of this test. 2. Issue the **list conf** command for the cabinets and carriers where the Expansion Interface circuit packs are located in all other EPNs. If the results returned indicated that the circuit packs are not recognized by software, they are out of service for this reason. 3. Issue the **display errors** command and resolve any EXP-PN errors. Re-execute this test. 4. If the test continues to abort with this error code reseat the Expansion Interface circuit packs (or DS1 CONV circuit pack if so equipped) on the EPNs. This will not be destructive since the circuit pack cannot be serving as the Expansion Archangel if it is not in service. 5. Run Test #237 on each of the EPN Expansion Interface circuit packs and check for EXP-INTF circuit pack Error Type 1281 in the error log. If Error Type is present and/or Test #237 does not pass, refer to repair procedures for Test #237. 6. Repeat this test.
1033 *(cont'd.)*	ABORT *(cont'd.)*	*If the Expansion Interface circuit pack under test is located in the EPN:* The Expansion Interface circuit located in the PPN is out of service. 1. Run Test #237 on each of the EPN Expansion Interface circuit packs and check for EXP-INTF circuit pack Error Type 1281 in the error log. If Error Type is present and/or Test #237 does not pass, refer to repair procedures for Test #237. 2. Repeat this test.
1139	ABORT	The Packet Bus in the Expansion Port Network where this Expansion Interface circuit pack is located has a major alarm against it. This test needs to use the alarmed port network's Packet Bus. 1. Enter **display alarms** and resolve any PKT-BUS alarms. 2. Retry the command.

Continued on next page

Table 9-326. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1141	ABORT	The Packet Interface circuit pack is out of service. 1. Refer to "PKT-INT (Packet Interface Circuit Pack)" for the recommended repair procedure.
1144	ABORT	The Packet Bus in the PPN has a major alarm against it. This test needs to use the alarmed PPN Packet Bus. 1. Enter **display alarms** and resolve any PKT-BUS alarms. 2. Retry the command.
1394	ABORT	The Expansion Interface circuit pack is out of service and the test cannot be run. This condition is due to a change in the Expansion Interface circuit pack's ability to communicate with the Expansion Interface or Switch Node Interface circuit pack on the other end of the fiber. 1. Run Test #237 and check the Error Log for EXP-INTF Error Type 1281. If Error Type 1281 is present or if Test #237 does not pass, refer to the repair procedures for Test #237. 2. If Test #237 passes, rest the Expansion Interface pack. Note that this will not be destructive to the port network that the Expansion Interface circuit pack is located in because it will not be serving as the expansion archangel if it is not in service. 3. Repeat this test.
1395	ABORT	This test cannot be run on an Expansion Interface circuit pack if it is part of the B-side Port Network Connectivity and Duplicated Port Network Connectivity is not enabled. 1. If this test needs to run on this Expansion Interface circuit pack, enable Port Network Connectivity with the **change system-parameters duplication** command. 2. Prevent the system from doing a PNC interchange by executing the **set PNC lock** command. 3. Repeat this test.

Continued on next page

Table 9-326. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1421	ABORT	This abort code appears only when the Expansion Interface circuit pack addressed in the test command is one that terminates a fiber link between two EPNs in a direct connect system. It indicates that the test failed, but that this test was run on the EPN EI board that is: a) in the same EPN as the board under test b) on the active PNC (if duplicated) c) terminates the fiber from the PPN The EI tested is probably not at fault. 1. Enter **display alarms** and follow the EXP-INTF repair procedures for any alarms against the EPN EI that is: a. In the same EPN as the board just tested b. On the active PNC c. Terminates the fiber link from the PPN 2. If there are no alarms logged against that EI, run Test #589 on it and follow procedures for this test. 3. Try this command again.
1422	ABORT	This abort code is valid and will only appear when the EI circuit pack under test is one which is located in an EPN in a system that is configured with a Center Stage Switch. It means that the test failed, but that this test was then run on the PPN EI on the same PNC as the EI under test and that test failed. This means that the EI originally tested is probably not at fault. 1. Resolve any alarms that are logged against the PPN EI that is on the same PNC as the EI under test. 2. If there are no alarms logged against the PPN EI, run Test #589 against the PPN EI and follow procedures for this test. 3. Try this command again.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 3 retries.
2060	ABORT	The link on the Packet Bus being used to perform the test has failed. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to abort, enter **display errors** and resolve any PKT-INT errors.
2100 2500	ABORT ABORT	Could not allocate the necessary system resources to run this test. Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-326. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The transmitted data packet was not received correctly by the Packet Interface circuit pack. The failure may be in the EI under test, the DS1 CONV circuit packs, or the intervening Center Stage components. 1. Test the Packet Interface circuit pack with the **test packet- interface 1CS** command where C is the SPE carrier in a duplicated processor, and S is the slot number the Packet Interface is located in. If the Packet Interface circuit pack fails any tests, refer to "PKT-INTF". 2. If the EI under test is located in an EPN in a high reliability system (2 PPN-to-CSS fibers in a simplex PNC), run the short test sequence on both of the PPN EI boards and follow procedures for test #589. 3. Enter **display errors** and resolve any PKT-BUS errors. 4. Perform the "Fiber Fault Isolation Procedure".
	PASS	Although this test has passed, there may be related problems on other EI s used in connectivity to and from this EI. Software may have conducted tests on these other components and determined that this board was functioning properly and any problems were probably due to a problem with some other connectivity component. Check the error and alarm logs for problems with other EI circuit packs and resolve these errors. 1. Refer to other EI board tests if the link is not functioning correctly.
0	NO BOARD	No board was detected by the test. 1. Resolve either wrong board (Error 125) or no board (Error 131) issues. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Test (#244)

This test is potentially very destructive and requires the Expansion Interface circuit pack to be busied out prior to execution of this test.

The Expansion Interface Test, which is not a part of either the Short or the Long Test Sequences, is executed via the **reset board PCSS** command where PCSS is the address of the Expansion Interface circuit pack to be reset.

If the system only has one working Expansion Interface (EI) link between a pair of port networks and one of the EI circuit packs must be reset, the action of busying out the desired Expansion Interface circuit pack WILL DISRUPT SERVICE TO THE EPN until the circuit pack is released from the busyout state. If the circuit pack is part of a PPN to EPN link, the EPN WILL BE WITHOUT SERVICE. If the circuit pack is part of an EPN to EPN link CALLS BETWEEN THE TWO EPNs WILL BE DENIED.

If the system has working duplicate EI links, and the EI circuit pack to be reset is part of the active EI link, the system does not allow the busyout and instructs system technician to switch EI links via the **set expansion-link PCSS** command where PCSS is the address of either Standby Expansion Interface circuit pack on the Standby link. After executing the EI link switch, it is possible to busyout and then reset the original EI circuit pack.

However, if the EPN Maintenance (MAINT) circuit pack determines that the Expansion Interface (EXP-INTF) circuit pack is cycling between sane and insane several times within several minutes, MAINT may inhibit operation of the EXP-INTF by holding the EI circuit pack in a reset state. This condition may result in an unsuccessful reset of the EI circuit pack.

If the reset command returns with `EPN is unavailable`, execute the following:

1. Use the **change circuit-pack P** command, where P is the port network number of the EPN.
2. For the EI circuit pack you wish to reset, add an entry to the Circuit Pack form for the TN776 Expansion Interface circuit pack. Be sure to enter the appropriate carrier and slot (that is, A01 or B02).
3. Repeat the **reset board** command.

Table 9-327. TEST #224 Expansion Interface Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
4	ABORT	Could not reset EPN Expansion Interface circuit pack over optical fiber since PPN Expansion Interface circuit pack on opposite end of fiber is not inserted. 1. Insert opposite EI circuit pack and perform reset again.
1015	ABORT	The system does not allow this test to be run because the EI circuit pack has not been busied out. 1. Busyout the Expansion Interface circuit pack. Repeat the **reset board PCSS** command.

Continued on next page

Table 9-327. TEST #224 Expansion Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.
9999	ABORT	EI circuit pack reset successfully. Could not perform initialization test results query because link to EPN is not up. 1. Execute **release board PCSS**. Wait one minute. Issue the **display error** command. If you see Error Type 2049 logged against this EI circuit pack, then the EI Test has failed with an error code equal to the aux data of this entry. Otherwise, the initialization tests have passed.
12000	ABORT	EI circuit pack reset successfully. Response to the initialization test results query was not received within the allowable time period.
12100	ABORT	EI circuit pack reset successfully. System resources required to run initialization test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.
12026	ABORT	EI circuit pack reset successfully. It responded with an unknown reply to the query for the results of its initialization tests. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to abort, replace the circuit pack or transceiver.
1	FAIL	The EI did not successfully reset. 1. If the EI circuit pack is in the EPN, the EPN Maintenance Board may be holding the EI circuit pack reset. Attempt to rectify this condition by executing the **test maint P long** command on the maintenance board in the same EPN. 2. If Step #1 was not successful in releasing the EI circuit pack, temporarily remove the EPN maintenance circuit pack. 3. Repeat the **reset board PCSS** command. 4. If reset continues to fail, replace circuit pack. 5. Insert EPN maintenance circuit pack if it was removed.
2	FAIL	The EI circuit pack was successfully reset, but it did not begin running after the reset. 1. If the EI circuit pack is in the EPN, temporarily remove the EPN maintenance circuit pack. 2. Repeat the **reset board PCSS** command. 3. Re-insert the EPN maintenance circuit pack if it was removed.

Continued on next page

Table 9-327. TEST #224 Expansion Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The reset over the optical fiber failed. 1. Execute the **test board PCSS** command on the PPN neighbor EI circuit pack located on the opposite end of the fiber from this EI circuit pack. If Test #238 does not pass, follow the maintenance procedure associated with this test result. Then perform the reset again. 2. If the EI circuit pack is in the EPN, temporarily remove the EPN Maintenance circuit pack. 3. Repeat the **reset board PCSS** command. 4. Reinsert EPN Maintenance circuit pack if it was removed. 5. Follow the procedure described in the “Relationship Between Expansion Interface and Tone-Clock Circuit Packs” section if the symptoms match those described there. 6. Check the Error Log for the EPN Tone-Clock errors that were resolved about the same time when the EPN went down. These EPN Tone-Clock errors may have been resolved *because* the EPN went down. When there is no Tone-Clock generating the system clock on an EPN, then an EI circuit pack can only be reset once. All subsequent reset attempts fail. It is also possible that the system itself may have already tried to reset the EI circuit pack. Refer to the TONE-BD (Tone-Clock) Maintenance documentation for recommended maintenance strategy for Tone-Clock problems.
		7. If the reset still fails, execute the Manual Loop Back Procedure on the opposite PPN EI circuit pack. This procedure is described in the section preceding the Hardware Error Log Entries and Test to Clear Values table for this MO. If the EI circuit pack and the lightwave transceiver are healthy, the problem must lie with the EI circuit pack and its lightwave transceiver on the EPN end of the fiber or with the fiber itself. Test the EPN EI circuit pack with the manual loop back procedure and investigate the test results.

Continued on next page

Table 9-327. TEST #224 Expansion Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5001	FAIL	Initialization failure: the Expansion Interface circuit pack reset successfully and restarted execution, but the Expansion Interface circuit pack could not synchronize itself during hardware initialization. 1. Issue the **reset board PCSS** command. If the circuit pack is on the Active link, this procedure can be very destructive. If a **test board PCSS** shows all the tests passing, and there is no Standby link to which you can switch, perform this reset at a time when service is least disrupted by losing use of the EPN. 2. If the reset fails with the same error code, execute the **test tone-clock PC** command where P is the network that contains this Expansion Interface circuit pack and C is the carrier that contains the Active Tone-Clock on network P. Also look for SYNC and TONE-BD errors. Resolve any SYNC and TONE-BD errors by following the Maintenance documentation for these MOs. Then reissue the **reset board PCSS** command. 3. If the Expansion Interface circuit pack still fails to reset with the same error code, replace the Expansion Interface circuit pack.
5002	FAIL	**Initialization failure:** EI circuit pack reset successfully and restarted execution. But the EI circuit pack has determined that a lightwave transceiver was not attached to the backplane connector when the EI circuit pack was last reset. If this system does not have duplicate EI links, all users in the EPN will be without service until this problem is resolved. If this system does have duplicate links, the backup EI link is unavailable until this problem is resolved. 1. Attach lightwave transceiver to 25-pair backplane connector **in slot belonging to Expansion Interface circuit pack**. 2. Reset the circuit pack again. 3. If the reset fails with an Error Code other than 5002, refer to the appropriate maintenance section. 4. If the reset fails again with Error Code 5002, replace the lightwave transceiver, reset the circuit pack, and execute the **reset board PCSS** command again. 5. If the reset fails again with Error Code 5002, the new lightwave transceiver may be defective, or the EI circuit pack may need to be replaced.

Continued on next page

Table 9-327. TEST #224 Expansion Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5016 5017 5018 5019 5032 5033 5048 5064 5080 5096 5112	FAIL	Initialization failure: the EI circuit pack reset successfully and restarted execution, but the EI circuit pack detected communication errors during hardware initialization. The nature of the failure may prevent the EI circuit pack from communicating with its neighbor EI circuit pack on the opposite end of the fiber. The fault itself may be either on the EI circuit pack or on the lightwave transceiver. 1. If all other tests on this EI circuit pack are passing and no other errors have been logged against this circuit pack, replacement of the lightwave transceiver or the circuit pack are recommended, but not critical. 2. If all other tests on this EI circuit pack are not passing or other errors have been logged against this circuit pack, replace the lightwave transceiver and/or the EI circuit pack.
	PASS	The EI was successfully reset, and it did restart execution. Also, it passed all its initialization tests and detected a lightwave transceiver. Remove the EI circuit pack from the busyout state by using the **release board PCSS** command. 1. Execute **test board PCSS short** command. Refer to errors for each test.
0	NO BOARD	No board was detected by the test. 1. Resolve either wrong board (Error 125) or no board (Error 131) issues. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

EXP-PN (Expansion Port Network)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
EXP-PN	MAJOR	display errors[1]	Expansion Port Network

1. Investigate errors against EXP-PN and EXP-INTF.

The EXP-PN maintenance object is responsible for overall maintenance of an Expansion Port Network (EPN). The focus of EPN maintenance is on the Expansion Interface or on the ATM Expansion Interface circuit pack that is acting as the Expansion Archangel in an EPN. EXP-INTF or ATM-EI covers maintenance of the Expansion Interface or ATM Expansion Interface circuit pack, while EXP-PN covers a much broader area of activities and problems on an EPN. The alarming strategy for EXP-PN is fairly simple and does not make use of any failure analysis routine for spawning maintenance actions. EXP-PN alarming is based on the availability of an EPN for service and the EPN's response to various recovery actions.

When investigating alarms logged against an EPN, problems involving the Expansion Interface, an ATM Expansion Interface circuit pack acting as the Expansion Archangel, and problems that may involve loss of communication between the EPN and the SPE should be investigated. This could ultimately include fiber links (FIBER-LK), DS1 CONV circuit packs (DS1 CONV-BD), Switch Node Interface circuit packs (SNI-BD) and Switch Node Configurations (SN-CONF) for CSS. For ATM, this could include the PPN ATM Expansion Interface (ATM-EI) circuit pack, the ATM switch (ATM-NTWK), and EPN ATM Expansion Interface (ATM-EI) circuit pack.

EPN Restarts

While not an exhaustive discussion of EPN recovery actions, this section describes at a high level the causes and effects of EPN restarts so that these Error Log events can be understood.

EPN Warm Restarts

EPN Warm Restart (EPN Reset Level 1) is generally performed on an EPN when the recovery of that EPN can be accomplished in less than 30 seconds. When possible, Warm Restart minimizes the work required to reinitialize an EPN, and reduces the impact of an EPN failure by avoiding the longer and highly destructive EPN Cold Restart. The primary cause of EPN restarts is failure of the link from the SPE to the EPN due to a hardware fault in the link's path. For most hardware failures, this link, and thus the EPN, cannot be recovered until the failed hardware is replaced. However, several failures modes exist for which hardware redundancy allows the link to be recovered quickly. For instance, in a duplex SPE system, a Packet Interface circuit pack failure causes an SPE interchange, which allows the link to be recovered quickly over the newly active Packet Interface. Or on a Center Stage Switch, a link carried on one of the multiple fibers interconnecting the switch nodes may be rerouted over an alternate fiber.

If the EAL is recovered quickly, the EPN Warm Restart returns the EPN to service with minimal effects on user service. If the EAL cannot be recovered quickly, the EPN is taken out-of-service and an EPN Reset Level 2 (EPN Cold Restart) is required to return it to service.

EPN Cold Restarts

If the PPN to EPN link has failed and has not been recovered within 30 seconds, the EPN is taken out of service and can be brought back into service only with an EPN Reset Level 2 (EPN Cold Restart). Effects of an EPN Cold Restart include a reset of all circuit packs in the EPN, and the disconnection of all calls to or from the EPN. Calls with both endpoints within the EPN are dropped upon recovery.

EPN Restart Escalation

EPN restarts follow an escalation strategy controlled by maintenance software. Whenever a request for an EPN Reset Level 1 (EPN Warm Restart) is made, software checks to see if the restart should be escalated to an EPN Reset Level 2 (EPN Cold Restart). If any of the following are true, the restart is escalated:

- At least two level 1 restarts have occurred and less than two hours has elapsed since the last occurrence.
- Current EPN conditions do not allow a level 1 restart, such as when the EPN is out-of-service.
- Less than 3 minutes has elapsed since the last EPN Cold Restart, indicating that the EPN is unstable.

If two EPN Cold Restarts have been executed in less than an hour and the link is functional, but the EPN has not recovered to an in-service state, a MAJOR alarm is raised against EXP-PN, and the EPN is put into Emergency Transfer by system software. (Software can invoke EPN Emergency Transfer only when the link to the EPN is up. If the link is down, the hardware automatically invokes Emergency Transfer 1 minute after it detects a link failure).

Connectivity Alarming

When an EPN is out of service, a MAJOR EXP-PN alarm is raised against that EPN. An EPN can only be alarmed if it is out of service *and* the fiber between the PPN and EPN is up. If the fiber from the PPN to the Center Stage Switch is down (by removing it from administration, for example), all EPNs are lost but not alarmed, since they are not the cause of the problem. If, however, connectivity is restored and the EPN fails to recover, the EPN is alarmed.

For ATM, an EPN can only be alarmed if it is out of service and the connections to the PPN, ATM switch, and EPN are up. If the connection from the PPN to the ATM switch is down (by removing it from administration, for example), all EPNs are lost but not alarmed, since they are not the cause of the problem. As for CSS, if connectivity is restored and the EPN fails to recover, the EPN is alarmed.

Error Log Entries and Test to Clear Values

Table 9-328. Expansion Port Network (EXP-PN) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1(a)	0	None	None		
257(b)	0	None	None		
513(c)	0	None	MAJOR	OFF	
769(d)	0	None	MAJOR	OFF	

Notes:

a. This is an informational entry only, indicating that an EPN Reset Level 1 (EPN Warm Restart) has been executed on this EPN.

b. This is an informational entry only, indicating that an EPN Reset Level 2 (EPN Cold Restart) has been executed on this EPN. This does not include restarts done at system initialization time.

c. Indicates that an EPN is not in-service when it is expected to be. The value specified in the port field of the error log, is the PN number of the affected PN. When this condition occurs, examine all system link errors and EXP-INTF or ATM-PNC errors to aid in resolving the alarm (examples of system link errors are errors logged against PKT-INTF, EXP-INTF, SNI-BD, FIBER-LK, and PKT-BUS and for ATM, PKT-BUS, ATM-EI, ATM-NTWK). Also check that all fiber connectivity matches that which has been administered for the system. This alarm and error is resolved and removed from the logs only when the EPN comes back into service, or after fiber administration is changed to remove a fiber such that there is no connectivity from the PPN to this EPN.

d. This alarm is raised when EPN maintenance has attempted to execute a Cold Restart recovery action two times, and both restarts failed. This will cause the EPN to be placed in Emergency Transfer. Examine all EXP-INTF or ATM-EI errors which, when cleared, may aid in resolving this alarm. Also check for any SNI-BD, SNI-PEER, FIBR-LK, SN-CONF, or DS1 CONV-BD errors or for ATM, ATM-EI or ATM-NTWK errors that may indicate a communication problem between the processor and the EPN. Make sure that the physical fiber connectivity matches that of system administration.

System Technician-Demanded Tests: Descriptions And Error Codes

EXP-PN does not support demand testing. A demand reset can be executed to perform a demand reset on an EPN by using the **reset port-network P level [1 | 2]** command (P is the port network number, and 1 or 2 specifies the reset level).

EPN Cold Restart (#955)

EPN Cold Restart, or EPN Reset Level 2, using the command **reset port-network P level 2** is used as a recovery mechanism for an EPN that has been taken out-of-service. It is executed as a result of EPN recovery escalation when a Warm Restart is not possible, or as a result of a system technician demanded EPN restart. Once an EPN has gone out-of-service, an EPN Cold Restart is required to bring it back into service.

This is the most severe of the EPN restarts, and users will experience a service outage. For the first 30 seconds after the occurrence of an event that requires a restart, all stable calls are preserved (although new calls will be denied). All calls terminating in the EPN are then dropped, and EPN users are not able to place new phone calls during the restart. All EPN hardware will also be re-initialized during this restart. The restart takes no longer than 2 minutes with service being restored much quicker in a typical restart situation.

Table 9-329. TEST #955 EPN Cold Restart

Error Code	Test Result	Description/ Recommendation
1386	ABORT	The system link to this EPN is unavailable and cannot be used. This reset cannot be executed without the link being operational. 1. Refer to SYS-LINK and resolve the link problem.

Continued on next page

Table 9-329. TEST #955 EPN Cold Restart — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to execute this reset.
2000	ABORT	Response to a request made in the internal portion of this reset procedure was not received within the allowable time period.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	The EPN Cold Restart procedure completed successfully.

EPN Warm Restart (#956)

The EPN Warm Restart, or EPN Reset Level 1, using the command **reset port-network P level 1** is used to restart an EPN that has not been taken out-of-service. It is the least severe of the EPN restart levels and is used in an attempt to preserve the state of the system as much as possible, thereby reducing user impact. This restart is attempted on a EPN if it is still in-service, or as a result of a system technician-demanded EPN Warm Restart.

During an EPN Warm Restart all calls are preserved including voice, data, and packet calls. Once an event has occurred that requires a warm restart, service is fully restored within 35 seconds.

Table 9-330. TEST #956 EPN Warm Restart

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to execute this reset. 1. Retry the command at 1-minute intervals for a maximum of 3 times.
1386	ABORT	The system link to this EPN is unavailable and cannot be used. This reset cannot be executed without the link being operational. 1. Refer to SYS-LINK and resolve the link problem.
1387	ABORT	This EPN is not in a state where it is possible to perform a Warm Restart on the EPN. It is necessary to perform an EPN Cold Restart (EPN Reset Level 2) because of one of the following reasons: ■ The EPN is in an out-of-service state. ■ Insufficient time has elapsed since the last EPN Cold Restart was performed on this EPN.
2000	ABORT	Response to a request made in the internal portion of this reset procedure was not received within the allowable time period.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 3 times.
	FAIL	Internal system error 1. Retry the reset command at 1-minute intervals for a maximum of 3 times.
	PASS	The EPN Warm Restart procedure completed successfully.

EXT-DEV ADMIN? Y (External Device Alarm)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run [1]	Full Name of MO
EXT-DEV	MAJOR	test eda-external-device-alrm physical location	External Device Alarm
EXT-DEV	MINOR	test eda-external-device-alrm physical location	External Device Alarm
EXT-DEV	WARNING	test eda-external-device-alrm physical location	External Device Alarm

1. UU is a cabinet number determined in the `Port` field of the Alarm or Error Log.

NOTE:
Use this MO when the *External Device Alarm Admin?* field on the *change system-parameters customer-options* form is set to (**y**). You must have INADS or INIT login permission to administer EXT-DEV Alarm.

Generic 3r SYSAM and EPN Maintenance circuit packs each have two alarm ports that connect to such external devices as Uninterruptible Power Supplies (UPS) or adjuncts (AUDIX).

Certain conditions on the external device close the contacts on the alarm leads to notify the switch which in turn originates an EXT-DEV alarm. One set of leads generates a major alarm; the other set generates a minor alarm.

The special locations UUmajor and UUminor are used to designate the major or minor maintenance board alarm connection for cabinet UU. The major/minor designation specifies the port, not the alarm level associated with the connection; *for example,* the “major” port can be administered as a major, minor, or warning alarm, and the “minor” port can be administered as a major, minor, or warning alarm. In addition Analog line ports can also be administered as external device alarms.

NOTE:
An unadministered maintenance board external device alarm port, that is sensing a contact closure will have an entry in the Error Log and in the Alarm Log. INADS will not receive warning alarms.

Error Log Entries and Test to Clear Values

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	test eda-external-device-alrm physical location r 2 or 6
1 or 5	Any	External Device Alarm Test (#120)	Any	OFF	test eda-external-device-alrm physical location r 2 or 6

NOTE:
The loss of -48 volt power prevents detection of an external device alarm. AC-POWER, CARR-POW, and DC-POWER alarms could indicate the loss of the external device alarm -48 volt power source. ALARM-PT alarms may also indicate a loss of power. When analog line ports are administered as analog line external device alarms loss of -48 volts prevents detection of an external device alarm.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
External Device Alarm Test (MAJOR port) (#120)	X	X	ND
External Device Alarm Test (MINOR port) (#120)	X	X	ND
External Device Alarm Test (WARNING port) (#120)	X	X	ND

1. D = Destructive; ND = Nondestructive

External Device Alarm Test (#120)

The External Device Alarm Test requests the state of the External Device Alarm from a Maintenance circuit pack and reports the results. The test has no effect on the external device itself

Table 9-331. TEST #120 External Device Alarm Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1035	ABORT	The EPN containing this equipment is not available. Resolve all EPN problems with this cabinet.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. (Maintenance Board) If the test continues to ABORT with Error Code 2000, check for system powering problems with the A carrier. Resolve all AC-POWER and CARR-POW alarms in a multi-carrier cabinet or DC-POWER alarms in a single-carrier cabinet. Then, repeat the test. 3. (Maintenance Board) If the test continues to ABORT with a 2000 Error Code, resolve all maintenance circuit pack errors. Then, repeat the test.
2029 2100 2319 2320 2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
ANY	FAIL	The External Device Alarm has been activated by the external device. 1. Clear the major alarm on the external device, and rerun the test. 2. If the test still fails, then disconnect the External Device Alarm Leads from the Maintenance circuit pack and rerun the test. 3. If the test still fails, then there is a problem with the analog external device alarm port or the Maintenance circuit pack that is reporting the alarm. This circuit pack should be replaced. There are failures that can occur on the Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many environment tests to fail. If many environment tests are failing, the suspect circuit pack should be replaced and the test rerun.
	PASS	If there is a problem with the external device, but the administered analog line external device alarm, or the administered Maintenance circuit pack connected to the device reports no alarm, then the External Device may not be properly reporting the problems or the External Device may not be properly connected to the External Device Alarm Leads.

FIBER-LK (Fiber Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
FIBER-LK	MAJOR	test fiber *F pnc* s	Fiber Link
FIBER-LK	MINOR	test fiber *F pnc* s	Fiber Link
FIBER-LK	WARNING	test fiber *F pnc* s	Fiber Link

1. F is the fiber link number; pnc is "a-pnc" or "b-pnc" (always "a-pnc" in simplex systems).

A fiber link consists of the endpoint boards that are connected via the optical fiber, the lightwave transceivers or metallic connections on the endpoint boards, and, if administered, the DS1 Converter (DS1 CONV) complex that exists between the two fiber endpoints. The fiber endpoints are Expansion Interface (EI) circuit packs and/or Switch Node Interface (SNI) circuit packs.

Three types of fiber links exist in G3r systems:

EI-EI fiber	This type of fiber is an EI to EI connection and is only used in direct connect port network connectivity (PNC).
EI-SNI fiber	This type of fiber is an EI to SNI connection and is only used in Center Stage Switch (CSS) PNC.
SNI-SNI fiber	This type of fiber is an SNI to SNI connection and is only used in CSS PNC when two switch node carriers are connected in a two or three switch node configuration.

Fiber link errors and alarms are generated only on fibers that have at least one SNI endpoint. Fiber errors for fibers that have EI s as both endpoints are detected by the EI circuit pack, thus generating off-board EXP-INTF errors and alarms. Fiber errors and alarms on EI-SNI fiber links generate FIBER-LK and/or off-board EXP-INTF errors and alarms.

Fiber links are administered via **add fiber-link F** or **add fiber-link next**, where F is the fiber-link number. The 2 endpoints of the fiber are administered (EI and EI, EI and SNI, or SNI and SNI). In duplicated PNC configurations, both the a-pnc fiber-link and the b-pnc fiber-link are administered to the same fiber link number. The fiber links are designated by F P, where F is the fiber-link number and P is the pnc, a-pnc or b-pnc. In addition, a DS1 converter complex may be administered on the fiber link. In duplicated PNC configuration, the a-pnc and b-pnc DS1 converter complexes are administered to the same fiber-link number. DS1 facilities and parameters can be modified via **change fiber-link F P**.

An individual fiber link can be displayed with the **display fiber-link F** command. All fiber links can be listed via the **list fiber-link** command.

The following terms are used in the error descriptions:

Control Path	The path between the two fiber endpoints that is necessary for the two endpoint circuit packs to communicate.
Circuit Path	The path between the two fiber endpoints that is necessary for circuit switched phone calls to work.
Neighbor	The circuit pack on the other end of the fiber.
Out of Frame	A circuit pack reports fiber out of frame if it cannot detect valid data coming from the fiber.
Packet Path	The path between the two fiber endpoints that is necessary for packet switched messages to be sent between the two fiber endpoints.

LEDs for Circuit Packs on a Fiber Link

The yellow LEDs on the three types of boards, SNI (TN573), EI (TN570), and DS1 Converter (TN574 or TN1654), that may be a part of the fiber link can help in diagnosing problems with the fiber link. The yellow LED states are as follows. The flashing LED patterns take precedence over the active or standby LED patterns.

If both endpoints of a fiber link (EI and/or SNI) are flashing with a fiber out of frame pattern, a fast yellow LED pattern (0.1 second on and 0.1 second off), check the lightwave transceivers (if present). Both lightwave transceivers on the fiber link must be of the same type. The 9823a shortwave transceiver and the 9823b longwave transceiver must never be combined on the same fiber link because a fiber out of frame condition will exist. The 9823a lightwave transceiver should be used for distances up to 4900 feet and the 9823b lightwave transceiver should be used for distances up to 25,000 feet.

Table 9-332. Switch Node Interface Yellow LED Flashing Codes

Condition	LED on	LED off
Fiber out of Frame	0.1 second	0.1 second
In Frame, No Neighbor[1]	0.5 second	0.5 second
SNI active	Solid on	Never off
SNI standby	Never on	Solid off

1. The fiber is in frame, but no communication exists to the neighbor

Table 9-333. Expansion Interface Circuit Pack Yellow LED Flashing Codes

Condition	LED on	LED off
Fiber Out-of-Frame	0.1 second	0.1 second
(a) In frame-No Neighbor	0.5 second	0.5 second
(b) Expansion Interface Active	2 second	0.2 second
(c) Expansion Interface Active	Solid on	Never off
(d) Expansion Interface Standby	Never on	Solid off

Notes:

a. The fiber is in frame, but no communication exists to the neighbor.

b. This is the normal state for an active EPN EI circuit pack that is also the bus master (expansion archangel) in the EPN.

c. This is the normal state for an active EI circuit pack that is not the bus master (expansion archangel) for an EPN. This applies only in the direct connect configuration where the EI circuit pack in an EPN connects via a fiber link to an EI circuit pack in the other EPN. This state also applies for an active EI circuit pack located in the PPN.

d. This is the normal state for a standby expansion Interface circuit pack in both the PPN and EPNs.

For more details about how the Expansion Interface circuit pack error codes relate to the LED states, see the EXP-INTF section.

Table 9-334. DS1 CONV Yellow LED Flashing Codes

Condition	LED on	LED off
(a) Fiber out of Frame	0.1 second	0.1 second
(b) In frame, fiber channel is down	0.5 second	0.5 second
(c) In frame, DS1 channel down	1 second	1 second
(d) DS1 CONV no response from SPE	2 second	0.2 second
DS1 CONV active	Solid on	Never off
DS1 CONV standby	Never on	Solid off

Notes:

a. A Fiber is out of frame or a fiber loss of signal condition exists.

b. DS1 CONV/fiber endpoint communication is down.

c. The DS1 channel is down between the two DS1 CONVs in the DS1 converter complex.

d. The SPE is not acknowledging messages from the DS1 CONV circuit pack or the DS1 CONV circuit pack does not have a processor route. This pattern indicates a probable software problem.

In addition to the traditional red, green, and yellow LEDs, the DS1 CONV circuit pack has four green LEDs that indicate whether a receive signal is present for each DS1 facility.

Error Log Entries and Test to Clear Values

Table 9-335. Fiber Link Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test fiber-link F P r 1
1 (b)	any	failure audit (#777) (a)	WAR/MIN/MAJ	OFF	test fiber-link F P r 1
18 (c)	0	busyout fiber F P	WARNING	OFF	release fiber F P
257 (d)	any	failure audit (#777) (a)	WAR/MIN/MAJ	OFF	test fiber-link F P r 1
513 (e)	any	failure audit (#777) (a)	WAR/MIN/MAJ	OFF	test fiber-link F P r 1
76 9(f)	any	failure audit (#777) (a)	WAR/MIN/MAJ	OFF	test fiber-link F P r 1
1025 (g)	any	failure audit (#777) (a)	WAR/MIN/MAJ	OFF	test fiber-link F P r 1
1281 (h)	any	failure audit (#777) (a)	WAR/MIN/MAJ	OFF	test fiber-link F P r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The failure audit test (#777) should be run to confirm whether the error still exists.

b. This error indicates problem with the control path to the neighbor.

c. This error indicates that the fiber link has been busied out via the **busyout fiber F P** command. To resolve this error, release the fiber link with the **release fiber F P** command.

d. This error indicates problem with the circuit path to the neighbor.

e. This error indicates problem with the packet path to the neighbor.

f. This error indicates problem with the control path from the neighbor.

g. This error indicates problem with the circuit path from the neighbor.

h. This error indicates problem with the packet path from the neighbor.

For note b and notes d through h, perform the following steps:

1. Perform the "Fiber Fault Isolation Procedure".
2. Enter **display errors** and if any of the slip errors listed below exist, follow the associated repair procedures in the SYNC section for slip errors.

Table 9-336. Error Log Entries for Slip Errors

Circuit Pack Name	Error Log Name	Error Log Entry for Slips
DS1 Interface	DS1-BD	3073 to 3160
Expansion Interface	EXP-INTF	2305
Switch Node Interface	SNI-BD	1537
Tone-Clock	TDM-CLK	1025
UDS1 Interface	UDS1-BD	3073 to 3160

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with one test, you may also clear errors generated by other tests later in the sequence.

Table 9-337. Tests Run for an EI-to-EI Fiber Link

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Fiber Sequence	D/ND[1]
EI Out-of-Frame Query Test(#238)	X	X		ND
EI Neighbor Query Test(#237)	X	X		ND
Fiber Link Reset Test(#768)			X	D

1. D = Destructive; ND = Nondestructive

Table 9-338. Tests Run for an EI-to-SNI Fiber Link

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Fiber Sequence	D/ND[1]
EI Out-of-Frame Query Test(#238)	X	X		ND
EI Neighbor Query Test(#237)	X	X		ND
Configuration Audit(#759)	X	X		ND
Failure Audit(#777)	X	X		ND
Fiber Out of Frame Query(#989)	X	X		ND
Destructive Facility Test(#757)		X		D
Off-Board Destructive Facility Test(#756)		X		D
Fiber Link Reset Test(#768)			X	D

1. D = Destructive, ND = Non-destructive

Table 9-339. Tests Run for an SNI-to-SNI Fiber Link

Fiber Out of Frame Query(#989)	X	X		ND
Destructive Facility Test(#757)		X		D
Off-Board Destructive Facility Test (#756)		X		D
Fiber Link Reset Test(#768)			X	D

1. D = Destructive; ND = Nondestructive

Expansion Interface Neighbor Query Test (#237)

This test is non-destructive. The Expansion Interface Neighbor Query Test is a request to an EI circuit pack to determine if it has established communication with the EI or Switch Node Interface circuit pack on the opposite end of the fiber.

For EI-EI fiber links, this test is run on both EI circuit pack endpoints of the fiber link.

Table 9-340. TEST #237 Expansion Interface Neighbor Query Test

Error Code	Test Result	Description/ Recommendation
1033	ABORT	The EI circuit pack does not have a fiber link administered to it. There is not sufficient data to run test. Since the **test fiber-link** command was run, the expansion interface should be administered on a fiber link, therefore this must be a software problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Run the **test board UUCSS** test separately for each EI endpoint on this fiber link and follow the procedures for this test in the "EXP-INTF (Expansion Interface Circuit Pack)" section.
2031	ABORT	The attempt to send the message to the Expansion Interface circuit pack, asking it who it's neighbor is, was not successful. 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures for this test in the "EXP-INTF (Expansion Interface Circuit Pack)" section.
2100	ABORT	System resources required to run this test are not available. 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures in the EXP-INTF section.
2500	ABORT	Internal system error 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures in the EXP-INTF section.
1033	FAIL	The Expansion Interface circuit pack under test cannot make contact with opposite end Expansion Interface or Switch Node Interface circuit pack. 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures in the "EXP-INTF (Expansion Interface Circuit Pack)" section.
2027	FAIL	The Expansion Interface circuit pack has contact with the opposite Expansion Interface or Switch Node Interface circuit pack, but it is the incorrect Expansion Interface or Switch Node Interface circuit pack. 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures in the "EXP-INTF (Expansion Interface Circuit Pack)" section.

Continued on next page

Table 9-340. TEST #237 Expansion Interface Neighbor Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The EI circuit pack(s) have successfully established a link with the opposite Expansion Interface or Switch Node Interface circuit pack. 1. If the **status port-network** command still indicates that this link is down, it is possible that one or both of the EI and/or Switch Node Interface circuit packs have been busied out. 2. If the link still does not come up, reset one or both EI and/or Switch Node Interface circuit packs on the link.

Expansion Interface Fiber Out-of-Frame (FOOF) Query Test (#238)

This test is non-destructive.

This test is a request to an EI circuit pack to determine if it is currently detecting the framing sequence on the incoming fiber data stream. If it cannot detect this framing signal, the EI circuit pack will not be able to establish a link with the opposite EI or Switch Node Interface circuit pack.

For EI-EI fiber links, this test is run on both EI circuit pack endpoints of the fiber link.

Table 9-341. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error (software). 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures for this test in the "EXP-INTF (Expansion Interface Circuit Pack)" section of the maintenance manual. 2. If th test continues to abort or fail, excalate the problem.
1033	ABORT	The Expansion Interface circuit pack does not have a fiber link administered to it. There is not sufficient data to run test. Since the **test fiber-link** command was run, the expansion interface should be administered on a fiber link, therefore this must be a software problem.

Continued on next page

Table 9-341. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures in the EXP-INTF section.
2100	ABORT	System resources required to run this test are not available. 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures in the EXP-INTF section.
2500	ABORT	Internal system error 1. Run the **test board UUCSS** test separately for each Expansion Interface endpoint on this fiber link and follow the procedures in the EXP-INTF section.
	FAIL	Expansion Interface circuit pack can't frame up to incoming signal. Several fail codes may be returned depending on which endpoint can't frame up. Error codes 2326, 2327, and 2328 denote endpoint 1, endpoint 2, and both endpoints, respectively. 1. Clear any SYNC and TDM-CLK errors listed in the error log. 2. Run the **test board UUCSS** test for each Expansion Interface board on this fiber link and follow the apporpriate repair sequence for any failing tests. 3. If the Expansion Interface circuit pack fails Test #238 and is in the EPN, and the red LEDs are ON for a large number of circuit packs, then reseat any Tone-Clock circuit packs in the EPN. See the "How to replace Tone/Clock circuit packs" section of "TDM-CLK (TDM Bus Clock)" on page 9-1901 Maintenance documentation. 4. Enter display errors and follow the associated repair procedures for any SNC-BD (if applicable to this fiber link configuration) or TDM-BUS errors. 5. Perform the "Fiber Fault Isolation Procedure" on page 5-20", described in Chapter 5 of the Maintenance manual. 6. If the test continues to abort, follow normal escalation procedures.
	PASS	The Expansion Interface circuit pack(s) have detected the valid framing signal on the fiber. 1. Refer to errors from other EI circuit packs, Switch Node Interface tests, or DS1 Converter tests (if present) if the link is still not functioning.

SNI Off-Board Destructive Facility Test (#756)

This test is destructive.

The SNI runs a destructive looparound of the off-board and on-board looparounds. This test returns the result of the off-board looparound, while test 757 returns the result of the on-board looparound. For SNI-SNI fiber links, this test is run on both SNI circuit pack endpoints of the fiber link.

Table 9-342. TEST #756 SNI Off-Board Destructive Facility Test

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The system will not allow this test to be run because the fiber link has not been busied out. Busy out the fiber link with **busyout fiber-link** F P. Repeat the **test fiber-link** F P **long** command.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test.
2304	ABORT	SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	An SNI circuit pack on the fiber link is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node(s) that the SNI (s) reside in to verify whether the LED s on the board(s) light. Follow the steps below for the SNI (s) from step 1 that had no LED s light. 2. If the LED s on the other boards in the carrier light, but the LED s on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LED s on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LED s light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use **list fiber-link** to determine the fiber connections to this carrier. Check the LED s on all SNI s and EI s and fix any fiber problems. Enter **display errors** and resolve any EXP-INTF error entries associated with the PPN. Also, resolve any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.

Table 9-342. TEST #756 SNI Off-Board Destructive Facility Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1415	ABORT	The lightwave transceiver is not present for endpoint 1 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. If a lightwave transceiver is not supposed to be present, do nothing. For example, an SNI connected to a DS1 CONV circuit pack or an SNI with a metallic connection does not have a lightwave transceiver. This test can only be run when a lightwave transceiver exists. 2. Otherwise, continue with the following steps. 3. Check the lightwave transceiver connections. 4. Replace the lightwave transceiver. If a fiber out of frame condition exists and lightwave transceivers are used, check that the lightwave transceivers are of the same type (both are 9823a or both are 9823b). If they are not the same type, replace one of the lightwave transceivers. 5. Replace the SNI circuit pack.
1416	ABORT	The lightwave transceiver is not present for endpoint 2 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. If a lightwave transceiver is not supposed to be present, do nothing. For example, an SNI connected to a DS1 CONV circuit pack or an SNI with a metallic connection does not have a lightwave transceiver. This test can only be run when a lightwave transceiver exists. 2. Check the lightwave transceiver connections. 3. Replace the lightwave transceiver. If a fiber out of frame condition exists and lightwave transceivers are used, check that the lightwave transceivers are of the same type (both are 9823a or both are 9823b). If they are not the same type, replace one of the lightwave transceivers. 4. Replace the SNI circuit pack.
127	FAIL	The data is not correctly looped around on endpoint 1 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. Check the lightwave transceiver. 2. Replace the lightwave transceiver. If a fiber out of frame condition exists and lightwave transceivers are used, check that the lightwave transceivers are of the same type (both are 9823a or both are 9823b). If they are not the same type, replace one of the lightwave transceivers. 3. Replace the SNI circuit pack.

Continued on next page

Table 9-342. TEST #756 SNI Off-Board Destructive Facility Test — *Continued*

Error Code	Test Result	Description/ Recommendation
227	FAIL	The data is not correctly looped around on endpoint 2 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. Check the lightwave transceiver. 2. Replace the lightwave transceiver. If a fiber out of frame condition exists and lightwave transceivers are used, check that the lightwave transceivers are of the same type (both are 9823a or both are 9823b). If they are not the same type, replace one of the lightwave transceivers. 3. Replace the SNI circuit pack.
	PASS	No problems associated with this test are detected on the SNI (s).

SNI Destructive Facility Test (#757)

This test is destructive.

The SNI runs a destructive looparound of the off-board and on-board looparounds. This test returns the result of the on-board looparound, while test 756 returns the result of the off-board looparound.

For SNI-SNI fiber links, this test is run on both SNI circuit pack endpoints of the fiber link.

Table 9-343. TEST #757 SNI Destructive Facility Test

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The system will not allow this test to be run because the fiber link has not been busied out. Busy out the fiber link with **busyout fiber-link** F P. Repeat the **test fiber-link** F P **long** command.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test.
2304	ABORT	SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	An SNI circuit pack on the fiber link is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node(s) that the SNI (s) reside in to verify whether the LEDs on the board(s) light. Follow the steps below for the SNI(s) that had no LEDs light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If no LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and resolve any EXP-INTF error entries associated with the PPN. Also, resolve any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.
127	FAIL	The data is not correctly looped around on endpoint 1 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. Replace the SNI circuit pack.
227	FAIL	The data is not correctly looped around on endpoint 2 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. Replace the SNI circuit pack.
	PASS	No problems associated with this test are detected on the SNI(s).

Configuration Audit (#759)

This test is non-destructive.

This test is run via the **test board short** or **test board long** command for SNI circuit packs or via **test fiber-link** for fiber links with SNI endpoint(s).

This test queries the SNI for SNC s in the same switch node carrier, SNI peers, DS1 CONV s, and EI or SNI neighbors that the SNI can communicate with and compares this data to the administered data.

Failures of this test cause entries in the error and alarm logs against Switch Node Configuration (SN-CONF) with the board location of the SNI.

This test is unable to detect the case where an SNI is connected to the same type of board (EI or SNI) as administered but located in a different cabinet but the same carrier and same slot as the administered fiber endpoint. The administered fiber endpoint can be viewed with the **list fiber-link** command. This test can only detect if the fiber endpoint connected to the SNI is in a different carrier, slot location than the administered fiber endpoint.

If the SNI is connected to the same type of fiber endpoint as the administered fiber endpoint, but the location is the same as administered except for the cabinet, all phone calls will not work correctly; some phone calls will not go through and some phone calls will ring the wrong phone.

The **test led** command can be used in this case to check connectivity.

1. First, run the **test led port-network** command on each administered port network and verify that the LEDs on the correct port network are lit.
2. If not, check that the fiber connections to the port network are consistent with the administered fibers (**list fiber-link**) that does not light the LEDs as expected.
3. Then run the test led switch-node command on each administered switch node carrier and verify that the LEDs on the correct switch node carrier are lit.
4. If not, check the connectivity to the switch node carrier that does not light the LEDs as expected.

Table 9-344. TEST #759 Configuration Audit

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test for endpoint 1 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). If this fiber link has two SNI endpoints, run the **test board UUCSS** test separately for each SNI and follow the repair procedures in section SNI-BD.
2300	ABORT	The downlink message necessary to run this test could not be sent. If this fiber link has two SNI endpoints, run the **test board UUCSS** test separately for each SNI and follow the repair procedures in section SNI-BD (**list fiber-link** can be used to display fiber link endpoints).
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. If this fiber link has two SNI endpoints, run the **test board UUCSS** test separately for each SNI and follow the repair procedures in section SNI-BD (**list fiber-link** can be used to display fiber link endpoints). 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	An SNI circuit pack on the fiber link is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node(s) that the SNI(s) reside in to verify whether the LEDs on the board(s) light. Follow the steps below for the SNI(s) that had no LEDs light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNI s and EI s and fix any fiber problems. Enter **display errors** and resolve any EXP-INTF error entries associated with the PPN. Also, resolve any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.
2500	ABORT	Internal system error If this fiber link has two SNI endpoints, run the **test board UUCSS** test separately for each SNI and follow the repair procedures in section SNI-BD (**list fiber-link** can be used to display fiber link endpoints). Otherwise: 1. Retry the command at 1-minute intervals a maximum of 3 times.

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
113	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 13 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2049, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2049, replace the SNI in slot 13.
114	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 14 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2305, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2305, replace the SNI in slot 14.
115	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 15 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2561, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2561, replace the SNI in slot 15.

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
116	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 16 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2817, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2817, replace the SNI in slot 16.
117	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 17 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3073, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3073, replace the SNI in slot 17.
118	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 18 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3329, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3329, replace the SNI in slot 18.

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
119	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 19 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3585, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3585, replace the SNI in slot 19.
120	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with the equipped SNI in slot 20 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3841, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3841, replace the SNI in slot 20.
133	FAIL	No neighbor link is administered, but the SNI (endpoint 1) has an EI neighbor (**list fiber-link** can be used to display fiber link endpoints). 1. Administer the SNI on a fiber link to the EI neighbor it is connected to via the **add fiber-link next** command. Or remove both fiber endpoints (i.e., this SNI and its EI neighbor) and remove the fiber endpoints from circuit pack administration via **change circuit-pack**.
134	FAIL	No neighbor link is administered, but the SNI (endpoint 1) has an SNI neighbor (**list fiber-link** can be used to display fiber link endpoints). 1. Administer the SNI on a fiber link to the SNI neighbor it is connected to via the **add fiber-link next** command. Or remove both fiber endpoints (i.e., this SNI and its SNI neighbor) and remove the fiber endpoints from circuit pack administration via **change circuit-pack**.

Continued on next page

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
135	FAIL	The SNI circuit pack (endpoint 1) cannot communicate with its neighbor (**list fiber-link** can be used to display fiber link endpoints). The SNI has an administered neighbor, but cannot communicate with its neighbor. 1. Check if the administered neighbor is inserted. If not, insert the neighbor circuit pack. 2. Perform the "Fiber Fault Isolation Procedure".
136	FAIL	The endpoint 1 SNI's administered neighbor does not match the physical neighbor connected (**list fiber-link** can be used to display fiber link endpoints). The type of neighbor administered is an SNI and the type of neighbor physically connected is an EI. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered.
137	FAIL	The endpoint 1 SNI's administered neighbor does not match the physical neighbor connected (**list fiber-link** can be used to display fiber link endpoints). The type of neighbor administered is an EI and the type of neighbor physically connected is an SNI. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered.
138	FAIL	The physical neighbor location of endpoint 1 SNI does not match administered neighbor location (**list fiber-link** can be used to display fiber link endpoints). The carrier and slot of the administered neighbor do not match the carrier and slot of the physical neighbor. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered. If the problem does not seem to be caused by a physical connection problem or an administration problem, replace the neighbor circuit pack. It is possible for the neighbor circuit pack to have a hardware problem that causes it to report a wrong angel address (physical carrier/slot address) to software.
139	FAIL	The endpoint 1 SNI is administered to be connected to a DS1 CONV but is not physically connected to a DS1 CONV (**list fiber-link** can be used to display fiber link endpoints). If a DS1 CONV is not supposed to be connected to this SNI, change administration to remove the DS1 converter complex from the fiber link associated with this SNI by: 1. Check for the fiber that this SNI is an endpoint of by checking **list fiber-link** 2. **Remove fiber-link** for the fiber that this SNI is an endpoint of. 3. Add the fiber back via **add fiber-link** and this time do not administer the DS1 converter complex. If a DS1 CONV should be connected to this SNI, enter **list fiber-link** and verify that the fiber optic cable and/or metallic cable connections are installed as administered.

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
140	FAIL	The endpoint 1 SNI is physically connected to a DS1 CONV but is not administered to be connected to a DS1 CONV (**list fiber-link** can be used to display fiber link endpoints). Either add the DS1 converter complex to the fiber that this SNI is associated with by: 1. Check for the fiber that this SNI is an endpoint of by checking **list fiber-link**. 2. **Remove fiber-link** for the fiber that this SNI is an endpoint of. 3. Add the fiber back via **add fiber-link** and this time administer the DS1 converter complex also. Or, remove the DS1 CONV connection and connect the SNI directly to its administered fiber endpoint by entering **list fiber-link** and verifying that the fiber optic cable and metallic cable connections are installed as administered.
202	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 2 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 1, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 1, replace the SNI in slot 2.
203	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 3 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 257, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 257, replace the SNI in slot 3.

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
212	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the active SNC (**list fiber-link** can be used to display fiber link endpoints). 1. Check the error log for other SNI circuit packs in the same carrier with a 257 SNI-BD error. Use **display errors** with category PNC to view SNI-BD errors. If other SNI circuit packs in the same switch node carrier have error 257, then replace the active SNC in this switch node carrier. Replacing an SNC may be service interrupting. Refer to the SNC-BD section for the procedure for replacing an SNC. 2. Replace this SNI. 3. Replace the active SNC in the same switch node carrier.
213	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 13 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2049, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2049, replace the SNI in slot 13.
214	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 14 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2305, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2305, replace the SNI in slot 14.

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
215	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 15 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2561, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2561, replace the SNI in slot 15.
216	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 16 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 2817, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 2817, replace the SNI in slot 16.
217	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 17 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3073, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3073, replace the SNI in slot 17.

Continued on next page

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
218	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 18 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3329, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3329, replace the SNI in slot 18.
219	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 19 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3585, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3585, replace the SNI in slot 19.
220	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with the equipped SNI in slot 20 (**list fiber-link** can be used to display fiber link endpoints). 1. Perform the "Fiber Fault Isolation Procedure". This should resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER Error Type 3841, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested still has SNI-PEER Error Type 3841, replace the SNI in slot 20.
233	FAIL	No neighbor link is administered, but the SNI (endpoint 2) has an EI neighbor (**list fiber-link** can be used to display fiber link endpoints). 1. Administer the SNI on a fiber link to the EI neighbor it is connected to via the **add fiber-link next** command. Or remove both fiber endpoints (i.e., this SNI and its EI neighbor) and remove the fiber endpoints from circuit pack administration via **change circuit-pack**.

Continued on next page

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
234	FAIL	No neighbor link is administered, but the SNI (endpoint 2) has an SNI neighbor (**list fiber-link** can be used to display fiber link endpoints). 1. Administer the SNI on a fiber link to the SNI neighbor it is connected to via the **add fiber-link next** command. Or remove both fiber endpoints (i.e., this SNI and its SNI neighbor) and remove the fiber endpoints from circuit pack administration via **change circuit-pack**.
235	FAIL	The SNI circuit pack (endpoint 2) cannot communicate with its neighbor (**list fiber-link** can be used to display fiber link endpoints). The SNI has an administered neighbor, but cannot communicate with its neighbor. 1. Check if the administered neighbor is inserted. If not, insert the neighbor circuit pack. 2. Perform the "Fiber Fault Isolation Procedure".
236	FAIL	The endpoint 2 SNI's administered neighbor does not match the physical neighbor connected (**list fiber-link** can be used to display fiber link endpoints). The type of neighbor administered is an SNI and the type of neighbor physically connected is an EI. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered.
237	FAIL	The endpoint 2 SNI's administered neighbor does not match the physical neighbor connected (**list fiber-link** can be used to display fiber link endpoints). The type of neighbor administered is an EI and the type of neighbor physically connected is an SNI. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered.
238	FAIL	The physical neighbor location of endpoint 2 SNI does not match administered neighbor location (**list fiber-link** can be used to display fiber link endpoints). The carrier and slot of the administered neighbor do not match the carrier and slot of the physical neighbor. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered. If the problem does not seem to be caused by a physical connection problem or an administration problem, replace the neighbor circuit pack. It is possible for the neighbor circuit pack to have a hardware problem that causes it to report a wrong angel address (physical carrier/slot address) to software.

Continued on next page

Table 9-344. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
239	FAIL	The endpoint 2 SNI is administered to be connected to a DS1 CONV but is not physically connected to a DS1 CONV (**list fiber-link** can be used to display fiber link endpoints). If a DS1 CONV is not supposed to be connected to this SNI, change administration to remove the DS1 converter complex from the fiber link associated with this SNI by: 1. Check for the fiber that this SNI is an endpoint of by checking **list fiber-link** 2. **Remove fiber-link** for the fiber that this SNI is an endpoint of. 3. Add the fiber back via **add fiber-link** and this time do not administer the DS1 converter complex. If a DS1 CONV should be connected to this SNI, enter **list fiber-link** and verify that the fiber optic cable and/or metallic cable connections are installed as administered.
240	FAIL	The endpoint 2 SNI is physically connected to a DS1 CONV but is not administered to be connected to a DS1 CONV (**list fiber-link** can be used to display fiber link endpoints). Either add the DS1 converter complex to the fiber that this SNI is associated with by: 1. Check for the fiber that this SNI is an endpoint of by checking **list fiber-link**. 2. **Remove fiber-link** for the fiber that this SNI is an endpoint of. 3. Add the fiber back via **add fiber-link** and this time administer the DS1 converter complex also. Or, remove the DS1 CONV connection and connect the SNI directly to its administered fiber endpoint by entering **list fiber-link** and verifying that the fiber optic cable and metallic cable connections are installed as administered.
	PASS	The administered data and the circuit packs the SNI (s) can communicate with match.

Fiber Link Reset Test (#768)

This test is destructive.

This test resets both endpoints of the fiber link and is executed via the **reset fiber-link F P** command. Any DS1 CONV circuit packs on the fiber link are not reset. The **reset fiber-link** command should almost never be used. It may be necessary to use it when the endpoint circuit packs enter a mode in which they cannot communicate with software. When necessary, always reset fiber endpoints with the command instead of reseating the endpoint circuit packs.

For EI-EI fibers that connect an EPN to the PPN, the EI on the EPN is reset first followed by the EI on the PPN. For EI-EI fiber links that connect two EPN s, one EI is reset first followed by the other.

For an EI-SNI fiber link in which the EI is on the PPN, the SNI is reset first followed by the EI.

For an EI-SNI fiber link in which the EI is on an EPN, the SNI is reset first followed by the EI.

For an SNI-SNI fiber link, the SNI farthest from the PPN is reset first followed by the SNI nearest to the PPN.

When an EI endpoint is reset, the Expansion Interface Reset Test (#336) is executed. When an SNI endpoint is reset, the SNI Reset Test (#761) is executed. These tests are described in the EXP-INTF and SNI-BD sections.

This test starts the other reset test mentioned above and returns PASS without waiting for the results of the other reset test. For a better indication of how the other reset tests are running, use the **reset board UUCSS** command on each individual fiber link endpoint.

Table 9-345. TEST #768 Fiber Link Reset Test

Error Code	Test Result	Description/ Recommendation
1703	ABORT	Both fiber endpoints are in the hardware path for INLs to their respective switch node carriers and, thus, cannot get a response from this test because the INLs response should come on will go down as a result of the reset. 1. Reset the individual fiber-link endpoints via the **reset board** command.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	The reset of both fiber endpoints successfully completed.

Failure Audit (#777)

This test is non-destructive.

This test queries the SNI (s) on the fiber link for any existing failures and any unacknowledged cleared failure messages. Each failure generates an error and alarm entry against SNI-BD, SNI-PEER, or FIBER-LK. An unacknowledged cleared failure message is a message the SNI circuit pack sent to software indicating a previous failure is now gone and the SNI circuit pack did not receive a message from software indicating that the failure message was received by software.

If no failures are detected by the SNI circuit pack, this test will pass.

If this test reports failures, the results screen for the **test fiber-link** command will show **FAIL** with no FAIL code. The error log must then be displayed via **display errors** with category PNC to view SNI-BD and FIBER-LK errors and **display errors** with category PNC-PEER to view SNI-PEER errors.

For EI-EI fiber links, this test is not run. For EI-SNI fiber links, this test is run on the SNI circuit pack endpoint of the fiber link. For SNI-SNI fiber links, this test is run on both SNI circuit pack endpoints of the fiber link.

Table 9-346. TEST #777 Failure Audit

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test.
2300	ABORT	The downlink message necessary to run this test could not be sent.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test.
2302	ABORT	The SNI circuit pack claims that it received a bad message from software.
2303	ABORT	The SNI circuit pack claims that the test requested by software is invalid.
2304	ABORT	SNI firmware is not able to run the test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	An SNI circuit pack on the fiber link is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node(s) that the SNI (s) reside in to verify whether the LED s on the board(s) light. Follow the steps below for the SNI (s) from step 1 that had no LED s light. 2. If the LED s on the other boards in the carrier light, but the LED s on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LED s on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LED s light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use **list fiber-link** to determine the fiber connections to this carrier. Check the LED s on all SNI s and EI s and fix any fiber problems. Enter **display errors** and resolve any EXP-INTF error entries associated with the PPN. Also, resolve any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.

Continued on next page

Table 9-346. TEST #777 Failure Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The SNI circuit pack reported failures or retransmitted a cleared failure message. 1. If this is the first time this test was run, run the test again. If there were any previous failure messages that software did not acknowledge, this test will FAIL even if the failure messages indicate a FAIL to PASS transition, i.e., a problem has gone away. If this test is run twice and FAILs both times, then at least one problem still exists. 2. Resolve any errors or alarms (**display errors** and **display alarms**) for SNI-BD, SNI-PEER, and FIBER-LK entries. 3. If no SNI-BD, SNI-PEER, or FIBER-LK entries exist in the error and alarm logs, retry the command.
	PASS	No problems are detected on the board.

SNI Fiber Out of Frame Query (#989)

This test is non-destructive.

The SNI circuit pack reports whether a fiber out of frame condition exists, whether a loss of signal condition exists, and whether the lightwave transceiver is present.

Table 9-347. TEST #989 SNI Fiber Out of Frame Query

Error Code	Test Result	Description/ Recommendation
1415	ABORT	The lightwave transceiver is not present for endpoint 1 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. If a lightwave transceiver is not supposed to be present, do nothing. For example, an SNI connected to a DS1 CONV circuit pack or an SNI with a metallic connection does not have a lightwave transceiver. 2. Otherwise, continue with the following steps. 3. Check the lightwave transceiver connections. 4. Replace the lightwave transceiver. 5. Replace the SNI circuit pack.

Continued on next page

Table 9-347. TEST #989 SNI Fiber Out of Frame Query — *Continued*

Error Code	Test Result	Description/ Recommendation
1416	ABORT	The lightwave transceiver is not present for endpoint 2 of the fiber link (**list fiber-link** can be used to display fiber link endpoints). 1. If a lightwave transceiver is not supposed to be present, do nothing. For example, an SNI connected to a DS1 CONV circuit pack or an SNI with a metallic connection does not have a lightwave transceiver. 2. Otherwise, continue with the following steps. 3. Check the lightwave transceiver connections. 4. Replace the lightwave transceiver. 5. Replace the SNI circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	The SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	An SNI circuit pack on the fiber link is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node(s) that the SNI (s) reside in to verify whether the LED s on the board(s) light. Follow the steps below for the SNI (s) from step 1 that had no LED s light. 2. If the LED s on the other boards in the carrier light, but the LED s on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LED s on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LED s light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use **list fiber-link** to determine the fiber connections to this carrier. Check the LED s on all SNI s and EI s and fix any fiber problems. Enter **display errors** and resolve any EXP-INTF error entries associated with the PPN. Also, resolve any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.

Table 9-347. TEST #989 SNI Fiber Out of Frame Query — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
141	FAIL	The SNI circuit pack (endpoint 1 of the fiber-link) has a fiber out of frame condition, but no loss of signal condition. Also, a lightwave transceiver is connected to the SNI circuit pack. 1. Check that the connected circuit pack is physically installed. The connected circuit pack is the other endpoint of the fiber-link if no DS1 CONV complex is administered (check via **list fiber-link**). Otherwise, if a DS1 CONV complex is administered, the connected circuit pack is the DS1 CONV circuit pack connected to the SNI circuit pack. 2. Perform the Fiber Fault Isolation Procedure described in Chapter 5. 3. Replace this SNI circuit pack. 4. Replace the connected circuit pack.
142	FAIL	The SNI circuit pack (endpoint 1 of the fiber-link) has a fiber out of frame condition, but no loss of signal condition. Also, no lightwave transceiver is connected to the SNI circuit pack. 1. Check that the connected circuit pack is physically installed. The connected circuit pack is the other endpoint of the fiber-link if no DS1 CONV complex is administered (check via **list fiber-link**). Otherwise, if a DS1 CONV complex is administered, the connected circuit pack is the DS1 CONV circuit pack connected to the SNI circuit pack. 2. Perform the Fiber Fault Isolation Procedure described in Chapter 5. 3. Replace this SNI circuit pack. 4. Replace the connected circuit pack.
143	FAIL	The SNI circuit pack (endpoint 1 of the fiber-link) has a loss of signal condition, but no fiber out of frame condition. Also, a lightwave transceiver is connected to the SNI circuit pack. 1. Check that the connected circuit pack is physically installed. The connected circuit pack is the other endpoint of the fiber-link if no DS1 CONV complex is administered (check via **list fiber-link**). Otherwise, if a DS1 CONV complex is administered, the connected circuit pack is the DS1 CONV circuit pack connected to the SNI circuit pack. 2. Perform the Fiber Fault Isolation Procedure described in Chapter 5. 3. Replace this SNI circuit pack. 4. Replace the connected circuit pack.

Table 9-347. TEST #989 SNI Fiber Out of Frame Query — *Continued*

Error Code	Test Result	Description/ Recommendation
244	FAIL	The SNI circuit pack (endpoint 2 of the fiber-link) has a loss of signal condition, but no fiber out of frame condition. Also, no lightwave transceiver is connected to the SNI circuit pack. 1. Check that the connected circuit pack is physically installed. The connected circuit pack is the other endpoint of the fiber-link if no DS1 CONV complex is administered (check via **list fiber-link**). Otherwise, if a DS1 CONV complex is administered, the connected circuit pack is the DS1 CONV circuit pack connected to the SNI circuit pack. 2. Perform the Fiber Fault Isolation Procedure described in Chapter 5. 3. Replace this SNI circuit pack. 4. Replace the connected circuit pack.
245	FAIL	The SNI circuit pack (endpoint 2 of the fiber-link) has a fiber out of frame condition and a loss of signal condition. Also, a lightwave transceiver is connected to the SNI circuit pack. 1. Check that the connected circuit pack is physically installed. The connected circuit pack is the other endpoint of the fiber-link if no DS1 CONV complex is administered (check via **list fiber-link**). Otherwise, if a DS1 CONV complex is administered, the connected circuit pack is the DS1 CONV circuit pack connected to the SNI circuit pack. 2. Perform the Fiber Fault Isolation Procedure described in Chapter 5. 3. Replace this SNI circuit pack. 4. Replace the connected circuit pack.
246	FAIL	The SNI circuit pack (endpoint 2 of the fiber-link) has a fiber out of frame condition, and a loss of signal condition. Also, no lightwave transceiver is connected to the SNI circuit pack. 1. Check that the connected circuit pack is physically installed. The connected circuit pack is the other endpoint of the fiber-link if no DS1 CONV complex is administered (check via **list fiber-link**). Otherwise, if a DS1 CONV complex is administered, the connected circuit pack is the DS1 CONV circuit pack connected to the SNI circuit pack. 2. Perform the Fiber Fault Isolation Procedure described in Chapter 5. 3. Replace this SNI circuit pack. 4. Replace the connected circuit pack.
	PASS	No problems associated with this test are detected on the SNI.

GPTD-PT (General Purpose Tone Detector Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
GPTD-PT	MAJOR	test port UUCSSpp sh	General Purpose Tone Detector Port
GPTD-PT	MINOR	test port UUCSSpp sh	General Purpose Tone Detector Port
GPTD-PT	WARNING	release port UUCSSpp	General Purpose Tone Detector Port

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPN s). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The General Purpose Tone Detector (GPTD) Ports, also known as Call Progress Tone Receivers (CPTR), reside on the following circuit packs:

- TN748 all suffixes (mu-law companding)

The GPTD port performs level measurements of test tones and to detect call progress tones. Examples of call progress tones are dial tone, ring back, busy, alert, confirmation, and recall dial. The abilities of the GPTD port to perform level measurements of test tones and to detect call progress tones are essential for maintenance of other circuit packs (for example, Tone-Clock).

The GPTD maintenance object defines a set of tests to ensure that the general purpose tone detection capability of the GPTD port is functioning properly. For all Tone Detector circuit pack level errors (DETR-BD), refer to “XXX-BD (Common Port Circuit Pack)”.

Error Log Entries and Test to Clear Values

Table 9-348. General Purpose Tone Detector Port (CPTR) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1	17664	Tone Detector Audit/ Update Test (#43)	MAJOR/ MINOR (a)	ON	test port UUCSSpp r 2
18	0	busyout port UUCSSpp	WARNING	ON	release port UUCSSpp
130 (d)		None	WARNING	ON	test port *UUCSSpp* sh r 2
257 (b)	17666	Tone Detector Audit/ Update Test (#43	MAJOR/ MINOR (a)	ON	test port UUCSSpp r 3
513 (c)	Any	Tone Detection Verification Test (#42	MAJOR/ MINOR (a)	ON	test port UUCSSpp r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. A Major or a Minor alarm may be logged with this error. A Major alarm is raised when the total number of GPTD ports currently in service is less than or equal to 1/2 of the threshold number administered via the **change system-parameters maintenance** command. Otherwise a Minor alarm is raised. In either case, run the Short Test Sequence on the alarmed GPTD port and follow procedures for the individual test results.

b. The GPTD port lost its translation. Testing the GPTD port is sufficient to reload its translation. If testing the GPTD port does not clear the error, then replace the Tone Detector circuit pack containing the defective GPTD port.

c. This error indicates the GPTD port is having problems detecting call progress tones. If this error is logged constantly, replace the Tone Detector circuit pack containing the defective GPTD port.

d. This Error Type indicates that the circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.

Technician-Demand Tests: Descriptions and Error Codes

Always investigate tests in the order presented below when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test (#42)	X	X	ND
Tone Detector Audit/Update Test (#43)	X	X	ND

1. D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test verifies that the call progress tones detection and the tone level measurement capabilities of the GPTD port are functioning properly.

Table 9-349. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system was not able to allocate all the resources needed for this test or there was an Internal system error.
1	ABORT	The system could not allocate all the resources needed to test the call progress tones.
1001	ABORT	The system was unable to put the GPTD port in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This can happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the **test tdm [1|2]** command. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-349. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a Tone-Clock for the test connection. This may be caused by a heavy load on the system or by a faulted Tone-Clock. 1. Check to see if there are any alarms against the Tone-Clock in the port network where the test aborted. If so refer to the recommended procedures for TONE-BD or TONE-PT. 2. If a new Tone-Clock has been inserted, allow about 1 minute for maintenance to run on the newly inserted circuit pack. 3. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2006	ABORT	The active Tone-Clock circuit pack or a Tone Detector circuit pack may not be functioning properly. 1. Test the *active* Tone-Clock circuit pack in the port network with the **test tone-clock** UUC command and refer to the "TONE-BD (Tone-Clock Circuit Pack)" section for failures. 2. Retry the command at 1-minute intervals up to 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. Retry the command at 1-minute intervals a maximum of 5 times.
101-1 22	FAIL	1. Run the Short Test Sequence: **test port UUCSSpp sh r 1**. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore the system performance to normal, replace the tone detector circuit pack containing the defective GPTD port.
1022	FAIL	Tone detection for the system is administered as part of a wideband configuration, and the tone detector is not a TN420C (the only circuit pack with this capability). GPTD ports on other types of tone detector circuit packs are taken out of service since they cannot provide the administered function. 1. Change the tone-detection mode administered on the system-parameters country-options form (see *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description)* or remove all non-TN420C tone detector circuit packs from the system.
	PASS	Tone Detection Verification is successful. The GPTD port is able to detect all call progress tones and perform level measurements of test tones.

Tone Detector Audit/Update Test (#43)

The GPTD port is refreshed with all time slot information and sanity audit is performed on the GPTD port

Table 9-350. TEST #43 Tone Detector Audit/Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system was not able to allocate the resources needed for this test. 1. Wait 1 minute and try again.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Hardware audit failed. 1. Run the Short Test Sequence: **test port UUCSSpp short repeat 1**. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. To restore the system performance to normal, replace the Tone Detector circuit pack containing the defective GPTD port.
	PASS	The GPTD port has been successfully refreshed with its translation.

H323-BCH (H.323 B-Channel)

No maintenance diagnostic tests exist for this object.

H.323 signaling is very similar to ISDN Q.931 signaling. In order to take advantage of existing Definity ISDN call processing software, H.323 trunk call processing includes H.323 signaling groups, H.323 D-channels and H.323 B-channels. H.323 Signaling groups are similar in concept to ISDN PRI signaling groups. H.323 D-channels are an artificial fabrication created only to allow maximum re-use of system ISDN code. H.323 B-channels are also an artificial fabrication.

No physical hardware components make up the H.323 B-channel object discussed here. Along with the D-channel, these objects allow existing ISDN call processing to be re-used for H.323 trunking. The H.323 signaling group is not a collection of physical D-channels that exist on one or more DS1 facilities. The H.323 signaling group can be considered to be one D-channel that physically rides on a C-LAN port and the IP network. Unlike ISDN D-channels, the H.323 D-channel may actually come up and down on a call-by-call basis. So the H.323 D-channel is actually a TCP/IP signaling channel. Layer 1 and 2 of this signaling channel can be monitored by IP PING testing.

Performance in terms of voice latency for a signaling group is monitored by background measurements being collected by the TN802B Media Processor board.

H.323 B-channels actually use TN802B Media Processor ports to carry the actual bearer. The TN802B is a service circuit. On a call-by-call basis, any port of a TN802B may be serving an H.323 station or a H.323 B-channel. Status information may exist for a specific H.323 B-channel, and an H.323 B-channel may be busied out and released, but no maintenance diagnostic tests will exist for the object.

Errors are logged for *craft* busyout conditions. The system receives service state updates for *craft*-driven busyout/release. Under normal conditions the system automatically places H.323 B-channels into or out of service when it receives an H.323 signaling-group service state update. *Craft* busyout drops active calls.

Error Log Entries and Test to Clear Values

Table 9-351. H323-BCH B-Channel Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Service State
18	Any	B-channel busied out	Warning	off	*OOS*

Notes:

a. **Error Type 18**: this error indicates that this specific H323 trunk group member has been *craft* busied-out.

System Technician Commands

The following commands are available to the system technician:

- **busyout port UUCSSpp** – this command on a specific H.323 B-channel drops any active call that may exist on that B-channel and effectively reduces the trunk group capacity by one. No physical piece of hardware is removed from service.
- **release port UUCSSpp** – this command on a specific H.323 B-channel effectively increases the trunk group capacity by one. No physical piece of hardware is actually added to service.
- **status trunk grp/mbr** – this command is used to find the current status of the specific B-channel. Additional status for an H.323 B-channel shows near and far-end IP signaling addresses, near and far-end H.245 addresses, tunneling status, call reference value for an active call and the H.323 conference ID.
- **test port UUCSSpp** – this command results in the message `No tests applicable to this object.`

H323-SGRP (H.323 Signaling Group)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
H323-SGRP	MINOR	test sig-group *grp#*[1]	H323 Signaling Group
H323-SGRP	WARNING	test sig-group *grp#*[1]	H323 Signaling Group

1. *grp#* is the signaling group number (1-166); the test sequence can be either short or long.

The H.323 Signaling Group (H323-SGRP) maintenance object supports a signaling channel for H.323 Trunk connections. The Media Processor (MedPro) TN802B circuit pack provides audio connectivity, working in concert with a C-LAN (TN799B) circuit pack that provides control signaling to support an H.323 connection.

The H.323 signaling group (323-SGRP) is a signaling channel that physically rides on a C-LAN ethernet port (socket) and the IP network. Unlike ISDN D-channels, the H.323 channel may actually come up and down on a call by call basis. The H.323 channel is actually a TCP/IP signaling channel. Layers 1 and 2 of this signaling channel are monitored by IP PING testing.

Error Log Entries and Test to Clear Values

Table 9-352. 323-SGRP Signaling Group Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any		test sig-group *grp#*
1 (a)	Any	Ethernet Port Status Test #1386	MINOR	OFF	test sig-group *grp#*
257 (b)	Any	H.323 SGRP PING Test #1387	MINOR	OFF	test sig-group *grp#*
513(c)	Any	H.323 SGRP PING Test #1387	WARNING	OFF	test sig-group *grp#*
769(d)	Any		WARNING	OFF	
1025(e)	Any		MINOR	OFF	
1281(f)	Any	MEDPRO Status Test #1392	NONE		test sig-group *grp#*
1537(g)	Any		NONE		

Notes:

a. **Error Type 1**: this error indicates that the C-LAN ethernet port used to carry the signaling for this H.323 signaling group is out of service. To determine which C-LAN had been administered for this signaling group, find the near-end node name on the **signaling group** form; then find the C-LAN with the same node name on the **ip-interfaces form**. Check for errors on this C-LAN board.

b. **Error Type 257**: this error tracks failures of the H.323 signaling-group PING test. See H.323 signaling-group PING test failures documented later in this maintenance object.

c. **Error Type 513**: this error tracks excessive round trip delay of the H.323 signaling-group PING test (if the round-trip delay exceeds 4 seconds).

d. **Error Type:769**: this error indicates that test packets sent from a media processor circuit pack to the far-end ip address specified on the **signaling-group** form have exceeded the IP latency and loss thresholds, as administered on the **system-parameters maintenance** form. Exceeding these thresholds indicates that the IP network may not be providing sufficient quality service for adequate transmission of voice. If the signaling group has been administered to enable BYPASS, then error type 1025 should also occur.

e. **Error Type 1025**: this error indicates that the signaling group has been placed into a BYPASS condition due to IP network congestion. The signaling group accepts incoming calls, but all outgoing calls are denied. The system routes these calls over a secondary route if one has been administered.

f. **Error Type 1281**: this error implies that no MedPro resources are in-service to provide media connections for the trunk members of the signaling group. Check for errors against the MEDPRO and MEDPROPT maintenance objects. This error causes all H323 B Channels to be in an out-of-service near-end state.

g. **Error Type 1537**: this error indicates that the far end of the signaling group is not ready to handle audio bearer. If the other end of this signaling group is also a DEFINITY, this error means the DEFINITY on the other end does not have MEDPRO in-service for its signaling group.

   In the absence of error 1281, this error will place the H323 B Channels into an out-of-service far-end state.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *CLAN Ethernet Status Test (#1386)*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
CLAN Ethernet Status Test (#1386)	X	X	ND
MedPro Status Test (#1392)	X	X	ND
H.323 Signaling Group Ping Test (#1387)	X	X	ND

1. D = Destructive; ND = Nondestructive

CLAN Ethernet Status Test (#1386)

This test is non-destructive.

This test checks the status of the C-LAN ethernet port that originated this signaling group. If the C-LAN ethernet port is in-service, the test passes, if it is out of service the test fails.

NOTE:
Failure of this test puts the SIG-GRP in the OOS state.

Table 9-353. TEST #1386 CLAN Ethernet Status Test

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system Error. 1. Retry the command at 1-minute intervals a maximum of 3 times
2800	ABORT	A C-LAN ethernet port that corresponds to the near-end address of the signaling group has not been administered.
	FAIL	The C-LAN ethernet port that corresponds to the near-end address of this signaling group and all trunk members controlled by this signaling group are out of service. 1. Check the system for errors against the out of service C-LAN board.
	PASS	The C-LAN ethernet port that corresponds to the near-end address of this signaling group is in-service.

H.323 Signaling Group Ping Test (#1387)

This test is nondestructive.

This test is only run for those signaling groups that have an administered far-end IP address. If the H.323 signaling group does not have an administered far-end IP address the test aborts.

The test determines the local C-LAN through which the signaling originates and the far-end terminating IP address. It then requests the local C-LAN to execute a PING on the far-end address. If the ping is successful, the test passes, if the PING is not successful, the test fails.

NOTE:
Multiple failures of this test can take the H.323 signaling group out of service.

If the PING is successful, this test looks at the PING round trip delay. If a round trip delay of greater than 4 seconds is reported, a separate error is logged. Excessive round trip delays within the signaling group do not take the signaling group out of service.

Services can execute the standard **ping** command using the C-LAN board address and far-end IP address from the signaling group form to see the actual round-trip delay.

This test checks the circuitry involved in the data path of a peer-to-peer IP layer connection.

This nondestructive test runs due to in-line errors, during periodic and schedule maintenance, and on demand.

Table 9-354. TEST #1387 H.323 Signaling Group Ping Test

Error Code	Test Result	Description/ Recommendation
1005	ABORT	This signaling group has no administered far-end address. The test does not apply to this configuration.
2800	ABORT	A C-LAN ethernet port that corresponds to the near-end address of the signaling group has not been administered.
ANY	ABORT	Refer to ETH-PT, Test #1281, C-LAN port PING test for a more detailed description of the reasons for the abort.

Continued on next page

Table 9-354. TEST #1387 H.323 Signaling Group Ping Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The far-end of the signaling group could not be reached. 1. Refer to ETH-PT, Test #1281, C-LAN port PING test for a more detailed description of the reasonds for the failure.
	PASS	The system can PING the administered far-end address of the H323 signaling group.

MedPro Status Test (#1392)

This test is non-destructive.

Voice calls over H.323 signaling groups are carried by media processor resources. If there are no media processor resources in-service for the specified signaling group, the H323 B Channels are placed into out-of-service near-end, so that calls may flow to other trunk groups controlled by different signaling groups.

On the **ip-interfaces form**, the field `Inter-region IP connectivity allowed?` may be set to **y** or **n**. If the field is set to **n**, only media processors in the same region as the signaling group can carry calls.

This test determines if a media processor is in-service in the same region as the C-LAN that carries this signaling group. If the field is set to **y**, any media processor in the system can carry calls. This test determines if a media processor is in-service in any region.

Table 9-355. TEST #1392 MedPro Status Test

Error Code	Test Result	Description/ Recommendation
ANY	ABORT	Internal system Error.
	FAIL	No in-service Medpro ports exist for use by this signalling group. The H323 B Channels are placed into OOS-NE. 1. Check the system for errors against MEDPRO and MEDPROPT maintenance objects.
	PASS	In-service Medpro ports exist for use by this signaling group.

H323-STN (H.323 IP Station)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
H323-STN	WARNING	test station *extension*	H.323 IP Station

This maintenance object covers implementation of the maintenance for native mode H.323 endpoints. Native mode H.323 applications such as NetMeeting or Proshare only provide what is needed to support the H.323 standard. There is very little that Definity can invoke in the maintenance area. Definity will report errors as they are detected via the RAS registration and keep-alive mechanism. Definity will PING the endpoint both via the signaling path (i.e. via C-LAN) and via the media path (i.e. via Medpro).

This station type is not attached to a port board. Insertion of the station is not driven by board insertion, rather it is driven by successful registration of the endpoint. It is maintained via a set of explicit TCP/IP ping requests and errors reported by the switch software, which terminates the H.323 signaling portion of each endpoint. The MO follows standard maintenance methodology and supports test, busyout, release and status commands.

Error Log Entries and Test to Clear Values

Table 9-356. H323-STN IP Station Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any		test station *extension*
1 (a)		Registration Status Inquiry Test (#1372)	WARNING	OFF	
257 (b)		Signaling Path PING Test (#1373)	WARNING	OFF	
513(c)		Media Path PING Test (#1374)	WARNING	OFF	

Notes:

a. **Error Type 1**: this error reports the registration status of the endpoint. If call processing SW claims the endpoint is registered and receives keep-alive handshakes from the endpoint, the test passes. If keep-alive handshaking has failed, the test fails. If the user has intentionally un-registered from DEFINITY, the station is now basically an AWOH station and is no longer being maintained; no tests will run for this station.

b. **Error Type 257**: this error tracks failures of the signaling path PING test. The test attempts to send a PING packet to the endpoint IP address, as reported during registration. The PING packet originates with the C-LAN board through which the endpoint is registered. If the PING response packet is received, the test passes. If the PING response packet times out, the test fails.

c. **Error Type 513**: this error tracks failures with the media path PING test. The test attempts to send a PING packet to the endpoint IP address, as reported during registration. The PING packet originates with a Media Processor board. Any Media Processor board may be used as long as it is administered to be in the same network region as the C-LAN board through which the endpoint is registered. If the PING response is received, the test passes. If the PING response packet times out, the test fails.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the Signaling Path PING Test (#1373), for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Registration Status Inquiry Test (#1372)	X	X	ND
Signaling Path PING Test (#1373)	X	X	ND
Media Path PING Test (#1374)	X	X	ND

1. D = Destructive; ND = Nondestructive

Registration Status Inquiry Test (#1372)

The Registration status inquiry reports the H.323 registration status of the endpoint. An endpoint must be registered and authenticated in order to receive service from the system.

Registration is initiated when the endpoint user attempts to login using the Lucent registration software application running on the endpoint PC. The user must provide a valid extension and security code. The registration messages are sent to the IP address of a C-LAN ethernet port.

A registered extension has a port type SNNNNN, where N is a digit from 0-9. A non-registered extension has an X port.

Table 9-357. TEST #1372 Registration Status Inquiry

Error Code	Test Result	Description/Recommendation
1,2,3	FAIL	The endpoint is not successfully registered. 1. Verify that the user is entering: ■ the correct extension and security code ■ the C-LAN IP address 2. Verify that the extension has been enabled for IP softphone operation. 3. If many endpoints cannot register, investigate any errors of the C-LAN ethernet port. 4. Examine the ethernet cabling from the endpoint PC to the ethernet hub.
	PASS	The endpoint is successfully registered and continues to respond to registration handshaking.

Signaling Path PING Test (#1373)

This test is nondestructive.

The test determines the local C-LAN through which the signaling originates and the endpoint's IP address. It then requests the local C-LAN to execute a PING on the endpoint's address. If the PING is successful, the test passes, if the PING is not successful, the test fails.

NOTE:
Multiple failures of this test can take the H.323 IP Station out of service.

This test checks the circuitry involved in the data path of a peer-to-peer IP layer connection.

This nondestructive test runs due to in-line errors, during periodic and schedule maintenance, and on demand.

Table 9-358. TEST #1373 Signaling Path PING Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
1003	FAIL	Ping to the destination failed. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Investigate any C-LAN ethernet port errors.

Continued on next page

Table 9-358. TEST #1373 Signaling Path PING Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1007	FAIL	The system could not PING the registered endpoint via the C-LAN. 1. Verify that at least one destination reachable through this port. PING this destination (**ping ip-address *xxx.xxx.xxx.xxx***). 2. If the PING to any destination is successful through this port, the link is up. 3. If PING to all destinations fail, test the C-LAN port (**test port UUCSSpp short**) and follow repair procedures for Session Status Test (#1286) failures. 4. If only this station cannot be pinged: ■ Make sure the PC is up ■ Make sure the PC has a network connection (ethernet or dialup) ■ Check the ethernet cabling
	PASS	The system can successfully send IP packets to the registered endpoint from the C-LAN.

Media Path PING Test (#1374)

This test is nondestructive.

The test selects a Media Processor board. It then requests the local Media Processor to execute a PING on the endpoint address. If the PING is successful, the test passes, if the PING is not successful, the test fails.

Services can execute the standard **ping** command using the Media Processor board address and endpoint IP address to see the actual round-trip delay.

This test checks the IP network connectivity needed for audio packets to be sent to the endpoint.

This nondestructive test runs due to in-line errors, during periodic and schedule maintenance, and on demand.

Table 9-359. TEST #1374 Media Path PING Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
2806	ABORT	No Media Processor board found to use for this test.
ANY	FAIL	The system could not PING the registered endpoint from a Media Processor board. This may result in calls with no talk path. 1. If the Registration Status Inquiry Test (#1372) fails, follow those procedures. 2. Refer to MEDPRO, Test #1378, for a detailed description of the error codes.
	PASS	PING through this Media Processor is successful.

H-ADAPTR (MSS Host Adapter)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
H-ADAPTR	MINOR	test host-adapter a|b long	MSS Host Adapter
H-ADAPTR	WARNING	test host-adapter a|b long	MSS Host Adapter

1. In a system with a simplex SPE, the carrier need not be specified. In a system with duplicated SPE s, carrier a or b must be specified.

The Host Adapter circuit is located on the UN332 Mass Storage System/Network Control circuit pack (MSSNET) and is part of the Mass Storage System (MSS) which also contains the Switch Control (SW-CTL) circuit. The MSS provides non-volatile removable media and disk storage for booting the PBX system and for saving system translation data.

The Host Adapter circuit provides the interface between the Switch Processing Element (SPE) system bus and the Small Computer System Interface (SCSI) bus. The SCSI bus is an industry standard bus that connects a removable media drive and disk drive to the PBX.

Note that the red LED on the MSSNET board is shared by both the switch control and host adapter circuits. A failure of either circuit will cause the LED to light. A reset of the host adapter also causes this LED to light. A separate MO (SW-CTL) and its associated tests are used for maintenance of the switch control circuit.

The removable media and disk drives are treated as separate, but related, maintenance objects (R-MEDIA and DISK). Problems with the host adapter may affect the operation of the removable media and disk circuit packs.

When the host adapter is taken out of service because of a failure of a critical host adapter test, or by use of the **busyout** command, the R-MEDIA and DISK maintenance objects are also placed in an out-of-service state.

In a system with duplicated SPEs, the tests run on the standby host adapter circuit are identical to those run on the active host adapter circuit. The DUPINT circuit pack handles communications between the active and standby SPEs for both the control channel and memory shadowing. Therefore, problems with the DUPINT circuit pack may affect maintenance tests of the standby host adapter circuit pack.

Circuit Pack Replacement Procedures

If the MSSNET circuit pack needs to be replaced:

1. If the SPE is not duplicated:
2. Power down the SPE carrier by:
   a. Remove the power plug from the **left side** of the carrier first.
   b. Remove the second power plug from the **right side** of the carrier.
3. Replace the MSSNET circuit pack.
4. Power up the SPE carrier by:
   a. Insert the power plug in the right side of the carrier first.
   b. After inserting the first power plug in the right insert the second power plug in the left side of the carrier.
5. Wait for the system to reboot.
   c. Test the MSSNET circuit pack using the **test mssnet long** command.
   d. Verify that the removable media and disk are in service by issuing the **status spe** command.
6. If the SPE is duplicated:
   a. Refer to “Replacing SPE Circuit Packs” in Chapter 5.
   b. After the standby SPE is powered up and fully refreshed, test the standby MSSNET circuit pack using the **test mssnet long command.**

Error Log Entries and Test to Clear Values

Table 9-360. Host Adapter Error Log Entries

1. If Error Type 3585 with aux data of 5302 is present, this field will have the out of service cause data. See the *MSS Error Actions* table at the end of the section on R-MEDIA.
2. In a system with a simplex SPE, the carrier does not have to be specified. In a system with duplicated SPE, the carrier (a or b) must be specified.
3. See the MSS Error Actions table at the end of the section on R-MEDIA.

The `Service State` field in the alarm log refers to the accessibility of the device. IN (in service) means that users can access the device and all maintenance tests will run. MTC (maintenance busy) means the device is busied out; users cannot access it, but all maintenance tests will run. OUT (out of service) means that users cannot access the device and background testing will not run. Demand testing may or may not run depending on the severity of the error.

Notes:

a. Indicates that the host adapter hardware is in a “held reset” state.

b. Indicates that the host adapter has been “busied out.”

c. Indicates that non-critical host adapter diagnostics failed.

d. Indicates that critical host adapter diagnostics failed.

e. Indicates that the Host Adapter Reset (#820 or #893) failed or that the hardware is in a “held reset” state.

f. Indicates that the Host Adapter Looparound Test (#824) failed.

g. Indicates that the host adapter detected a processor bus error.

h. Indicates that the host adapter could not access SCSI memory.

i. Indicates that the host adapter detected an illegal command or a command was aborted.

j. Indicates that the host adapter detected an internal firmware or OS software error.

k. Indicates that the host adapter detected an interrupt or exception.

l. Indicates that the host adapter detected a flash prom programming error.

m. Indicates that the Host Adapter Status Test (#825) detected an error in the host adapter configuration status or in the LED status test. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

n. Indicates internal host adapter software errors.

o. Indicates in-line errors reported by the host adapter firmware. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

p. This is used to record miscellaneous data when an out-of-service condition occurs. See the *MSS Error Actions* table at the end of the section on R-MEDIA.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Host Adapter Diagnostic Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-361. System Technician-Demanded Tests: DS1-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Host Adapter Reset Test (#820)		X		ND

Continued on next page

Table 9-361. System Technician-Demanded Tests: DS1-BD — *Continued*

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Host Adapter Diagnostic Test (#823)	X	X		ND
Host Adapter Looparound Test (#824)	X	X		ND
Host Adapter Status Test (#825)	X	X		ND
Host Adapter Firmware Error Counters	X	X		ND
Read and Clear Test (#822)				
Host Adapter Reset (#893)			X	ND

1. D = Destructive, ND = Non-destructive

Host Adapter Reset Test (#820 and #893)

The Reset Test #820 resets the host adapter circuit on the MSSNET circuit pack and runs an initialization test. The initialization test is similar to the Diagnostic Test #823 with two exceptions: a test is run on the host adapter dual port RAM during the reset test and a test involving system bus mastership is run during the diagnostic test.

The reset test can be run in two ways: as a part of the long host adapter test sequence (**test host-adapter long**) or as a result of the reset host adapter command (**reset host-adapter**). Failure of the reset command cause the host adapter to be placed in an internal "held reset" state. In this state the host adapter will not run any background maintenance and will not respond to any commands except a reset command. The only way to restore the host adapter to service is for it to pass the reset command. Demand tests will not run until then.

If the reset test is requested as part of the long host adapter test sequence, failure of the test causes the host adapter to be placed in a software "out-of-service" state. From this state the host adapter can be restored to service by either passing the long host adapter test sequence the proper number of times or by passing the reset command. Refer to the Diagnostic Test #823 for a more complete description of the test coverage.

Table 9-362. TEST #820/#893 Host Adapter Reset Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to "STBY-SPE". 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to "STBY-SPE". 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to "STBY-SPE". 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).

Continued on next page

Table 9-362. TEST #820/#893 Host Adapter Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The host adapter has been placed in the "uninstalled" state. 1. Verify that the host adapter is fully inserted and powered up. 2. Attempt a demand reset of the host adapter.
1	FAIL	The host adapter could not be reset successfully. 1. Retry the command after 1 minute. 2. If the test fails, issue the **reset host-adapter** command. 3. If the command fails, replace the MSSNET circuit pack (see the circuit pack replacement section above) and issue the **test mssnet long** command.
	PASS	The host adapter was reset correctly. Check results of other tests to see if it is operating correctly.

1. See the MSS Error Actions table at th end of the section on R-MEDIA.

Host Adapter Read and Clear Firmware Error Counters Test (#822)

The host adapter firmware constantly executes background testing of the host adapter hardware. If any irregularities are detected, counters in dual port RAM are incremented. The Read and Clear Firmware Error Counters test reads these counters from the host adapter dual port RAM and increments the appropriate software counters based on which ones are non-zero. The dual port RAM counters are then cleared.

The firmware maintains sixteen counters that record the following errors:

- Unexpected interrupt from the SCSI Bus Interface Controller Chip (SBICC).
- SBICC timed out during SCSI command.
- Direct Memory Access Controller (DMAC) generated error interrupt.
- DMAC timed out without interrupt.
- Universal Synchronous/Asynchronous Receiver/Transmitter (USART) diagnostics failed.
- Host adapter LED test failed.
- Removable Media LED test failed.

- Disk LED test failed.
- Processor bus dual port RAM test failed.
- Processor bus IO registers test failed.
- External host adapter loop around failed.
- Illegal SCSI target controller requested.
- Interrupt during processor bus access.
- Bus timeout during processor bus access.
- Parity error during processor bus access.
- Error Detection and Correction (EDC) error during processor bus access.

Table 9-363. TEST #822 Host Adapter Read and Clear Firmware Error Counters Test

Error Code	Test Result	Description/ Recommendation
1311	ABORT	Could not read the firmware error counters 1. Retry the command at 1-minute intervals a maximum of 5 retries.
1316	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to “STBY-SPE”. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to “STBY-SPE”. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to “STBY-SPE”. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Continued on next page

Table 9-363. TEST #822 Host Adapter Read and Clear Firmware Error Counters Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The host adapter has been placed in the "uninstalled" state. 1. Verify that the host adapter is fully inserted and powered up. 2. Attempt a demand reset of the host adapter.
[1]	FAIL	The Read and Clear Firmware Error Counters test detected a non-zero firmware error counter. 1. Retry the command at 1-minute intervals a maximum of 5 retries. 2. If the command continues to fail, replace the MSSNET circuit pack (see the circuit pack replacement section above) and issue the **test mssnet long** command.
	PASS	The Read and Clear Firmware Error Counters test completed successfully without detecting a non-zero firmware error counter. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on R-MEDIA.

Host Adapter Diagnostic Test (#823)

The Host Adapter Diagnostic test runs a set of non-destructive diagnostic tests for the Host Adapter. This includes tests requiring system bus mastership. Specific tests include:

- Micro processor testing including exception processing
- Private RAM test
- EPROM and FLASHPROM checksum test
- SPE side Dual Port RAM test
- Control and status register test
- System memory access test
- SCSI bus access test
- SCSI memory access test
- Sanity timer test
- SCSI side Dual Port RAM test

A more complete test of the access to the disk and removable media drives over the SCSI bus is provided by the DISK and R-MEDIA tests.

Table 9-364. TEST #823 Host Adapter Diagnostic Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to “STBY-SPE”. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to “STBY-SPE”. 2. After interchange occurs, run test on new active SPE.

Continued on next page

Table 9-364. TEST #823 Host Adapter Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to “STBY-SPE”. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The host adapter has been placed in the "uninstalled" state. 1. Verify that the host adapter is fully inserted and powered up. 2. Attempt a demand reset of the host adapter.
[1]	FAIL	The Host Adapter Diagnostic test could not be run successfully. 1. Replace the MSSNET circuit pack (see the circuit pack replacement section above) and issue the **test mssnet long** command.
	PASS	The Host Adapter Diagnostic Test completed successfully. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on R-MEDIA.

Host Adapter Looparound Test (#824)

The Host Adapter Looparound test provides a partial functional test which verifies that the host adapter can perform data transfer functions.

This test performs two subtests:

- Internal loop-around test
- External loop-around test

Note that this test is entirely contained in the host adapter and does not test access to the system.

Table 9-365. TEST #824 Host Adapter Looparound Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to "STBY-SPE". 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to "STBY-SPE". 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to "STBY-SPE". 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Continued on next page

Table 9-365. TEST #824 Host Adapter Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The host adapter has been placed in the "uninstalled" state. 1. Verify that the host adapter is fully inserted and powered up. 2. Attempt a demand reset of the host adapter.
[1]	FAIL	The host adapter loop around test could not be run successfully. 1. Replace the MSSNET circuit pack (see the circuit pack replacement section above) and issue the **test mssnet long** command.
	PASS	The host adapter loop around Test completed successfully. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on R-MEDIA.

Host Adapter Status Test (#825)

This test verifies the following host adapter circuit operations:

- The LED s on the MSSNET circuit pack can be turned on and off correctly.

  Note that this only verifies that the control and status logic for the LED s is operating correctly. The operation of the LED s may be tested visually by using the **test led** command.

- The MSS configuration information is correct (the host adapter is not in the "held reset" state).

Table 9-366. TEST #825 Host Adapter Status Test

Error Code	Test Result	Description/ Recommendation
1312 1313 1314	ABORT	Internal software error between maintenance software and mss driver. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
1316	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the 'y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to "STBY-SPE". 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to "STBY-SPE". 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to "STBY-SPE". 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error 1. Retry the command at 1-minute intervals for a maximum of 5 retries.

Continued on next page

Table 9-366. TEST #825 Host Adapter Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the 'y/n" option for saving translation daily).
	NO BOARD	The host adapter has been placed in the "uninstalled" state. 1. Verify that the host adapter is fully inserted and powered up. 2. Attempt a demand reset of the host adapter.
[1]	FAIL	The host adapter status test could not be run successfully. 1. Replace the MSSNET circuit pack (see the circuit pack replacement section above) and issue the **test mssnet long** command.
	PASS	The host adapter status test completed successfully. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on R-MEDIA.

Host Adapter Reset Test (#893)

The Host Adapter Reset Test #893 is run on demand in response to the **reset host-adapter** command. This test resets the host adapter circuit on the MSSNET circuit pack and runs an initialization test.

Failure of the reset command will cause the host adapter to be placed in an internal "held reset" state. In this state the host adapter will not run any background maintenance and will not respond to any commands except a reset command. The only way to restore the host adapter to service is for it to pass the reset command. Demand tests will not run until then.

The test results for Test 893 are the same as those for Test 820. Refer to the information presented for Test 820 for the appropriate repair procedures.

HYB-BD (Hybrid Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
HYB-BD	MIN	test board UUCSS sh	Hybrid Line Circuit Pack
HYB-BD	WRN	test board UUCSS sh	Hybrid Line Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPN s). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also HYB-LINE (Hybrid Line) Maintenance documentation for related line information.

HYB-LINE (Hybrid Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
HYB-LINE	Minor	test port UUCSSpp l	Hybrid Line
HYB-LINE	Warning	test port UUCSSpp l	Hybrid Line

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPN s). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

Hybrid Line is another term for the Multi-Function Analog Telephone (MFAT). The Hybrid Line set is also known as an SCS (Small Communications System).

The TN762B Hybrid Line circuit pack supports eight of these multifunction analog telephone sets. The Hybrid Line sets use three pairs of wires: an analog voice pair, a transmit/receive pair, and a power pair.

This section describes HYB-LINE (Hybrid Line) maintenance. HYB-LINE maintenance is closely related to, and sometimes interacts with, HYB-BD (Hybrid Line circuit pack) maintenance. This interaction should be kept in mind when troubleshooting Hybrid Line problems.

This section occasionally refers to a station's service state. These service states are defined as follows:

Out-of-Service	The port, and thus the station, have been removed from service. A busyout of a port will cause it to be out-of-service.
Ready-for-Service	The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.
In-Service	The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally, but it can also be forced into the in-service state if it goes off-hook.

Use **status station** to determine terminal service state. Status is reported as either out-of-service, in-service, or disconnect. The latter is equivalent to the ready-for-service state.

Error Log Entries and Test to Clear Values

Table 9-367. Hybrid Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	40987	None	WARNING	OFF	
15(j)	Any	Hybrid Line Audits Test(#161)			
18(b)	0	busyout port UUCSSpp	WARNING	OFF	release port UUCSSpp
130(c)		None	WARNING	ON	test port UUCSSpp sh
257(d)	40988	None	MIN/WRN	OFF	
513(e)	40965	Hybrid Line Audits Test (#61)	WARNING	OFF	test port UUCSSpp sh r 4
769(f)		Remote Dig Looparound Test (#59)	WARNING	OFF	test port UUCSSpp sh r 3
1025		Hybrid & Conf. Circuits Test (#57)	MIN/WRN	ON	test port UUCSSpp l r 3
1281(f)		Local Digital Looparound Test (#58)	WARNING	ON	test port UUCSSpp l r 3
1537(g)	40968	None	WARNING	OFF	
1793		TDM NPE Crosstalk Test (#6	MIN/WRN[2]	ON	test port UUCSSpp l r 3
2049(h)	32770	None			
2049(i)	40967	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major or minor alarms may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. The data link between the port and the terminal is not operational. (An off-board problem was detected by port circuit). Verify that the Hybrid set is connected and that the Electronic Power Feed (EPF) test passes. If data transmission problems are experienced, check for defective wiring or a defective voice terminal, or move terminal closer to the switch (reduce the length of the wiring between the terminal and the switch). If the problem persists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined delay.

b. Error type 18 indicates the port is busied out. The port is released with **release port** UUCSSpp.

c. The circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. The EPF has been turned off due to an overcurrent condition at the voice terminal. Check for defective wiring or a damaged jack, and make sure the voice terminal is a Hybrid set. Once the problem has been resolved, the alarm will be retired after a predetermined delay.

e. The voice terminal has been disconnected or there is a problem in the wiring to the terminal. Make sure that the voice terminal is connected or check for defective wiring to the voice terminal.

f. Note that Error Types 769 and 1281 by themselves create Warning alarms only, but if both are present, a Minor alarm will be logged.

g. The port has reported a problem with the data link to the voice terminal. Ignore this error if there are no complaints about the voice terminal. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and decrease the length of the wiring between the voice terminal and the switch. If the problem persists, replace the circuit pack.

h. The voice terminal went off-hook while in the disconnect state. Use the **status station** command to determine the state of the terminal. The off-hook should have moved the terminal to in-service. No repair action is necessary.

i. The link between the circuit pack and the voice terminal has been successfully reset. No repair action is necessary.

j. Error 15 indicates a software audit error that does not indicate any hardware malfunction. Run the short test sequence and investigate any errors.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Local Digital Looparound Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-368. System Technician-Demanded Tests: DS1-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Hybrid Electronic Power Feed Test (#56)		X	ND
Hybrid Circuit and Conference Circuit Test (#57)		X	ND
Local Digital Looparound Test (#58)		X	ND
Remote Digital Looparound Test (#59)	X	X	ND
Station Lamp Update Test (#60)	X	X	ND
Station Audits Test (#61)	X	X	ND
Ringer Update Test (#62)	X	X	ND

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-369. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. This could be a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-369. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Test disabled via administration. This only applies to analog stations. The default for this field is ‘y,’ so you may want to determine why it has been turned off for this station. 1. To enable test, set the Test field on the station administration screen for the particular analog station being tested to ‘y.’ Use the **change station <extension>** command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Resolve any “EXP-PN” and “EXP-INTF” errors in the error log. 2. Resolve any “TDM-BUS” errors in the error log. 3. Retest the board when the faults from steps 1 and 2 are cleared.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 9-369. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Electronic Power Feed Test (#56)

In this test, the software requests that the EPF be turned on for a given port. Then hardware attempts to turn on the power unit from the station. If no current is drawn, the station is probably not connected. If an overcurrent condition is sensed (that is, too much current is being drawn), this may indicate a short in the loop or a defective voice terminal. A message is returned stating that either the EPF was turned on successfully, or that an overcurrent condition exists. This test is repeated once more 5 seconds later. If either test is not successful, the test will abort (see first ABORT entry in Table 9-370).

Table 9-370. TEST #56 Hybrid Electronic Power Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port staLus is idle, then retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Electronic Power Feed test passed. The message to turn on the power to the station was successfully sent to the port. 1. Although this test will never actually return a FAIL result except for the **Internal system error** described above, it will log an error if the overcurrent case is detected by the hardware. Check the Error Log for any entries with Error Type 257 when the test has completed. 2. If Error Type 257 does not appear in the Error Log within 10 seconds after completion of this test, it is safe to assume that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station, if available, and check that all the feature buttons are operating. 3. If Error Type 257 appears in the Error Log, this indicates some problem with the power to the station. Check for a short in the wiring, a damaged jack, a defective voice terminal, or an incorrect type of terminal.

Continued on next page

Table 9-370. TEST #56 Hybrid Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Circuit and Conference Circuit Test (#57)

This test checks two different port circuit functions. The Hybrid Circuit test performs an analog reflective looparound measurement on the port's hybrid circuitry. The conference circuit test performs a conference test on the port's NPE.

For the *Hybrid Circuit Test* results to be valid, a voice terminal must be connected to the port being tested. The test instructs the on-board microprocessor to put the port in analog reflective looparound mode.

The *Conference Test* is performed only if the Hybrid Test passes. The Conference Circuit Test verifies that the Network Processing Element (NPE) is able to correctly conference several test tones together.

Table 9-371. TEST #57 Hybrid Circuit and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. This could be a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-371. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	The system could not allocate a tone generator for the test. 1. Resolve any TONE-PT errors. 2. If no TONE-PT errors appear in the Error Log, retry the test at 1-minute intervals a maximum of 5 times.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
7	FAIL	Conference Test failed. User may be able to use conference circuit without difficulty in some cases. In other extreme cases, conference calling will be totally restricted. The failure may be due to off-board circumstances, the most common of which is an off-hook occurring during the test. Also, check the error logs against the GPTD-BD, the TONE-BD, and the TONE-PT. 1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK. 2. Then, issue the **display port** and the **status station** commands to determine if the station is idle. If it is idle, issue the **test port** command for this port. 3. If test continues to fail, issue the **busyout port** and the **release port** commands, and then retest the port. 4. It is possible that the port may still be functional from a user's point of view.

Continued on next page

Table 9-371. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
57	FAIL	Hybrid Circuit Test failed. This could result in noisy or bad connections. 1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK. 2. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using the **test board UUCSS short** command. 3. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 4. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Hybrid Line circuit pack. **NOTE:** If the Hybrid Circuit and Conference Circuit Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. The AC power unit may be defective. The system may contain a TN752 power unit circuit pack OR a 631DB AC power unit, *but not both types of power units.* To investigate problems with a power unit, refer to "CARR-POW".
	PASS	Hybrid Circuit and Conference Circuit Test passed. The hybrid circuitry is transmitting properly. 1. If complaints still exist, investigate by using other port tests, and by examining the station, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board inserted, an incorrect board inserted, or an insane board inserted. 1. Check that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check that there is a valid board inserted.

Hybrid Line Local Digital Looparound Test (#58)

This test checks the control channel between the Switch Processing Element (SPE) and the port's digital circuitry. The SPE sends transparent data to the on-board microprocessor and compares the data echoed back. This test is repeated three times.

Table 9-372. TEST #58 Hybrid Line Local Digital Looparound Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1,2,3	FAIL	The control channel between the processor and the port is not transmitting properly. This port is not operable. 1. Retry the test. 2. If the failure still occurs, issue the **busyout** and the **release busy** commands, and then retest. 3. If the failure is occurring on more than one port on the board, suspect the board. 4. If the failure is occurring on several boards in the same carrier, escalate the problem. 5. If the failure appears to be isolated to one port, check all wiring to the set and all set connections. 6. Replace the circuit pack as a last resort.
	PASS	Hybrid Line Local Digital Looparound Test passed. The control channel is transmitting properly. 1. If complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.

Continued on next page

Table 9-372. TEST #58 Hybrid Line Local Digital Looparound Test *— Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Remote Digital Looparound Test (#59)

This test checks the digital control pair from the port circuit to the terminal. The on-board microprocessor sends a message to the terminal and checks for a proper return message. This test is repeated three times, with two out of the three attempts passing being sufficient for this test to pass. This test will run if the station is in-service or out-of-service.

Table 9-373. TEST #59 Hybrid Line Remote Digital Looparound Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-373. TEST #59 Hybrid Line Remote Digital Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	ABORT	A request for a remote station audit aborted even though all internal resources were correctly allocated. 1. Look in the error log for Error Type 18 (port busied out) for this port. If this Error Type is present, release the port via the **release port UUCSSpp** command or the **release station extension** command, and then run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1,2,3	FAIL	No response was received within the allowable time period on one of the transmissions to the terminal. This indicates a problem with the data link to the voice terminal. This could be a sleeping set problem or it may be due to wiring or an unplugged or defective set. 1. Check for errors in the error log, for example, error 1537. 2. Remotely issue the **busyout** and **release busy** commands, and run the short test sequence on the port to check for other errors associated with the port or terminal. 3. Check the wiring to the set if it appears that the terminal is not responding to any tests; otherwise, replace the terminal and rerun the test. 4. If the test still fails, replace the circuit pack and reconnect the original terminal.
	PASS	Hybrid Line Remote Digital Looparound Test passed. The hybrid circuit pack is sending and receiving proper messages to and from the voice terminal. 1. If problems still exist, investigate using other circuit pack tests and by examining the station, wiring, and connections.

Table 9-373. TEST #59 Hybrid Line Remote Digital Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Lamp Updates Test (#60)

For this test, the software lights the lamps on the terminal based on the status record contained in the processor. The lamp updates will run only if the station is in-service.

Table 9-374. TEST #60 Hybrid Line Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	A request for a remote station lamp update aborted even though all internal resources were correctly allocated. 1. Look in the error log for Error Type 18 (port busied out) for this port. If this Error Type is present, release the port via the **release port UUCSSpp** command or the **release station extension** command, and then run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
2	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-374. TEST #60 Hybrid Line Lamp Updates Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	ABORT	The station is in a ready for service or an out of service state. This may be due to wiring or an unplugged or defective set. 1. Make sure terminal is connected and the wiring is correct. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Hybrid Line Lamp Updates completed successfully 1. If complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Audits Test (#61)

This is a series of three tests that are classified as audits. These audits will abort if attempted on an out-of-service station. The tests are as follows:

- Switchhook Audit—This is an update of the SPE records according to the circuit packs' records.
- Bad Scan Inquiry—A message is sent uplink that contains a count that is generated due to certain events relating to the data link conditions. This is an indication of data transmission problems between the Hybrid circuit pack and the voice terminal.
- EPF Inquiry—The status of the Electronic Power Feed is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, EPF-no-load, and EPF-on-overcurrent.

Table 9-375. TEST #61 Hybrid Line Audits Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
1	ABORT	The test was aborted due to an internal system error during the switchhook audit.
2	ABORT	Internal system error occurred during bad scan inquiry audit. 1. Make sure that the station is not in an out of service state. 2. Retry the command at 1-minute intervals a maximum of 5 times.
3	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this Error Type is present, release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-375. TEST #61 Hybrid Line Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Hybrid Line Audits Test passed. 1. Although this test will never actually return a FAIL result except for the **Internal system error** described above, it is possible that it will enter Error Types 257 or 513 into the Error Log. To determine if there are any problems that don't show up in the test result, look for these Error Types in the Error Log. 2. If these errors appear in the Error Log, or if user complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.

Continued on next page

Table 9-375. TEST #61 Hybrid Line Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Ringer Update Test (#62)

In this update, a "ringer on" or a "ringer off" message is sent to the firmware to start and stop the ringer on the set.

Table 9-376. TEST #62 Hybrid Line Ringer Update Test

Error Code	Test Result	Description/ Recommendation
3	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this Error Type is present, release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Hybrid Station Ringer Update passed 1. If complaints still exist, investigate using other circuit pack tests on this circuit pack, and by examining the terminal, wiring, and connections.

Continued on next page

Table 9-376. TEST #62 Hybrid Line Ringer Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

INADS (INADS Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
INADS	none	test inads-link	INADS Link

The INADS Link maintenance object (MO) represents the software and communications link required by the switch to make a call to the Initialization and Administration System (INADS). The purpose of the INADS Link MO is to check the communications link between the system and INADS and verify that the alarm notification process works correctly. An INADS technician can test the process remotely to verify that alarms will be reported to INADS, or a system technician may want to test the connection while on-site at installation time or during subsequent service calls.

Although the INADS Link MO is never alarmed, the errors are logged. The errors are only logged as a result of the **test inads-link** command being issued.

Error Log Entries and Test to Clear Values

The Hardware Error Log entries are described as part of the INADS Link Test description below.

System Technician-Demanded Tests: Descriptions and Error Codes

The **test inads-link** command is different from other test commands. This command does not have a long or short option, and the test on the INADS Link does not have an associated test number. When the **test inads-link** command is issued, the user immediately sees either the “Command successfully completed” or “Command failed” message.

INADS Link Test (No Test Number)

The INADS Link Test attempts to place a call to INADS (in the background) to verify the communications link to INADS. When the **test inads-link** command is entered, the user immediately sees either `Command successfully completed` or `Command failed`. The "Command failed" message appears when a previously run **test inads-link** command is in progress or the system has active alarms which must be reported to INADS. The "Command successfully completed" means the switch will start the attempt to call INADS in 2 minutes (the test will still run even if Alarm Origination is disabled). The 2-minute delay allows a remote INADS technician time enough to hang up the call and thus free up the INADS line so that the switch can call INADS back. As error conditions are encountered, errors are logged against INADS. Error codes 1 through 9 can be logged if the test result was "Command successfully completed" and Error Codes 10 and 11 can be logged if the test result was "Command failed." An error is also logged against INADS if the call to INADS finally succeeds. The INADS software (release 3.2 or later) recognizes this special ''test inads'' type of alarm and will automatically open and then close a trouble ticket which indicates that the reason for the trouble ticket is a **test inads-link** command. The trouble ticket alarm will contain a ''TESTING INADS LINK'' description field.

After entering the command, it may take as long a 9 minutes for the switch to place the call and for INADS to respond. The Error Log should be examined using the category **inads** 10 minutes after successfully entering the command to determine if the call was successful. Table 9-377 explains the error codes.

Table 9-377. INADS Link Test Error Log Entries

Error Code	Test Result	Description/ Recommendation
1	0	The call was successfully placed to INADS. No trouble found.
2	0	Informative error indicating that alarm origination was disabled at the time of the test. The test will still run even if alarm origination is disabled. 1. If Alarm Origination is desired, then enable this feature via the Maintenance-Related System Parameters Form. 2. Repeat the test.
3	0	The INADS connection is currently in use. 1. Wait 10 minutes and retry this command.

Continued on next page

Table 9-377. INADS Link Test Error Log Entries — *Continued*

Error Code	Test Result	Description/ Recommendation
4	0	INADS did not answer the alarm origination call. 1. Verify INADS is up and running. 2. Verify that the INADS phone number and switch product id are correct via the Maintenance-Related System Parameters Form. 3. Enable alarm origination via the Maintenance-Related System Parameters Form and test the SYSAM (System Access Maintenance) by issuing the **test maintenance a|b** command. If SYSAM Tests #916 and #917 do not pass, then refer to SYSAM (System Access Maintenance) Maintenance documentation. 4. Retry the command.
5	0	No INADS phone number administered. 1. Administer the INADS phone number via the Maintenance-Related System Parameters Form. 2. Retry the command.
6	0	INADS did not send the acknowledgment message to the ‘‘test inads alarm’’ message. 1. Verify that the INADS phone number and switch product id are correct via the Maintenance-Related System Parameters Form. 2. Verify INADS is up and running. 3. Retry the command.
7	0	INADS sent a negative acknowledgment to the ‘‘TESTING INADS LINK’’ message. 1. Verify that the product id on the switch and in the INADS database are the same. Use the Maintenance-Related System Parameters Form to determine the product id the switch has. 2. Rerun the test.
8	0	Internal system error; system received an invalid return code.

Continued on next page

Table 9-377. INADS Link Test Error Log Entries — *Continued*

Error Code	Test Result	Description/ Recommendation
9	0	Internal system error 1. Try the command again at 1-minute intervals up to 5 times.
10	0	There is already a **test inads-link** command in progress. 1. Wait 10 minutes for the present command to finish. 2. Review the results of the present command by viewing the Error Log and selecting the category "inads-link."
11	0	The switch is trying to report alarms to INADS. The test cannot be run at this time. 1. Wait 10 minutes and retry the command.

ISDN-PLK (ISDN-PRI Signaling Link Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ISDN-LNK[2]	MINOR	test port *UUCSSpp* l	ISDN-PRI Signaling Link Port
ISDN-LNK	WARNING	test port *UUCSSpp* sh	ISDN-PRI Signaling Link Port

1. pp is *24* for 24-channel interfaces and *16* for 32-channel interfaces>
2. For additional related information, see "UDS1-BD (UDS1 Interface Circuit Pack)"

NOTE:
This MO was formerly known as "ISDN-LNK (ISDN-PRI Signaling Link Port)".

The ISDN-PRI interface uses out-of-band signaling (as opposed to robbed-bit, in-band signaling) to transmit control messages between two endpoints. User information channels carry digitized voice and digital data and are known as bearer channels (B-channels). B-channels are assigned to DS1 ISDN trunks or PRI endpoints. Call control signaling for the B-channels is combined and carried over the separate ISDN-PRI Signaling Link Port D-channel.

The ISDN-PRI Signaling Link Port (ISDN-LNK) is a port on a TN464C/D UDS1 Interface circuit pack, which has a direct interface to the packet bus which carries D-channel messages to the processor. The associated B-channels can use ports on the same circuit pack or ports on other TN464C/Ds or TN767 DS1 Interface circuit packs. (The TN722 cannot be used for this application). The B-channels are connected to the TDM Bus.

Two types of DS1 interfaces exist:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link

On 24-channel interfaces, the B-channels may use any of the first 23 ports. The signaling link is assigned to the 24th port. On 32-channel interfaces, the DS1 ISDN Trunks (B-channels) may use any of ports 1 to 15 and 17 through 31. The signaling link is assigned to the 16th port. The 32nd channel (port 0) is used for framing. In NFAS configurations, the 24th or 16th ports on some of the DS1 circuit packs may be used for B-channels. Refer to ISDN-SGR for further information.

A problem with the ISDN-LNK will have an effect on all of the associated B-channels since without it no call control information can be conveyed to the far-end switch or terminal adapter. Stable calls may remain operational, but no new calls can be made. The ISDN-LNK in turn depends on the TN464C/D UDS1 Interface circuit pack it resides on and the packet bus which provides the link to the processor. If there are problems with the ISDN-LNK, also investigate the TN464C/D UDS1 Interface circuit pack (UDS1-BD) and the packet bus (PKT-BUS).

Error Log Entries and Test to Clear Values

Table 9-378. ISDN-PRI Signaling Link Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port *UUCSSpp*[2]
18 (a)	0	busyout port *UUCSSpp*[2]	WARNING	OFF	release port *UUCSSpp*[2]
130 (b)		None	WARNING	ON	test port *UUCSSpp*[2]
1537 (c)	46210		WARNING	OFF	
1793 (d)					test board UUCSS l
3585 (e)	46222		MINOR	ON	
3841 (f)	46211				
3842 (g)	46223				
3843 (h)		Signaling Port LAN Loopback test (#939)			test port *UUCSSpp*[2] l

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. pp is 24 for 24-channel interfaces and 16 for 32-channel interfaces.

Notes:

a. The D-channel is demand busied out. No calls can be made over this D-channel.

b. This Error Type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. Link error. This error occurs when the port receives an invalid frame over the D-channel. This error normally indicates an off-board problem usually related to transmission errors on the DS1 facility. Execute **list measurements ds1-log** for the UDS1 TN464 circuit pack on which the D-channel resides. If the UDS1 is reporting some errors, then the DS1 facility has experienced transmission problems which could have caused the ISDN-LNK to report a Link Error.

   If the UDS1 is not reporting errors, execute the long test sequence for the D-channel. Investigate any errors. If there are none, execute a long test sequence for the UDS1 circuit pack (UDS1-BD). Investigate any errors.

   If no errors could be found by testing, the Link Error is probably not affecting service. However, if this Link Error continues to be logged, follow normal escalation procedures.

d. UDS1 Interface circuit pack is out-of-service. Look for and resolve UDS1-BD errors in the Hardware Error Log.

e. Transmit FIFO Overflow error. This error indicates that the circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signaling information over the D-channel. Specifically, this error occurs when the Packet Bus transmit buffers overflow. This condition probably indicates a hardware problem.

   The actual alarming level will depend on the options chosen via the **set options** command on the G3-MT terminal. ISDN-PRI Signaling Link Port alarms are treated as Station alarms, and their default alarming option is to downgrade all alarms to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option “y” on the set options form).

f. Bad DLCI error. This error occurs when a LAPD frame is received across the DS1 facility which contains a DLCI which does not have a valid entry in the on-board translation memory. This error normally indicates an off-board problem usually related to a broken endpoint or a state mismatch between a remote endpoint and the local call processing software. Maintenance will not start any testing or generate any alarms in response to this error.

g. Receive FIFO Overflow error. This error occurs when the circuit pack detects an overflow of its receive buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch between the two end-points of a packet switched connection. LAPD should be able to recover from this problem, but it may degrade the performance of the LAN Bus. Maintenance will not start any testing or generate any alarms in response to this error.

h. This error occurs when the *Signaling Port LAN Loopback Test (#939)* fails. Run the long test sequence and pay particular attention to the results of Test #939.

System Technician-Demanded Tests: Descriptions and Error Codes

The command to test the ISDN-LNK MO is **test port** UUCSSpp where pp is 24 for 24-channel interfaces and 16 for 32-channel interfaces.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Signaling Port LAN Loopback Test (#939)		X	D
Signaling Link Board Check (#643)	X	X	ND

1. D = Destructive; ND = Nondestructive

Signaling Link Board Check (#643)

This test checks the health of the TN464C/D UDS1 Interface transporting the ISDN-PRI Signaling Link Port

Table 9-379. TEST #643 Signaling Link Board Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this D-channel port is detached from the circuit pack. This is normal when the rollabout video feature is enabled. To complete a test on this port: 1. Re-attach the disconnected PRI terminal adapter 2. Disable the rollabout video feature on this board by entering **change ds1 UUCSS** and set the ‘‘Alarm when PRI Endpoint Detached?’’ field to ‘‘y.’’
8	FAIL	The UDS1 TN464C/D circuit pack is not in-service. 1. Check the Hardware Error Log for entries logged against UDS1-BD, and consult “UDS1-BD” for repair procedures.
	PASS	The UDS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port is in-service.

Signaling Port LAN Loopback Test (#939)

This test is destructive.

This test verifies the connectivity of an ISDN-PRI signaling port (D-channel) across the LAN bus, also known as the packet bus. It will execute only if the port is out-of-service. Failure of this test indicates a fault associated with the port hardware on the circuit pack.

Table 9-380. TEST #939 Signaling Port LAN Loopback

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The port is not in the out-of-service state. Use the **busyout port UUCSSpp** command to place it in the out-of-service state and repeat this test. **CAUTION:** *The **busyout** will prevent new call originations on all B-channels in the signaling group until the port is released.*
1139	ABORT	The Packet Bus in this port network is out-of-service. 1. Follow repair procedures for the Packet Bus. 2. Enter **test port UUCSSpp long** command and check results of this test (#939).
1141	ABORT	The Packet Interface circuit pack is out-of-service. 1. Follow repair procedures for PKT-INT. 2. Enter **test port UUCSSpp long** command and check results of this test (#939).
1144	ABORT	The Packet Bus in the PPN is out-of-service. 1. Follow repair procedures for the Packet Bus. 2. Enter **test port UUCSSpp long** command and check results of this test (#939).
2012	ABORT	Internal system error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Loopback Test has failed. 1. If the test fails repeatedly, attempt to reset the circuit pack when the other ports on the board are not in use. Reset the circuit pack by entering **busyout board UUCSS** and **reset board UUCSS**. 2. Repeat the test and, if it continues to fail, replace the circuit pack.
	PASS	Connectivity of the D-channel over the Packet Bus is operational.

ISDN-LNK (ISDN-PRI Signaling Link Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ISDN-LNK[2]	MINOR	test port *UUCSSpp* l	ISDN-PRI Signaling Link Port
ISDN-LNK	WARNING	test port *UUCSSpp* sh	ISDN-PRI Signaling Link Port

1. pp is *24* for 24-channel interfaces and *16* for 32-channel interfaces
2. For additional related information, see "UDS1-BD (UDS1 Interface Circuit Pack)".

NOTE:
See the figures in the "ISDN-SGR (ISDN-PRI Signaling Group)" section of this chapter for an illustration of the principles described below.

The ISDN-PRI interface uses out-of-band signaling (as opposed to robbed-bit, in-band signaling) to transmit control messages between two endpoints. User information channels carry digitized voice and digital data and are known as bearer channels (B-channels). B-channels are assigned to DS1 ISDN trunks or PRI endpoints. Call control signaling for the B-channels is combined and carried over the separate ISDN-PRI Signaling Link Port D-channel.

The ISDN-PRI Signaling Link Port (ISDN-LNK) is a port on a TN464C/D UDS1 Interface circuit pack, which has a direct interface to the packet bus which carries D-channel messages to the processor. The associated B-channels can use ports on the same circuit pack or ports on other TN464C/Ds or TN767 DS1 Interface circuit packs. (The TN722 cannot be used for this application). The B-channels are connected to the TDM Bus.

Two types of DS1 interfaces exist:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link

  The 32-channel mode is supported only on TN464 series circuit packs and on G3r V2 systems.

On 24-channel interfaces, the B-channels may use any of the first 23 ports. The signaling link is assigned to the 24th port. On 32-channel interfaces, the DS1 ISDN Trunks (B-channels) may use any of ports 1 to 15 and 17 through 31. The signaling link is assigned to the 16th port. The 32nd channel (port 0) is used for framing. In NFAS configurations, the 24th or 16th ports on some of the DS1 circuit packs may be used for B-channels. Refer to ISDN-SGR for further information.

A problem with the ISDN-LNK will have an effect on all of the associated B-channels since without it no call control information can be conveyed to the far-end switch or terminal adapter. Stable calls may remain operational, but no new calls can be made. The ISDN-LNK in turn depends on the TN464C/D UDS1 Interface circuit pack it resides on and the packet bus which provides the link to the processor. If there are problems with the ISDN-LNK, also investigate the TN464C/D UDS1 Interface circuit pack (UDS1-BD) and the packet bus (PKT-BUS).

Hardware Error Log Entries and Test to Clear Values

ISDN-PRI Signaling Link Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port *UUCSSpp*[2]
18 (a)	0	busyout port *UUCSSpp*[2]	WARNING	OFF	release port *UUCSSpp*[2]
130 (b)		None	WARNING	ON	test port *UUCSSpp*[2]
1537 (c)	46210		WARNING	OFF	
1793 (d)					test board UUCSS l
3585 (e)	46222		MINOR	ON	
3841 (f)	46211				
3842 (g)	46223				
3843 (h)		Signaling Port LAN Loopback test (#939)			test port *UUCSSpp*[2] l

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. pp is 24 for 24-channel interfaces and 16 for 32-channel interfaces.

Notes:

a. The D-channel is demand busied out. No calls can be made over this D-channel.

b. This Error Type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. Link error. This error occurs when the port receives an invalid frame over the D-channel. This error normally indicates an off-board problem usually related to transmission errors on the DS1 facility. Execute **list measurements ds1-log** for the UDS1 TN464 circuit pack on which the D-channel resides. If the UDS1 is reporting some errors, then the DS1 facility has experienced transmission problems which could have caused the ISDN-LNK to report a Link Error.

   If the UDS1 is not reporting errors, execute the long test sequence for the D-channel. Investigate any errors. If there are none, execute a long test sequence for the UDS1 circuit pack (UDS1-BD). Investigate any errors.

   If no errors could be found by testing, the Link Error is probably not affecting service. However, if this Link Error continues to be logged, follow normal escalation procedures.

d. UDS1 Interface circuit pack is out-of-service. Look for and resolve UDS1-BD errors in the Hardware Error Log.

e. Transmit FIFO Overflow error. This error indicates that the circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signaling information over the D-channel. Specifically, this error occurs when the Packet Bus transmit buffers overflow. This condition probably indicates a hardware problem.

   The actual alarming level will depend on the options chosen via the **set options** command on the G3-MT terminal. ISDN-PRI Signaling Link Port alarms are treated as Station alarms, and their default alarming option is to downgrade all alarms to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option “y” on the set options form).

f. Bad DLCI error. This error occurs when a LAPD frame is received across the DS1 facility which contains a DLCI which does not have a valid entry in the on-board translation memory. This error normally indicates an off-board problem usually related to a broken endpoint or a state mismatch between a remote endpoint and the local call processing software. Maintenance will not start any testing or generate any alarms in response to this error.

g. Receive FIFO Overflow error. This error occurs when the circuit pack detects an overflow of its receive buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch between the two end-points of a packet switched connection. LAPD should be able to recover from this problem, but it may degrade the performance of the LAN Bus. Maintenance will not start any testing or generate any alarms in response to this error.

h. This error occurs when the *Signaling Port LAN Loopback Test (#939)* fails. Run the long test sequence and pay particular attention to the results of Test #939.

System Technician-Demanded Tests: Descriptions and Error Codes

The command to test the ISDN-LNK MO is **test port** UUCSSpp where pp is 24 for 24-channel interfaces and 16 for 32-channel interfaces.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Signaling Port LAN Loopback Test (#939)		X	D
Signaling Link Board Check (#643)	X	X	ND

1. D = Destructive; ND = Nondestructive

Signaling Link Board Check (#643)

This test checks the health of the TN464C/D UDS1 Interface transporting the ISDN-PRI Signaling Link Port

Table 9-381. TEST #643 Signaling Link Board Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this D-channel port is detached from the circuit pack. This is normal when the rollabout video feature is enabled. To complete a test on this port, do one of the following: 1. Re-attach the disconnected PRI terminal adapter 2. Disable the rollabout video feature on this board by entering **change ds1 UUCSS** and set the field labeled "Alarm when PRI Endpoint Detached?" to "y."
8	FAIL	The UDS1 TN464C/D circuit pack is not in-service. 1. Check the Hardware Error Log for entries logged against UDS1-BD and consult the "UDS1-BD (UDS1 Interface Circuit Pack)" Maintenance documentation for repair procedures.
	PASS	The UDS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port is in-service.

Signaling Port LAN Loopback Test (#939)

This test is destructive.

This test verifies the connectivity of an ISDN-PRI signaling port (D-channel) across the LAN bus, also known as the packet bus. It will execute only if the port is out-of-service. Failure of this test indicates a fault associated with the port hardware on the circuit pack.

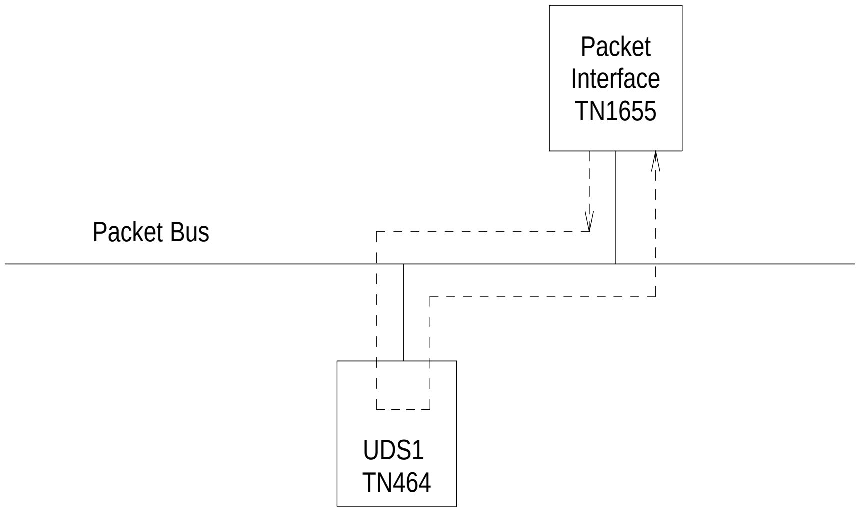

Figure 9-49. Signaling Port LAN (Packet Bus) Loopback

Table 9-382. TEST #939 Signaling Port LAN Loopback

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The port is not in the out-of-service state. Use the **busyout port** UUCSSpp command to place it in the out-of-service state and repeat this test. **CAUTION:** *The **busyout** will prevent new call originations on all B-channels in the signaling group until the port is released.*
1139	ABORT	The Packet Bus in this port network is out-of-service. 1. Follow repair procedures for the Packet Bus. 2. Enter **test port** UUCSSpp **long** command and check results of this test (#939).
1141	ABORT	The Packet Interface circuit pack is out-of-service. 1. Follow repair procedures for PKT-INT. 2. Enter **test port** UUCSSpp **long** command and check results of this test (#939).
1144	ABORT	The Packet Bus in the PPN is out-of-service. 1. Follow repair procedures for the Packet Bus. 2. Enter **test port** UUCSSpp **long** command and check results of this test (#939).
2012	ABORT	Internal system error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The Loopback Test has failed. 1. If the test fails repeatedly, attempt to reset the circuit pack when the other ports on the board are not in use. Reset the circuit pack by entering **busyout board UUCSS** and **reset board UUCSS**. 2. Repeat the test and, if it continues to fail, replace the circuit pack.
	PASS	Connectivity of the D-channel over the Packet Bus is operational.

ISDN-SGR (ISDN-PRI Signaling Group)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ISDN-SGR	MINOR	test sig-group *grp#*	ISDN-PRI Signaling Group
ISDN-SGR	WARNING	test sig-group *grp#*	ISDN-PRI Signaling Group

1. *grp#* is the signaling group number (1-166); the test sequence can be either short or long.

An ISDN-PRI Signaling Group is a collection of B-channels for which a given ISDN-PRI Signaling Channel Port (D-channel) carries signaling information. B-channels carry voice or data and can be assigned to DS1 ISDN trunks (ISDN-TRK) or PRI endpoint ports (PE-BCHL).

NOTE:
Throughout this discussion the term B-channels refers to ISDN-TRKs or PE-BCHLs, depending on the application under investigation.

The following circuit packs are supported in the implementation of ISDN-PRI.

Circuit Pack	Channel Types	Interface
TN464C/D	B and D channels	24 or 32 channel
TN767	B channels	24 channel
TN464B	B channels	32 channel (G3r V2 only)

The TN464C/D UDS1 Interface circuit pack, which has a direct interface to the packet bus, is required for D-channel signaling. There are two types of DS1 interfaces:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link

The following discussion describes 24-channel interface signaling groups. The 32-channel interface works the same way, except that only port number 16 is used for signaling instead of port number 24. Ports 1 through 15 and 17 through 31 are used for B-channels. The 32nd channel (port 0) is always used for framing.

ISDN-PRI D-channel signaling can be combined with a group of B-channels in three basic ways:

- Facility-associated signaling (FAS)
- Nonfacility-associated (NFAS) simplex signaling
- NFAS duplex signaling

In a FAS signaling group, the 24th port of the TN464C/D UDS1 Interface circuit pack carries D-channel signaling for up to 23 B-channel ports on the same circuit pack.

In an NFAS signaling group, the 24th port of one TN464C/D UDS1 Interface can carry D-channel signaling for B-channels on several other DS1 circuit pack as well, including TN767s and TN464Bs. The 24th port on the other circuit packs can be used for B-channels. A D-channel in an NFAS group can signal for B-channels on a total of 20 DS1 circuit packs.

NFAS duplex signaling provides increased reliability, which is highly desirable since NFAS permits the D-channel to signal for many more B-channels. NFAS Duplex allows the administration of a backup D-channel which remains in a standby state until the active D-channel goes down. If the active D-Channel does go down, the backup D-Channel takes over and provides signaling for all the B-channels in the signaling group.

The operation of the entire ISDN-PRI signaling group depends on several other entities: the ISDN-PRI signaling channel ports, the TN464C/D UDS1 Interface circuit pack on which the D-channels reside and the system link that is carried over the packet bus to the processor. When there are problems with the ISDN-PRI signaling group, also investigate ISDN-LNK, UDS1-BD, SYS-LINK. and PKT-BUS.

Error Log Entries and Test to Clear Values

Table 9-383. ISDN-PRI Signaling Group Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any		test sig-group *grp#*
1 (a)	Any	None			
257 (b)	Any	None			test sig-group *grp#*
513 (c)	Any	None			test sig-group *grp#*
769	Any	Primary Signaling Link Hardware Check (#636)			test sig-group *grp#*

Continued on next page

Table 9-383. ISDN-PRI Signaling Group Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1025	Any	Secondary Signaling Link Hardware Check (#639)			test sig-group *grp#*
1793 (d)	Any	Layer 2 Status (Test #647)	WARNING	OFF	test sig-group *grp#*
2049 (e)	Any	Layer 2 Status (Test #647)	WARNING	OFF	test sig-group *grp#*
2305 (f)	Any	Remote Layer 3 Query (Test #637)	MINOR	OFF	test sig-group *grp#*
3585 (g)	Port number	None			
3840 to 3928(h)	Port number	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This switch sent a message to the far-end switch or terminal adapter, and the far-end did not respond in the allotted time. Possible causes include link failure and congestion or outage at the far-end. The Aux Data field contains Layer 3 protocol information used by internal counters.

   If no other symptoms are not present, no action is required. If Layer 3 communication is down, there should be indications in the form of alarms and errors for link components. Check out other errors against ISDN-SGR, ISDN-TRK, and other hardware components on the link.

   There is no test to clear these errors. The error counter is decremented by 1 every 15 minutes.

b. This error indicates that the primary signaling channel connection has been lost for more than 90 seconds. If a secondary signaling channel does not exist or is not in-service, the associated B-channels will be placed in the ISDN Maintenance/Far-End state. The B-channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Pay particular attention to the results of Test #636 (Primary Signaling Link Hardware Check) in the test sequence. When the link does recover, the B-channels will be negotiated back to the In-Service state and their alarms will be retired.

   When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the **status sig-group** command).

c. This error indicates that the secondary signaling channel connection has been lost for more than 90 seconds. If the primary signaling channel is not in-service, B-channels will be placed in the ISDN Maintenance/Far-End state. The B-channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Pay particular attention to the results of Test #639 (Secondary Signaling Link Hardware Check) in the test sequence. When the link does recover, the B-channels will be negotiated back to the In-Service state and their alarms will be retired.

   When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the **status sig-group** command).

d. This error indicates a failure of the Layer 2 Query Test for the primary signaling channel

e. This error indicates a failure of the Layer 2 Query Test for the secondary signaling channel.

f. This error indicates a failure of Test #637, the Remote Layer 3 Query. A specific message was sent to the far-end switch, and it did not respond within the allotted time. Investigate elements of the ISDN PRI D-channel(s) (ISDN-LNK) for both this switch and the Far-end switch. If Test #637 fails twice in a row, the B-channels will be alarmed and made unavailable for outgoing calls (although incoming calls will still be accepted). When Test #637 succeeds and the Far-end switch starts responding properly, the DS1 ISDN Trunk (B-channels) will be placed back into normal operation and their alarms will be retired.

g. A SERV or SERV ACK ISDN D-channel message has been received by a non-US-type interface (country option other than 1 on the DS1 administration form). However, these messages are used only for duplex NFAS signaling which is supported only by country protocol 1.

   Thus, there may be a mismatch in administration between the local and far-end switches. Consult with the customer’s network provider to determine whether the D-channel is set up correctly on the far-end switch.

h. These Error Types are used to report certain error messages received by the ISDN-PRI Signaling Group for one of its associated B-channels. The aux data field shows for which B-channel (port number) the message was received.

   The error code generated equals 3840+*x*, where *x* is a Cause Value defined by the ISDN PRI Specification. Note that there is no Test to Clear Value for these Error Types; selected ISDN cause values are placed in the log when they are received, but no direct action or alarming is performed solely in response to receiving them. They provide added data that may prove useful when tracking down obscure networking and routing problems. The following table provides more information:

Table 9-384. Descriptions and Recommendations for Error Types 3840-3928

Error Code	Description	Recommendation
3842	A request has been made to use a transit network or common carrier that cannot be accessed.	1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Check all routing patterns containing this trunk group for validity of interexchange carriers requested (IXC field).
3846	The far-end switch has indicated that the B-channel (trunk) is not acceptable for use in the call for which it was requested.	This could indicate an administration problem (for example, the local switch and the far-end switch have different B-channels administered), or could reflect the occurrence of a normal race condition (for example, the local switch has requested use of a B-channel which the far-end switch had just reserved for use on another call). 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Issue the **status trunk** command for the indicated trunk. 3) Refer to the "DS1 ISDN Trunk Service States" and "ISDN-PRI Trunk Service States" sections of ISDN-TRK for recovery suggestions.
3858	Similar to Error Type 1. The switch sent an ISDN message to the far-end switch or terminal adapter which did not respond in the allotted time.	Follow same recommendations as for Error Type 1.
3878	The far-end switch has indicated that the network is not functioning correctly and that the condition may last a relatively long period of time (for example, immediately re-attempting the call may not be successful).	1. From the circuit pack and port number (in the Aux Data field, determine the trunk group against which the error was reported. 2. Consult with the network provider to determine the nature and expected duration of the out of service condition. 3. Consider modifying all routing patterns containing this trunk group, to route calls around the network which is out of service.

Continued on next page

Table 9-384. Descriptions and Recommendations for Error Types 3840-3928 — *Continued*

Error Code	Description	Recommendation
3890	A request to use a network service (e.g., SDN) has been denied. Administration somewhere on the network has indicated that the requested service has not been subscribed to or purchased for this trunk.	This could be a local administration problem only, or a mismatch between the local administration and that of the network provider. 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Display the trunk group form: If the trunk group is Call-by-Call (Service Type is "cbc"), check all routing pattern forms containing this trunk group to see if the Service/Feature fields contain the correct network services purchased for this trunk. If the trunk group is not Call-by-Call, check that the Service Type field contains the single network service purchased for this trunk. 3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.
3892	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3894	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	First, eliminate any transitory state mismatch problems by issuing the **test port UUCSSpp** command for the trunk port shown in the aux data field. Test #256 (Service State Audit) is the important test in the sequence. If this passes satisfactorily, yet the customer continues to complain of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3905	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3906	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate to the problem and provide the next tier with this Error Log information.

Continued on next page

Table 9-384. Descriptions and Recommendations for Error Types 3840-3928 — *Continued*

Error Code	Description	Recommendation
3909	A request to use a network service has been made, but the network has rejected the request because the requested service is not implemented.	Follow the recommendations listed above for Error Type 3890.
3928	A call was denied because of a basic incompatibility between the type of call and either the facilities selected by the routing pattern or the called user itself.	This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone after accessing ISDN trunks or PRI endpoints. Determine the trunk group from the circuit pack and port number (in the aux data field) and then check the BCC fields of the pertinent routing patterns. Also, investigate whether or not the calling and called endpoints are compatible (for example, some ISDN switches may not allow a voice station to call a data extension).

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Primary Signaling Link Hardware Check*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Primary Signaling Link Hardware Check (#636)	X	X	ND
Secondary Signaling Link Hardware Check (#639)	X	X	ND
Layer 2 Status Test (#647)	X	X	ND
Remote Layer 3 Query Test (#637)	X	X	ND

1. D = Destructive; ND = Nondestructive

Primary Signaling Link Hardware Check (#636)

The ISDN-PRI Signaling Group D-Channel port depends on the health of the TN464C/D UDS1 Interface circuit pack on which it resides. This test will fail if there are problems with either the ISDN-PRI Primary D-channel port or the UDS1 circuit pack. If there are problems with the ISDN-PRI Primary Signaling Channel port (ISDN-LNK), also investigate the UDS1 circuit pack (UDS1-BD).

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with the primary D-channel port is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete test on this port, either: 1. Re-attach the disconnected PRI terminal adapter, or 2. Disable the rollabout video feature on this board by entering **change ds1 UUCSS** and set field ‘‘Alarm when PRI Endpoint Detached?’’ to “y.’’
8	FAIL	There is a problem with the UDS1 TN464C/D Circuit Pack or the ISDN-PRI Signaling Channel (D-Channel). No ISDN trunk or PRI endpoint calls can be made until the problem is resolved. 1. Consult the procedures for the UDS1 TN464C/D Circuit Pack (UDS1-BD) and the ISDN-PRI Signaling Channel (ISDN-LNK).
	PASS	The basic physical connectivity of the primary D-channel is intact and functional. One might try this test repeatedly to ensure the link is up and to uncover any transitory problems.

Remote Layer 3 Query (#637)

This test will query the far-end switch or terminal adapter to determine if the signaling connection is functioning properly at Layer 3. It will select a B-channel in the in-service or maintenance service state and send an ISDN Layer 3 SERVice message, which requires a response from the far end (similar to performing Test #256 on an ISDN trunk. The test will not be performed if there are no B-channels in an appropriate ISDN service state (as when none are administered or they are all out of service).

NOTE:
The service state can be displayed by using the **status trunk <trunk group/trunk member>** or **status pri-endpoint** command.

As is the case with Test #256 for an ISDN trunk, a PASS only indicates that a message was composed and sent to the far-end switch or terminal adapter. The ISDN PRI Specification allows up to 2 minutes for a response. Check the Error Log for ‘‘ISDN-SGR (ISDN-PRI Signaling Group)’’ errors of type 2305 for evidence of a Remote Layer 3 Query failure.

Tests #639 and #636 check the health of the D-channels and DS1/UDS1 Interface Circuit Packs. As shown in Figure 9-50, this test goes one step further by checking the communication path from the processor from the processor, through the TDM/Packet Bus and DS1/UDS1 Interface circuit pack, and on to the far-end switch or terminal adapter. A special ISDN message is sent to the far-end switch or terminal adapter, which must respond within a specified amount of time. This test is designed to ensure that the communication path between the switch and the far-end is up and operational, and that the two endpoints can properly exchange ISDN control messages.

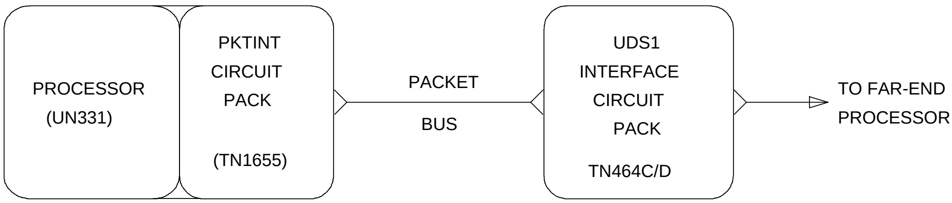

Figure 9-50. Remote Layer 3 Query (Test #637)

Figure 9-50 illustrates a UDS1 Interface Circuit Pack located in the PPN. When the UDS1 board is located in an EPN, there is additional Port Network Connectivity hardware connecting the packet busses of the PPN and EPN. Examples of such hardware are the Center Stage Switch and fiber-optic cables.

Table 9-385. TEST #637 Remote Layer 3 Query

Error Code	Test Result	Description/ Recommendation
1006	ABORT	There are no associated B-channels in an ISDN ‘‘in-service’’ or ‘‘maintenance’’ service state. This is a NORMAL ABORT. 1. Administer or release an ISDN trunk or PRI endpoint before retrying the test. For an ISDN trunk, use the **status trunk** group#/member# command to verify the ISDN trunk state. For a PRI endpoint use **status pri-endpoint** extension. Then, retry this test when at least one B-channel is in the "in-service" or "maintenance" states.
1113	ABORT	The signaling channel is down. Therefore, no messages can be sent to the far-end switch or terminal adapter. 1. Examine the results of Tests #636 and #639 and follow recommendations provided there.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500 or none	ABORT	Internal system error OR Administration Problem 1. Determine if any B-channels are administered. If there are none, then this is a normal ABORT, since this test cannot run unless at least one B-channel is administered. If at least one B-channels is administered, there is an internal system error. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error. See description of ABORT with error code 2500.
	PASS	A message was composed and sent to the far-end switch or terminal adapter. The ISDN PRI specification allows up to 2 minutes for a reply. Check the Error Log for ‘‘ISDN-SGR (ISDN-PRI Signaling Group)’’ for errors of type 2305 for evidence of a Remote Layer 3 Query failure. If no new errors were logged since this test was run, then this switch and the far-end switch or terminal adapter can exchange call control messages. If there is still a problem with a particular ISDN trunk or PRI endpoint, busyout the trunk and run the long test sequence, paying particular attention to the results of Test #258 (ISDN Test Call).

Secondary Signaling Link Hardware Check (#639)

The ISDN-PRI Signaling Group D-Channel port depends on the health of the TN464C/D UDS1 Interface circuit pack on which it resides. This test will fail if there are problems with either the ISDN-PRI Secondary D-channel port or the UDS1 circuit pack. This test will abort if a Secondary D-channel is not administered for the signaling group. If there are problems with the ISDN-PRI Secondary Signaling Channel port (ISDN-LNK), also investigate the UDS1 circuit pack (UDS1-BD).

Table 9-386. TEST #639 Secondary Signaling Link Hardware Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1132	ABORT	The Secondary D-Channel is not administered for this Signaling Group. This is a NORMAL ABORT. Only a Primary D-Channel must be administered for a Signaling Group.
8	FAIL	There is a problem with the TN464C/D UDS1 Interface circuit pack or the ISDN-PRI Secondary Signaling Channel (D-Channel). No ISDN trunk or PRI endpoint calls can be made until the problem is resolved. 1. Consult the procedures for the UDS1 TN464C/D Circuit Pack (UDS1-BD) and the ISDN-PRI Signaling Channel (ISDN-LNK).
	PASS	The basic physical connectivity of the Signaling Group’s Secondary D-channel is intact and functional. Try this test repeatedly to ensure the link is up and to uncover any transitory problems.

Layer 2 Status Test (#647)

The Layer 2 Status Test checks the layer 2 status of the ISDN-PRI Signaling Channel (D-channel). This test will fail if there is a hardware failure or a facility problem, or if the primary and secondary ISDN-PRI D-channels are not administered correctly.

The Primary and Secondary Signaling Link Hardware tests (test 637 and 639) and the Remote Layer 3 Query test (test 637) will detect most problems caused by hardware failures or incorrect administration. However, the Layer 3 test (test 637) cannot detect end-to-end transmission problems with the Standby D-channel since Layer 3 messages are not sent on the standby channel.

For G3r, the SYS-LINK Maintenance Object reports Layer 2 ISDN-PRI D-channel problems and for G3i/s/vs, the PI-LINK Maintenance Object reports Layer 2 ISDN-PRI D-channel problems (if the D-channel is connected to the Processor Interface circuit pack). However, for G3i, the PI-LINK Maintenance Object does not monitor the Layer 2 status of the ISDN-PRI D-channel when the D-channel is connected to the Packet Control circuit pack for the ISDN-PRI over PACCON feature. The Layer 2 Query test is provided to detect D-Channel Layer 2 failures and generate an associated Warning alarm independent of the hardware configuration used for the D-channels.

Table 9-387. TEST #647 Layer 2 Status Query Test

Error Code	Test Result	Description/ Recommendation
1132	ABORT	Internal system error: The port location for the primary ISDN-PRI D-channel is not known. This condition should not be possible since an administered DS1 circuit pack must be specified when a Signaling Group is administered: 1. Retry the command at one minute intervals a maximum of five times.
1134	ABORT	Internal system error: The associated DS1 circuit pack is not administered. This condition should not be possible since an administered DS1 circuit pack must be specified when a Signaling Group is administered. 1. Retry the command at one minute intervals a maximum of three times.
2500	ABORT	Internal system error: 1. Retry the command at one minute intervals a maximum of five times.

Continued on next page

Table 9-387. TEST #647 Layer 2 Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Layer 2 of the primary signaling channel is down: 1. Examine the results of the Primary Signaling Test (#636) and follow recommendations provided there. 2. If test #636 passes, the Layer 2 Query test may still fail if the Signaling Channel at the far end has not been administered correctly or if the Signaling Channel has been busied out. Verify that the Primary Signaling Channel (D-channel) at the far end has been administered correctly. Verify that the DS1 port used for the Primary D-channel has not been busied out at the far end.
2	FAIL	Layer 2 of the secondary signaling channel is down. 1. Examine the results of Secondary Signaling Link Hardware Test (#639) and follow recommendations provided there. 2. If tests #639 passes, the Layer 2 Query test may still fail if the Signaling Channel at the far end has not been administered correctly or if the Signaling Channel has been busied out. Verify that the Secondary Signaling Channel (D-channel) at the far end has been administered correctly. Verify that the DS1 port used for the Secondary D-channel has not been busied out at the far end.
3	FAIL	Both the primary and secondary are down. 1. Examine the results of the Primary and SecondarySignaling Link Hardware Tests (#636 and #639) and follow recommendations provided there. 2. If tests #636 and #639 pass, the Layer 2 Query test may still fail if the Signaling Channel at the far end has not been administered correctly or if the Signaling Channel has been busied out. Verify that the Primary and Secondary Signaling Channel (D-channel) at the far end has been administered correctly. Verify that the DS1 port used for the Primary and Secondary D-channels has not been busied out at the far end.
	PASS	The Primary Signaling Channel is up and, if administered the Secondary Channel is up.

ISDN-TRK (DS1 ISDN Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ISDN-TRK[2]	MAJOR[3]	test port UUCSSpp l	DS1 ISDN Trunk
ISDN-TRK	MINOR	test port UUCSSpp l	DS1 ISDN Trunk
ISDN-TRK	WARNING	test port UUCSSpp sh	DS1 ISDN Trunk

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPN s). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. For additional repair information, see also DS1-BD for TN767 ports and UDS1-BD for TN464C/D ports.
3. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

NOTE:
See the figures in the "ISDN-SGR (ISDN-PRI Signaling Group)" section of this chapter for an illustration of the principles described below. Throughout this section, the general term DS1 circuit pack refers to TN464 and TN767 series circuit packs.

A DS1 ISDN trunk is a 64 Kbps bearer channel used to transmit digitized voice or data traffic. These trunks, or B-channels, use a separate channel, the D-channel for call-control signaling. This mode of operation is known as out-of-band signaling, as opposed to in-band robbed-bit signaling, in which signaling is carried in the same channel as the voice or data traffic. One D-channel, or ISDN signaling link (ISDN-LNK), carries signaling messages for several B-channels, forming an ISDN signaling group (ISDN-SGR).

A B-channel may be a port on either a TN464 series UDS1 circuit pack or a TN767 series DS1 Interface circuit pack.

Two types of DS1 interfaces exist:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link

On 24-channel interfaces, any of the first 23 ports on the DS1 circuit packs can be a B-channel. On the TN464C/D UDS1 circuit pack, the 24th port may be used as a B-channel or as a D-channel depending on the type of ISDN-PRI signaling group (FAS or NFAS) implemented on the circuit pack. For more details, refer to ''ISDN-SGR (ISDN-PRI Signaling Group)''P in this chapter. On the TN767 DS1 circuit pack, all 24 ports are used as B-channels since D-channel signaling is not supported on the TN767 circuit pack. The signaling for these B-channels is done over a D-channel located on a UDS1 TN464C/D board.

On 32 channel interfaces, any of ports 1-15 and 17-31 on the DS1 interface circuit pack can be a B-channel. The 16th port may be used as a B-channel or as a D-channel depending on the type of ISDN-PRI signaling group (FAS or NFAS) to which it belongs. For more details, refer to ''ISDN-SGR (ISDN-PRI Signaling Group)'' and "DS1-BD (DS1 Interface Circuit Pack)" in this chapter.

For interfaces using country protocol 1 on the DS1 circuit pack administration form (including US), the signaling protocol used for the maintenance of the B-channel is defined by the Lucent ISDN-PRI specification. For interfaces using country protocols other than 1, the signaling protocol used for the maintenance of the B-channel is defined by the CCITT ISDN-PRI Specification.

There are five possible service states for a B-channel. the service state is negotiated with the far-end switch, changes over time, and may have a far-end and near-end components. The service state is initialized to out-of-service/Far-End and an attempt is made to negotiate it to in-service.

The Lucent ISDN-PRI Specification defines the possible SERVICE STATES for a B-channel. The service state is negotiated with the far-end switch, changes over time, and may have a far-end or near-end component. The service state is initialized to the Out-Of-Service/Far-End state and an attempt is made to negotiate it to In-Service.

NOTE:
The service state of a particular DS1 ISDN Trunk B-channel can be displayed by issuing the **status trunk** *trunk group/trunk member* system technician command.

When a call is present, the specification defines the permissible call states as well. There are tests in the short and long test sequences for DS1 ISDN Trunk designed to audit these states and ensure agreement between both ends of the PRI connection.

Alarming Based on Service States

A warning alarm is logged against a DS1 ISDN B-channel trunk when it is placed in the Maintenance/Far-End or Out-Of-Service/Far-End states, during which the trunk is unusable for outgoing calls. When a warning alarm is present, use **status trunk** group#/member# command to determine the exact state. Other alarms can be diagnosed by using the short and/or long test sequences. Note that an ISDN B-channel trunk can be placed in a Far-End service state by either action taken by the far-end switch or by failure of the far-end switch to respond. For example, if the far-end does not respond to a Remote Layer 3 Query (Test #637 for ISDN-SGR), the associated DS1 ISDN trunk B-channels will be placed in the Maintenance/Far-End service state.

As a port on a DS1 circuit pack (DS1-BD or UDS1-BD), and as part of a signaling group dependent on a D-channel (ISDN-LNK) for signaling, operation of the ISDN-TRK is dependent on the health of these other maintenance objects. The ISDN D-channel in turn depends on the Packet Bus (PKT-BUS) for transmission through the system. Keep this hierarchy of dependencies in mind when diagnosing problems.

DS1 ISDN Trunk Service States

The **status trunk** command displays the following possible service states for ISDN trunks. Table 9-388 gives recommended procedures for each state.

- In-Service (INS)

  The B-channel is in its normal operating state.

- Out-of-Service/Far-End (OOS/FE)

  A B-Channel is initialized to this state when administered. The switch sends messages to the far-end to negotiate the B-channel into service. If the far-end does not respond to the messages within a certain time period, then the service state remains out-of-service and maintenance will periodically resend the messages. The trunk is unusable for incoming and outgoing calls.

- Out-of-Service/Near-End (OOS/NE)

  This is the state of the trunk when the NPE Crosstalk Test fails or when the trunk is busied out by system technician. In this state, the trunk is unusable for incoming or outgoing calls. No messages are sent to the far-end until the signaling link comes back into service or the trunk is released by system technician.

- Maintenance/Far-End (MTC/FE)

  This state is reached when the far-end does not respond to messages sent over the signaling link for a particular trunk after a certain amount of time. This state is different from OOS/FE since the signaling link must have initially been up and the B-Channels in-service. The switch will periodically send messages to the far-end to try to negotiate the trunk (B-channel) into service. The trunk is unusable for outgoing calls but will service incoming call requests from the far-end. Note that transitions into MTC/FE do not drop stable calls. Therefore, if the service state changes from in-service to MTC/FE, then stable calls are unaffected.

- Maintenance/Near-End (MTC/NE)

  The trunk (B-channel) is in this state if the signaling channel (ISDN-LNK) is busied out by system technician. The trunk (B-channel) is also temporarily in this state if system technician has issued a **test trunk** *trunk group/trunk member long* command. This command will execute the ISDN-PRI test call. This test will change the state of the trunk member to MTC/NE for the duration of the test unless a call request comes in from the far-end. In that case, the test would abort. Note that transitions into MTC/NE do not drop stable calls. In this state, the B-Channel is not usable for new incoming or outgoing calls.

- Pending States

  In addition to one of the above components, the service state may have a *pending* component, indicating that the switch is waiting for a reply from the far-end. These service states remain in effect until either a response is received or the allotted waiting time expires.

  — Pending-in-Service

    The near-end is waiting for a response from the far-end to a B-channel maintenance message requesting that the B-channel be transitioned to in-service.

  — Pending-Maintenance

    This state is supported only by systems using country protocol 1 (including US). The near-end is waiting for a response from the far-end to a maintenance message requesting that the B-channel be transitioned to the maintenance service state.

- Call Activity States

  The in-service service state also has a call activity component.

  — Active

    A call is connected over the B-channel (for example, *in-service/active*).

  — Idle

    There is no call currently on the B-channel (for example, *in-service/idle*).

Table 9-388. TEST #161 Looparound Test

Service State	Alarm[1]	Possible Cause	Possible Solution
out-of-service/NE	Warning	Trunk is demand busied out.	Enter **release trunk** grp#/mbr#.
	Minor	NPE Crosstalk Test (#6) failed.	Replace DS1/UDS1 circuit pack.
	None	DS1 or UDS1 circuit pack lost its signal.	Is the DS1/UDS1 circuit pack or cable removed? Is the far-end switch restarting? Check circuit pack using procedures in DS1-BD or UDS1-BD.
out-of-service/FE	Warning	Unadministered far-end	Administer corresponding trunk on far-end switch.
	Warning	The far-end trunk is busied out.	Check the status of the far-end switch.
pending-in-service, pending-maint	None	Maintenance message was sent and the switch is waiting up to 2 min. for a reply from the far-end.	Wait 2 minutes and check service state after the pending state has cleared.
maint-NE	None	ISDN test call in progress (**test trunk long** and **test isdn-testcall** commands)	Wait several minutes for test to finish and check status again.
	None	System link has been busied out by command.	Check link status. Release link with **release link** link#.
maint-FE	Warning	Signaling channel has been down for over 90 sec.	Consult ISDN-SGRP and/or ISDN-LNK. Far-end signaling channel may be busied out, or the far-end switch may currently be restarting.
	Warning	Repeated failure of far end to respond to messages.	Maintenance software will periodically try to resend messages. You can speed the process with **test trunk** grp#/mbr# and/or **test signaling-gr** #.
	Warning	The far-end trunk is being tested.	Check status of the far-end switch. Wait for testing to finish.
in-service	None	Normal operating state	

1. ISDN-TRK alarms; alarms against other objects may also be present.

Error Log Entries and Test to Clear Values

Table 9-389. DS1 ISDN Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port *UUCSSpp*
1(a)	Any	None			test port *UUCSSpp*
15(b)	Any	Audit and Update Test (#36)			
18	0	busyout trunk *grp/mbr*			release trunk *grp/mbr*
129(c)		None	WARNING	OFF	test port *UUCSSpp*
130(d)		None	WARNING	ON	test port *UUCSSpp*
257(e)	Any	None			test port *UUCSSpp*
513(f)	Any	None	WARNING	OFF	test port *UUCSSpp*
769(e)	Any	None			test port *UUCSSpp*
1281	Any	Conference Circuit Test (#7)	MAJ/MIN/WRN[2]	ON	test port *UUCSSpp* l r 4
1537	Any	NPE Crosstalk Test (#6)	MAJ/MIN/WRN[2]	ON	test port *UUCSSpp* l r 3
1793(g)	Any	None			test port *UUCSSpp*
3073(h)	Any	Service State Audit (#256)			test port *UUCSSpp*
3585(i)	Any	None			none
3841(j)	Any	None	WARNING	OFF	None

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major or minor alarms may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. These Error Types indicate a disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN call state of the DS1 ISDN Trunk. This switch will automatically try to recover by clearing the call, (that is, call will be torn down). You can use the **status trunk** group#/member# command to determine the state of the trunk.

   When running the Short Test Sequence of tests, pay close attention to the results of the Call State Audit Test (#257).

b. Software audit error and does not indicate a hardware malfunction. Run the Short Test Sequence and investigate associated errors.

c. The far-end switch changed its ISDN service state to either *out-of-service* or *maintenance*. This may be a temporary condition due to testing of that trunk by the far-end, or a hardware problem with the trunk. Outgoing calls will not be allowed over the trunk. To investigate the status of the trunk, issue the **status trunk** group#/member# command.

d. This Error Type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. These Error Types indicate a disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN service state of the DS1 ISDN Trunk. This switch will automatically try to recover by performing a service state audit. You can use the **status trunk** group#/member# command to determine the state of the trunk.

   When running the Short Test Sequence, pay close attention to the results of the Service State Audit Test (#256).

f. This trunk is not recognized by the far-end switch. Investigate the trunk administration for both switches and make changes as necessary.

g. This error indicates a failure of the DS1/UDS1 Interface circuit pack. When running the Short Test Sequence, the results of the Signaling Link State Check Test (#255) are important.

h. Service State Audit attempt failed (see Test #256). The trunks will not be usable for any outgoing calls (although incoming calls will be accepted) until the test passes and the trunk state is changed to in-service (use **status trunk** group#/member# to investigate trunk status).

i. Error Type 3585 appears when the switch receives an ISDN RESTART message for an ISDN trunk. Calls are cleared with the RESTART message. Therefore, this Error Type may be associated with a dropped call report from a user.

   The following Aux Data values for Error Type 3585 represent the trunk's ISDN call state at the time the unexpected request to restart the channel was received from the remote switch. This information can be useful if dropped calls (cutoffs) are reported by users of the ISDN-PRI trunks.

The meanings of Aux Data values are shown below; ignore any others.

Aux Data	Cause
0	A idle trunk receved a restart.
10	A call in a stable, talking state was cleared unexpectedly by the far-end with an ISDN RESTART message. This state is called the "active" state.
4 7 8 260 263	A call that has not reached the active state, but has at least reached a ringing state, was cleared unexpectedly by the far-end with an ISDN RESTART message.
1 3 6 9 265	A call that has not yet reached a ringing state was cleared unexpectedly by the far-end with an ISDN RESTART message.
11 12 19 531 267 268	A call that was in the process of clearing anyway has been cleared by the far-end with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far-end is attempting to clear trunks that it thinks are in a ‘‘hung’’ state. The RESTART message brings the trunk to an idle condition.

j. An ISDN trunk selected by the near-end has been rejected 10 times by the far-end without a successful call. This may indicate a service state mismatch between the near-end and far-end for this trunk that is effecting the end user (that is, customer receives unexpected intercept tones when accessing ISDN trunks). This may indicate that the ISDN trunk is not administered on the far-end.

The Aux field contains the physical name of the ISDN trunk in decimal. Then, verify that the far-end has this trunk administered.

The Warning alarm will be retired automatically whenever an outgoing or incoming call that uses this trunk is answered by the called endpoint. If problems persist, then busy-out the ISDN trunk to take it out of the hunt group.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-390. System Technician-Demanded Tests: DS1-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Audit and Update Test (#36)	X	X	ND
Signaling Link State Check Test (#255)	X	X	ND
Service State Audit Test (#256)	X	X	ND
Call State Audit Test (#257)	X	X	ND
ISDN Test Call Test (#258)		X	ND

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port’s NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port’s long test sequence and takes about 20 to 30 seconds to complete.

NOTE:
The TN464C/D UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.

Table 9-391. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. 1. Use **status station** or **status trunk** commands to determine when the port is available for testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-Bus errors. 1. If system has no TDM-Bus errors and is not handling heavy traffic, repeat test at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use **status station** or **status trunk** commands to determine when the port is available for testing. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering “y” in the “Maintenance Tests?” field on page 2 of the **change trunk-group** form.
1117	ABORT	A service state audit message is outstanding. 1. Wait 2 minutes and then try again.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-391. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. The ISDN-TRK is moved to out-of-service/near-end state. 1. Replace the circuit pack.
	PASS	The port is able to communicate over the TDM Bus.

Conference Circuit Test (#7)

The Conference Circuit test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

NOTE:
The TN464C/D UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.

Table 9-392. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status station** or **status trunk** commands to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use status station or status trunk to determine when the port is available for testing. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1018	ABORT	Maintenance is disabled on this trunk. 1. Enable maintenance by entering "y" in the "Maintenance Tests?" field on page 2 of the **change trunk-group** form.
1020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 interface circuit pack to assure that the trunk's translation is correct. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 interface circuit pack and in the switch software.

Table 9-393. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Maintenance is disabled on this trunk. 1. Enable maintenance by entering "y" in the "Maintenance Tests?" field on page 2 of the **change trunk-group** form.
	ABORT	Internal system error
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Test failed due to internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 interface circuit pack and switch software are consistent.

Signaling Link State Check Test (#255)

The DS1 ISDN Trunk depends on the health of the appropriate TN464C/D UDS1 Interface circuit pack or TN767 DS1 interface circuit pack for proper operation. It also depends on the ISDN-PRI D-channel (ISDN-LNK) trunk. This test checks the status of those critical elements.

Table 9-394. TEST #255 Signaling Link State Check Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	Internal system error
0	ABORT	
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering ‘‘y’’ in the “Maintenance Tests?” field on page 2 of the **change trunk-group** form.
4	FAIL	There is a problem with the signaling channel. 1. Consult the procedures for the ISDN-PRI Signaling Group (ISDN-SGRP). Further information may also be obtained by consulting the procedures for the ISDN-PRI Signaling Channel (ISDN-LNK).
8	FAIL	There is a problem with the DS1 interface circuit pack. 1. Consult the procedures for the appropriate DS1 interface circuit pack (DS1-BD or UDS1-BD).
	PASS	The signaling link hardware is OK.

Service State Audit (#256)

As noted in the general description for DS1 ISDN Trunk, these trunks may be in one of several service states. This test performs a Service State Audit with the far-end switch.

For interfaces using country protocol 1 (including the US) the Service State Audit executes in all trunk service states. A message is sent to the far-end switch to ensure that both sides agree on the service state. A PASS for this test simply means that the message has been successfully sent. Two minutes are allowed for a reply. If no reply is received within that 2 minute window, the message is sent out again. If that attempt fails, an Error Type 3073 will be logged and the switch will attempt another Service State Audit every 15 minutes. If the trunk was initially in-service, it is placed in the maintenance/far-end state. No outgoing calls will be placed over this trunk, but incoming calls will be accepted. If an incoming call is presented with the trunk in such a state, a Service State Audit is immediately be attempted (the switch does not wait for the 15-minute cycle, but tries to recover immediately).

For interfaces not using country protocol 1, the Service State Audit executes only if the trunk is in the out-of-service/far-end state. A message is sent to the far-end switch to attempt to bring the trunk back into the in-service state. A PASS for this test simply means that the message has been successfully sent. Two minutes are allowed for a reply. If no reply is received within that two minute window, the message is sent out again. If again no response is received within two minutes, the trunk remains in the out-of-service/far-end state. The switch will attempt another Service State Audit after an hour has passed.

To investigate the service state of the DS1 ISDN Trunk, issue the **status trunk** group#/member# command.

Table 9-395. TEST #256 Service State Audit Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	Resources required to run this test were not available. The port may be on a valid call or initializing. Use **status station** or **status trunk** to determine when the trunk is available for testing. Check the results of Test #255.
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering “y” in the “Maintenance Tests?” field on page 2 of the **change trunk-group** form.
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #255 and consult procedures for “ISDN-SGR (ISDN-PRI Signaling Group)” in this chapter.

Continued on next page

Table 9-395. TEST #256 Service State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1116	ABORT	The trunk is not in the out-of-service/far-end state, which is required to run this test on systems using a country protocol other than 1.
1117	ABORT	A service state audit message is outstanding. 1. Wait 2 minutes and then try again.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1113	FAIL	The signaling link has failed; the system cannot send any messages on behalf of this trunk. 1. Consult procedures for ISDN-SGR (ISDN-PRI Signaling Group) and ISDN-LNK (ISDN Signaling Link Port).
	FAIL	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	Wait 4 minutes and then check the Error Log for any new errors of type 3073. If there are none, then both sides of the ISDN connection agree on the service state; the negotiation succeeded. If there is a new 3073 error, then the negotiation failed (the far-end switch twice failed to respond within 2 minutes). The switch will automatically retry every 15 minutes. If the trunk was initially in-service, it is now placed in the maintenance/far-end state. Incoming calls will be accepted, but no outgoing calls can be originated. If an incoming call is presented, another Service State Audit will be immediately performed in an attempt to put the DS1 ISDN Trunk in the proper state.

Call State Audit Test (#257)

If a call is active on the trunk, the switches on both sides of the connection should agree on the ISDN state of the call, as defined in the ISDN Protocol Specification. This test audits internal call state data by querying the far-end switch as to the ISDN state of the call. It can be helpful when trying to clear a hung call. If the internal call state data on the near-end switch is different than that of the far-end switch, then *the call will be torn down.*

As with Test #256 (Service State Audit), a PASS simply means that an appropriate message was composed and sent to the far-end switch. The ISDN Specification allows up to 2 minutes for a reply. If a reply is not received within the 2 minute window, a protocol time-out violation will be recorded in the error log against the associated signaling channel (ISDN-LNK, Error Type 1).

Table 9-396. TEST #257 Call State Audit Test

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering “y” in the “Maintenance Tests?” field on page 2 of the **change trunk-group** form.
1019	ABORT	An audit is already in progress. 1. Wait 2 minutes and try again.
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #255 (Signaling Link State Check).
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1116	ABORT	The trunk is in an out-of-service ISDN service state. 1. A call cannot be present if the trunk is in an ISDN out-of-service state, so a call state audit would be inappropriate. No action necessary. (Use the **status trunk** group#/member# command to investigate the ISDN state of the trunk).
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-396. TEST #257 Call State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	This switch sent a call state auditing message to the far-end switch to verify the state of the call active on this trunk. If a call state mismatch is found, then the call will be torn down within two minutes. If no call was active, then no message was sent.

ISDN Test Call Test (#258)

This test performs a far-end loop around to a far-end switch over an ISDN trunk. The trunk's service state must be in-service, maint-NE, or out-of-service/NE, and no call can be active on the trunk. The test call can be initiated as part of a long test sequence, or as an individual test, as described below. This test is valid only for systems using country protocol 1 (including US), or when the far end has loop-around capability.

A test call connection is established to a far-end switch over the ISDN trunk to be tested. The digital port on a TN711D Maintenance/Test circuit pack generates a test-pattern bit stream which is sent to the far-end switch and echoed back. The received pattern is then compared to the sent pattern and checked for errors that indicate a loss of integrity on the communications path.

If a test call is running when scheduled maintenance starts, the green LED is turned off. To determine if a test call is still running, use the **list isdn-testcall** and **status isdn-testcall** commands. A lit yellow LED on the Maintenance/Test circuit pack also indicates that a test call is running.

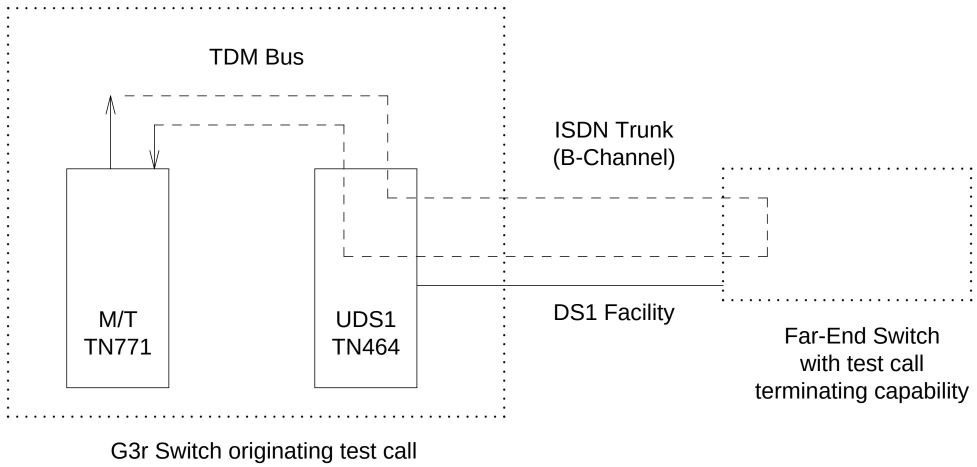

Figure 9-51. Outgoing ISDN-PRI Test Call

Synchronous Test Calls

You can initiate a synchronous outgoing test call by entering one of the following commands:

- **test trunk** group#/member# **long [repeat** #**]**
- **test board** UUCSS **long [repeat** #**]**
- **test port** UUCSSpp **long [repeat** #**]**

The above test sequences include a test-call for ISDN-PRI trunks. The duration of the test call is 8.6 seconds for If unrestricted (B8ZS) B-channels and 9.4 seconds for restricted (ZCS) B-channels. The test fails if the bit error rate retrieved from the Maintenance/Test digital port is greater than 0. When this occurs, you will need to perform further diagnostics, such as the **test isdn-testcall** command described below.

Asynchronous Test Calls

You can start, query, and stop an outgoing test call by using the following maintenance commands:

- **test isdn-testcall** group#/member# **[minutes** #**]**

  This command initiates an outgoing ISDN-PRI test call for a maximum of 120 minutes. Default times are as above. Only one trunk per port network can be tested at one time.

- **status isdn-testcall** group#/member#

  This command displays the progress of the outgoing test call by reporting bit and block error rates of the tested B-Channel.

- **clear isdn-testcall** group#/member#

  This command terminates an outgoing test call already in progress. Measurements already collected are not cleared until the next test call begins.

A PASS of the asynchronous test indicates only that the test call was successfully established. Use the **status** and **list** commands to get the results of the test.

NOTE:
Before attempting to make an ISDN-PRI test call to the public network (that is, the network is the far-end), make sure that test call service is provisioned by the network. The user must subscribe to Test Type 108 service and have the correct far-end test call number administered on the trunk group form for the call to be allowed.

Table 9-397. TEST #258 ISDN Test Call

Error Code	Test Result	Description/ Recommendation
4	ABORT	There is a problem with the Signaling Channel. 1. Consult the procedures for the ISDN-PRI Signaling Group (ISDN-SGRP). Further information may also be obtained by consulting the procedures for the ISDN-PRI Signaling Channel (ISDN-LNK).
8	ABORT	There is a problem with the DS1 interface circuit pack. 1. Consult the procedures for the appropriate DS1 interface circuit pack (DS1-BD or UDS1-BD).
1004	ABORT	B channel in use. 1. Determine if a call is active on this DS1 ISDN Trunk via the **status trunk** group#/member# command. 2. When the service state indicates in-service/idle, retry the test.
1005	ABORT	Bad Configuration (such as no Maintenance/Test circuit pack) 1. Make sure the Maintenance/Test Circuit Pack is inserted. 2. Repeat the test.
1018	ABORT	Test call is disabled. 1. Enable Maintenance on the Trunk Group form.

Continued on next page

Table 9-397. TEST #258 ISDN Test Call — *Continued*

Error Code	Test Result	Description/ Recommendation
1019	ABORT	Another Test call is in progress. 1. Issue the **list isdn-testcall** command to locate the test call. 2. Issue the **status isdn-testcall** command to find out the duration and start time of the test call. 3. Issue the **clear isdn-testcall** command to stop the test call from running. 4. If time and duration indicate that the test call should have stopped, and the **clear isdn-testcall** command does not work, refer to M/T-DIG (Maintenance/Test Digital Port) for recommended maintenance strategy.
1020	ABORT	There is a problem with the DS1 Interface Circuit Pack. 1. Refer to "DS1-BD or UDS1-BD".
1024	ABORT	(M/T-DIG) Maintenance/Test Digital Port in use. 1. Wait until yellow and green LED s are turned off on the M/T-BD (Maintenance/Test circuit pack). 2. Retry test. If problem persists, refer to M/T-DIG (Maintenance/Test Digital Port).
1113	ABORT	The signaling link has failed. Therefore, the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #255 (Signaling Link State Check Test).
1116	ABORT	The switch could not appropriately change the ISDN service state. 1. Determine if a call is active on this DS1 ISDN Trunk (use the **status trunk** group#/member# command). If so, proceed as for Error Code 1119. 2. If not, check the Error and Alarm Logs for problems with this ISDN-TRK (DS1 ISDN Trunk) MO.
1117	ABORT	ISDN Service message is already outstanding. 1. Wait 2 minutes. Then try again.
1118	ABORT	Far-end of ISDN trunk is not administered. 1. Check the administration of the far-end ISDN trunk. 2. Issue the **status trunk** group#/member# command. 3. Try the test again.
1119	ABORT	The test call was aborted due to a normal call attempt on this trunk. **NOTE:** The test call will only be performed if the trunk is idle. 1. Either wait for the normal call to terminate normally, or force it to be dropped by using the **busyout trunk** trunk group/trunk member command to busyout the DS1 ISDN Trunk. When the trunk is idle, retry the test.

Continued on next page

Table 9-397. TEST #258 ISDN Test Call — *Continued*

Error Code	Test Result	Description/ Recommendation
1120	ABORT	The DS1 ISDN Trunk is in the ISDN out-of-service/far-end state. 1. Try to change the service state via Test #256 (Service State Audit Test) and then try this test again. Keep in mind that the trunk may be in the out-of-service/far-end state due to problems at the far-end switch. If that is the case, no remedial action can be taken at this end.
1122	ABORT	There is no test line number for the far-end switch. 1. Check the Trunk Group Administration form.
1123	ABORT	There is no Feature Access Code administration for this Facility Test. 1. Check the Dial Plan and Feature Administration forms.
2000 2012 None	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2035	ABORT	The call has timed out, perhaps because of a lack of system resources. 1. Wait 1 minute and try again.
2036 2037	ABORT	Internal system error. 1. Follow recommendation for ABORT code 2012.
2038 2039	ABORT	A problem occurred while trying to read the test data. 1. Wait 1 minute and then try again. If the test aborts again in the same manner, there is a serious internal problem.
2040	ABORT	Internal system error. Follow recommendations for ABORT code 2012.
2041	ABORT	The call has timed out, perhaps because of a lack of system resources. Follow recommendations for ABORT code 2035.
2066	ABORT	Could not establish test call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2067	ABORT	The call has timed out, perhaps because of a lack of system resources. Follow recommendations for ABORT code 2035.
2074	ABORT	Bit and Block Error query failed. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, there may be a serious internal problem with M/T-DIG (Maintenance/Test Digital Port). If this is the case, refer to the M/T-DIG (Maintenance/Test Digital Port).
2075	ABORT	Internal system error. Follow recommendations for ABORT code 2012.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-397. TEST #258 ISDN Test Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2104	ABORT	Call dropped or could not be originated. 1. Make sure service is provisioned by the network. 2. Check the administration of the far-end test line extension on the trunk group administration form. 3. Check the administration of the Testcall BCC (Bearer Capability Class) on the trunk group administration form. 4. Check the reason for termination with **status isdn-testcall**. 5. For further instructions see Troubleshooting ISDN Testcalls in Chapter 6. 6. Try the test again.
2201 2202 2203 2204 2205	ABORT	Internal system error. Follow recommendations for ABORT code 2012.
2206	ABORT	Could not allocate the necessary system resources to run this test. Follow recommendations for ABORT code 2100.
2208	ABORT	Internal system error. Follow recommendations for ABORT code 2012.
2209 2210	ABORT	Could not allocate the necessary system resources to run this test. Follow recommendations for ABORT code 2100.
2211	ABORT	Internal system error. Follow recommendations for ABORT code 2012.
2212	ABORT	Call terminated by unexpected disconnect. 1. Wait 1 minute and then try again.
2213	ABORT	The call has timed-out, perhaps because of a lack of system resources. Follow recommendations for ABORT code 2035.
2214	ABORT	Call terminated by unexpected disconnect. 1. Wait 1 minute and then try again.
2215 2216 2217 2218 2219	ABORT	Internal system error. Follow recommendations for ABORT code 2012.
2220	ABORT	Call terminated prematurely. 1. Wait 1 minute and try again.

Continued on next page

Table 9-397. TEST #258 ISDN Test Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2221 2222 2223 2224 2225 2226	ABORT	Internal system error. Follow recommendations for ABORT code 2012.
2227	ABORT	Could not allocate the necessary system resources to run this test. Follow recommendations for ABORT code 2100.
2042	FAIL	Comparison of data sent to data received indicates a loss of integrity on the communications path. 1. Take the trunk out of service and check the quality of the DS1 connection, including the transmission facility and any external equipment such as DAC s, CSU s, etc. Use **test isdn-testcall** and **status isdn-testcall** commands to get the bit and block error rates.
	PASS	The test pattern was sent and received properly. If the synchronous test call was performed (long test sequence), this indicates that the communications path is operating properly. If the **test isdn-testcall** command was used, PASS indicates only that the test call was established. Use the **status isdn-testcall** command to get the bit and block error rates detected by the test. If the bit and block error rates are not acceptable, perform a complete analysis of the DS1 facility including the transmission facility and any external equipment such as DAC s, CSU s, etc.

JNL-PRNT (Journal Printer Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
JNL-PRNT	MINOR	test journal wakeup-log	Journal Printer Link
JNL-PRNT	WARNING	test journal wakeup-log	Journal Printer Link

The maintenance strategies for JNL-PRNT (Journal Printer Link) and PMS-PRNT (PMS Printer Link) are the same. Refer to the "PMS-PRNT/JNL-PRNT (PMS Printer Link)" section of this chapter.

LGATE-BD

See BRI-BD

LGATE-PT

See BRI-PT

LOG-SVN (Login Security Violation)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
LOG-SVN	MAJOR	enable login <login ID>	Login Security Violation

1. Where <login ID> is the Lucent services login ID for which the security violation was detected. The **Alt Name** field indicates the login ID associated with the security violation and the major alarm.

The Security Violation Notification (SVN) feature provides notification when the number of failed attempts to access the system administration/maintenance interface meets or exceeds customer administered threshold parameters.

A major alarm is logged whenever a security violation is detected involving an Lucent services login ID and that login ID has been disabled as a result of detection of the security violation. The capability to disable a login ID following detection of a security violation involving that login ID is administrable on a per login ID basis.

Refer to the *DEFINITY Communications System Generic 3 V2 Implementation*, 555-230-653, Issue 1 for information on administration required for the Security Violation Notification feature, and the option to disable a login ID following detection of a security violation involving the affected login ID.

Error Log Entries and Test to Clear Values

Table 9-398. Security Violation Notification Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1-15	None	None	Major	OFF	enable login <login ID>

General Information about **log-svn** error log entries:

a. The number (1 - 15), that appears in the error type field, corresponds to the location of the login in the internal login data structure.

b. The *Alt Name* field on the alarm report indicates the login ID associated with the security violation and major alarm.

c. These errors/alarms are associated with a number of failed attempts to access the system management/maintenance interface using an Lucent services login ID that meet or exceed the customer administered threshold parameters. The associated alarm is immediately raised as a major alarm.

d. The affected login ID will be disabled as a result of detection of the security violation, unless it is the last enabled INADS type login on the system. The provision to disable a login ID following detection of a security violation involving that login ID is administerable on a login ID basis.

e. The **enable login** command is used to both enable a login that has been disabled, and to retire any login security violation alarms associated with the login ID.

f. Use of the **enable login** command to enable a login and/or retire alarms must be executed using a login ID with greater service level hierarchy permissions.

g. Access to the **enable login** command is controlled through the Administer Permissions field on the Command Permission Categories form. This field (Administer Permissions) must be set to "y" to access the enable login command.

h. The *Port* alarm report field will set to the port where the final invalid login attempt, involving the alarmed login ID, was detected. Valid port values for G3i products include:

- MGR1 — Dedicated manager 1 or G3 management terminal connection
- NET-n — Network controller dial up port
- INADS — INADS port
- EPN — EPN maintenance EIA port
- EIA — Other EIA port

Valid port value for G3r products include:

- SYSAM _LOC — Local administration port
- SYSAM _RMT — Remote administration port
- SYS_PORT — System Port
- MAINT — Maintenance port

i. The *Svc State* alarm report field will be set to OUT if the login ID is in the disabled state as a result of detection of a security violation involving the login ID. Once the login ID has been enabled, the field will be set to IN.

j. The source or reason of the failed login attempts should be identified and the cause corrected prior to re-enabling a login ID and/or retiring any alarms associated with the login ID. The cause may be something as innocuous as the failure of Lucent services automatic login software, to something as insidious as a hacker attempting to gain access to the switch system management interface.

Prior to retiring an SVN alarm and enabling the associated login ID, the **monitor security-violations login** command can be used to access information about the invalid login attempts that caused the security violation. This information can be useful in determining the source of the invalid attempts and analyzing why they occurred.

The **list logins** command provides status information about logins on the system. If a login has been disabled as a result of a security violation, the status will be "*svn-disabled*."

Procedure to Retire SVN Alarm

To retire a SVN alarm:

1. Enter the command **enable login <login ID>**.

   The login ID associated with that alarm is displayed in the *Alt Name* field of the alarm report and the alarm is retired.

MAINT (EPN Maintenance Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
MAINT	MINOR	test maintenance sh	EPN Maintenance Circuit Pack
MAINT	MAJOR	test maintenance l	EPN Maintenance Circuit Pack

The TN775B EPN Maintenance circuit pack monitors and supports environmental maintenance for EPN multicarrier or single-carrier cabinets. The EPN Maintenance circuit pack provides switch software with a mechanism to activate or deactivate Emergency Transfer in the EPN. Control by the system of Emergency Transfer can be overridden by the Emergency Transfer Switch on the faceplate of the circuit pack. The EPN Maintenance circuit pack invokes Emergency Transfer when the EPN loses contact with the PPN or when the EPN Maintenance circuit pack loses contact with all Expansion Interface circuit packs. The EPN Maintenance circuit pack handles loss of AC power in the EPN multicarrier cabinet by supplying battery power for 15 seconds to the EPN cabinet and then an additional 10 minutes of power to just the control carrier in the EPN. When power fails in a single-carrier EPN cabinet, no such power holdover is available. In the event that an Expansion Interface circuit pack goes insane and is reset six times within 15 minutes, the EPN Maintenance circuit pack will hold the Expansion Links reset preventing the Expansion Interface circuit pack from running.

The EPN Maintenance circuit pack has alarm LED s which indicate the presence of Major, Minor, and Warning alarms. A flashing LED indicates the presence of an alarm within the cabinet. A continuously lit LED indicates the presence of an alarm elsewhere in the system.

A management terminal (G3-MT) can be directly connected to the TN775B EPN Maintenance circuit pack. This link operates at 9600 baud, but system software throttles the rate of data flow to the TN775B for display on the G3-MT to about 1200 baud. All system commands can be executed via the EPN G3-MT login. However, due to the slow speed at which the EPN login operates, it is recommended that it be used only for maintenance sessions and not for system administration.

The PPN communicates with the EPN Maintenance circuit pack via the following path; uplink messages from the EPN Maintenance circuit pack to the PPN take exactly the reverse path. Messages flow from the UN331B Processor circuit pack in the SPE to the TN1655 Packet Interface circuit pack, over the Lan Bus to the Active PPN Expansion Interface circuit pack, across the fiber link to the Active EPN Expansion Interface circuit pack, and over a serial link to the EPN Maintenance circuit pack.

The EPN Maintenance circuit pack must be physically inserted into the dedicated slot marked Maintenance in the A carrier of the EPN. The serial links from the EPN Maintenance circuit pack to the Expansion Interface circuit packs are physically connected from this dedicated slot to slots 2A01 and 2B02 (2B02 is used only if there is duplicated Port Network Connectivity). The serial link from slot 2A01 to the maintenance slot is hard-wired into the backplane of carrier A, whereas the serial link from slot 2B02 to the maintenance slot is a ribbon cable connecting the two slots. The serial link from the EPN Maintenance circuit pack to the terminal is also a ribbon cable which plugs into a connector labeled TERM on the back of carrier A.

The maintenance strategy for the EPN Maintenance circuit pack consists of checking the integrity of the communications path to/from the EPN Maintenance circuit pack, testing individual hardware components on the EPN Maintenance circuit pack, and keeping the alarm LED s up-to-date. The individual hardware components include the serial interfaces which handle the serial links connected to the EPN Maintenance circuit pack. There are three serial interfaces, one for each possible Expansion Interface circuit pack and one for the terminal.

Since the EPN Maintenance circuit pack supports environmental maintenance in the EPN, trouble with the EPN Maintenance circuit pack can cause environmental maintenance to falsely detect problems. In a multicarrier cabinet EPN, these environmental MOs include: POWER (Battery & Battery Charger), CARR-POW (Carrier Port Power Unit), AC-POWER (AC Power), CABINET (Cabinet Sensors), EMG-XFER (Emergency Transfer), EXT-DEV (External Device Alarm), and CUST-ALM (Customer-Provided Alarming Device). In a single carrier cabinet EPN, these environmental MOs include DC-POWER (Single Carrier Cabinet Power), EMG-XFER (Emergency Transfer), EXT-DEV (External Device Alarm), and CUST-ALM (Customer-Provided Alarming Device).

Error Log Entries and Test to Clear Values

Table 9-399. EPN Maintenance Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test maintenance sh r 1
1(a)	0 1	EPN Maintenance Circuit Pack Reset Test (#306)	MINOR	ON	test maintenance l
513(a)	0 1	MGR I Channel Loop Test (#228)	MINOR	ON	test maintenance sh r 3
769(b)	Any	Sanity Handshake Test (#106)			
1537(a)	0 1	Sanity Maze Test (#303)	MINOR	ON	test maintenance sh r 3
2561(a)	0 1	Sanity Handshake Test (#106)	MINOR	ON	test maintenance sh r 3
2817(a)	0(b) 1	Serial Channel Loop Test (#229)	MINOR	ON	test maintenance sh r 3
3329(c)	Any	Serial Link Test (#337)	MINOR/ WARNING[2]	OFF	test maintenance sh r 3
3585(d)	Any	Serial Link Test (#337)	MINOR/ WARNING[2]	OFF	test maintenance sh r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major and Minor alarms may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. A value of 0 indicates that PNC-A (and therefore, the Expansion Interface circuit pack located on PNC-A) was active when this error occurred. A value of 1 indicates that PNC-B (and therefore, the Expansion Interface circuit pack located on PNC-B) was active when this error occurred. To clear this problem, make sure the Active PNC is the same as that indicated by the Aux Value.

b. Multiple values can appear in the Aux Data field. There will be other errors in the log if there is a real problem. Use these other errors to troubleshoot the problem.

c. The serial link between the Expansion Interface circuit pack in the A carrier and the EPN Maintenance circuit pack is defective.

d. The serial link between the Expansion Interface circuit pack in the B carrier and the EPN Maintenance circuit pack is defective.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Sanity Handshake Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Sanity Handshake Test (#106)	X	X	ND
EPN Maintenance Circuit Pack Reset Test (#306)		X	D
Serial Channel Local Looparound Test (#229)	X	X	ND
MGR I Channel Local Looparound Test (#228)		X	D
EPN Maintenance Circuit Pack Sanity Maze Test (#303)	X	X	ND
EPN Maintenance Circuit Pack Serial Link Test (#337)	X	X	ND

1. D = Destructive, ND = Non-destructive

Sanity Handshake Test (#106)

This test checks the EPN Maintenance circuit pack's ability to respond to queries. A message is sent to the EPN Maintenance circuit pack which then sends a message back. If the response message is received, then the EPN Maintenance circuit pack is queried for the EPN cabinet type (valid EPN cabinet types are single carrier and multicarrier cabinets). The EPN Maintenance circuit pack reads pins on the backplane of carrier A that identify the type of cabinet and report this information. If a valid cabinet type is returned, then the test passes.

Table 9-400. TEST #106 Sanity Handshake Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error.
1000	ABORT	System resources required for this test are not available.
2000	ABORT	Response to cabinet query was not received in the allowable time period.
2033	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of five times.
2046	ABORT	The EPN Maintenance circuit pack reported an invalid cabinet type. Not knowing the cabinet type of the EPN will prevent all EPN environment maintenance from running. 1. Retry the command. 2. If the test continues to abort with 2046, then either the EPN Maintenance circuit pack is defective, or the EPN cabinet wiring is defective. First, replace the EPN Maintenance circuit pack. 3. If the test continues to abort with 2046, then the EPN cabinet wiring is defective in the A carrier and the EPN Maintenance circuit pack cannot read the backplane pins to determine the cabinet type.
10601	ABORT	Test disabled via software patch.

Continued on next page

Table 9-400. TEST #106 Sanity Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	EPN Maintenance circuit pack did not respond to Sanity Handshake and the test timed out. 1. Verify that the carrier A power units are good. If the -5 volt unit is defective in the A carrier, then communication with the EPN Maintenance circuit pack will not be possible. 2. If the -5 volt unit is good and this test continuously fails, background maintenance will automatically escalate to an EPN Maintenance circuit pack Reset (Test #306). Otherwise, manually invoke an EPN Maintenance circuit pack Reset by issuing the **test maintenance long** command and evaluating any generated error codes from Test #306. If Test #306 passes, this test should also PASS. Use the following steps to determine if the EPN Maintenance circuit pack, or the serial link to the EPN Maintenance circuit pack, is defective: Duplicated Port Network Connectivity: 1. Switch Port Network Connectivity by entering **reset pnc interchange**. 2. Run the Short Test Sequence against the EPN Maintenance circuit pack. If Test #106 still fails, replace the EPN Maintenance circuit pack and retest. Otherwise, follow the error routines for any errors that are logged by this Short Test. Simplex Port Network Connectivity: 1. Replace the EPN Maintenance circuit pack and invoke the Short Test Sequence against it. 2. If error persists, replace the EPN Expansion Interface circuit pack, **at a time when the EPN can go down with minimal inconvenience**. 3. If the error still persists, the problem is with the actual serial link in A carrier backplane and not with the EPN Maintenance circuit pack.
	PASS	The communications path to and from the EPN Maintenance circuit pack is sane, and the EPN Maintenance circuit pack can read and report the correct EPN cabinet type. The EPN Maintenance circuit pack may still have problems related to Tests #228, #229, #303, or #306.

Management Terminal Channel Local Loop-Around Test (#228)

This test is destructive.

This test checks TN775B on-board circuitry associated with the serial link for the management terminal connection. This test will not cause the local terminal login to drop, but any data displayed on the terminal while the test is running will be lost.

The EPN Maintenance circuit pack has 3 separate serial interfaces:

- One to the management terminal which is tested by Test #228
- One to the active EI circuit pack which is tested by Test #229
- One to the standby EI circuit pack which is tested by Test #229

Table 9-401. TEST #228 Management Terminal Channel Local Loop-Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required for this test are not available.
2000	ABORT	Response to the test was not received within the allowable time period.
2033	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2034	ABORT	Background EPN Maintenance circuit pack maintenance is running the MGR I Channel Local Looparound Test. 1. Wait 30 seconds and retry the test a maximum of 5 times.

Continued on next page

Table 9-401. TEST #228 Management Terminal Channel Local Loop-Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2280 1	ABORT	Test disabled via software patch.
	FAIL	Test failed which means the EPN terminal is not usable. 1. Run the test three more times. Replace the EPN Maintenance circuit pack if the test continues to fail.
	PASS	The serial interface circuitry on the EPN Maintenance circuit pack which controls the EPN-connected terminal is functioning properly. If there are still troubles with the EPN G3-MT terminal, the problem may be one of the following: 1. The EPN-connected terminal is not configured properly. The connection between the terminal and the EPN Maintenance circuit pack must be set up at 9600 baud. 2. The serial link from the back of carrier A to the EPN terminal may be defective. The serial link consists of the connector on the back of carrier A labeled TERM and the ribbon cable running to the terminal. 3. The terminal may be defective. Try another terminal. 4. Since this test is not 100 percent accurate, there may still be problems with the EPN Maintenance circuit pack.

Serial Channel Local Looparound Test (#229)

This test checks TN775B on-board circuitry associated with the serial links to the Expansion Interface circuit packs. A request is sent to the EPN Maintenance circuit pack over the Active link via the Active Expansion Interface circuit pack serial interface circuitry to test the serial interface circuitry of the standby Expansion Interface circuit pack link. If a response is received, then by definition the serial interface circuitry associated with the Active link is good.

The EPN Maintenance circuit pack has 3 separate serial interfaces:

- One to the management terminal which is tested by Test #228
- One to the active EI circuit pack which is tested by Test #229
- One to the standby EI circuit pack which is tested by Test #229

Table 9-402. TEST #229 Serial Channel Local Looparound Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
2034	ABORT	Background EPN Maintenance circuit pack maintenance is running the Serial Channel Local Looparound Test. 1. Wait 30 seconds, and retry the test a maximum of 5 times.
2290 1	ABORT	Test disabled via software patch.
	FAIL	The on-board circuitry associated with the Standby serial link is defective. Since the EPN Maintenance circuit pack reported this failure, the on-board circuitry associated with the Active serial link is functional. 1. This test checks the circuitry on the EPN Maintenance circuit pack associated with the Standby Expansion Interface link. a. In a switch without duplicated Port Network Connectivity, current service will not be affected because the circuitry failing is not being used. Nevertheless, a Minor alarm will remain in the Alarm Log against MAINT. Therefore, the EPN Maintenance circuit pack must be replaced. b. In a switch with duplicated Port Network Connectivity, service will not be affected as long as you DO NOT INTERCHANGE THE PNCS; otherwise, the connection to the EPN Maintenance circuit pack will be lost. Losing the EPN Maintenance circuit pack connection will mean loss of the connection to the terminal and EPN Environment maintenance. The EPN Maintenance circuit pack must be replaced to correct this problem.

Continued on next page

Table 9-402. TEST #229 Serial Channel Local Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The on-board circuitry associated with both Expansion Interface circuit pack serial links is good. If there is still a problem communicating with the EPN Maintenance circuit pack, check the following: 1. The cable comprising the serial link (B carrier Expansion Interface circuit pack to EPN Maintenance circuit pack only) may be defective. 2. The EPN Maintenance circuit pack may actually be defective. **NOTE:** This test may not be 100 percent accurate. 3. The Expansion Interface circuit pack on the Standby link may be defective.

EPN Maintenance Circuit Pack Sanity Maze Test (#303)

The EPN Maintenance circuit pack processor has direct access to special registers in the EPN Maintenance circuit pack. These registers are tied to such things as the Expansion Interface circuit pack reset leads and Carrier Port Power Unit reset leads (which enable the EPN Maintenance circuit pack to recycle carriers). To prevent an insane EPN Maintenance circuit pack from inadvertently controlling these external devices, a special interface called the Sanity Maze is provided that must first be navigated by the EPN Maintenance circuit pack processor prior to any register access. There are two parts to the test. Part 1 involves navigating the Sanity Maze to toggle an unused lead. Part 2 attempts to toggle an unused lead without first navigating the Sanity Maze. The Sanity Maze test passes if Part 1 is successful and Part 2 fails.

Table 9-403. TEST #303 EPN Maintenance Circuit Pack Sanity Maze Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test was not received within the allowable time period.
2033	ABORT	1. Retry the command at one-minute intervals a maximum of 5 times.
	FAIL	The Sanity Maze of the EPN Maintenance circuit pack is defective. 1. Replace the EPN Maintenance circuit pack.
	PASS	The Sanity Maze is working properly, and the EPN Maintenance circuit pack can access the unused register. If **recycle carrier** commands (for EPN carriers) do not work, the following problems may still exist: 1. The Carrier Port Power Unit or wiring to the Carrier Port Power Unit may be defective. Refer to CARR-POW (Carrier Port Power Unit) Maintenance documentation. 2. Since this test only tests the EPN, there is a very small probability that the EPN Maintenance circuit pack cannot access those registers that deal with EPN devices. The EPN Maintenance circuit pack may need to be replaced.

EPN Maintenance Circuit Pack Reset Test (#306)

This test is destructive.

The terminal connection will be dropped and, if the Emergency Transfer switch is in the AUTO position, Emergency Transfer will be disabled for the duration of the test.

The EPN Maintenance circuit pack is reset by the Active Expansion Interface circuit pack. After the Expansion Interface circuit pack reports that the EPN Maintenance circuit pack has reset, a handshake message is sent to the EPN Maintenance circuit pack. If the EPN Maintenance circuit pack responds to the handshake, the test passes. If not, it fails. If the test passes, the EPN-connected terminal is brought back up, and Emergency Transfer is restored to its previous state.

Table 9-404. TEST #306 EPN Maintenance Circuit Pack Reset Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via software patch.
2029	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
1204 1205	FAIL	EI circuit pack could not reset the EPN Maintenance circuit pack. For duplicated Port Network Connectivity: 1. The standby EI circuit pack may be defective and, thereby, preventing the active EI circuit pack from resetting the EPN Maintenance circuit pack. Unplug the standby EI circuit pack, and attempt to reset the EPN Maintenance circuit pack using the **test maint long** command. If Test #306 passes, replace the standby EI circuit pack, and attempt the reset test again. If Test #306 fails, then replace the Standby EPN EI circuit pack. 2. The active EI circuit pack may be defective and unable to reset the EPN Maintenance circuit pack. Interchange the PNC by entering the **reset pnc interchange** command. Now reset the EPN Maintenance circuit pack again by using the **test maintenance long** command. If the test passes, the problem is with the known standby EI circuit pack. Repeat Step 2 to determine if the standby EI circuit pack should be replaced.

Continued on next page

Table 9-404. TEST #306 EPN Maintenance Circuit Pack Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1205 *(cont'd.)*		3. Replace the EPN Maintenance circuit pack, and run the test again. If the test passes, the problem is with the EPN Maintenance circuit pack. Interchange the PNC by entering the **reset pnc interchange** command and run the test again. The test should pass with both EI circuit packs being active. 4. If the B carrier EI circuit pack is active, the ribbon cable connecting the Expansion Interface circuit pack and the EPN Maintenance circuit pack may be defective. Check the ribbon cable to make sure it is connected properly and is not damaged. For simplex Port Network Connectivity: 1. Replace the EPN Maintenance circuit pack, and run the test again. If it passes, the problem is with the EPN Maintenance circuit pack. 2. If the test fails, replace the EI circuit pack. If the tests passes, the problem is with the EI circuit pack. 3. If the test still fails, the problem is with the serial link wired into the backplane of carrier A.

Continued on next page

Table 9-404. TEST #306 EPN Maintenance Circuit Pack Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2005	FAIL	EPN Maintenance Circuit Pack Reset passed, but the EPN Maintenance circuit pack did not respond to subsequent handshake message. Retry this command three more times. If it continues to fail, the EPN Maintenance circuit pack, the active EI circuit pack, or the serial link is defective. To determine which is defective, follow the appropriate procedures that follow. Duplicated Port Network Connectivity: 1. Interchange PNCs by entering **reset pnc interchange**. 2. Run the Short Test Sequence against the EPN Maintenance circuit pack. If Test #306 still fails, replace the EPN Maintenance circuit pack and retest. Otherwise, follow the error routines for any errors that are logged by this Short Test Sequence. Simplex Port Network Connectivity: 1. Replace the EPN Maintenance circuit pack and invoke the Short Test Sequence against it. 2. If the error persists, replace the EI circuit pack, at a time when the EPN can go down with minimal inconvenience. 3. If the error still persists, the problem is with the actual serial link in A carrier backplane and not with the EPN Maintenance circuit pack.
	PASS	The active EI circuit pack can reset the EPN Maintenance circuit pack. This implies the EPN Maintenance circuit pack, the active EI circuit pack, and Active serial link are sane. There could still be a problem with the standby EI circuit pack and standby serial link in a Duplication Option system.

EPN Maintenance Circuit Pack Serial Link Test (#337)

This test is destructive.

This test checks the serial link from the standby EI circuit pack to the EPN Maintenance circuit pack. If there is no standby link, or the standby link is down at the time of the test, this test will abort.

NOTE:
The status of the link is changed to "down" when the standby EI circuit pack begins initialization tests (for example, after being reset). The link status is then updated at the conclusion of these tests.

Table 9-405. TEST #337 EPN Maintenance Circuit Pack Serial Link Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of 5 times.
2029 2500	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	FAIL	The serial link between the currently standby EI circuit pack and the EPN Maintenance circuit pack is defective. If the standby EXP-INTF is on the A carrier, then error type 3329 is logged. If the standby EXP-INTF is on the B carrier, then error type 3585 is logged. 1. *If error type 3585 was logged,* check to see if the ICCA/ICCB cables between carriers A and B are present and properly connected (ICCA to ICCA, and ICCB to ICCB). The location of these connectors is shown in the figures "Expansion Control Carrier (J58890AF)" in Chapter 2. Install or reconnect the cables if necessary and rerun the test. 2. Replace the EPN Maintenance circuit pack. 3. Rerun the test. If the test continues to fail, replace the Standby EPN Expansion Interface circuit pack. 4. Rerun the test. If the test continues to fail and the Standby link is on the B carrier, then replace the ribbon cable that carries the serial link from Expansion Interface circuit pack B to the EPN Maintenance circuit pack.
	PASS	The serial link from the Standby Expansion Links to the EPN Maintenance circuit pack is working.

MAPD-BD (MAPD Interface Circuit Pack TN802)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MAPD-BD	MAJOR	test board UUCSS sh	MAPD Interface Circuit Pack
MAPD-BD	MINOR	test board UUCSS l	MAPD Interface Circuit Pack
MAPD-BD	WARNING	test board UUCSS sh	MAPD Interface Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The TN802 Multiple Application Platform for DEFINITY (MAPD) circuit pack allows sending voice and fax from DEFINITY ECS through the Internet to another DEFINITY also having this feature or to other PBXs that are equipped with the Internet Telephony Server (ITS-E).

Throughout this section the term TN802 means the MAPD IP trunk circuit pack.

Be sure to observe these special considerations for the TN802:

- Port alarms on this circuit pack display as “TIE-DS1” in the Alarm and Error logs.
- The **reset board** command reboots the MAPD PC CPU, but **busyout board** only busys out all of the emulated ports on the board.
- Switch resets that take the switch out of service for more than 20 seconds also cause the MAPD's PC to reboot, which takes several minutes to complete.

Switch-demanded tests

Switch-demanded diagnostic tests on the TN802 do not run unless the Internet trunking application is running on Windows NT™, located on the circuit pack.

Feature limitations

The Internet trunking application relies on the single call scenario, or a direct, point-to-point call that does not terminate at multiple DEFINITY nodes through call processing. Table 9-406 describes the feature limitations for DEFINITY ECS.

Table 9-406. DEFINITY ECS IP trunk feature/performance limitations

Feature/ Performance	Description	Recommendation
Abbreviated Dialing	Abbreviated Dial strings with embedded pauses lose digits after the pause	Most calls work. Do not create Abbreviated dial strings with embedded pauses.
Compression limitations	All IP trunk calls go through A/D conversion, which uses compression to reduce bandwidth. Each compression degrades the voice signal and creates call processing delay.	No more than 3 compression/decompression cycles for any call. **NOTE:** The compression/ decompression that most voice mail systems use must be counted as 1 cycle.
Call Classifier	IP trunk's compression/ decompression cycle makes ringback, busy and voice detection	Do not administer these features: ■ Call Coverage Redirected Off-Net (CCRON) ■ Certain wireless phone coverage
Call Coverage Call Forwarding Call Transfer	Calls extended across multiple DEFINITY ECS nodes require multiple call paths. Significant voice quality degradation is likely.	Multiple call paths not recommended

Continued on next page

Table 9-406. DEFINITY ECS IP trunk feature/performance limitations — *Continued*

Feature/ Performance	Description	Recommendation
Conferencing	Voice quality and delay problems if the party controlling the conference is on the IP trunk (voice paths from external callers come in on the IP trunk, are conferenced, then sent out to other external parties across an IP trunk)	Avoid conference calls where at least two other parties are on the other side of the IP trunk. **NOTE:** The following conferences work OK: ■ Conferences of parties on the local DEFINITY ECS ■ Conferences controlled by the local DEFINITY ECS, involving local parties and only 1 party on the other side of an IP trunk
DCS	Know limitations: ■ Auto Callback	Coordinate specific administration and between the IP trunk and DEFINITY ECS for any DCS functionality. Some limitations on routing flexibility may apply.
ISDN	IP trunking has no signalling capability.	ISDN not supported. This includes: ■ 10-digit number display ■ QSIG ■ Path replacement
Voice mail	Calls that have terminated at one location and then cover to a second site for voice mail coverage can have voice quality degradation.	Centralized voice mail through an IP network is not recommended.

Backing up to the PCMCIA disk

Table 9-407 details how to back up administration data for the IP trunk application to and restored from the local PCMCIA disk and the Ethernet port. Before backing up, be sure to shut down the application running on the circuit pack, following the procedures in the "Shutting down NT on the TN802" section.

Table 9-407. Backing up TN802 administration data

Step	Description	Comments
1.	Busyout circuit pack	At the DEFINITY ECS terminal type **busyout board UUCSS** (the address of the TN802 circuit pack) and press Enter.
2.	Backup administration TN802 to disk	At the Windows NT desktop, double-click on the **IP Trunk Backup Restore** icon. The IP Trunk Backup/Restore Utility screen appears.
3.	Select utility	In the IP Trunk Backup/Restore Utility dialog screen, click on **Files, Backup**. The IP Trunk Backup screen appears.
4.	Select backup	In the IP Trunk Backup screen, click on the **Backup** button
5.	Wait	Backup can take as much as 20 minutes to complete.
6.	Release circuit pack	At the DEFINITY ECS terminal type **release board UUCss** (the address of the TN802 circuit pack) and press Enter.

NOTE:
Local restore of a complete system from the PCMCIA disk should not require more than 20 minutes assuming that a replacement MAPD pack is available and pre-loaded with the IP trunk application software.

Restoring data from the PCMCIA disk

Before you start

1. Shut down the application running on the circuit pack. See "Shutting down NT on the TN802".
2. Remove the defective IP Trunk circuit pack from the switch (if applicable).
3. Install the replacement IP Trunk circuit pack in the switch (if applicable).
4. Insert the backup diskette into the IP Trunk circuit pack.

Table 9-408. Restore TN802 administration data

Step	Description	Comments
1.	Restore IP Trunk administration	At the Windows NT desktop, double-click on the IP Trunk Back UP Restore icon. The IP Trunk Backup/Restore Utility screen appears.
2.	Select utility	In the IP Trunk Backup/Restore Utility dialog screen, click **Files, Restore**. The IP Trunk Backup screen appears
3.	Select restore	In the IP Trunk Backup screen, click on the **Restore** button.
4.	Wait	Wait until the yellow Disk-In-Use LED (Note 5 in Figure 9-52) light is out.

PSTN fallback feature

The Public Switched Telephone Network (PSTN) fallback feature is available on the Internet trunk application software, which periodically pings the remote destinations that the software calls. When the far end returns a poor response time to the ping, DEFINITY's ARS or AAR network routing patterns bypass those ports and direct the call to another port, typically on a PSTN trunk.

When the remote destinations show acceptable response times to subsequent pings, the corresponding ports are returned to "idle," where they are available for service.

Cabinet configuration

Because of overheating, the TN802 circuit pack should not be placed directly above or below another MAPD circuit pack.

UPS protection

Because Windows NT is more vulnerable to damage from a power interruption than the DEFINITY ECS, uninterrupted power supply (UPS) protection is strongly recommended for systems using the TN802 circuit pack.

Faceplate

Figure 9-52 shows the TN802 faceplate.

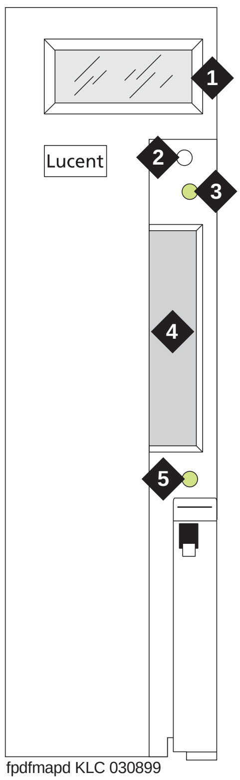

Figure Notes:

1. LCD display (see Table 9-409)
2. Reset button (recessed)
3. Red board status LED
4. PCMCIA card slot
5. Yellow PCMCIA disk-in-use LED

Figure 9-52. TN802 faceplate

Table 9-409 lists the TN802 LCD messages that you might see if installing or servicing an IP Trunk.

Table 9-409. TN802 LCD messages for IP trunks

Display	Explanation
PC BOOT	The TN802 MAPD PC is booting up.
IP TRK #	IP Trunk application is running (# character blinks)
IML DWN #	Internal error on the IP Trunk. System shuts down and sends and error message to the board.
MSHUT # where both MSHUT and # are blinking	The system is in the process of shutting down due to a front panel button press. DO NOT attempt to remove board.
MSHUT #, where # is blinking	The system has shut down gracefully.

Support for laptop PCs

Field technicians can access the TN802 circuit pack through:

1. "pcANYWHERE® client software"
2. "Directly-connected keyboard, monitor, and mouse"

pcANYWHERE® client software

1. Attach a male-to-male serial cable and a NULL modem connector (if not built into the cable you use) to the COM2 connector (Note 8 in Figure 9-53) Attach the other end to the serial port of your laptop.
2. Launch the pcANYWHERE® application.
3. Click on Add Remote Control Item.
4. In the Properties window, choose the communication port to which you connected the cable in Step 1.

5. Click on Details and configure the settings (Table 9-410):

Table 9-410. Remote connection settings

Field	Value
`Speed`	38,400
`Parity`	None (default)
`Flow Control`	RTS/CTS
`Started by`	Carrier detect (DCD)
`Ended by`	Carrier detect (DCD)

6. Click on the new item icon and the laptop connects to the host pcANYWHERE® application on the TN802 circuit pack.

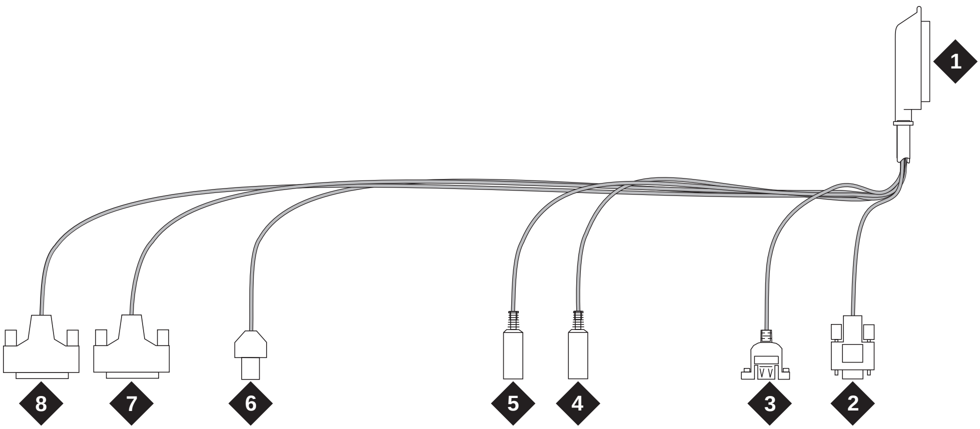

Figure Notes:

1. To TN802 cabinet backplane
2. VGA monitor
3. USB (Universal Serial Bus)
4. Keyboard
5. Mouse
6. Ethernet
7. 25-pin modem connection
8. 25-pin COM2 connection

Figure 9-53. TN802 external cable assembly

Directly-connected keyboard, monitor, and mouse

NOTE:
You need 2 power sources for the monitor and the modem in order to complete this procedure.

NOTE:
The TN802 circuit pack must be booted with a local mouse and keyboard connected to it for these devices to work.

1. Connect the VGA monitor to the VGA connector of the TN802 external cable.
2. Plug the monitor into an AC power receptacle, and turn it on.
3. Attach the keyboard to the keyboard connector of the TN802 external cable assembly.
4. Attach the mouse to the mouse connector of the TN802 external cable assembly.
5. Insert the circuit pack to cause it to boot.

Troubleshooting LAN connections

This section contains information for troubleshooting

- "External connections to the LAN"
- "Internal connections to the LAN"

External connections to the LAN

Test the external connections to the LAN by pinging the

- local host
- external IP trunk server
- another device connected to the network:

1. Click Start in Windows (lower lefthand corner), then select Programs, then Command Prompt.

   This starts a DOS command line session.

2. At the command prompt, type **ping 127.0.0.1** (the local host default address) and press Enter.

   If configured correctly, the system displays:

   ```
   Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###
   ```

If there is no reply:

a. Escalate the problem or replace the circuit pack. The problem is not with the external network but within the circuit pack.

3. At the command prompt, type **ping *nnn.nn.nn.nn*** (the external IP trunk server address) and press Enter.

   If configured correctly, the system displays:

   `Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###`

   If there is no reply, verify the IP address and check the physical connections to and from the TN802 circuit pack.

4. At the command prompt, type **ping *nnn.nn.nn.nn*** (the IP address of another computer on the network) and press Enter.

   If configured correctly, the system displays:

   `Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###`

   If there is no reply

   a. Verify the IP address
   b. Check the physical connections to and from the TN802 circuit pack.
   c. Check the internal cables on the TN802 circuit pack (Notes 4 and 6 in Figure 9-55).
   d. Try pinging another device on the same subnet.
   e. Try pinging the gateway to the rest of the network from the subnet.
   f. Try pinging a device not on the local subnet but on the network or another subnet.

5. When finished, at the command prompt type **exit** and press Enter.

Internal connections to the LAN

Test the internal connections to the LAN by pinging the

- local host
- internal IP trunk server
- another device connected to the network:

1. Click Start in Windows (lower lefthand corner), then select Programs, then Command Prompt.

   This starts a DOS command line session.

2. At the command prompt, type **ping 127.0.0.1** (the local host default address) and press Enter.

   If configured correctly, the system displays:

   `Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###`

   If there is no reply:

   a. Check that the internal cables on the TN802 circuit pack (Notes 4 and 6 in Figure 9-55) have not worked loose.

   b. Otherwise, replace the circuit pack.

3. At the command prompt, type **ping 10.32.64.97** (the internal IP trunk server address) and press Enter.

   If configured correctly, the system displays:

   `Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###`

   If there is no reply:

   a. Check that the internal cables on the TN802 circuit pack (Notes 4 and 6 in Figure 9-55) have not worked loose.

   b. Otherwise, replace the circuit pack.

4. At the command prompt, type **ping 10.32.64.96** (the IP address of the internal Motorola MPC860 processor) and press Enter.

   If configured correctly, the system displays:

   `Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###`

   If there is no reply:

   a. Check that the internal cables on the TN802 circuit pack (Notes 4 and 6 in Figure 9-55) have not worked loose.

   b. Otherwise, replace the circuit pack.

5. Ping the gateway: at the command prompt, type **ping XX.XXX.XXX.XXX** (the IP address of the gateway) and press Enter.

6. When finished, at the command prompt type **exit** and press Enter.

Board assembly and cables

Figure 9-54 shows the circuit pack with the two additional boards connected through the side plane.

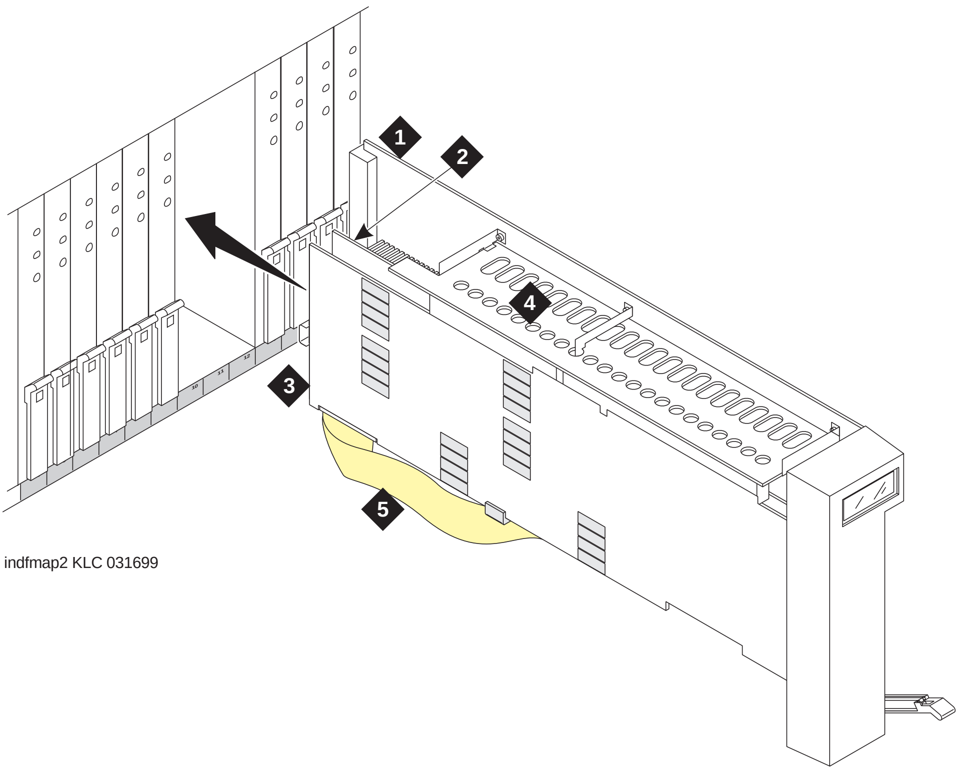

Figure Notes:

1. Main TN802 board
2. Texas Microsystems Inc. (TMI) board
3. Analogic board
4. Side plane
5. SCSA (Signal Computing System Architecture) ribbon cable

Figure 9-54. TN802 board assembly

Figure 9-55 shows a side view of the thee boards and interconnecting cables that make up the TN802.

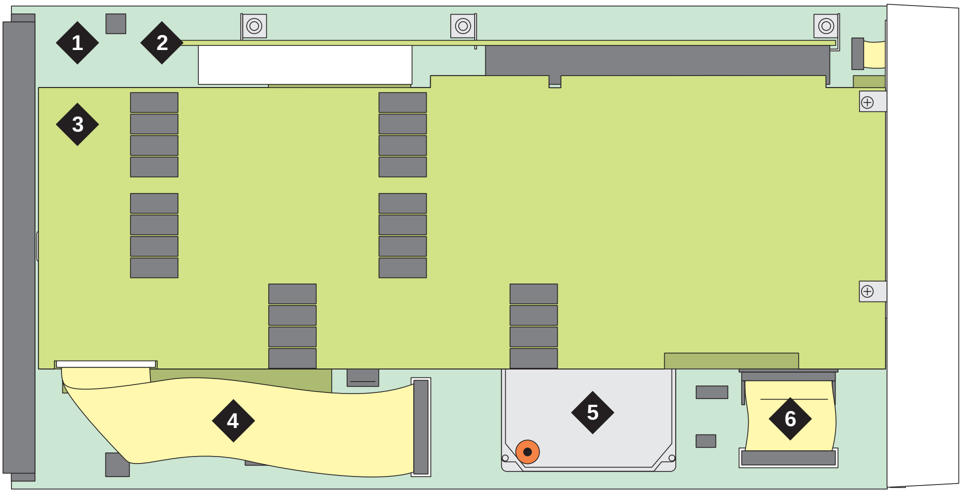

Figure Notes:

1. Main TN802 board
2. Side plane
3. Analogic board
4. SCSA (Signal Computing System Architecture) ribbon cable
5. Hard drive
6. Processor I/O ribbon cable

Figure 9-55. TN802 board assembly and cables (side view)

Figure 9-56 shows the end view of the thee boards and interconnecting cables on the TN802.

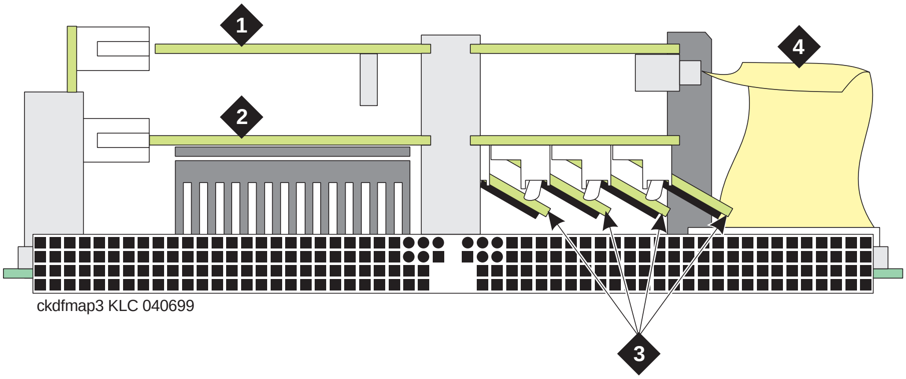

Figure Notes:

1. Analogic board
2. Texas Microsystems Inc. (TMI) board
3. SIMMs (memory)[1]
4. SCSA (Signal Computing System Architecture) ribbon cable

1. If the board is seated and you hear fast beeping, it means that one of the small boards containing the memory chips is dislodged. Secure the memory board firmly in the receptacle and reseat the circuit pack.

Figure 9-56. TN802 board assembly and cables (end view)

Replacing the hard disk

The TN802 hard drive (Note 5 in Figure 9-55) is field-replaceable.

Table 9-411. Replacing the TN802 hard drive

Step	Description	Comments
1.	Shut down NT	Shut down Windows NT by either method described in the "Shutting down NT on the TN802" section.
2.	Remove the circuit pack	Unlatch the circuit pack and remove it from the carrier.

Continued on next page

Table 9-411. Replacing the TN802 hard drive — *Continued*

Step	Description	Comments
3.	Remove the hard drive	Remove the 2 screws and lift the hard drive out of its mounting bracket.
4.	Replace the hard drive	Position the new hard drive in the mounting bracket and replace the 2 screws (Step 3).
5.	Replace the circuit pack	Slide the circuit pack into the slot and lock the latching lever.
6.	Wait for initialization	Wait for ■ the circuit pack to reseat (faceplate LEDs light then go out ■ Windows NT boots (PC BOOT displays on the faceplate LCD) ■ IP Trunk application to run (IP TRK # displays on the faceplate LCD)

Error Log Entries and Test to Clear Values

Table 9-412. MAPD (TN802) Error Log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS
1 (a)	0	Circuit pack removed or SAKI Test (#53)	MIN/ WRN[2]	ON	
2 (b)					
18 (c)	0	busyout board UUCSS	WRN	OFF	release board UUCSS
257 (f)	Any	None			
513 (g)	Any		MIN/ WRN[3]	ON	
514 (h)	46086		MIN/ WRN[3]	ON	
769 (i)	46085		MIN/ WRN[3]	ON	
770 (j)	46096		MIN/ WRN[3]	ON	
1025 (d)	4363	NPE Audit Test (#50)			
1281	Any	Loss of Signal Alarm Inquiry Test (#138)	MIN/ WRN[3]	OFF	test board UUCSS
1537 (k)	46082		MIN/ WRN[3]	ON	
1538 (l)	Any		MIN/ WRN[3]	ON	
1793	Any	Blue Alarm Inquiry Test (#139)	MAJ/ MIN/ WRN [3]	OFF	test board UUCSS
2049	Any	Red Alarm Inquiry Test (#140)	MIN/WRN[3]	OFF	test board UUCSS
2305	Any	Yellow Alarm Inquiry Test (#141)	MIN/ WRN[3]	OFF	test board UUCSS
2306	Any	Yellow Alarm Inquiry Test (#141)	MIN/ WRN[3]	OFF	test Board UUCSS

Continued on next page

Table 9-412. MAPD (TN802) Error Log entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
2561	Any	Major Alarm Inquiry Test (#142)	MIN/ WRN[3]	OFF	test board UUCSS
2817		Minor Alarm Inquiry Test (#143)	MIN/ WRN[3]	OFF	test board UUCSS
3073 to 3160 (m)	Any	Slip Alarm Inquiry Test (#144)	MIN/ WRN[3]	OFF	test board UUCSS r 6
3330 (n)	4608 3		MIN/ WRN[3]	ON	
3585 to 3601 (o)	Any	Misframe Alarm Inquiry Test (#145)	MIN/ WRN[3]	OFF	test board UUCSS r 6
3840 (p)	Any	None			
3841 (q)	4358				
3842 (r)	4609 7				
3843 (s)	4608 1				
3999 (t)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.
3. Major alarms on this MO may be downgraded to minor or warning alarms based on values set in the **set options** command.

Notes:

a. Error Type 1: indicates that the circuit pack has totally stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI Test (#53) fails.

   To be fully administered, a MAPD circuit pack must meet all of these conditions:

   - Have an entry in the circuit plan (**change circuit pack**)
   - Be administered (**add ds1 UUCSS**)
   - Be physically inserted into the correct slot

   If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error, either:

   1. Make sure the circuit pack is properly administered and that a functioning MAPD circuit pack is inserted in the correct slot, OR
   2. Completely remove the MAPD-BD from the system:
      a. Shut down NT (see "Shutting down NT on the TN802")
      b. Remove any administered DS1 trunks, access endpoints, or PRI endpoints associated with the circuit pack from their respective trunk groups.
      c. Remove the DS1 (**remove ds1 UUCSS**) and circuit pack (**change circuit pack UUCSS**) administration.

   If the circuit pack is properly administered and the red LED is still on, follow the instructions for LED Alarms with Error Type 1 in Chapter 7.

b. Error Type 2: NT is down and the system attempts to reset the board. If the reset fails, the board is probably bad.

   1. Replace the circuit pack.

c. Error Type 18: the circuit pack has been busied out.

   1. Release the board (**release board UUCSS**).

d. Error Type 23 and 1025: the MAPD-BD circuit pack is not completely administered. In addition to insertion, the MAPD circuit pack must have all of the following administration:

   - Have an entry in the circuit plan (**change circuit pack**)
   - Be administered as DS1 (**add ds1 UUCSS**)

   The MAPD circuit pack differs from others in that inserting it into the switch backplane is not enough to make the board usable.

e. Error Type 125, no Aux Data: A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either:

   1. Remove the wrong circuit pack and insert the logically administered circuit pack, OR
   2. Re-administer this slot (**change circuit-pack**) to match the circuit pack inserted.

f. Error Type 257: this error is associated with the Common Port Circuit Pack Maintenance Test. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for details.

g. Error Type 513: transient hardware problem.

   Aux Data:

4352	External RAM failure
4353	Internal RAM failure
4355	Internal ROM failure

   1. If the same Error Type/Aux Data value occurs more than once in a 24 hour period, the circuit pack should be replaced. See "Shutting down NT on the TN802" before removing the circuit pack.

   If the MAPD board detects only one of these hardware problems, then the error is resolved when none of these faults are detected for 10 minutes.

h. Error Type 514: LAN External RAM Error; hardware fault in the PPE external RAM, used for message buffering to and from the Packet Bus. This error should not occur regularly.

   1. If this error occurs 10 times within 30 minutes, replace the circuit pack. See "Shutting down NT on the TN802" before removing the circuit pack.

i. Error Type 769: Transmit FIFO Underflow (threshold is 3 errors within 10 minutes); the circuit pack cannot find the "end of frame" bit when transmitting a frame to Packet Bus.

   1. Clear the alarm using the following command sequence:
      a. busyout board UUCSS
      b. reset board UUCSS
      c. test board UUCSS long clear
      d. release board UUCSS
   2. If the error recurs within 10 minutes, replace the circuit pack. See "Shutting down NT on the TN802" before removing the circuit pack.

j. Error Type 770: unable to Write LAN Translation RAM (threshold is 2 errors within 10 minutes); a call is aborted because there are no available translation RAM locations for the call connection attempt.

1. Clear the alarm using the following command sequence:

   a. **busyout board UUCSS**

   b. **reset board UUCSS**

   c. **test board UUCSS long clear**

   d. **release board UUCSS**

2. If the error recurs within 10 minutes, replace the circuit pack. See "Shutting down NT on the TN802" before removing the circuit pack.

k. Error Type 1537: LAN Bus Timeout; the circuit pack transmitted too many bytes on the LAN bus for a single frame. This condition may be caused by:

- an on-board fault
- faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those maintenance objects.

If the error occurs 3 times within 10 minutes, the system raises the board alarm and isolates it from the Packet Bus.

1. Clear the alarm and restore the board to the Packet Bus using the following command sequence:

   a. **busyout board UUCSS**

   b. **reset board UUCSS**

   c. **test board UUCSS long clear**

   d. **release board UUCSS**

2. If the problem persists, and there are no PKT-BUS alarms or port alarms, then replace the circuit pack. See "Shutting down NT on the TN802" before removing the circuit pack.

l. Error Type 1538: hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

- The common circuit pack tests (for example, Test #50 and/or Test #52) abort with Error Code 2000.
- Port tests on this circuit pack return NO-BOARD.
- A busyout/release of the circuit pack has no affect on test results.
- A **list configuration** command shows that the circuit pack and ports are properly installed.

The circuit pack is isolated from the system and all trunks or ports on this circuit pack are placed into the out-of-service state. The system attempts to restore the circuit pack within 20-30 minutes. When no faults are detected for 20-30 minutes, the MAPD Interface circuit pack is restored to normal operation and all trunks or ports on the MAPD Interface circuit pack return to the in-service state.

1. If the board is not restored to normal operation, or the error recurs after the board is restored to normal operation, escalate the problem.

m. Error Type 3073 - 3160: board is reporting slip errors. Aux Data shows the last reported slip count.

n. Error Type 3330: LAN Critical error; critical failure in the Packet Bus interface to the circuit pack. This failure may be due to an on-board or a Packet Bus fault.

1. If the Packet Bus is alarmed, refer to the PKT-BUS Maintenance documentation for recommended repair procedures.
2. If the Packet Bus is not alarmed, clear the alarm and restore the board to the Packet Bus using the following command sequence:
   a. **busyout board UUCSS**
   b. **reset board UUCSS**
   c. **test board UUCSS clear**
   d. **release board UUCSS**
3. If the problem persists, and there are no PKT-BUS alarms, then replace the circuit pack. See “Shutting down NT on the TN802” before removing the circuit pack.

o. Error Type 3585 - 3601: the board received misframe errors; the Aux Data shows the last reported misframe count.

p. Error Type 3840: the circuit pack received a bad control channel message from the switch. This error is not service-affecting, and requires no action. The Aux Data describes the following error events:

4096	Bad major heading
4097	Bad port number
4098	Bad data
4099	Bad sub-qualifier
4100	State inconsistency
4101	Bad logical link

q. Error Type 3841: the circuit pack detected a transient hardware logic error (for example, program logic inconsistency). This error resolves when no faults are detected for 100 minutes. The value in Aux Data field (4358) indicates the type of hardware problem.

r. Error Type 3842: Bad Translation RAM Location Found error; the call continues by using another translation location. This error is not service-affecting and requires no action.

s. Error Type 3843: LAN Receive Parity error; the circuit pack detected an error in a received frame from the Packet Bus. These errors are most likely caused by a Packet Bus problem, but may be due to a circuit pack fault.

   1. Determine whether the problem is isolated to this circuit pack or if the problem is caused by Packet Bus faults (see PKT-BUS).

t. Error Type 3999: the circuit pack sent a large number of control channel messages to the switch within a short period of time.

Error Type 1538 (hyperactivity) also present?	Then the switch:
Y	Takes the circuit pack out-of-service due to hyperactivity
N	Does not take the circuit pack out-of-service, but the circuit pack has generated 50% of the messages necessary to be considered hyperactive. This may be normal during heavy traffic periods.

Shutting down NT on the TN802

Before removing the TN802 circuit pack from the carrier, shut Windows NT™ down first by *following either procedure* described in Table 9-413:

Table 9-413. Windows NT shutdown procedures

Step	Faceplate button	PC interface
1.	Push the recessed button on the front faceplate and hold it in.	Click on the “Start” button in the lower, lefthand corner.
2.	“M shut” flashes on the LCD display	Click on “Shut Down.”
3.	When shutdown is complete, “MSHUT #” displays (“#” is blinking).	Choose the “Shut down the computer?” radio button.
4.	Remove the circuit pack.	Click on “OK.”
5.		Wait for the message indicating that shutdown is complete.
6.		Remove the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Investigate tests in the order they are presented in Table 9-414. By clearing error codes associated with the NPE Connection Audit Test, for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-414. System Technician-Demanded Tests

Order of Investigation	Apply to TN802?[1]	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[2]
NPE Connection Audit Test (#50)	Y		X		ND
Control Channel Loop Test (#52)	Y		X		ND
Loss of Signal Alarm Inquiry Test (#138)	N	X	X		ND
Blue Alarm Inquiry Test (#139)	N	X	X		ND
Red Alarm Inquiry Test (#140)	N	X	X		ND
Yellow Alarm Inquiry Test (#141)	N	X	X		ND
Major Alarm Inquiry Test (#142)	N	X	X		ND
Minor Alarm Inquiry Test (#143)	N	X	X		ND
Slip Alarm Inquiry Test (#144)	N	X	X		ND
Misframe Alarm Inquiry Test (#145)	N	X	X		ND
Translation Update Test (#146)	N	X	X		ND
SAKI Sanity Test (#53)	Y			X	D

1. N = No; this test either passes or ABORTS with Error Code 2000 (problem with NT)
2. D = Destructive; ND = Nondestructive

NPE Connection Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for the SCOTCH-NPE chip on the circuit pack.

Table 9-415. TEST #50 NPE Connection Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1019	ABORT	The test aborted because a test was already running on the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The circuit pack's SCOTCH-NPE chip has been updated with its translation.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the MAPD interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board re-initializes the board. 3. If the board was found to be correctly inserted in Step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Control Channel Looparound Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 9-416. TEST #52 Control Channel Looparound Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The circuit pack failed to return the circuit pack code or vintage. 1. Retry the command a maximum of 5 times. 2. If the problem continues, and if the circuit pack is one of the Port circuit packs, replace the circuit pack. 3. Otherwise, if the circuit pack is part of the SPE, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	Communication with this circuit pack is successful.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the MAPD interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board re-initializes the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack. The test is highly destructive and can only be initiated by a system technician-demanded **reset board UUCSS** command.

Table 9-417. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack (**busyout board UUCSS**). 2. Execute the **reset board** command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times.
1 2	FAIL FAIL	The circuit pack failed to reset. The circuit pack failed to restart. 1. Execute the **reset board** command again. 2. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.

Continued on next page

Table 9-417. TEST #53 SAKI Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the MAPD interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board re-initializes the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Loss of Signal Alarm Inquiry Test (#138)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-418 details the test results.

Table 9-418. Loss of Signal Inquiry Test (#138) results

Windows NT up on the TN802?	Then	Cause
Y	Test passes	
Y	Test aborts with ABORT 2000 Error Code.	Windows NT is not communicating with the angel firmware.
N	Test aborts with ABORT 2000 Error Code.	Windows NT down.

Blue Alarm Inquiry Test (#139)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-419 details the test results.

Table 9-419. Blue Alarm Inquiry Test (#139) results

Windows NT up on the TN802?	Then	Cause
Y	Test passes	
Y	Test aborts with ABORT 2000 Error Code.	Windows NT is not communicating with the angel firmware.
N	Test aborts with ABORT 2000 Error Code.	Windows NT down.

Red Alarm Inquiry Test (#140)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-420 details the test results.

Table 9-420. Red Alarm Inquiry Test (#140) results

If Windows NT is up on the TN802	When the switch confirms Red alarm:
Y	Test passes
N	Test aborts with ABORT 2000 Error Code.

Yellow Alarm Inquiry Test (#141)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-421 details the test results.

Table 9-421. Yellow Alarm Inquiry Test (#141) results

If Windows NT is up on the TN802	When the switch confirms Yellow alarm:
Y	Test passes
N	Test aborts with ABORT 2000 Error Code.

Major Alarm Inquiry Test (#142)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-422 details the test results.

Table 9-422. Major Alarm Inquiry Test (#142) results

If Windows NT is up on the TN802	When the switch confirms Major alarm:
Y	Test passes
N	Test aborts with ABORT 2000 Error Code.

Minor Alarm Inquiry Test (#143)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-423 details the test results.

Table 9-423. Minor Alarm Inquiry Test (#142) results

If Windows NT is up on the TN802	When the switch confirms Minor alarm:
Y	Test passes
N	Test aborts with ABORT 2000 Error Code.

Slip Alarm Inquiry Test (#144)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-424 details the test results.

NOTE:
The query for slips always returns a 0 count.

Table 9-424. Slip Alarm Inquiry Test (#144) results

If Windows NT is up on the TN802	When the switch confirms Slip alarm:
Y	Test passes
N	Test aborts with ABORT 2000 Error Code.

Misframe Alarm Inquiry Test (#145)

This test is meaningless for the TN802 MAPD circuit pack. Table 9-425 details the test results.

NOTE:
The query for misframes always returns a 0 count.

Table 9-425. Misframe Alarm Inquiry Test (#145) results

If Windows NT is up on the TN802	When the switch confirms Misframe alarm:
Y	Test passes
N	Test aborts with ABORT 2000 Error Code.

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information to the MAPD Interface circuit pack. Translation includes the following data administered for a MAPD Interface circuit pack (report from **display ds1 UUCSS** command):

- DS1 Link Length between two DS1 endpoints
- Synchronization Source Control
- All Zero Suppression
- Framing Mode
- Signaling Mode
- Time Slot Number of the 697-Hz tone
- Time Slot Number of the 700-Hz tone

Table 9-426. TEST #146 Translation Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute interval s a maximum of 5 times.
	FAIL	Internal system software error. 1. Verify the MAPD Interface circuit pack translation (**display ds1 UUCSS**).

Continued on next page

Table 9-426. TEST #146 Translation Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Translation data has been downloaded to the MAPD Interface circuit pack successfully.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the MAPD interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board re-initializes the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

MEDPRO (Media Processor MAPD Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MEDPRO	MAJOR	test board UUCSS sh	Media Processor MAPD Circuit Pack
MEDPRO	MINOR	test board UUCSS l	Media Processor MAPD Circuit Pack
MEDPRO	WARNING	test board UUCSS sh	Media Processor MAPD Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The TN802B MedPro circuit board is used by the DOLAN (Definity on the LAN) feature to provide voice over IP connectivity. The TN802B can run either:

- R8.1 IP Trunk application — allows the TN802B to emulate a DS1 circuit pack. In this mode, the circuit pack is maintained as a standard DS1 board with its associated Tie trunk ports. The TN802B operates as an integrated Internet Telephony Server. It communicates with other ITS boxes or IP trunk boards.
- the Media Processor (MedPro) application — allows the TN802B to act as a service circuit to terminate generic RTP streams used to carry packetized audio over an IP network. As part of the overall H.323 implementation, the TN802B or later circuit pack handles the audio streams while the TN799 C-LAN handles the TCP/IP signaling channels. This maintenance plan applies only to a TN802B MedPro running the Media Processor application.

The MedPro hardware combines an angel complex, a Windows NT PC and a TAP802 DSP card in a 3-slot package. When operating as an IP trunk circuit pack, the MedPro emulates a DS1 Tie Trunk circuit pack and blindly responds to DS1 trunk maintenance requests. Actual maintenance is accomplished via the windows NT interface and the ITS software diagnostics.

The Media Processor application is built upon the existing ITS software, and as such is not administered in DEFINITY as a DS1 trunk, and does not emulate a DS1 for maintenance purposes. Use the following Maintenance procedures for this application.

Error Log Entries and Test to Clear Values

Table 9-427. DS1 Interface Circuit Pack Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS
1(a)	0	Circuit pack removed or SAKI Test (#53)	MIN/WRN[2]	ON	
18(b)	0	busyout board UUCSS	WARNING	OFF	release board UUCSS
23(c)	0		WARNING	OFF	add ds1 UUCSS
125(d)	None	None	MIN/WRN[3]	ON	
257(e)	65535	Control Channel Loop Test (#52)	MINOR	ON	test board UUCSS l r 2
257(e)	Any	None			
1538	Any	Hyper activity	MIN/WRN[3]	ON	
1793	Any	NIC Los Of Signal	MIN/WRN[3]		test board UUCSS l r 2
2049(f)	Any	NT PC Failure	MIN/WRN[3]		reset board UUCSS
2305	Any	IP Address Inconsistency			test board UUCSS l r 2
2561	Any	Ping Error	MIN/WRN[3]		test board UUCSS l r 5
3841(g)	4358		Log Only		
3999(h)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.
3. Minor alarms on this MO may be downgraded to warning alarms based on values set in the **set options** command.

Notes:

a. **Error Type 1** -This error indicates that the circuit pack has totally stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11-minutes after the SAKI Test (#53) fails.

To be fully administered, a MedPro circuit pack must meet *all of these 4 conditions*:

1. Have an entry in the circuit pack form (**change circuit pack**)
2. Have the MedPro ip address administered (**change node-names**)
3. Be enabled (**change ip-interface**)
4. Be physically inserted into the correct slot

If the circuit pack has an entry in the circuit packform and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

1. Make sure all conditions for administration are met and that a functioning MedPro circuit pack is inserted in the correct slot

   OR

2. Completely remove the MedPro from the system using the following steps:
   a. Remove the administered IP-Interface associated with the circuit pack.
   b. Physically remove the circuit pack from the slot.
   c. Execute the **remove medpro UUCSS** and **change circuit pack UUCSS** commands.

b. **ErrorType 18** -The MedPro Interface circuit pack has been busied out by a **busyout board UUCSS** command.

   1. Release the circuit pack (**release board UUCSS**).

c. **Error Type 23** -The MedPro circuit pack is not completely administered. To be fully administered, a MedPro circuit pack must meet *all of these 4 conditions*:

   1. Have an entry in the circuit plan (**change circuit pack**)
   2. Have the MedPro IP address administered (**change node-names**)
   3. Be enabled (**change ip-interface**)
   4. Be physically inserted into the correct slot.

   A DS1 (MEDPRO, MAPD, UDS1-BD and DS1-BD) differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered.

d. **Error Type 125 -** no Aux Data: The wrong circuit pack is inserted in the slot where this circuit pack is logically administered.

   1. Remove the wrong circuit pack and insert the logically administered circuit pack

      OR

   2. Re-administer this slot to match the circuit pack inserted (**change circuit-pack**).

e. **Error Type 257** - this error is associated with the Common Port Circuit Pack Maintenance Test. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for details.

f. **Error Type 2049 -** This error indicates that the operating system is down; an attempt is made to reset the board automatically. If the reset fails, the board is probably bad and should be replaced.

g. **Error Type 3841 -** inconsistent downlink message. This error is not service-affecting. No action is required.

h. **Error Type 3999 -** indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If Error Type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If Error Type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Investigate tests in the order they are presented in Table 9-414. By clearing error codes associated with the *Control Channel Loop Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-428. System Technician-Demanded Tests

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Control Channel Loop Test (#52)		X		ND
SAKI Sanity Test (#53)			X	D
IP Address Query (#1371)	X	X		D
NIC Query Test (#1383)	X	X		ND
PING Test (#1379)	X	X		ND
NT Reset Test (#1381)			X	D

1. D = Destructive; ND = Nondestructive

Control Channel Looparound Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 9-429. TEST #52 Control Channel Looparound Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The circuit pack failed to return the circuit pack code or vintage. 1. Retry the command a maximum of 5 times. 2. If the problem continues, and if the circuit pack is one of the Port circuit packs, replace the circuit pack. Otherwise, if the circuit pack is part of the SPE, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5. 3. Retry the command a maximum of 5 times.
	PASS	Communication with this circuit pack is successful.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Administer the MedPro interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board re-initializes the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board UUCSS** command. 4. Issue the **reset board UUCSS** command. 5. Issue the **release board UUCSS** command. 6. Issue the **test board UUCSS long** command. This should re-establish the linkage between the internal ID and the port.

SAKI Sanity Test (#53)

This is a destructive test.

This test is only run as a part of a reset board procedure. For the Media Processor, it is necessary to use the **change ip-interfaces** form to disable the Media Processor IP interface before performing this reset board procedure. Other common circuit packs can be reset with the **reset board UUCSS** command which also executes this test.

A reset of this circuit pack will take about 3 1/2 minutes.

Table 9-430. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Port is not out-of-service. 1. Busy out the circuit pack. 2. Execute command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2803	ABORT	It is necessary to reset the board. 1. Use the change ip-interfaces form to disable the Media Processor IP interface. 2. Execute the command again.
1	FAIL	The circuit pack failed to reset.
2	FAIL	The circuit pack failed to restart. 1. Execute command again. 2. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the short test sequence.
Any	NO BOARD	This is normal if the test is being done when (a) the board is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the board is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at 1-minute intervals for a maximum of 5 times.

IP Address Query Test #1371

This test is destructive.

The Media Processor has two interfaces for configuring the board, through the NT PC interface and the SAT via CCMS messages. For R8 DoLAN, the SAT and CCMS are the only approved interface. However, the NT PC interface cannot easily be disabled. It is possible that changes can be made via the NT PC interface that cause the Media Processor board to be inconsistent with DEFINITY translation. The area of concern is the IP address, subnet mask, and gateway translation.

This test sends the Media processor the IP address, subnet mask, and gateway translation (IP parameters). If the parameters do not match DEFINITY translation, the new values are written into the Windows registry, and the NT PC asks the maintenance sub-system to reboot the board. The board goes through a physical board removal and insertion.

When this test fails, it is an indication that an illegal change was made and the customer should be notified. Also, writing the IP address parameters to the registry requires NT to reboot. If the IP addresses match, there is no need to update the registry and reboot NT

Table 9-431. TEST #1371 IP Address Query Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The IP address, subnet mask, and gateway translation parameters do not match DEFINITY translations. After the new values are written into the Windows registry, the NT PC must go through a reboot. The board goes through a physical board removal and insertion. 1. If the problem persists, replace the circuit pack.
	PASS	Translation data matches the Windows Registry.

Ping Test (#1379)

This test is non-destructive

This test verifies that the MedPro circuit pack can communicate to other nodes on the LAN.

This test pings the gateway IP address as defined on the IP Interface form.

If the PING is successful, this test looks at the PING round trip delay. If a round trip delay of greater than 4 seconds is reported, a separate error is logged. Excessive round trip delays do not take the MedPro out of service.

Services can execute the standard PING command using the C-LAN board address and MedPro IP address to see the actual round-trip delay. (See **ping** commands).

This test is a nondestructive test. It runs due to in-line errors, during periodic and schedule maintenance, and on demand.

Table 9-432. TEST #1379 Ping Test

Error Code	Test Result	Description/ Recommendation
1, 2	ABORT	Internal Error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
7	ABORT	Destination unreachable. 1. Verify that at least one destination reachable through this port is up. 2. Repeat the test. 3. If the test still aborts, escalate the problem.
2000	ABORT	Response to the test was not received from the Media Processor circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack. Reset the circuit pack by issuing the **busyout board UUCSS** and the **reset board UUCSS** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	The necessary system resources to execute the test could not be allocated. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-432. TEST #1379 Ping Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2801	ABORT	No IP address defined. Verify IP Interfaces translations and retest.
2802	ABORT	Different IP address pinged than software had allocated for the test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2805	FAIL	The number of pings received did not match the number sent (normally one ping sent). This means that no ping responses were received from the gateway defined on the ip-interfaces form for the Media Processor. 1. Retry the command at 1-minute intervals a maximum of 3 times.
7, 89, 1007	FAIL	Ping to the destination failed through this port due to the destination down. 1. Verify that at least one destination reachable through this port is up. 2. Once verified, execute **test port UUCSSpp** command to verify that the H.323 Signaling Group Ping Test (#1387) passes.
	PASS	Ping through this port successful.

NT Reset Test (#1381)

This test is destructive.

This test resets the circuit pack. The test is highly destructive and can only be initiated by a system technician-demanded **reset board UUCSS** command.

Table 9-433. TEST #1381 NT Reset Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the **reset board UUCSS** command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack (**busyout board UUCSS**). 2. Execute the **reset board UUCSS** command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the **reset board UUCSS** command at 1-minute intervals a maximum of 5 times.
1 2	FAIL FAIL	The circuit pack failed to reset. The circuit pack failed to restart. 1. Execute the **reset board UUCSS** command again. 2. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Administer the MEDPROMEDPRO interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board re-initializes the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board UUCSS** command. 4. Issue the **reset board UUCSS** command. 5. Issue the **release board UUCSS** command. 6. Issue the **test board UUCSS long** command. This should re-establish the linkage between the internal ID and the port.

NIC Query Test (#1383)

This test is non-destructive.

This test passes if the Ethernet port is connected and you can talk on the network. Otherwise it fails with no fail code or AUX data.

Table 9-434. TEST #1383 NIC Query Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack (**busyout board UUCSS**). 2. Execute the command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Ethernet port is not connected and you cannot talk on the network.
	PASS	The Ethernet port is connected and you can talk on the network
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Administer the MedPro interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board re-initializes the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board UUCSS** command. 4. Issue the **reset board UUCSS** command. 5. Issue the **release board UUCSS** command. 6. Issue the **test board UUCSS long** command. This should re-establish the linkage between the internal ID and the port.

MEDPROPT (TN802 MED PRO DSP PORT)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
MEDPROPT	MINOR/WARNING	test port UUCSS or PCSS [short/long] [repeat#] | [clear]	TN802 MED PRO DSP PT

The MEDPROPT maintenance object monitors the health of the MEDPRO digital signal processors (DSPs).

The TN802B MAPD (Multi-Application Platform for DEFINITY) Media Processor circuit pack provides the audio bearer channels for H.323 voice over IP calls. One TN802B circuit pack has one MEDPROPT media processing resource. Based on system administration of audio codecs, a MEDPROPT can handle either 31 or 22 simultaneous channels of H.323 audio processing. If the **ip-parameters** form specifies only G.711 Mulaw or G.711 Alaw as the audio codecs, the MEDPROPT can service 31 channels. If any other codec type (G.723-5.3K, G.723-6.3K, or G.729) is administered, the MEDPROPT can only service 22 channels.

The MEDPROPT is physically made up of 11 individual DSPs, but is treated logically as one port. If individual DSPs on the TN802B MAPD fail, the MEDPROPT remains in-service at lower capacity.

The MEDPROPT is a shared service circuit. It is shared between H.323 trunk channels and H.323 stations. An idle channel is allocated to an H.323 trunk/station on a call-by-call basis.

Error Log Entries and Test to Clear Values

Table 9-435. MEDPROPT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCCSS
1(a)		DSP Capacity Test (#1382)		ON	test board UUCCSS l r5
258(b)		DSP Capacity Test (#1382)	WARNING	ON	test board UUCCSS l r5

Continued on next page

Table 9-435. MEDPROPT Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
515(c)		DSP Capacity Query Test (##1382)	MINOR	ON	test board UUCCSS l r5
18(d)	0	busyout port UUCSS	WARNING	OFF	release port UUCCSS
769	Any	TDM NIC Looparound Test (#1380)	MIN	ON	test port UUCCSS l r10

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. **Error Type 1** - this error type indicates that less than three DSPs are out of service (OOS), and no alarm is raised. The Aux Data field contains the number of DSPs that are Out of Service (OOS).

b. **Error Type 258** - this error type indicates that more than three, but less than 9 DSPs are out of service (OOS), and a WARNING alarm is raised. The Aux Data field contains the number of DSPs that are Out Of Service (OOS).

c. **Error Type 515** - this error type indicates that all DSPs are out of service (OOS), and a MINOR alarm is raised. The Aux Data field contains the number of DSPs that are Out Of Service (OOS).

d. **Error Type 18** - the MEDPRO has been busied out by a **busyout port UUCSS** command.

    1. Release the port (**release port UUCSS**).

System Technician-Demanded Tests: Descriptions and Error Codes

Investigate tests in the order they are presented in Table 9-436. By clearing error codes associated with the *DSP Capacity Query Test,* for example, you may also clear errors generated from the other test in the testing sequence.

Table 9-436. System Technician-Demanded Tests

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	test ds1-loop	D/ND[1]
DSP Capacity Query (#1382)	X	X			ND
TDM NIC Looparound Test (#1380)	X	X			ND

1. D = Destructive; ND = Nondestructive

DSP Capacity Query Test (#1382)

This test is non-destructive

This test polls the circuit pack for the number of failed DSPs. If all DSPs are functional, the test passes and the board is operating at maximum capacity. If any DSPs have failed, the test fails and reports the number of failed DSPs.

A failure of 3 or fewer DSPs does not result in an alarm. A failure of more than 3 up to 8 DSPs results in a warning alarm. A failure of more than 8 DSPs results in a minor alarm. In all cases, except all DSPs failing, the MEDPROPT continues to provide reduced capacity.

Table 9-437. DSP Capacity Query Test (#1382)

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-437. DSP Capacity Query Test (#1382) — *Continued*

Error Code	Test Result	Description/ Recommendation
1-11	FAIL	Some DSPs on the circuit pack have failed. The FAIL code is the number of bad DSPs reported.
	PASS	All 11 DSPs are functioning and in-service.
0	NO BOARD	No board was detected by the test. 1. Check the Error Log for wrong board (Error Type 125) or no board (Error Type 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity. If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the circuit pack may be bad. Replace the circuit pack and retest.

TDM NIC Looparound Test (#1380)

This test is non-destructive

This test sets up a loopback path from the TDM bus out to the NIC edge of the Media processor and back to the TDM bus. The loopback is established by setting up the outbound IP connection to send IP packets to the MedPro's own IP address. The tone generator places a test tone (440Hz) onto a timeslot. The timeslot is listened to by the Media processor board. The tone is routed through the TAP802 DSP farm, where it may undergo transcoding to G.723, etc. The tone is looped back at the Network interface and back through the TAP802 where it is converted back into standard PCM. The tone is placed onto a TDM timeslot and detected by a tone detector port. The test passes if 440Hz is reported by the tone detector

Table 9-438. TDM NIC Looparound Test (#1380)

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 3 times. 2. If system has TDM-BUS errors, clear any errors, and retry the command at 1-minute intervals a maximum of 3 times. 3. If the command continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out of service. 1. Resolve any TTR-LEV errors. Even if there are no TTR-LEV errors, there may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. This does not harm the system. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
2000	ABORT	Response to the test was not received in the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-438. TDM NIC Looparound Test (#1380) — *Continued*

Error Code	Test Result	Description/ Recommendation
2801	ABORT	The TN802B Media Processor board has not been administered on the **ip-interfaces** form.
ANY	FAIL	The test did not detect the test tone through the looparound connection. 1. Test the tone-clock in the port network that contains the media processor under test. 2. If the tone-clock is healthy, test the media processor board again. 3. If the test continues to fail, replace the media processor board.
	PASS	The board is functioning properly.
0	NO BOARD	No board was detected by the test. 1. Resolve either wrong board (Error 125) or no board (Error 131) issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the NCE chip on board may be bad. Replace the board and retest.

MEM-BD (32MB Memory Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MEM-BD	MAJOR[2]	test memory UUCS l	32M Memory Circuit Pack
MEM-BD	MINOR	test memory UUCS s	32M Memory Circuit Pack
MEM-BD	WARNING		32M Memory Circuit Pack

1. UU is the cabinet number (always 1, not required). With simplex SPE, carrier designation is not required. With duplicated SPEs, carrier a or b must be specified. *S* is the number of the circuit pack slot (1 to 4 for Memory slots). If the slot number is *not* specified, all Memory circuit packs in the specified carrier will be tested.
2. After a spontaneous SPE interchange has occurred, the Alarm Log retains for three hours a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.

The memory circuit packs contain the system software which is executed after it is loaded from removable media or disk. The processor and the memory circuit packs form the most critical component for all system operation.

The processor must be able to access the memory for all system activity or the system will go into SPE-down mode. In SPE-down mode, fatal memory errors may show up as processor circuit pack errors.

Each memory circuit pack has 32 Mbytes of capacity. The SPE carrier(s) contain four dedicated slots for Memory circuit packs. Depending on its size, the system uses from two to four of these slots. Memory circuit packs must reside in contiguous slots, starting Memory slot one.

Each Memory circuit pack contains its own error detection and correction (EDC) circuit, parity checker and burst read function.

The EDC circuit operates by checking the contents of memory both as memory locations are accessed by the Processor and periodically by a built-in "scrubbing" function. The scrubbing function checks for errors through the entire Memory circuit pack every 111 seconds. It flags and corrects single-bit errors automatically and flags (but does not correct) multiple bit errors. If the EDC circuit fails, the Memory circuit pack will not be able to detect and correct single bit errors or detect and flag multiple bit errors. If a single or multiple bit error occurs, the system may not continue to operate correctly.

The Memory parity checker detects bad parity over the Processor Bus when any Bus Master writes memory. It also generates parity (for checking by the Processor) on Memory reads. If the parity checking logic fails, it will either generate errors when it shouldn't (a serious error condition that will probable result in SPE Down) or miss errors when present (less serious).

The burst read circuit supports a special, block read mode used by the Processor to quickly load program instructions into the Processor cache. Given a single starting address over the Processor Bus, the Memory transfers four words of data back to the Processor. This reduces the time it takes for the Processor to get instructions. Problems in this circuit may be due to the Memory circuit pack or Processor and will result in SPE Down.

If the PBX system is equipped with High Reliability or Critical Reliability option (i.e. with duplicated SPEs), and if a failure of the active Memory circuit pack causes a MAJOR on-board alarm, a SPE interchange will occur if the health of the standby SPE permits the interchange.

Error Log Entries and Test to Clear Values

Table 9-439. MEM-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test memory UUCS sh r 1
1		Memory RAM Checksum Test (#903)	MAJOR	OFF	test memory UUCS l r 1
3(a)		Memory RAM Checksum Test (#903)	MAJOR[2]	OFF	test memory UUCS l r 1
101(b)		none	WNG	OFF	
150(c)		none	MAJOR[2]	ON	test memory UUCS l c
257		Memory Parity Checker Test (#906)	MINOR	ON	test memory UUCS sh r 2
513	Any(d)	Memory Single Bit Errors (#902)	MINOR	ON	test memory UUCS l r 10
769		Memory Multiple Bit Errors (#902)	MAJOR[2]	ON	test memory UUCS l r 2
1025		Memory Error Detection/Correction Test (#907)	MINOR	ON	test memory UUCS sh r 1
1281		Memory Burst Read Test (#908)	MAJOR[2]	ON	test memory UUCS sh r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.

Notes:

a. This error (3) indicates that a software patch has been applied and either the software patch is bad or was installed incorrectly.

   1. Back out the software patch and run the **test memory UUCS long** command to verify that the problem has been cleared.

2. If the PBX system is equipped with High Reliability or Critical Reliability option (i.e. with duplicated SPEs), and this error occurs, a SPE interchange will occur if the health of the standby SPE permits the interchange.

b. This error (101) indicates that this Memory circuit pack is not required.

1. Remove the extra Memory circuit pack at the earliest convenience to resolve this alarm. To replace the Memory circuit pack, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5, ''Alarms, Errors, and Troubleshooting''.

c. This error (150) indicates that a SPE interchange has occurred and that the Memory circuit pack was the cause of the spontaneous interchange.

1. If other MEM-BD errors are present, investigate these errors.
2. If no other MEM-BD errors are present, run the **test memory UUCS long clear** command and investigate any test failure.

d. The aux data indicates the number of single bit errors detected since the last time the test was run.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Memory Single/Multiple Bit Error Audit*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Single/Multiple Bit Error Audit (#902)		X		ND
Memory Burst Read Test (#908)	X	X		ND
Memory Error Detection/Correction Test (#907)	X	X		ND
Memory RAM Checksum Test (#903)		X		ND
Memory Parity Checker Test (#906)	X	X		ND

1. D = Destructive, ND = Non-destructive

Memory Single/Multiple Bit Error Audit (#902)

This audit waits for the hardware scrubbing circuits in the Memory circuit packs to make a complete pass through Memory and reports any single or multiple bit errors that may have been found. If the **test memory a|b long** command is used, this test executes once for each equipped Memory circuit pack

Table 9-440. TEST #902 Memory Single/Multiple Bit Error Audit

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error. 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Memory circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the section on "STBY-SPE (Standby SPE Maintenance)" procedures for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected field* on the **status spe-standby** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Memory circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (handshake communication down). 1. Retry the command at 1-minute intervals, a maximum of 3 times.

Continued on next page

Table 9-440. TEST #902 Memory Single/Multiple Bit Error Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
2315	ABORT	The test was not run, because this is an extra Memory circuit pack. No testing is allowed for extra Memory circuit packs.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The audit detected one or more single or multiple bit errors on the indicated Memory circuit pack(s). 1. Retry the command. 2. If the test continues to fail, replace the affected Memory circuit pack. 3. If the test continues to fail after replacing the Memory circuit pack, replace the Processor circuit pack. To replace the circuit packs, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The Memory does not contain any single or multiple bit errors.

Memory RAM Checksum Test (#903)

This test computes the checksum of the system software text module. This test is only run when the Memory circuit pack in slot one is being tested. If this test fails, the RAM is corrupt. It does NOT indicate a hardware problem.

DO NOT REPLACE the Memory circuit pack when this is the only error or failing test.

For systems equipped with the Standard Reliability configuration, do a system restart (enter **reset system 4**) as soon as possible. For systems equipped with the High Reliability or Critical Reliability configuration, perform the following steps as soon as possible:

1. Busyout the standby SPE (enter **busyout spe-standby**).
2. Reboot the standby SPE (enter **reset spe-standby 4**).
3. Wait for the standby SPE to reboot (about 5 minutes).
4. Lock the standby SPE into active mode using the SPE-SELECT switches on the DUPINT circuit packs. This will cause the new active SPE to perform COLD reset and the new standby SPE will perform a reboot

Table 9-441. TEST #903 RAM Checksum Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error. 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Memory circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the section on "STBY-SPE (Standby SPE Maintenance)" procedures for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected field* on the **status spe-standby** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Memory circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (handshake communication down). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2315	ABORT	The test was not run, because this is an extra Memory circuit pack. No testing is allowed for extra Memory circuit packs.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.

Continued on next page

Table 9-441. TEST #903 RAM Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The system may or may not continue to operate correctly. The system may fail at some future date when some action requires access to the corrupted area of the RAM. For systems equipped with the Standard Reliability configuration: 1. Restart the system with a **reset system 4** and observe the startup memory tests (refer to Chapter 4, "Initialization and Recovery", for a list of tests). For systems equipped with the High Reliability or Critical Reliability configuration: 1. Busyout the standby SPE (enter **busyout spe-standby**). 2. Reboot the standby SPE (enter **reset spe-standby 4**). 3. Wait for the standby SPE to reboot (about 5 minutes). 4. Lock the standby SPE into active mode using the SPE-SELECT switches on the DUPINT circuit packs. This will cause the new active SPE to perform COLD reset and the new standby SPE will perform a reboot.
	PASS	The RAM checksum is correct.

Memory Parity Checker Test (#906)

This test checks the operation of the Memory circuit pack parity generators and checkers. If the **test memory a|b** command is used, this test executes once for each equipped Memory circuit pack

Table 9-442. TEST #906 Memory Parity Checker Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error. 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Memory circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the section on "STBY-SPE (Standby SPE Maintenance)" procedures for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected field* on the **status spe-standby** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Memory circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (handshake communication down). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2315	ABORT	The test was not run, because this is an extra Memory circuit pack. No testing is allowed for extra Memory circuit packs.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.

Continued on next page

Table 9-442. TEST #906 Memory Parity Checker Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Memory circuit pack cannot detect parity error conditions. If the test fails on all equipped Memory circuit packs, the Processor may be at fault. Run the tests described in the "PROCR (RISC Processor Circuit Pack)" section of this manual. 1. Retry the command. 2. If the test continues to fail, replace the Memory circuit pack. 3. If the test continues to fail, replace the Processor circuit pack. To replace the circuit packs, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The Memory Parity Checker circuit is operating properly.

Memory Error Detection/Correction Test (#907)

This test checks the error detection/correction circuitry on the Memory circuit pack. It tests a few reserved memory locations to verify that single bit errors can be corrected and multiple bit errors can be detected. If the **test memory a|b** command is used, this test executes once for each equipped Memory circuit pack

Table 9-443. TEST #907 Memory Error Detection/Correction Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error. 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-443. TEST #907 Memory Error Detection/Correction Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	The test could not run on the standby Memory circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the section on "STBY-SPE (Standby SPE Maintenance)" procedures for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected field* on the **status spe-standby** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Memory circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (handshake communication down). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2315	ABORT	The test was not run, because this is an extra Memory circuit pack. No testing is allowed for extra Memory circuit packs.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.

Continued on next page

Table 9-443. TEST #907 Memory Error Detection/Correction Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Memory EDC circuitry is not working correctly. The system may not continue to operate correctly if single or multiple bit errors occur in Memory at a later time. If the test fails on all equipped Memory circuit packs, the Processor may be at fault. Run the tests described in the Processor section of this manual. 1. Replace the affected Memory circuit when convenient. 2. If the test continues to fail after replacing the Memory circuit pack, replace the Processor circuit pack. To replace the circuit packs, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The Memory EDC circuitry is working normally.

Memory Burst Read Test (#908)

This test verifies that the Memory Burst Read function works properly on both the Memory and Processor circuit packs. If the **test memory a|b** command is used, this test executes once for each equipped Memory circuit pack

Table 9-444. TEST #908 Memory Burst Read Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error. 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-444. TEST #908 Memory Burst Read Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	The test could not run on the standby Memory circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the section on "STBY-SPE (Standby SPE Maintenance)" procedures for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected field* on the **status spe-standby** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Memory circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (handshake communication down). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2315	ABORT	The test was not run, because this is an extra Memory circuit pack. No testing is allowed for extra Memory circuit packs.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The Burst Read circuit is not functioning properly. 1. If the test fails on more than one Memory circuit pack, replace the Processor and retry the test. 2. If the test fails only on one Memory circuit pack, replace the affected Memory circuit pack. 3. If the test continues to fail only on the same Memory circuit pack, replace the Processor. To replace the circuit packs, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The Burst Read portion of the Memory and Processor circuit packs is operating correctly.

MET-BD (MET Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MET-BD	MINOR	test board UUCSS sh	MET Line Circuit Pack
MET-BD	WARNING	test board UUCSS sh	MET Line Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also MET-LINE (MET Line) Maintenance documentation for related line information.

MET-LINE (MET Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MET-LINE	MINOR	test port UUCSSpp l	MET Line
MET-LINE	WARNING	test port UUCSSpp sh	MET Line

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The TN735 MET Line circuit pack supports four of these sets as shown below. Each MET set uses three pairs of wires: an analog voice pair, a transmit pair, and a receive pair. Power is sent over the transmit and receive pairs. The MET Line circuit pack supports all 10-, 20-, and 30-button sets.

This section describes MET-LINE (MET Line) maintenance. MET-LINE maintenance is closely related to, and interacts with, MET-BD (MET Line circuit pack) maintenance. This interaction should be kept in mind when troubleshooting MET Line problems.

This section occasionally refers to a station's *service states*. The service states are defined as follows:

Out-of-Service	The port, and thus the station, have been removed from service. A busyout of a port will cause it to be out-of-service.
Ready-for-Service	The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.
In-Service	The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally, but it can also be forced into the in-service state if it goes off-hook.

Use the **status station** command to determine terminal service state. Status is reported as either out-of-service, in-service, or "disconnect," which means the station is in the ready-for-service state.

Error Log Entries and Test to Clear Values

Table 9-445. MET Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1 (a)	40987	None			
18 (b)	0	busyout port UUCSSpp	WARNING	OFF	release port UUCSSpp
130 (c)		None	WARNING	ON	test port UUCSSpp sh
257 (d)	40988	None	MIN/WRN[2]	OFF	
513 (e)	40965	Hybrid Line Station Audits Test (#61)	WARNING	OFF	test port UUCSSpp sh r 4
769		Port Diagnostic Test (#35)	MIN/WRN[2]	ON	test port UUCSSpp l r 3
1025		Hybrid & Conf. Circuits Test (#57)	MIN/WRN[2]	ON	test port UUCSSpp l r 3
1537 (f)	40968	None	MIN/WRN[2]	OFF	
1793		TDM NPE Crosstalk Test (#6	MIN/WRN[2]	ON	test port UUCSSpp l r 3
2049 (g)	32770				
2049 (h)	40967				
3840 (i)	40989				

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major or Minor alarms MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. The data link between the port and the terminal is not operational, i.e., the port circuitry has detected an off-board problem. Verify that the MET set is connected and that the Electronic Power Feed (EPF) test passes. If data transmission problems are experienced, check for defective wiring or a defective voice terminal, or move terminal electrically closer to the switch (i.e., reduce the length of the wiring between the terminal and the switch). If the problem persists, replace the circuit pack. Once the problem is resolved, the system retires the alarm after a predetermined time delay.

b. Error type 18 is logged when maintenance personnel busyout the port. maintenance personnel. The port is released from busyout via the **release port UUCSSpp** command.

c. The circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. The EPF has been turned off due to an overcurrent condition at the voice terminal. Check for defective wiring or a damaged jack, and verify that the voice terminal is an MET set. Once the problem is resolved, the system retires the alarm after a predetermined time delay.

e. The EPF inquiry audit has returned "epf-no-load" messages. This usually indicates that the voice terminal has been disconnected or that there is a defect in the wiring to the terminal. Check out both possibilities.

   When the EPF inquiry audit subsequently receives an "epf-on-ok" or an "epf-off-ok" message, the system will take action to retire the alarm.

f. The port has reported a problem with the data link to the voice terminal. Ignore this error if there are no complaints about the voice terminal. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and decrease the length of the wiring between the voice terminal and the switch. If the problem persists, replace the circuit pack.

g. The voice terminal went off-hook while it was in the ready-for-service state. Use the **status system** command to determine the state of the voice terminal. The off-hook should have moved the station to in-service. No repair action is necessary.

h. This code is generated when the link between the circuit pack and the voice terminal is successfully reset. No repair action is necessary.

i. The hardware sent an uplink message indicating that the Electric Power Feed (EPF) is not loaded, that is, it is not currently supplying power to a voice terminal. No repair action is necessary.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Port Diagnostic Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-446. System Technician-Demanded Tests: MET-LINE

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Port Diagnostic Test (#35)		X	ND
MFAT Electronic Power Feed Test (#56)		X	ND
Hybrid Circuit and Conference Circuit Test (#57)		X	ND
Station Lamp Update Test (#60)	X	X	ND
Station Audits Test (#61)	X	X	ND
Ringer Update Test (#62)	X	X	ND

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-447. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use **status station** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-447. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Test disabled via administration. This only applies to analog stations. The default for this field is ‘y,’ so you may want to determine why it has been turned off on this station. 1. To enable the test for the particular analog station being tested, enter the **change station extension** command and change the 'Test' field on the 'Station' form from 'n' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2100	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Resolve any EXP-PN and/or EXP-INTF errors. 2. Resolve any TDM-BUS errors. 3. Resolve any TONE-BD and/or TONE-PT errors. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.

Continued on next page

Table 9-447. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The port uses its allocated time slots correctly. Investigate user-reported troubles on this port using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Port Diagnostic Test (#35)

This test checks a port's battery feed circuitry. The battery feed circuitry is tested for proper battery voltage by testing the switchhook state. In response to the test message, the on-board firmware terminates the line and checks for switch-hook presence. The termination is then removed, and a check is made for no switch-hook presence. The MET set must be on-hook for the test to execute.

Table 9-448. TEST #35 Port Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. **NOTE:** The battery feed circuitry is tested for proper battery voltage by testing the switchhook state. In response to the test message, the on-board firmware terminates the line and checks for switch-hook presence. The termination is then removed, and a check is made for no switch-hook presence. The MET set must be on-hook for the test to execute. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via software patch.
2000	ABORT	This port may have been busied out. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-448. TEST #35 Port Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Battery Feed Test failed. This port is out-of-service. 1. Other ports on this circuit pack are not affected. Place user on a different port, if available, until a replacement circuit pack can be obtained. 2. Replace circuit pack when available.
	PASS	Battery Feed Test passed. Current flow is properly detected for this port. 1. If users are reporting problems, examine connections to the port.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MFAT Electronic Power Feed (#56)

The software requests that the EPF be turned on for a given port. The hardware then attempts to turn on that port's station power unit. If no current is drawn, the station is probably not connected. If an overcurrent condition is sensed (too much current is drawn), a short may exist in the loop, or the voice terminal may be defective. The test results in a message indicating that either the EPF was turned on successfully with no problems, or an overcurrent condition exists. This test is repeated after a 5 second delay. If either test is not successful, the test aborts. Although this test will never actually return a fail result (except for the internal system error), an error type 257 entry will be made in the error log when the test has completed if the overcurrent case is detected by the hardware.

Table 9-449. TEST #56 MFAT Electronic Power Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The test was aborted due to an internal system error on a software request to the board. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The test failed with an internal error while it was attempting to turn on the EPF. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-449. TEST #56 MFAT Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Electronic Power Feed Test passed. The message to turn on the power to the station was successfully sent to the port. 1. Although this test will never actually return a FAIL result except for the **Internal system error** described above, it will log an error if the overcurrent case is detected by the hardware. Check the Error Log for any entries with Error Type 257 when the test has completed. 2. If Error Type 257 does not appear in the Error Log within 10 seconds after completion of this test, it is safe to assume that the test sensed no problems with the power to the station. You can verify that the station is powered up correctly by executing a self-test on the station, and checking that all the feature buttons are operating. 3. The appearance of Error Type 257 in the Error Log indicates a station power problem. Check for a wiring short, a damaged jack, a defective voice terminal, or an incorrect type of terminal.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Circuit and Conference Circuit Test (#57)

This test checks two different port circuit functions. The Hybrid Circuit test performs an analog reflective looparound measurement on the port's hybrid circuitry. The Conference Circuit test performs a conference test on the port's NPE.

For Hybrid Circuit Test results to be valid, a voice terminal must be connected to the port being tested. The test instructs the on-board microprocessor to put the port in analog reflective looparound mode. The Tone-Clock circuit pack supplies a 1004-Hz tone to the port's listen time slot and a General Purpose Tone Detector (GPTD) measures the level of the reflected signal appearing on port's talk time slot.

The Conference Test is performed only if the Hybrid Circuit Test passes. The Conference Circuit Test verifies that the Network Processing Element (NPE) is able to correctly conference several test tones together. The test is executed in two parts. The first half of the test verifies operation of the NPE's first three conference channels, and the second half verifies the NPE's remaining four conference channels. The test puts the NPE in loop-around mode and instructs it to talk on a specified time slot while listening to a 1004-Hz tone using the Conference Channels. A GPTD then measures the signal and noise levels of the conferenced output and reports whether or not these fall within a specified acceptable range.

Table 9-450. TEST #57 Hybrid Circuit and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before retesting. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required to run this test were not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-450. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2012	ABORT	Internal system error.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-450. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	The conference circuit test failed. The conference circuit test is performed only if the hybrid test passes. The conference circuit test verifies that the network processing element (NPE) is able to correctly conference several test tones together. The test is executed in two parts. The first half of the test verifies the operation of the NPE's first three conference channels, while the second half verifies the NPE's remaining four conference channels. The test puts the NPE in loop around mode and instructs it to talk on a specified time slot while listening to a 1004 Hz tone, using the conference channels. A GPTD then measures the signal and noise levels of the conferenced output and reports whether or not these are within an acceptable range. The failure may be due to off-board circumstances, the most common of which is an off-hook occurring during the test. It is possible that the port may still be functional from a user's point of view. Also, check the error logs against the GPTD-BD, the TONE-BD, and the TONE-PT. 1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK. 2. Then, issue the **display port** and the **station status** commands to determine if the station is idle. If it is idle, issue the **test port** command for this port. 3. If test continues to fail, issue the **busyout port** and the **release port** commands, and then retest the port.
57	FAIL	Hybrid Circuit Test failed. This can result in noisy or bad connections. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack, using **test board UUCSS short** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the MET Line circuit pack. **NOTE:** If the Hybrid Circuit and Conference Circuit Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. To investigate problems with a power unit, refer to "CARR-POW".

Continued on next page

Table 9-450. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Hybrid Circuit and Conference Circuit Test passed. The hybrid circuitry is transmitting properly. 1. If complaints persist, investigate by using other port tests, and by examining the station, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Line Station Lamp Updates Test (#60)

For this test, the software lights the lamps on the terminal based on the status record contained in the processor. The lamp updates run only if the station is in-service.

Table 9-451. TEST #60 MET Line Station Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	This port may have been busied out. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
2	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
3	ABORT	Station is in ready-for-service or out-of-service state. This may be due to wiring or an unplugged or defective set. 1. Make sure terminal is connected and the wiring is correct. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	MET Line Station Lamp Updates completed successfully. 1. If complaints persist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.

Continued on next page

Table 9-451. TEST #60 MET Line Station Lamp Updates Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Line Station Audits Test (#61)

This is a series of three tests that are classified as audits. These audits will abort if attempted on an out-of-service station. Although this test will never actually return a fail result (except for the internal system error), it is possible that it will enter error types 257 (over current) or 513 (open circuit) into the error log. To determine if there are any problems that do not show up in the test result, look for these error types in the error log. If these errors appear in the error log or if user complaints still exist, investigate by using other circuit pack tests and by examining the station, the wiring, and the connections. The tests are as follows:

Switchhook Audit	This is an update of the SPE records according to the circuit packs' records.
Bad Scan Inquiry	A message is sent uplink that contains a count that is generated due to certain events relating to the link conditions. This is an indication of data transmission problems between the MET Line circuit pack and the voice terminal.
EPF Inquiry	The status of the Electronic Power Feed is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, EPF-no-load, and EPF-on-overcurrent.

Table 9-452. TEST #61 MET Line Station Audits Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
1	ABORT	The test was aborted due to an internal system error during the switchhook audit.
2		The test was aborted due to an internal system error during the bad scan inquiry.
3		The test was aborted due to an internal system error during the EPF audit inquiry. 1. Make sure that the station is not in an out-of-service state. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The test failed due to an internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-452. TEST #61 MET Line Station Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Hybrid Line Station Audits passed. 1. Although this test will never actually return a FAIL result except for the **Internal system error** described above, it is possible that it will enter Error Types 257 or 513 into the Error Log. To determine if there are any problems that don't show up in the test result, look for these error types in the Error Log. 2. If these errors appear in the Error Log, or if user complaints persist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Line Ringer Update Test (#62)

In this update, a “ringer on” or a “ringer off” message is sent to the firmware to start and stop the ringer on the set.

Table 9-453. TEST #62 MET Line Ringer Update Test

Error Code	Test Result	Description/ Recommendation
3	ABORT	This port may have been busied out. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If present, release the port via **release station <extension>** and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the station extension of the port. Use **status station** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Hybrid Station Ringer Update passed. 1. If complaints persist, investigate using other circuit pack tests, and by examining the terminal, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port. This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MIS (Management Information System)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
MIS	WRN	release mis	Management Information System

The Management Information System (MIS)/Call Management System (CMS) maintenance object is used only to monitor MIS busyouts during administration of MIS translations. There are no hardware failures associated with this MO.

The MIS/CMS is an adjunct processor that collects Automatic Call Distribution (ACD) data sent from the switch. In order to change MIS translations, a switch administrator must first enter a **busyout mis** command at the G3-MT. When the MIS is busied out, the switch will stop sending ACD data to the MIS, and a Warning alarm will be raised.

When the switch administrator is finished, a **release mis** command should be entered at the terminal. This will clear the Warning alarm and allow the switch to send ACD data to the MIS.

Error Log Entries and Test to Clear Values

Table 9-454. Management Information System Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	release mis
18[2]	0	busyout mis	WARNING	ON	release mis

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. When the **busyout MIS** command is issued, no data is sent to the MIS/CMS regardless of the link state. To allow data to be sent to MIS/CMS, a **release mis** command must be issued from the terminal.

MMI-BD

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MMI-BD	MAJOR	test board UUCSS l r#	Multimedia Interface Circuit Pack
MMI-BD	MINOR	test board UUCSS l r#	Multimedia Interface Circuit Pack
MMI-BD[2]	WARNING	test board UUCSS s r#	Multimedia Interface Circuit Pack

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).
2. Refer to XXX-BD (Common Port Board).

Two circuit packs can be used for multimedia connections:

- "TN787D (or later)"
- "TN2207/Expansion Services Module"

TN787D (or later)

The Multimedia Interface Circuit Pack (TN787D or later and also called the MMCH circuit pack) provides a number of H.221 protocol terminations for bit streams received from the TDM bus. The Multimedia Interface demultiplexes the H.221 bit stream (audio, video, data, control, and indication signals) and transmits the bit streams onto the TDM bus so that the appropriate circuit packs can process them.

The Multimedia Interface circuit pack is commonly referred to as the MMI pack for H.221 protocol termination. There are 32 ports (also called resources) on the circuit pack. See "MMI-PT" for maintenance of these resources.

The MMI circuit pack contains 4 digital signal processors that manage the 32 resources.

NOTE:
Refer to "Multimedia Call Handling (MMCH)" in Chapter 5, "Alarms, Errors, and Troubleshooting" for MMCH troubleshooting information.

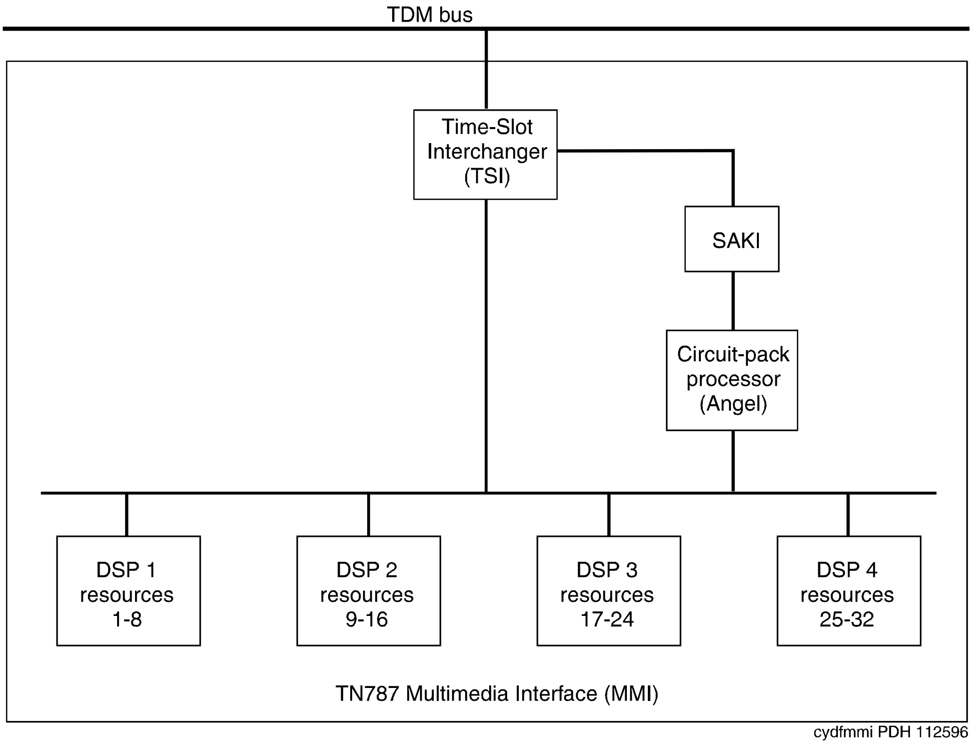

Figure 9-57. TN787 Multimedia Interface (MMI) Circuit Pack

TN2207/Expansion Services Module

The TN2207 circuit pack permits connecting an Expansion Services Module (ESM). See Figure 9-58 for connectivity.

- Provides T.120 data sharing capability on a MMCH multipoint H.320 video conference
- Each conference participant must have endpoints administered and a personal computer with the H.320 video application installed.
- The DEFINITY ECS must have the expansion service module installed.

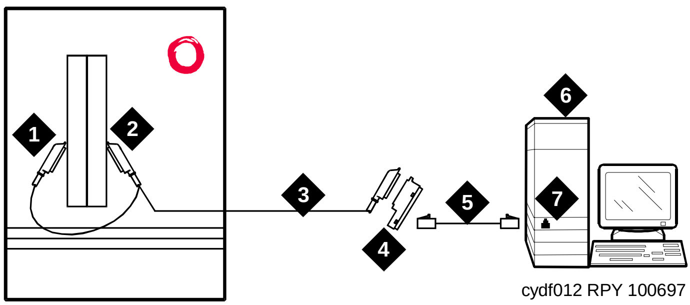

Figure 9-58. Typical ESM connections

Figure notes

1. Port B Y-cable connector to a TN787 Multimedia Interface (MMI) circuit pack
2. Port A Y-cable connector to a TN2207 PRI circuit pack
3. 25-pair Y-cable
4. 356A adapter
5. D8W cord connected to 356A adapter port 1
6. Expansion Service Module (ESM)
7. Port B on compatible primary rate interface (PRI) card

CAUTION:

The TN2207 circuit pack is the only pack allowing connection of an ESM to the DEFINITY ECS switch.

513 (e)	4352 to 4357	Uplink error from pack			
769 (f)	Any	MMI Synchronization Status Test #1123			
1281 (g)	Any	Circuit Pack Restart Test (#594)	MAJ	ON	
1538 (h)	Any	Software detected error	MIN	ON	
1793 (i)	ANY	TSI XTalk (#6)	MIN	ON	test board UUCSS l r 3
2049 (j)	Any	TSI Loop (#1108)	MAJ	ON	test board UUCSS l r 3

1. Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The circuit pack stopped functioning or it was physically removed from the system. The alarm logs approximately 11 minutes after the circuit pack has been removed and/or the SAKI Sanity Test (#53) fails.

   If the circuit pack is in the system and the red LED is on, follow the instructions for a red alarm in "Circuit Pack LEDs" in Chapter 7, "LED Interpretation". Also, see "Handling Common Port Circuit Packs."

b. This circuit pack has been busied out using the **busyout board UUCSS** command.

c. There are more than four MMI circuit packs in the system. Remove the circuit pack that generated the error in the error log by locating the slot indicated by the error.

d. Indicates transient communication problems between the switch and this circuit pack. Execute the **test board UUCSS** command and refer to the repair procedures for the Control Channel Looparound Test (#52) in the XXX-BD section.

e. The circuit pack detected an Angel on-board hardware failure. The reported aux data values correspond to the following detected errors:

   4352 - External RAM error
   4253 - Internal RAM error
   4355 - ROM Checksum error
   4357 - Instruction set error

   Reset the circuit pack by using the **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS** commands. When reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one these errors during initialization causes the circuit pack to lock up and appear insane to the system. See the repair procedures in note b for Error Type 1.

f. This MMI circuit pack reported a loss of MMI synchronization. Refer to test #1123 for repair procedures.

g. A failure of the time slot interchanger has been detected. Reset the circuit pack using the **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS** commands. If the reset passes, then the on-board circuitry is healthy. Retire the alarm using the **test board UUCSS long clear** command followed by **release board UUCSS**.

h. The circuit pack is hyperactive; that is, it is flooding the switch with messages sent over the control channel. The circuit pack is taken out of service when a threshold number of these errors is reported to the switch. Clear the alarm using the following commands: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long clear**, **release board UUCSS**. If the error recurs within 10 minutes, replace the circuit pack.

i. The TSI Cross Talk Test (#6) failed. See the description of this test and follow the repair procedures.

j. The TSI Looparound Test (#1108) failed. See the description of this test and follow the repair procedures.

System Technician-Demanded Tests: Descriptions and Error Code

Always investigate tests in the order presented in Table 9-456 below when inspecting errors in the system. By clearing error codes associated with the TSI Crosstalk Test (#6), for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-456. System Technician-Demanded Tests: MMI-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
TSI Crosstalk (#6)		X		ND
TSI Looparound Test (#1108)		X		ND
MMI SYNC Status Test (#1123)	X			ND
MMI SYNC Status Test (#1122)		X		ND
Control Channel Looparound Test (#52)[2]	X	X		ND
SAKI Sanity Test (#53)[2]			X	D

1. D = Destructive, ND = Non-destructive
2. Refer to the repair procedure described in XXX-BD (Common Port Circuit Pack) for a description of this test.

TSI Crosstalk Test (#6)

This test is non-destructive.

The Time Slot Interchanger (TSI) chip controls connectivity to the TDM bus. The TSI Cross Talk Test verifies that this TSI talks on the selected TDM bus time slot and never crosses over to time slots reserved for other connections. If the TSI is not working correctly, one-way and noisy connections may occur. If the test passes, then the TSI is able to communicate over the TDM bus. This test is part of the circuit pack's demand and scheduled long test sequence, and takes approximately 20 to 30 seconds to complete.

Table 9-457. TEST #6 TSI Crosstalk Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal system error. This is an abnormal abort. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test, the traffic load on the system is very high, or the time slots are out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone detector for the test. The system is oversized for the number of tone detectors present, or some tone detectors are out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received from the MMI-BD circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack if the other ports are not in use. Reset the circuit pack by issuing the **busyout board PCSS**, **reset board UUCSS**, followed by the **release board UUCSS** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error. This is an abnormal abort.
2100	ABORT	Could not allocate the necessary resources to run this test. This is an abnormal abort. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The TSI was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The TSI is correctly using its allocated time slots.

TSI Looparound Test (#1108)

This test is non-destructive.

During this test, the MMI's Time Slot Interchanger (TSI) is listens to a TDM timeslot. A digital count tone loops back in the TSI and onto another TDM timeslot without passing through any resource hardware. A tone detector port verifies the looped data. If the digital count is correct, then the test passes. The test is done for both TDM buses. Failures indicate that the TSI is unreliable.

Table 9-458. TEST #1108 TSI Looparound Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal system error. This is an abnormal abort. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. Either the traffic load on the system is very high or time slots is out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone detector for the test. The system may be oversized for the number of Tone Detectors present, or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received from the Tone Detector circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack (if the other ports are not in use). Reset the circuit pack by issuing the **busyout board UUCSSpp** and the **reset board UUCSSpp** commands followed by the **release board UUCSSpp** command. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error. This is an abnormal abort.
2100	ABORT	Could not allocate the necessary resources to run this test. This is an abnormal abort. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-458. TEST #1108 TSI Looparound Test — *Continued*

Error Code	Test Result	Description/Recommendation
	FAIL	The TSI was found to be transmitting in error, causing noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The TSI is correctly using its allocated time slots.

MMI Synchronization Status Test (#1122 and 1123)

This test is non-destructive.

To support applications involving multiple MMI circuit packs, the appropriate MMI circuit packs must be synchronized with one another. One such circuit pack is designated as the master sync source, which provides the synchronization signal onto the TDM bus. The other MMI circuit packs in the system listen to this signal.

This test monitors this synchronization state. The test fails if the MMI circuit pack is not in sync. The test passes with auxiliary code 1100 if the MMI circuit pack is in sync and is providing the synchronization signal for the system. The test also passes with an auxiliary code of 1101 if the MMI circuit pack is in sync and listening to the sync signal. MMI circuit packs do not lose the synchronization signal unless an MMI circuit pack is either pulled out of the system or reset by using a technician command.

Test #1122 runs when the **long** option of the **test board** command is entered, initiating the recovery of synchronization. Test #1123 runs when the **short** option of the **test board** command is entered, giving the status of the synchronization. You need not necessarily run the **long** option since synchronization signal recovery should be taking place within software running in the background. Use the **long** option only if synchronization is not established within 5 minutes of investigating the problem.

Table 9-459. TEST #1122/1123 MMI Synchronization Status Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal system error. This is an abnormal abort. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	A response to the test was not received from the MMI circuit pack within the allowable time period. 1. If this result occurs repeatedly and the MMI circuit pack is idle, reset the circuit pack using **busyout board UUCSS**, then **reset board UUCSS**, followed by **release board UUCSS**. 2. Rerun the test; if the same result occurs again, replace the MMI circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary resources to run this test. This is an abnormal abort. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The MMI circuit pack is out of MMI synchronization. Run the **long** option of the **test board** command. 1. Wait up to 5 minutes, and then reset the circuit pack with these commands: **busyout board UUCSS**, then **reset board UUCSS**, followed by **release board UUCSS**. 2. Rerun the test; if the same result occurs again, replace the circuit pack.
1100	PASS	The MMI circuit pack is providing the synchronization correctly. This MMI circuit pack is designated as the Master Sync source.
1101	PASS	The MMI circuit pack is listening to the synchronization signal correctly.

Control Channel Looparound Test (#52)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) maintenance documentation as Control Channel Looparound Test (#52).

SAKI Sanity Test (#53)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) maintenance documentation as SAKI Sanity Test (#53).

MMI-LEV (Multimedia Interface Resource Level)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
MMI-LEV	MAJOR	See ''Resolving MMI-LEV Errors/Alarms'' (below)	MMI-LEV

The Multimedia Interface Resource Level MO monitors MMI efficiency by tracking the number of MMI ports that are in-service, and then comparing that number with the value entered in the `MMIs` field on the System-Parameters Maintenance form. This `MMIs` field is located under the Minimum Maintenance Threshold section. The `MMIs` field contains the minimum number of MMI ports needed for the Multimedia Call Handling (MMCH) feature to run efficiently and is an administrable field. This field must contain a minimum threshold number for MMI port capacity of between 0-128. The MMCH feature must be enabled on the System-Parameters Customer-Options form before the `MMIs` field can be changed to a number greater than zero. The algorithm for determining that a low level of MMI resources exists uses the value entered in the `MMIs` field, and the number of MMI ports that are in-service in the system.

Each MMI circuit pack contains a maximum of 32 ports. If the number of in-service MMI ports falls below the minimum port capacity (value entered on the System Parameters Maintenance form under the Minimum Maintenance Threshold section and in the `MMI` field), a MMI-LEV error is logged. If this outage continues for 15 minutes, a MAJOR alarm is raised.

Resolving MMI-LEV Errors/Alarms

MMI ports are a key part of the MMCH feature, and any loss in the number of ports available for use degrades the MMCH customer-defined service level.

If a MMI circuit pack or port is busied out using the **busyout board** or **busyout port** commands, these out-of-service ports are not included in the MMI level calculation, thus allowing a technician to busy out a MMI circuit pack for maintenance reasons without causing a MAJOR alarm to be raised. However, if all of the ports on the MMI circuit pack are not made busy and the circuit pack is removed, an alarm is raised.

NOTE:
When diagnosing a MMI-LEV problem, begin by resolving any alarms raised against MMI-BD or MMI-PT maintenance objects. Clearing MMI-BD or MMI-PT alarms may clear the MMI-LEV alarm.

The MMI circuit pack is maintained by the software like the Tone Detector circuit pack, which can be removed and reinserted in any port board slot without administration. Similarly, if a MMI circuit pack is removed from service logically by failing the Archangel sanity scan test or is removed from service physically by removing the circuit pack from the carrier, no error/alarm is raised against either the MMI-BD or the MMI-PT maintenance objects. Therefore, if a MMI-LEV error/alarm exists, yet no alarms have been raised against MMI-BD or MMI-PT maintenance objects, a MMI circuit pack may have been removed from service causing the MMI-LEV error/alarm. To resolve a MMI-LEV MAJOR alarm, restore the number of MMI ports available for service to be equal to or greater than the calculated port capacity.

To determine how many MMI circuit packs are needed for the MMCH feature:

1. Using the **display system-parameters maintenance** command, locate the number listed in the Minimum Maintenance Thresholds (`MMIs`) field and record this number.
2. Use the **list configuration** command to verify the number of MMI ports.
3. Compare this number with the value listed in the `MMIs` field on the System-Parameters Maintenance form (number listed in step 1 a minimum thresholds number for MMI ports of between 0-128). Each MMI circuit pack contains a maximum of 32 ports. If this number in the `MMIs` field is less than or equal to 32, one MMI circuit pack is needed. If this number is 64, then two MMI circuit pack are needed.
4. Use the **list configuration** command to verify that the number of MMI circuit packs listed agrees with the required minimum port capacity (from step 1). If the number of MMI circuit packs listed in the step 2 differs from the calculated number, restore the number of MMI circuit packs to the correct value, in order to resolve the MMI-LEV alarm.

Error Log Entries and Test to Clear Values

Table 9-460. MMI-LEV Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/ Off Board	Test to Clear Value
1[1]	Any	None	MAJOR	OFF	

1. The number of MMI resources in the system that are in service has fallen below the calculated minimum value. If the number of in-service MMI ports falls below the MMCH port capacity (value entered in the Minimum Maintenance Thresholds for MMIs field) on the System-Parameters Maintenance form, a MMI-LEV error is logged. If this outage continues for 15 minutes, a MAJOR alarm is raised.

To resolve this alarm, correct the out-of-service problem by following these procedures:

1. See "MMI-PT" and "MMI-BD" and resolve any associated alarms.
2. If a MMI-LEV error/alarm exist and none has been raised against MMI-BD or MMI-PT maintenance objects, an MMI circuit pack may have been removed from service causing the MMI-LEV error/alarm. To resolve a MMI-LEV MAJOR alarm, restore the number of MMI ports available for service to be equal to or more than the calculated port capacity. See the ''Resolving MMI-LEV Errors/Alarms'' section above for details.
3. If the error contines to alarm, escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Code

There are no System Technician-Demanded tests for MMI-LEV.

MMI-PT

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MMI-PT	MAJOR	test port UUCSSpp l r#	Multimedia Interface Port
MMI-PT	MINOR	test port UUCSSpp l r#	Multimedia Interface Port
MMI-PT	WARNING	test port UUCSSpp l r#	Multimedia Interface Port

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).

NOTE:
Refer to Chapter 5, ''Alarms, Errors, and Troubleshooting'' for MMCH troubleshooting information.

The Multimedia Interface Circuit Pack provides a number of H.221 protocol terminations for bit streams received from the TDM bus. The Multimedia Interface demultiplexes the H.221 bit stream (audio, video, data, control, and indication signals) and transmits the bit streams onto the TDM bus to be processed by the appropriate circuit packs.

Each Multimedia Interface Circuit Pack contains 32 separately maintained “ports,” more commonly referred to as "resources." MMI-PT represents one of these 32 resources. At system boot or when the circuit pack is inserted, 32 resources are inserted into the system.

The MMI circuit pack contains 4 Digital Signal Processors (DSPs) which manage the 32 resources. These resources are directly mapped to DSPs:

Resource	Direct Map
1-8	DSP1
9-16	DSP2
17-24	DSP3
25-32	DSP4

All 8 resources that the circuit pack controls may be placed out of service by the failure of one of these DSPs.

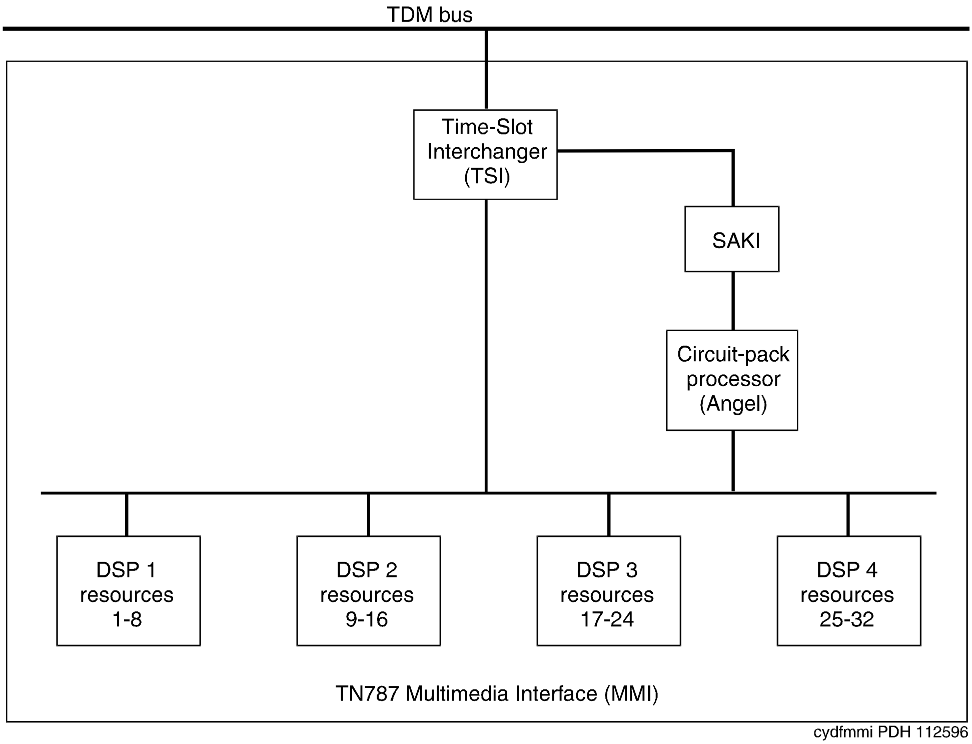

Figure 9-59. TN787 MULTIMEDIA INTERFACE (MMI) CIRCUIT PACK

Error Log Entries and Test to Clear Values

Table 9-461. MMI-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/ Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1 (a)	Any	Uplink error from pack			
18 (b)	0	Busyout port PCSSpp	WNG	OFF	release port UUCSSpp
130 (c)	Any	Software generated	WNG	ON	
257 (d)	Any	None	MAJ/ MIN	ON	
513 (e)	Any	Resource Loopback Test (#1111)	MIN	ON	test port UUCSSpp sh r 3
1025 (f)	Any	Uplink error from pack			
3841 - 3844 (g)	Any	Uplink error from pack			

1. Run the short test sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The customer endpoint connected on a conference sent too many messages to the VSP-MCU in a specified amount of time. Check the “status conference” forms to correlate which customer had the problem. This is a customer endpoint problem and not a VSP-MCU problem.

b. This port has been busied out by the **busyout port UUCSSpp** command.

c. Indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reseat the circuit pack.

d. This error occurs if the MMI circuit pack detects a DSP Error. Maintenance software will reset the DSP when this error is received. This error is logged for all 8 resources connected to this particular DSP. If this DSP continues to fail sanity, a Minor alarm is raised. Replace the circuit pack.

e. This error occurs when the Resource Looparound Test (#1111) fails. Run the Long Test Sequence and note the results of Test #1111.

f. This error occurs if either the MMI or Voice Conditioner (VC) circuit packs reports a loss of framing on the service channel between these two circuit packs. When a customer endpoint establishes a call to the VSP-MCU, a channel is established between the MMI resource and the VC port. If this channel is detected to go down by either circuit pack, an uplink message is sent. This error is then forwarded to maintenance for both circuit packs. Run the Long Test Sequence for this MMI resource, and if any of the tests fail, follow the repair procedures for that test. If all tests pass, the cause of the problem might be with the VC pack. See the “VC-DSPPT” repair procedures.

g. These errors are not related to VSP-MCU. They could be caused by network problems or from the customer endpoints. They are presented here for logging purposes only.

Code	Description
3841	CRC4 Error (Frame checksum error)
3842	Correctable BAS (Control msg single or double bit error, but correctable)
3843	Uncorrectable BAS (Control msg bit error -three or more bit, uncorrectable)
3844	Protocol Error (H.221 Protocol error from endpoint detected)

System Technician-Demanded Tests: Descriptions and Error Codes

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Resource Looparound Test (#1111)	X	X	D

1. D = Destructive; ND = Nondestructive

Resource Looparound Test (#1111)

This test is destructive.

This test checks the connectivity of the resource within MMI circuit pack and out to the TDM bus. The object is to test the circuitry that an H.221 bit stream comes in contact with when that stream is demultiplexed, pre-processed, written to the TDM bus and then reread (looped in the TSI), post-processed, multiplexed, and then written back to the TDM bus for verification. The video, audio, and data components of the bit stream are tested separately. If any one of these tests fails, then the resource is taken out of service.

Table 9-462. TEST #1111 Resource Looparound Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Retry the command at 1-minute intervals a maximum of five times. 2. Use the **status conference** command to determine if there is an active conference. If a call is active, the test cannot be run until the conference call terminates.
1002	ABORT	The system could not allocate time slots for the test. The traffic load on the system may be very high or time slots may be out-of-service due to TDM-Bus errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of five times.
1003	ABORT	The system could not allocate a tone detector for the test. The system is oversized for the number of tone detectors present or some tone detectors are out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of five times.
1004	ABORT	The resource has been seized by a user for a valid call. Use the **status conference** command to verify that there is a conference call active. 1. If there are no conference calls, retry the command at 1-minute intervals a maximum of five times.
2000	ABORT	Response to the test was not received from the Tone Detector circuit pack within the allowable time period. 1. If this result occurs repeatedly, reset the circuit pack, if the other ports are not in use. Reset the circuit pack by issuing the **busyout board UUCSSpp** and the **reset board UUCSSpp** commands, followed by the **release board UUCSS** command. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary resources to run this test. Abnormal abort. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-462. TEST #1111 Resource Looparound Test — *Continued*

Error Code	Test Result	Description/Recommendation
0, 1, 2	FAIL	This resource cannot guarantee data integrity and is out-of-service. The following error codes indicate failure of a particular media loop: 0 = video 1 = audio 2 = low-speed data 1. Replace the circuit pack
	PASS	The resource is functioning normally.

MMI-SYNC

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MMI-SYNC	MINOR	test board UUCSS l r#	Multimedia Interface Circuit Pack

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).

NOTE:
Refer to Chapter 5, ''Alarms, Errors, and Troubleshooting'' for MMCH troubleshooting information.

Each Port Network (PN) must have a TN787D or later MMI circuit pack assigned as the Multimedia Interface (MMI) master synchronization source for that PN. If one or more MMI circuit pack is administered in a PN, one MMI circuit pack is designated as the master synchronization source for all MMI circuit packs within that PN.

The MMI circuit pack generates a synchronization signal and puts that signal on the TDM bus. Other MMI packs or any other circuit pack within a PN can listen to this signal and “synchronize up” to it. The first MMI circuit pack inserted in a PN is normally designated as the master. As subsequent MMI packs are inserted, they are instructed to listen and synchronize to the time-slot of the master MMI. In the unlikely case of an MMI losing this reference, an uplink message is sent from the MMI circuit pack that lost the signal to maintenance, which also clears the “event” counter on this MMI with a downlink message. This forces the MMI circuit pack to return the current state of the synchronization signal. If the signal is still lost, then the recovery algorithm is entered. Note that during this time, the MMI circuit pack synchronizes to its internal clock, and there should be no service disruption. A loss of synchronization is usually the result of a circuit pack failure. The maintenance strategy is to switch the master source away from the bad pack to another healthy MMI circuit pack within the PN.

A synchronization switch takes place if half or more of the MMI circuit packs in a PN report a loss of synchronization. For example, a PN with two MMIs reporting a loss of sync source switches immediately, three and four MMIs switch if two report the loss, and so forth. A healthy MMI circuit pack becomes the master synchronization source providing the signal on a new timeslot. The other MMI circuit packs within the PN are instructed to listen to this new signal, and the old master stops providing the signal and now listens to the new master MMI. If an MMI is physically removed from the system, then the remaining MMIs report the loss of synchronization. The first MMI with no alarms present becomes the new master of that PN. Once a synchronization switch has occurred, another switch is not allowed for 15 minutes to avoid hyperactive switching. If all the MMIs have alarms, then no switch is made.

If the MMI circuit pack that provides synchronization is craft busied out, it will not affect the PN synchronization. The signal is still provided by the busied-out pack. There is no affect on synchronization if the technician issues a release of the busied-out MMI. Synchronization is not affected by a warm start of the system (reset system 1). For all other restarts (reboot through cold 2), MMI synchronization recovers during board insertion.

Error Log Entries and Test to Clear Values

Table 9-463. MMI-SYNC Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1	Any	None			See note [1]
257	Any	None	MINOR	OFF	See note [2]

1. An MMI synchronization switch was successful. Refer to MMI-BD errors for the reason for the switch.
2. The requested MMI synchronization switch failed. Resolve all MMI-BD alarms.

System Technician-Demanded Tests: Descriptions and Error Codes

There are no system technician-demanded tests for MMI-SYNC.

MODEM-BD (Modem Pool Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MODEM-BD	MIN	test board UUCSS sh	Modem Pool Circuit Pack
MODEM-BD	WRN	test board UUCSS sh	Modem Pool Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

Refer to XXX-BD (Common Port Circuit Pack) for circuit pack level errors. See also MODEM-PT (Modem Pool Port) for related port information.

MODEM-PT (Modem Pool Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
MODEM-PT	MINOR	test port UUCSSpp s	Modem Pool Port

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The Modem Pool Port provides an interface for digital and analog data communication devices or ports connected to the PBX. It may be thought of as a PBX data communications "conversion resource" because it converts analog modem signals typically used in the telephone network into digital signals that are compatible with the internal PBX network and vice versa.

There may be a number of these conversion resources available in the PBX, each assigned to an available Modem Pool Group. Only one conversion resource is used per data connection. The PBX software usually adds the conversion resource into a data connection if it determines that it is necessary for the call. Typical connections that include Modem Pool conversion resources include data calls from Analog Line or Central Office Trunk ports to any digital port or Digital Line or Trunk ports to any analog port. An example of a Data Module to Central Office Trunk connection using a Modem Pool conversion resource is shown in Figure 9-60. In the case where a local data call originates from an analog port normally used for voice service only and terminates on a digital port, a Data Origination access code must be dialed before the extension number for the Modem Pool conversion resource to be included in the connection.

Each Modem Pool conversion resource contains two ports. One of these, an analog port, is connected (via the PBX network) to the analog line or trunk port that is the source of the modem signal. The second port is referred to as the digital port and is connected (again through the PBX network) to the digital line or trunk port associated with the Data Module in the connection. The analog modem signals enter the analog port of the conversion resource in standard Pulse Code Modulation (PCM) format, but are converted into Data Communications Protocol (DCP) format before going to the digital line or trunk in the connection.

Integrated Modem Pools

There are two primary types of Modem Pool conversion resources available: an Integrated Pooled Modem and a Combined Modem Pool. The integrated TN758 Pooled Modem circuit pack contains two independent 300 or 1200 baud conversion resources. Each conversion resource contains two interfaces to the PBX digital network: an analog port and a digital port. The analog port is connected through the PBX network to the analog line or trunk port containing the analog modem signals. The digital port connects through the PBX network to the digital line or trunk port in the call. The figure below shows a typical end-to-end connection using a conversion resource on the integrated Pooled Modem circuit pack.

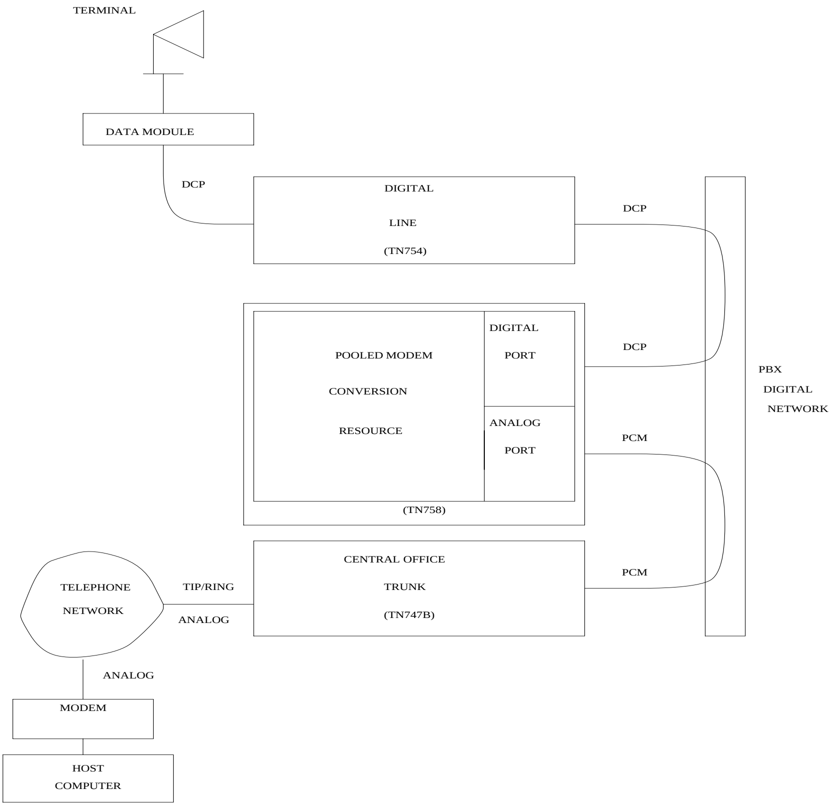

Figure 9-60. Typical Modem Pool Switched Connection with Integrated Pooled Modem

Combined Modem Pools

The Combined Modem Pool conversion resource is the second type available. The function served by the Combined Modem Pool is similar to that of the integrated Pooled Modem circuit pack, but the physical implementation is much different. It has the advantage of supporting any speed the external modem can support. The integrated Pooled Modem circuit pack can only support 300 or 1200 baud transmission rates. The Combined Modem Pool conversion resource consists of a port on an Analog Line circuit pack, an external modem, a Data Module, and a port on a TN754 Digital Line circuit pack. The tip and ring interface of the Analog Line is connected to the modem, the RS-232C interface of the modem connects to the Data Module, and the DCP interface on the Data Module is connected to the Digital Line port.

The analog modem signals pass through the Analog Line port to the modem. The modem converts these to RS-232C signals which are passed on to the Data Module. The Data Module further converts the signals to the DCP protocol for the Digital Line port which passes the signals on to the PBX network.

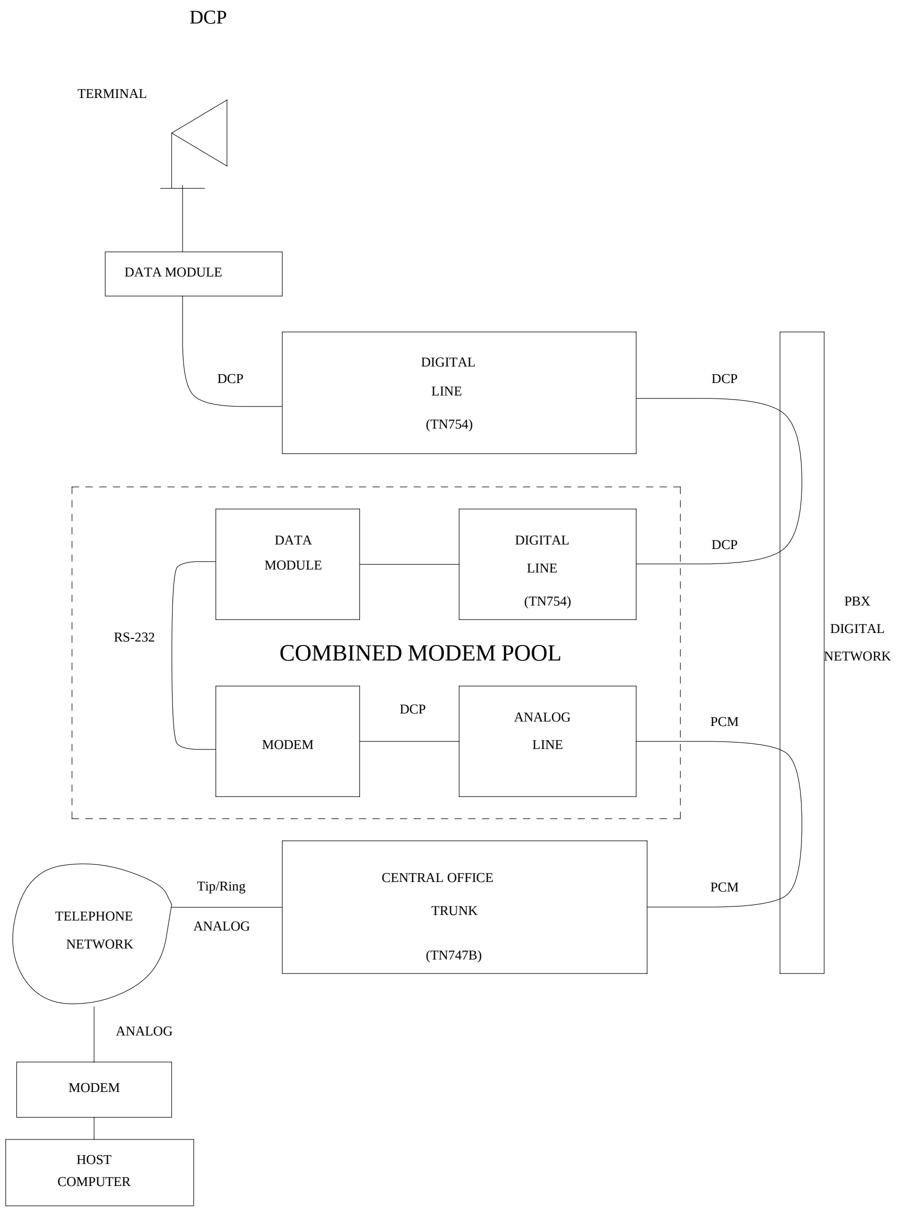

Figure 9-61. Typical Modem Pool Switched Connection with Combined Modem Pool

Troubleshooting Modem-Pool Symptoms

Certain customer-reported troubles may provide important information for troubleshooting Modem Pool problems. For example, if the customer tries to make a data call requiring a Modem Pool conversion resource, and the Modem Pool and Data Module speeds or other options do not match, they may receive a ‘‘CHECK OPTIONS’’ error message on the terminal. In this case, check the Modem Pool administration and Data Module option settings. If the Modem Pool is a Combined type, check also the option settings on the external Modem and Data Module, and cabling and connections between the Digital Line port, Data Module, Analog Line port, and Modem.

Testing Modem-Pools

There are three types of commands that can be used to test Modem Pool circuits: **test port, test modem-pool #,** and **test board.** The **test port** command is generally the first test to run after the Error Log is evaluated and an entry is found for a Modem Pool port. The **test modem-pool #** command runs the same tests as the **test port short** command performed on a Modem Pool port. However, the **test modem-pool #** command can automatically test all ports in the Modem Pool group number specified in #. The **test board** command performs the same tests as **test port** and **test modem-pool #** plus additional tests for circuits common to the entire circuit pack. Refer to the "XXX-BD (Common Port Circuit Pack)" section for information on additional tests performed with **test board** (#50, #52, and #53).

If the Modem Pool port or group being tested with **test modem-pool #** contains Combined Modem Pools, the ports on the associated Analog Line circuit pack and the TN754 Digital Line circuit pack are tested as a group. Note, however, that Combined Modem Pools are not tested with the tests described in this section and the repair information related to Tests # 96, 97, 98, and 99 is not applicable. The Analog port of the Combined Modem port is tested with Analog port tests, and the Digital port of the Combined Modem port is tested with TDMODULE/PDMODULE tests. Therefore, use the repair procedures outlined in the ANL-LINE, ANL-16-L, ANL-NE-L, and TDMODULE/PDMODULE Maintenance documentation when interpreting the results of the execution of the **test modem-pool #** command on Combined Modem Pools.

Error Log Entries and Test to Clear Values

Table 9-464. Modem Pool Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
18	0	busyout UUCSS	WARNING	OFF	release port UUCSS
130[2]		None	WARNING	ON	test port UUCSSpp sh
257		Conversion Resource Loop (#98)	MINOR	ON	test port UUCSS s r 3
513		Modem Conference (#97)	MINOR	ON	test port UUCSS l r 3
769		Modem NPE Crosstalk (#96)	MINOR	ON	test port UUCSS l r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This error type indicates that the circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Modem Pool Conference Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Modem Pool NPE Crosstalk Test (#96)		X	D
Modem Pool Conference Test (#97)		X	D
Modem Pool Conversion Resource Looparound Test (#98)	X	X	ND
Modem Pool Audits Test (#99)	X	X	ND

1. D = Destructive, ND = Non-destructive

NOTE:
The tests in this section do not apply to Combined Modem Pool conversion resources. The standard Digital Line and/or Analog Line port tests are run on the ports associated with the Combined Modem Pool. Consult the test descriptions for those maintenance objects when repairing Combined Modem Pool arrangements.

Modem Pool NPE Crosstalk Test (#96)

This test is destructive.

The Modem Pool Crosstalk Test verifies that the NPE is connected only to the desired time slot and is not crosstalking on other time slots. This test operates exactly like Test #6 for other types of port circuits but is performed twice in order to test both NPEs in the Modem Pool Port

Table 9-465. TEST #96 Modem Pool NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required for this test are not available. The port may be in use on a valid call. Determine if the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Determine whether the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to a previously existing error on the specific port or because of a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack, and attempt to diagnose the previously existing errors.

Continued on next page

Table 9-465. TEST #96 Modem Pool NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	A response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
6000	ABORT	System resources needed to complete the test could not be allocated for the digital section of the Modem Pool conversion resource. Ordinarily, this means the conversion resource or other hardware used during the test was in use. 1. Wait 1 minute and attempt the test again. 2. If the same error occurs, use the **status port** command to determine whether the Modem Pool conversion resource is in use. 3. If the conversion resource is in use, and it is absolutely necessary to test it, the call must be dropped by issuing a **busyout port UUCSS** command against the conversion resource. Run the test again. 4. If the same error occurs while the conversion resource is idle, busyout both Modem Pool conversion resources on the TN758 Pooled Modem circuit pack containing the conversion resource under test. 5. If the test continues to fail or abort, replace the Pooled Modem circuit pack and retest.
6001	ABORT	System resources needed to complete the test could not be allocated for the analog section of the Modem Pool conversion resource. Follow the test procedures for the previous error code.
NONE	FAIL	The test failed. This error is internal to the Pooled Modem circuit pack and does not involve external equipment or interfaces. 1. Busy-out both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to fail, replace the Pooled Modem circuit pack and retest.

Continued on next page

Table 9-465. TEST #96 Modem Pool NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The NPE of the tested port was found to be transmitting in error. This condition will cause noisy and unreliable connections. 1. If the remaining ports are currently not in use (the yellow LED is off), reset the circuit pack and repeat the test. 2. If the test fails again, replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. Investigate user-reported troubles on this port using other port tests and by examining station, trunk, or external wiring.

Modem Pool Conference Test (#97)

This test is destructive.

The Modem Pool Conference Test checks most of the switching and gain control functions provided by the NPE circuit in the analog section of the conversion resource. This test conferences a 1004-Hz tone through the NPE, looping it back so that it can be verified with a Tone Detector circuit

Table 9-466. TEST #97 Modem Pool Conference Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Determine whether the port is available for testing.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-466. TEST #97 Modem Pool Conference Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Determine whether the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to a previously existing error on the specific port or because of a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack, and attempt to diagnose previously existing errors.
2000	ABORT	The response to the test was not received in the allowable time period.
2012	ABORT	Internal system error.
2100	ABORT	System resources required for this test are not available.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-466. TEST #97 Modem Pool Conference Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4000	ABORT	System resources needed to complete the test could not be allocated. Ordinarily, this means the conversion resource or other hardware used during the test was in use. 1. Wait 1 minute and attempt the test again. 2. If the same error occurs, use the **status port** command to determine whether the Modem Pool conversion resource is in use. 3. If the conversion resource is in use, and it is absolutely necessary to test it, the call must be dropped by issuing a **busyout port UUCSS** command against the conversion resource. Run the test again. 4. If the same error occurs while the conversion resource is idle, busyout both Modem Pool conversion resources on the TN758 Pooled Modem circuit pack containing the conversion resource under test. Run the test again. 5. If the test continues to abort, replace the Pooled Modem circuit pack and retest.
65515	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. Issue the **test port long** command on the port on which the test aborted. If any test aborted or failed, follow recommended maintenance strategy for the appropriate port type (for example, ANL-LINE, DIG-LINE).
None	FAIL	The test failed. This error is internal to the Pooled Modem circuit pack and does not involve external equipment or interfaces. 1. Busy-out both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to fail, replace the Pooled Modem circuit pack and retest.

Continued on next page

Table 9-466. TEST #97 Modem Pool Conference Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The Network Processing Element (NPE) of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. If the remaining ports are currently not in use (the yellow LED is off), reset the circuit pack and repeat the test. 2. If the test fails again, replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Modem Pool Conversion Resource Loop-Around Test (#98)

The Modem Pool Conversion Resource Looparound Test is set up as follows:

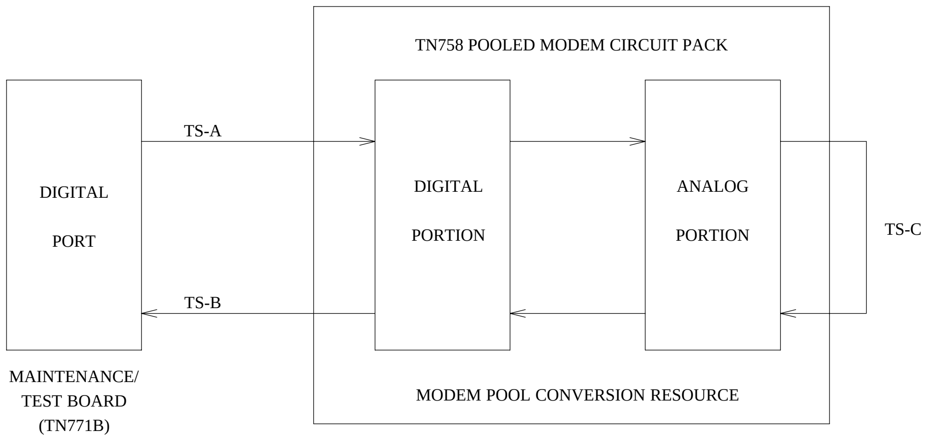

Figure 9-62. Modem Pool Conversion Resource Loop-Around

Test data patterns are transmitted from a Maintenance/Test Board digital port over network time slot A through the digital port on the conversion resource, looped around through the analog port via time slot C back to the Maintenance/Test Board digital port circuit via time slot B where the patterns are checked for accuracy. Finally, the test forces a disconnect by breaking the connection between the Maintenance/Test Board digital port and the Modem Pool Port (time slot A) and verifying that the Maintenance/Test Board digital port and Modem Pool Port go on-hook within the proper time.This test attempts to allocate a Maintenance/Test Board digital port, Modem Pool Port, and other internal resources. If any of these allocation attempts fail, the test cannot be completed and a specific abort error is reported.

Table 9-467. TEST #98 Modem Pool Conversion Resource Looparound Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources needed to complete the test could not be allocated for the digital section of the Modem Pool conversion resource. Ordinarily, this means the conversion resource or other hardware used during the test was in use. 1. Wait 1 minute and attempt the test again. 2. If the conversion resource is in use, and it is absolutely necessary to test it, the call will have to be dropped by issuing a **busyout port UUCSSpp** command against the conversion resource. Run the test again. If the test passes, release the port. 3. If the same error occurs while the conversion resource is idle, busy out both Modem Pool conversion resources on the TN758 Pooled Modem circuit pack containing the conversion resource under test. Rerun the test. 4. If the test continues to abort, replace the Pooled Modem circuit pack and retest.

Continued on next page

Table 9-467. TEST #98 Modem Pool Conversion Resource Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1180	ABORT	A Maintenance/Test Board digital port could not be allocated for this test. This error is more closely related to the digital port on the specific Maintenance/Test Board circuit pack used for this test than the TN758 Pooled Modem circuit pack itself. Therefore, any hardware testing or replacement activities will focus on the Maintenance/Test Board circuit pack. Verify that the digital ports of the Maintenance/Test Board are present if this error occurs. 1. Use the **list config** command to verify that both of the Maintenance/Test Board digital ports are present. The display should show entries for both port 02 and port 03. 2. If the digital ports (02 and 03) are not present, refer to the M/T-BD Maintenance documentation. 3. If the digital ports are present, retry the command at 1 minute intervals a maximum of 5 times.
1181	ABORT	No time-slots available to connect digital ports for the test. 1. Retry the command at 1 minute intervals a maximum of 5 times.
1182	ABORT	Internal system error. Failed to connect the digital ports with time-slots. 1. Retry the command at 1 minute intervals a maximum of 5 times.
1340	ABORT	No Maintenance/Test digital port is currently available to perform this test. 1. Use **list config** to determine whether any Maintenance/Test digital ports (ports 02 and 03 on the Maintenance/Test circuit pack) are present in the system. Because at least one Maintenance/Test circuit pack must always be present in the PPN of any G3r system, there should be at least two such ports present. If the ports are present, proceed to step 2. Otherwise, determine why no ports appear in the **list config** display. 2. If the ports are present and no errors are logged against them, retry the command at 1 minute intervals a maximum of 5 times. 3. If the test continues to abort, replace the Maintenance/Test circuit pack.

Continued on next page

Table 9-467. TEST #98 Modem Pool Conversion Resource Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2004	ABORT	Off-Hook was not received from the Pooled Modem. 1. Busy-out the digital port being tested on the Pooled Modem circuit pack. Retry the command at 1 minute intervals a maximum of 5 times. 2. If the test still aborts, replace the circuit pack.
2005	ABORT	The Maintenance/Test Board digital port and the Pooled Modem Board digital port failed to handshake. 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If the test still aborts, replace the Pooled Modem circuit pack.
2312	ABORT	The Looparound Test did not complete, failed to receive loop-back data. 1. Retry the test, if still aborts, replace the Pooled Modem Board.
2313	ABORT	The Maintenance/Test Board digital port allocated for this test did not respond to downlinked message. 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If the test continues to abort, replace the MTB.
2314	ABORT	The Modem Pool digital port did not respond to downlinked message. This error is internal to the Modem Pool circuit pack and does not involve external equipment or interfaces. 1. Busy-out the TN758 Pooled Modem conversion resources on the circuit pack. 2. If the test continues to abort, replace the Pooled Modem circuit pack and retest.
2500	ABORT	Internal system error. 1. Retry the command at 1 minute intervals a maximum of 5 times.
2323	ABORT	The Maintenance Test circuit pack digital port allocated for this test did not disconnect properly. This error is more closely related to the Maintenance Test circuit pack digital port used for this test than the TN758 Pooled Modem circuit pack itself. Therefore, any hardware testing or replacement activities will focus on the Maintenance Test circuit pack. 1. Wait 1 minute and attempt the test again a maximum of 5 times.

Continued on next page

Table 9-467. TEST #98 Modem Pool Conversion Resource Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2324	ABORT	The digital portion of the tested Modem Pool port did not disconnect properly. 1. Wait 1 minute and attempt the test again. 2. If the test continues to abort, replace the Pooled Modem circuit pack and retest.
2325	FAIL	The Modem Pool port did not respond with an on-hook message when the connection to the TN711 Maintenance/Test digital port was broken, indicating a likely problem with the TN758 Pooled Modem circuit pack. 1. Busy-out both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to fail, replace the Pooled Modem circuit pack and retest.
	FAIL	The Looparound Test failed, the loop-back data did not match the original data. 1. Repeat Test #98. 2. If the test fails again, replace the Pooled Modem circuit pack.
	PASS	The port can correctly transmit/receive data.

Modem Pool Audit Test (#99)

This audit updates the Modem Pool conversion resource status contained in the TN758 Pooled Modem circuit pack's microprocessor. It does not actually test the Pooled Modem circuit pack; therefore, there are no FAIL codes. The audit can only be performed on idle conversion resources. If the conversion resource is in use, the audit will abort.

Table 9-468. TEST #99 Modem Pool Audit Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	The system was not able to allocate all the necessary resources to execute this test. An ABORT simply indicates that the conversion resource was in use when the audit was performed. No repair action is necessary unless the conversion resource was known to be idle during the test (yellow in-use LED was off) or was busied out before the test was run. In that case, a TN758 failure condition may exist and the following procedure should be used: 1. Busyout both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to abort, replace the Pooled Modem circuit pack and retest.

M/T-ANL (Maintenance/Test Analog Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
M/T-ANL	Minor	test port UUCSSpp l	Maintenance/Test Analog Port
M/T-ANL	Warning	release port UUCSSpp	Maintenance/Test Analog Port

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The Maintenance/Test Analog Port is port number 1 on the TN771 Maintenance/Test circuit pack. This port is used by the Automatic Transmission Measurement System (ATMS) as an Originating Test Line (OTL) or Terminating Test Line (TTL) for test calls over analog trunks. For more details, see ‘‘Automatic Trunk Transmission System’’ in Chapter 6, ‘‘Additional Maintenance Procedures’’. Figure 9-63 shows a typical ATMS configuration.

M/T-ANL maintenance ensures that the analog trunk’s testing function is operating correctly. An alarm against M/T-ANL can reduce service, but it will not block it. To accurately measure performance and health of analog trunks, the TN771 should be replaced when a new circuit pack is available.

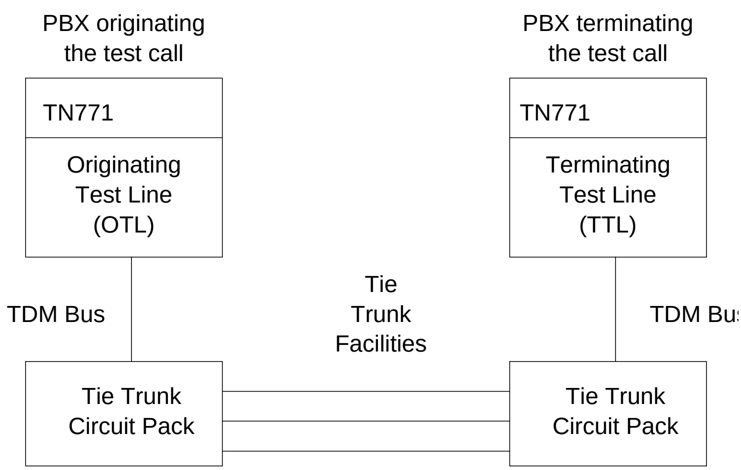

Figure 9-63. ATMS Tie Trunk Test Call

Error Log Entries and Test to Clear Values

Table 9-469. M/T-ANL Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1] (a)	0	Any	Any	Any	test port UUCSSpp
1 (b)	41018	none	MINOR	ON	test port UUCSSpp l r 3
18	0	busyout port UUCSSpp	WARNING	OFF	release port UUCSSpp
257	Any	NPE Crosstalk test (#9)	MINOR	ON	test port UUCSSpp l r 3
513	Any	Analog Port Sanity Test (#963)	MINOR	ON	test port UUCSS01 r 2
769	Any	Analog Port Digital Looparound Test (#13)	MINOR	ON	test port UUCSSpp r 3
3840(c)	Any	Hook State Inquiry test (#566)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error code appears in the Error Log only if the MTB circuit pack has been removed since the Error Log was last cleared. Verify that the circuit pack has been reinserted.

b. This error indicates a hardware failure on the Analog Port circuitry. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the command above.

c. This error indicates that call processing records did not agree with on-board records for the hook state (on-/off-hook) of the Maintenance/Test Analog Port. This error is not service-affecting and no action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Analog Port Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Analog Port Sanity Test (#963)	X	X	ND
Digital Looparound Test (#13)	X	X	ND
NPE Crosstalk Test (#9)		X	ND
Hook State Inquiry (#566)	X	X	ND
Clear Error Counters (#270)		X	ND

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#9)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections.

One or more Network Processing Elements (NPE) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity, gain, and provides conferencing functions on a per port basis. If the NPE is not working correctly, one way and/or noisy connections may be observed. This test is part of a port's long test sequence and takes approximately 10 to 20 seconds to complete.

Table 9-470. TEST #9 NPE Cross Talk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid ATMS trunk test call. 1. Retry the command at 1-minute intervals a maximum of 3 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out of service due to TDM-BUS errors. A system is considered under heavy traffic when the Call Processing Occupancy is greater than 50% or when the System Management and the Call Processing Occupancies together exceed 65%. To view the system occupancy measurements enter the command **status system health** on the system technician terminal. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 3 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 3 times.
1004	ABORT	The port has been seized by a valid ATMS test call. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to abort and the port is not in use on a valid ATMS Test Call, escalate the problem. To determine whether the port is in use by an ATMS Test Call enter **status station ext** where **ext** is the assigned ATMS station number.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-470. TEST #9 NPE Cross Talk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. If the remaining ports are currently not in use (yellow LED is off), try to reset the circuit pack via the **busyout board UUCSS**, **reset board UUCSS**, **release board UUCSS** command sequence. Then repeat the test. 2. If the test fails again, replace circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by examining station, trunk, or external wiring.

Analog Port Digital Looparound Test (#13)

This test is a modification of the Voice and Control Channel Local Loop Test used by Digital Station (DIG-LINE) maintenance. This test does not perform the control channel and secondary information channel loop around tests as described for DIG-LINE, as these data paths do not exist for the Maintenance/Test Analog Port. The primary information channel is tested by first looping back the data channel onto the TDM Bus, and then sending a digital count from the Tone-Clock circuit pack and receiving the same digital count with a general purpose tone detector. A conference test is done next for the primary information channel. This test is the same as Conference Test (#6).

Only one value (Pass, Fail, or Abort) is generated as a result of the two tests. If either fails or aborts, the sequence is stopped.

Table 9-471. TEST #13 Analog Port Digital Looparound Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
1000	ABORT	The port is in use on a valid ATMS Test Call. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to abort and the port is not in use on a valid ATMS Test Call, escalate the problem. To determine whether the port is in use by an ATMS Test Call enter **status station ext** where **ext** is the assigned ATMS station number.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. A system is considered under heavy traffic when the Call Processing Occupancy is greater than 50% or when the System Management and the Call Processing Occupancies together exceed 65%. To view the system occupancy measurements enter the command **status system health** on the system technician terminal. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 3 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. i 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
1004	ABORT	The port was seized by a valid ATMS Test Call. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort and the port is not in use on a valid ATMS Test Call, escalate the problem. To determine whether the port is in use by an ATMS Test Call enter **status station ext** where **ext** is the assigned ATMS station number.

Continued on next page

Table 9-471. TEST #13 Analog Port Digital Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals a maximum of 3 times.
7	FAIL	Conference test failed on the primary information channel. 1. Run the circuit pack tests to check the Tone/Clock (TONE-BD) circuit pack and the Tone Detector circuit pack via the **test board UUCSS** command. 2. Resolve any problems that are detected on the Tone/Clock (TONE-BD) circuit pack or Tone Detector circuit pack. See the section on Tone Generator circuit pack. 3. If the Tone/Clock and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test circuit pack.
14	FAIL	The primary information channel is not transmitting properly. User may not notice any interruption in service or may not be able to use this port. 1. Run the circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using **test board UUCSS**. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. See the section on Tone Generator circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test Circuit Pack.
	PASS	The Maintenance/Test Analog Port analog trunk testing capability is operating correctly.

Clear Error Counters (#270)

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed port/circuit pack from flooding the SPE with a string of messages). Many circuit packs have counters in the Angel firmware. These counters are used so that Control Channel Message Set (CCMS) messages are not continuously sent uplink. Using this method, the message will be sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared. This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel will send a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test Circuit Pack. Therefore, this test should never abort or fail.

Table 9-472. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
	PASS	The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent.

Hook State Inquiry (#566)

This test ensures that the Maintenance/Test Analog Port maintenance software and call processing agree on the on-/off-hook status of the Maintenance/Test Analog Port.

Table 9-473. TEST #566 Hook State Inquiry

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switch hook audit timed out. No response was received from the circuit pack for information about the switch hook state. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to abort, replace the circuit pack and repeat the test.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.
Any	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to fail reset the circuit pack via the **busyout board UUCSS**, **reset board UUCSS**, **release board UUCSS** command sequence. 3. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	Call processing and Maintenance/Test Analog Port maintenance software agree on the Maintenance/Test Analog Port hook state.

Analog Port Sanity Test (#963)

This test verifies that the port circuitry involved in the analog trunk testing on the Maintenance/Test Analog Port is functioning properly.

This test will abort if an ATMS Test Call is in progress on the Maintenance/Test Analog Port when the test is requested.

Table 9-474. TEST #963 Analog Port Sanity Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at 1-minute intervals a maximum of 3 times.
50	FAIL	The switch was unable to communicate with the port circuitry used for analog trunk testing. 1. Reset the circuit pack via the **busyout board UUCSS**, **reset board UUCSS**, **release board UUCSS** command sequence. 2. Test the port again via the **test port UUCSS01 l** command. 3. If the test fails again, replace the circuit pack.
	PASS	The Maintenance/Test Analog Port analog trunk testing capability is operating correctly.

M/T-BD (Maintenance/Test Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
M/T-BD	MIN	test board UUCSS l	Maintenance/Test Circuit Pack
M/T-BD	WRN	release board UUCSS	Maintenance/Test Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The Maintenance/Test Circuit Pack supports Packet Bus fault detection and bus reconfiguration for the port network in which it is installed. The circuit pack also provides Analog Trunk testing, and data loopback testing of DCP Mode 2 endpoints and Digital (ISDN) Trunk Facilities via the TDM bus.

Port 1 of the Maintenance/Test board is the Analog Test port which provides the Analog Trunk testing function for Automatic Transmission Measurement System (ATMS). ATMS is a feature in which calls are made from a device called an Originating Test Line (OTL) over a specific trunk to a device called a Terminating Test Line (TTL). The OTL and TTL can then send tones over the trunk under test and determine the quality of the connection. Ports 2 and 3 are the Digital ports which provide the Digital (ISDN) Trunk testing functions. Port 4 is the Packet port which provides the Packet Bus maintenance function.

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also M/T-ANA (Maintenance/Test Analog Test Port), M/T-DIG (Maintenance/Test Digital Port) and M/T-PKT (Maintenance/Test Packet Bus Port) Maintenance documentation for related analog test port digital port and Packet Bus port information, respectively.

All ports except the Analog port (port 1) of the Maintenance/Test Board are automatically administered when the circuit pack is inserted into the system and they are removed when the circuit pack is unplugged from the system. The Analog port however, is administered via the station screen with the type "105TL" for an OTL or a TTL. This port remains administered even after the circuit pack is physically removed from the system. Care should be taken to remove the OTL or the TTL before unplugging the circuit pack.

Hardware Error Log Entries and Test to Clear Values

Maintenance/Test Board Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level[1]	On/Off Board	Test to Clear Value
0[2]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	0	SAKI Sanity Test (#53)	MINOR	ON	See footnote a
18(b)	0	Busyout Board	WARNING	OFF	release board UUCSS
36(c)	0				
217(e)		WARNING	ON		
257(d)	0	CC Loop Test (#52)	MINOR	ON	test board UUCSS r3
267(e)		WARNING	ON		
513(f)	4352 to 4357				
769(g)	4358				
1025(h)	4363	NPE Audit Test (#50)			test board UUCSS l
1538(i)	0		MINOR	ON	
3840(j)	4096 to 4101				
3999 (k)	Any	None			

1. Major or Minor alarms on this MO may have been downgraded to Warning alarms based on the values used in the **set options** command.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates that the circuit pack has stopped functioning. Reset the circuit pack via **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS** commands. If the SAKI Sanity Test (#53) passes, then the on-board circuitry is healthy. If the SAKI Sanity Test (#53) fails, replace the circuit pack.

b. The circuit pack has been busied out via the **busyout board UUCSS** command. Execute **release board UUCSS** command.

c. A port processor on the circuit pack failed to initialize. Reset the circuit pack via **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**. if the problem does not go away, replace the circuit pack.

d. A Control Channel Protocol Error has occurred. This may be due to an on-board hardware failure detected by the circuit pack. Reset the circuit pack by executing **busyout board UUCSS** and **reset board UUCSS** commands. If there is a problem, it will be detected during initialization and will cause the circuit pack to lock up and appear insane to the system.

e. An extra TN771D circuit pack has been inserted into the port network.

f. An on-board hardware failure has been detected by the circuit pack. Reset the circuit pack via the **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS** commands. If SAKI Sanity Test (#53) passes, the circuitry is healthy. If SAKI Sanity Test (#53) fails, replace the circuit pack.

g. This error is reported by the circuit pack when it detects a program logic error. While no action is required, this error may lead to errors of other types being reported against this circuit pack.

h. This error is reported by the circuit pack when it cannot update NPE memory and read it back. This error type can be ignored, but may lead to errors of other types being reported against this circuit pack.

i. Excessive number of messages have been received from the Maintenance/Test circuit pack. This may be due to a hardware problem on the circuit pack. The switch will take the board out of service and periodically put it back into service to see if the problem has disappeared. If the problem persists, replace the circuit pack.

j. This error is not service affecting. No action is required. This error is reported by the circuit pack when it receives a bad control channel message from the switch.

k. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Control Channel Loop Around Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop-Around Test (#52)	X	X	ND
NPE Audit Test (#50)		X	ND

1. D = Destructive, ND = Non-destructive

Repair procedures for the above tests are described in "XXX-BD (Common Port Circuit Pack)" Maintenance documentation section.

M/T-DIG (Maintenance/Test Digital Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
M/T-DIG	Minor	test port UUCSSpp l	Maintenance/Test Digital Port
M/T-DIG	Warning	release port UUCSSpp	Maintenance/Test Digital Port

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The Maintenance/Test Digital Port is a port on the TN771D circuit pack. Ports 2 and 3 are Digital Ports. The Maintenance/Test Digital Port provides the ability to perform digital (i.e., ISDN-PRI) trunk testing via the TDM Bus. For an ISDN-PRI test call, connections are set up in the system as shown in Figure 9-64.

When the Maintenance/Test Digital Port is participating in an ISDN-PRI test call, the port sends a stream of pseudo-random data along the connected B-channel. The far end loops back this data, and the Maintenance/Test Digital Port compares the data to that which was sent. Errors are recorded on a bit and block basis. Refer to ISDN-TRK (DS1 ISDN Trunk) Maintenance documentation for more information on ISDN-PRI test calls.

The Maintenance/Test Digital Port maintenance ensures that the digital trunk testing function is operating correctly. The Maintenance/Test Digital Port is alarmed if maintenance determines that the digital port is operating incorrectly.

NOTE:
An alarm on the Maintenance/Test Digital Port reduces service, but does not block it since the ISDN-TRK has other means to determine the health of the ISDN-PRI trunk facility. However, to accurately measure the error performance and to ensure accuracy of the health of the ISDN-PRI trunk, the Maintenance/Test circuit pack should be replaced when a new circuit pack is available.

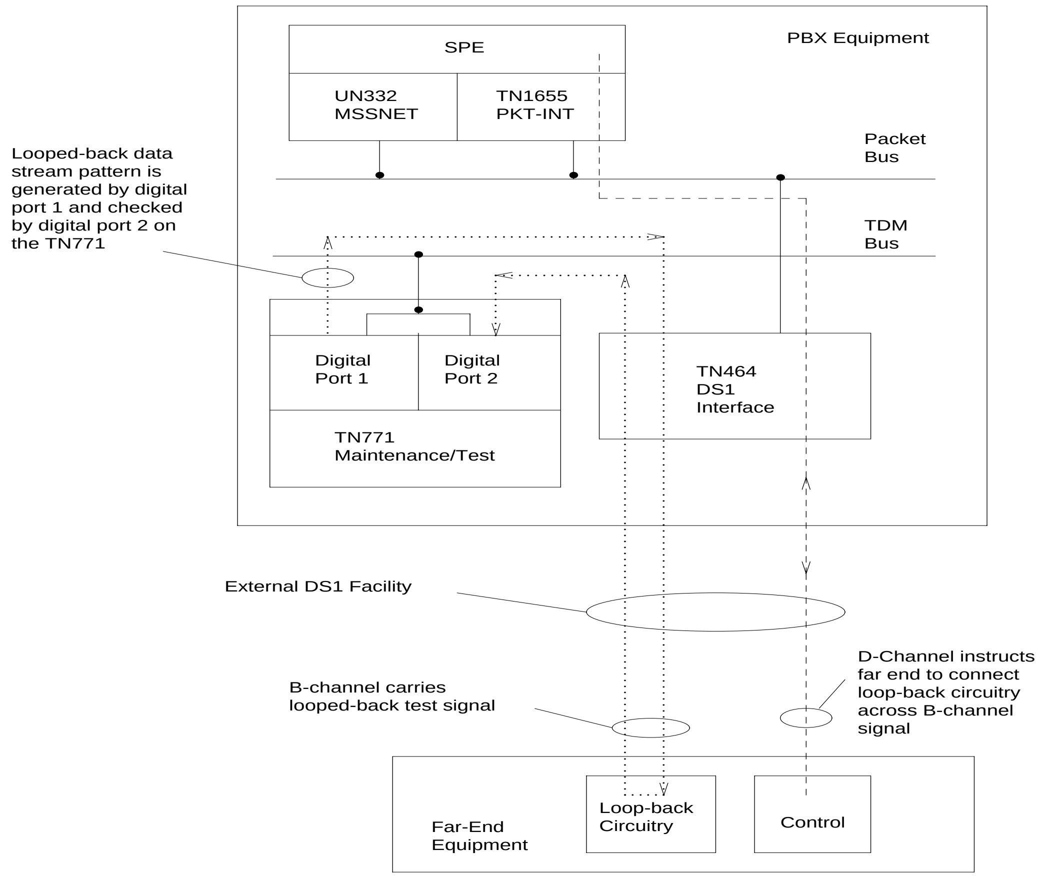

Figure 9-64. ISDN-PRI Outgoing Test Call

Hardware Error Log Entries and Test to Clear Values

M/T-DIG Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp
1 (a)	41018	none	MINOR	ON	test port UUCSSpp l r 3
18 (b)	0	busy-out port UUCSSpp	WARNING	OFF	release port UUCSSpp
257 (c)	Any	NPE Crosstalk Test (#9)	MINOR	ON	test port UUCSSpp l r 3
513 (d)	Any	Digital Port Sanity Test (#565)	MINOR	ON	test port *UUCSS*02 r 2
769 (e)	Any	Digital Port Loop Around Test (#13)	MINOR	ON	test port UUCSSpp r 3
3840 (f)	Any	Hook State Inquiry test (#566)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates a hardware failure on the Digital Port circuitry. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the command above.

b. The port has been busied out via the **busy-out port UUCSSpp** command.

c. This error indicates that Maintenance/Test Digital Port is talking on more than just its assigned time slot. Replace the Maintenance/Test circuit pack.

d. This error indicates that the Maintenance/Test Digital Port has failed its self-test. Since the Digital Port Sanity Test runs only on port 2, but tests both ports 2 and 3, both ports will be alarmed when the test fails. Note that the command above indicates to test port 2, even if the error is logged against port 3.

e. This error indicates that the Maintenance/Test Digital Port has been unable to successfully loop data from a tone generator to a tone detector.

f. This error indicated that call processing records did not agree with on-board records for the hook state (on-/off-hook) of the Maintenance/Test Digital Port. This error is not service-affecting and no action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Digital Port Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Digital Port Sanity Test (#565)	X	X	ND
Digital Port Loop Around Test (#13)	X	X	ND
NPE Crosstalk Test (#9)		X	ND
Hook State Inquiry (#566)	X	X	ND
Clear Error Counters (#270)		X	ND

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#9)

This test is a modified version of the Digital Line NPE Crosstalk Test used by DIG-LINE maintenance.

One or more Network Processing Elements (NPE) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity, gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and/or noisy connections may be observed. This test is part of a port's long test sequence and takes approximately 10 to 20 seconds to complete. This test is a modified version of the Digital Line NPE Crosstalk Test used by DIG-LINE maintenance

Table 9-475. TEST #9 NPE Cross Talk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid ISDN-PRI test call. Use the **list isdn-testcall** command to determine if the port is in use (if the port is listed in the M/T Port column). If it is in use, either wait for the test call to complete (as indicated in the Start Time and Duration fields in the above display), or abort the test call with the **clear isdn-testcall grp/mem** command, where **grp/mem** is determined from the B-channel field of the above display. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out of service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-475. TEST #9 NPE Cross Talk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port has been seized by a valid ISDN-PRI test call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall grp/mem** command, where grp/mem is determined form the B-channel field of the above display. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. If the remaining ports are currently not in use (yellow LED is off), try to reset the circuit pack. Then repeat the test. 2. If the test fails again, replace circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Digital Port Loop Around Test (#13)

This test is a modification of the Voice and Control Channel Local Loop Test used by Digital Station (DIG-LINE) maintenance. This test does not perform the control channel and secondary information channel loop around tests as described for DIG-LINE, as these data paths do not exist for the Maintenance/Test Digital Port. The primary information channel is tested by first looping back the data channel onto the TDM Bus, and then sending a digital count from the Tone-Clock circuit pack and receiving the same digital count with a general purpose tone detector. A conference test is done next for the primary information channel. This test is the same as Conference Test (#6).

Only one value (Pass, Fail, or Abort) is generated as a result of the two tests. If either fails or aborts, the sequence is stopped.

Table 9-476. TEST #13 Digital Port Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The port is use on a valid ISDN-PRI Test Call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields in the above display), or abort the test call with the **clear isdn-testcall grp/mem** command, where grp/mem is determined from the B-channel field of the above display. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-476. TEST #13 Digital Port Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid ISDN-PRI Test Call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall grp/mem** command, where grp/mem is determined from the B-channel field of the above display. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
7	FAIL	Conference test failed on the primary information channel. In most cases, the user may not notice a disruption in service. 1. Run the circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack via the **test board UUCSS** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test circuit pack.

Continued on next page

Table 9-476. TEST #13 Digital Port Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
14	FAIL	The primary information channel is not transmitting properly. User impact may range from nothing to not being able to use this port. 1. Run the circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using **test board UUCSS**. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test Circuit Pack.
	PASS	The Maintenance/Test Digital Port digital trunk testing capability is operating correctly.

Clear Error Counters (#270)

This test is not an actual test in the strict sense of the word. Many circuit packs have counters in the Angel firmware. These counters are used so that Control Channel Message Set (CCMS) messages are not continuously sent uplink. Using this method, the message will be sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared.

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed port/circuit pack from flooding the SPE with a string of messages). This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel will send a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test Circuit Pack. Therefore, this test should never abort or fail.

Table 9-477. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
	PASS	The message to clear the Maintenance/Test circuit pack’s counter for Background Maintenance Failures has been sent.

Digital Port Sanity Test (#565)

This test verifies that the port circuitry involved in the digital trunk testing on the Maintenance/Test Digital Port is functioning properly. This circuitry is common to both Maintenance/Test Digital Ports on the Maintenance/Test circuit pack. Therefore, this test is only run for port 2. The test will abort when run on port 3, as described in Table 9-478.

This test operates by connecting the two Maintenance/Test Digital Ports on the TDM Bus so that they talk and listen to each other. Then four self-tests are attempted: (a) sending data from port 2 to port 3 in asynchronous mode; (b) sending data from port 3 to port 2 in asynchronous mode; (c) sending data from port 2 to port 3 in synchronous mode; and (d) sending data from port 3 to port 2 in synchronous mode. The test passes if all four of these self-tests are successful. The test will stop as soon as any one of these self-tests fails.

This test will abort if an ISDN Test Call is in progress on either Maintenance/Test Digital Port when the test is requested, or if an ISDN Test Call is initiated while the Digital Port Sanity Test is in progress

Table 9-478. TEST #565 Digital Port Sanity Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	One of the Maintenance/Test Digital Ports is busy with background maintenance. 1. Either wait for the port to become idle, or busy-out both Maintenance/Test Digital Ports on the Maintenance/Test circuit pack via the **busy-out port** UUCSS**02** and **busy-out port** UUCSS**03** commands, respectively. 2. Release the ports (if they were busied out) via the **release port** UUCSS**02** and **release port** UUCSS**03** commands, respectively. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors, and if not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-478. TEST #565 Digital Port Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid ISDN-PRI Test Call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall grp/mem** command, where **grp/mem** is determined from the B-channel field of the above display.
1019	ABORT	An ISDN Test Call is in progress using this Maintenance/Test circuit pack. The Maintenance/Test circuit pack cannot perform a self-test on one of its Digital Ports while an ISDN Test Call is using either of the Digital Ports. Use the **list isdn-testcall** command to determine which call is using the port (form the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall grp/mem** command, where **grp/mem** is determined from the B-channel field of the above display. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1138	ABORT	This test does not run on port 3 of the Maintenance/Test circuit pack. This test will only run on port 2. Look at the results of the Digital Port Sanity Test for port 2. 1. Run the command again for port 2 via the **test port** UUCSS**02** or **test port** UUCSS**02 l** command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
50	FAIL	The switch was unable to communicate with the port circuitry used for digital trunk testing.

Continued on next page

Table 9-478. TEST #565 Digital Port Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
100	FAIL	Data was not sent from port 2 to port 3 successfully in asynchronous mode.
101	FAIL	Data was not sent from port 3 to port 2 successfully in asynchronous mode.
102	FAIL	Data was not sent from port 2 to port 3 successfully in synchronous mode.
103	FAIL	Data was not sent from port 3 to port 2 successfully in synchronous mode. 1. Reset the circuit pack via the **busy-out board UUCSS**, **reset board UUCSS**, **release board UUCSS** command sequence. 2. Test the port again via the **test port** UUCSS**02 l** command. 3. If the test fails again, replace the circuit pack.
	PASS	The Maintenance/Test Digital Port digital trunk testing capability is operating correctly.

Hook State Inquiry (#566)

This test ensures that the Maintenance/Test Digital Port maintenance software and call processing agree on the on-/off-hook status of the Maintenance/Test Digital Port.

Table 9-479. TEST #566 Hook State Inquiry

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switch hook audit timed out. No response was received from the circuit pack for information about the switch hook state. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, replace the circuit pack and repeat the test. 3. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	Internal System Error This test should never return a failure. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail reset the circuit pack via the **busy-out board UUCSS**, **reset board UUCSS**, **release board UUCSS** command sequence. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to fail, escalate the problem.
	PASS	Call processing and Maintenance/Test Digital Port maintenance software agree on the Maintenance/Test Digital Port hook state.

M/T-PKT (Maintenance/Test Packet Bus Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
M/T-PKT	Minor	test port UUCSSpp l	Maintenance/Test Packet Bus Port
M/T-PKT	Warning	release port UUCSSpp	Maintenance/Test Packet Bus Port

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The Maintenance/Test Packet Bus Port (M/T-PKT) is port number 4 on the TN771 Maintenance/Test circuit pack. The Packet Bus port provides the following Packet Bus maintenance functions:

- Packet Bus fault detection

  The ability to detect faults (e.g., shorts, open leads) on the Packet Bus autonomously (i.e. without SPE involvement).

- Packet Bus reconfiguration

  The ability to swap faulty leads with spare leads autonomously so that the Packet Bus remains operational. This is accomplished by sending messages to all Packet circuit packs [e.g., ISDN-BRI (TN556)] telling them which spare leads to use on the Packet Bus.

M/T-PKT maintenance ensures that these maintenance functions are operating correctly. The Maintenance/Test Packet Bus Port is alarmed if maintenance determines that the port’s maintenance functions are operating incorrectly.

When M/T-PKT maintenance determines that the Packet Bus Port is defective, the Packet Bus fault detection and Packet Bus reconfiguration functions provided by the port will be turned off.

M/T-PKT maintenance interacts with Packet Bus maintenance. Therefore, there may be alarms on the Packet Bus when there is a fault on the M/T-PKT. Refer to PKT-BUS (Packet Bus) Maintenance documentation for further information.

Hardware Error Log Entries and Test to Clear Values

M/T-PKT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp
1 (a)	41018	none	MINOR	ON	test port UUCSSpp l r 3
18 (b)	0	busyout port UUCSSpp	WARNING	OFF	release port UUCSSpp
257 (c)	Any	none	MINOR	ON	
513 (d)	Any	Packet Bus Port Health Inquiry Test (#567)	MINOR	ON	test port UUCSSpp r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates a hardware failure with the port circuitry which provides the Packet Bus maintenance functions. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the test command above.

b. The port has been busied out via the **busyout port UUCSSpp** command.

c. This error indicates that the Maintenance/Test Packet Bus Port has reconfigured the Packet Bus by swapping a bad lead to a spare. Note that this error is sent up whenever the Maintenance/Test Packet Bus Port is initialized (since the Packet Bus Port reconfigures the Packet Bus to whatever state it determines the Packet Bus is in). This will occur if the circuit pack is inserted, if the system is restarted, or if the port is released from a busyout state. Therefore, it is normal for this error to be present in the error log.

   If the M/T-PKT reconfigures the Packet Bus 6 times within 15 minutes, a Minor alarm is raised indicating that either Packet Bus maintenance functions are not operating correctly, or many changes are taking place on the Packet Bus (circuit pack insertions or removals). If the system has been in a stable state for more than 15 minutes, try the following procedure:

1. Reset the Maintenance/Test circuit pack from the G3-MT as follows:
   - Enter the **busyout board UUCSS** command.
   - Enter the **reset board UUCSS** command.
   - Enter the **release board UUCSS** command.
2. Wait 15 minutes.
3. If the error recurs, replace the Maintenance/Test circuit pack.

When this alarm is active, the yellow LED will be in one of three states:

- An unlit yellow LED indicates no activity on the Maintenance/Test circuit pack. You can replace the Maintenance/Test circuit pack.
- If there is an indication of an uncorrectable fault on the Packet Bus, the yellow LED will be blinking at a rate of 1 Hz. It is OK to replace the Maintenance/Test circuit pack. Ignore the Packet Bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.
- If there is other activity on the Maintenance/Test circuit pack (i.e. ISDN Test Call), or if there is an indication of a correctable fault on the Packet Bus, the yellow LED will be on steady. If there is an ISDN Test Call in progress, it must be halted via the **clear isdn-testcall grp/member** command prior to replacing the circuit pack. Ignore the Packet Bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.

d. This error indicates a failure of the Packet Bus Port Health Inquiry Test. Either the Packet Bus Port has reported a self-test failure, or the SPE is able to communicate with the Maintenance/Test Circuit Pack but not with the Maintenance/Test Circuit Pack Packet Bus Port. Refer to the description of the Packet Bus Port Health Inquiry Test, and follow the instructions indicated for the failure code that matches the Aux Data field.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Packet Bus Port Health Inquiry Test (#567)	X	X	ND
Clear Error Counters (#270)		X	ND

1. D = Destructive, ND = Non-destructive

Clear Error Counters (#270)

This test is not an actual test in the strict sense of the word. Many circuit packs have counters in the Angel firmware. The circuit pack's Angel continuously runs port self-tests on idle ports and keeps track of any errors it detects by incrementing a firmware counter. When the counter value reaches some preset threshold, the Angel sends a single CCMS (Control Channel Message Set) error message uplink to the SPE. No more error messages of that type are sent uplink until the SPE sends a downlink message to clear the counter. This strategy keeps a failed port/circuit pack from flooding the SPE with a continuous string of identical error messages). This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel will send a message to indicate that fact.

This test is only used to send a downlink message to the Angel on the Maintenance/Test circuit pack. Since the Angel normally provides no uplink response to this message, this test should never abort or fail.

Table 9-480. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
	PASS	The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent.

Packet Bus Port Health Inquiry Test (#567)

This test verifies that the Packet Bus fault detection maintenance function of the M/T-PKT is functioning properly. This is done by having the M/T-PKT perform a self-test. If this self-test passes, then the Packet Bus Port Health Inquiry Test passes. If the self-test fails, or the SPE cannot communicate with the M/T-PKT, then the test fails

Table 9-481. TEST #567 Consistency Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources necessary to run this test are not available.
2500	ABORT	An internal operation failed, and the test could not be completed. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2059	FAIL	The M/T-PKT has reported a failure of the on-board self-test.
2060	FAIL	The M/T-PKT has reported an invalid state for the Packet Bus.
2061	FAIL	The SPE cannot communicate with the M/T-PKT, but is able to communicate with the Maintenance/Test Circuit Pack. 1. Retry the command. 2. If the test continues to fail, replace the Maintenance/Test circuit pack and retry the command. 3. If the test continues to fail, refer to PKT-BUS Maintenance documentation to determine if the M/T-PKT failure is being caused by a Packet Bus fault.
	PASS	The M/T-PKT Packet Bus fault detection capability is operating correctly.

OPS-LINE (DS1 Off Premises Station Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
OPS-LINE	MINOR	test station *extension* l	DS1 OPS Line
OPS-LINE	WARNING	test station *extension*	DS1 OPS Line

An analog Off-Premises Station (OPS) can be connected to the system through a DS1 link. A TN767 DS1 Interface circuit pack or a TN464 UDS1 Interface circuit pack can support up to 24 DS1 OPSs. Since the DS1 OPS is an analog telephone set, a channel multiplexer is necessary as the remote DS1 endpoint that converts the digital signal of a DS1 port to the OPS Line and vice versa.

The DS1 OPS Line Maintenance provides a strategy to maintain an OPS Line via a trunk port of the TN767 DS1 Interface circuit pack or the TN464 UDS1 Interface circuit pack. (Throughout this section, the term DS1 Interface can apply to either of these circuit packs.) The strategy covers initialization tests, periodic tests, scheduled tests, system technician-demanded tests, and alarm resolution and escalation. Two service states are specified in a DS1 OPS Line maintenance. They are: *out-of-service*, in which the line is in a deactivated state and cannot be used for either incoming or outgoing calls; or *in-service*, in which the line is in an activated state and can be used for both incoming and outgoing calls. If the DS1 Interface circuit pack is out-of-service, then all lines on the DS1 Interface circuit pack are put into the out-of-service state, and a Warning alarm is raised.

For maintenance of the remote DS1 endpoint (for example, a Channel Division Multiplexer or D4 Channel Bank), refer to the maintenance documentation from its vendor for details.

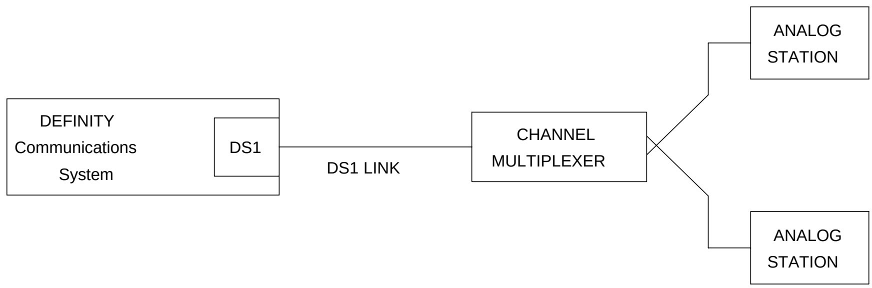

Figure 9-65. DS1 OPS Line Interactions

Error Log Entries and Test to Clear Values

Table 9-482. DS1 OPS Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test station <ext>
15(a)	Any	Audit and Update Test (#36)			
18(b)	0	busyout station <ext>	WARNING	OFF	release station <ext>
130(c)		None	WARNING	ON	test station <ext>
1281		Conference Circuit Test (#7)	MINOR	ON	test station <ext> l r 4
1537		NPE Crosstalk Test (#6)	MINOR	ON	test station <ext> l r 3
1793(d)					test board UUCSS l

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).

b. The DS1 OPS Line has been busied out by a **busyout station <ext>** command. No calls can be made on this line.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. Error Type 1793 indicates a problem with the DS1 Interface circuit pack. Since there is no error against the OPS-LINE port, no alarm is raised against the OPS-LINE port. However, there should be errors logged against the DS1 Interface circuit pack. Look for DS1-BD/UDS1-BD errors in the Hardware Error Log and follow the appropriate procedures provided in the DS1-BD/UDS1-BD (DS1/UDS1 Interface Circuit Pack) Maintenance documentation.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 OPS Switchhook Inquiry Test (#312)	X	X	ND
Audit and Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464 UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.) The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete

Table 9-483. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test or an internal system error (software) occurred. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-483. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. The **status health** command can be used to determine if the system is experiencing heavy traffic. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. The **list measurements tone-receiver** command will display information on the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The test was aborted because the port was seized by a user for a valid call. Use **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to an an already existing error on the specific port or due to a more general error on the circuit pack. 1. Examine the error log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error. (Error code 1793 indicates a problem with the DS1 interface board, and any problems on the associated DS1-BD or UDS1-BD should be resolved first.)

Continued on next page

Table 9-483. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test aborts with error code 2000 again, run short test sequence on the associated DS1-BD or UDS1-BD. If tests 138 through 145 on the associated DS1-BD or UDS1-BD are also aborting with error code 2000, hyperactivity on the board or facility is indicated. In this case, the hyperactivity problem should be dealt with first.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The test failed. This can be due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Resolve any TONE-BD and/or TONE-PT errors. 2. Retest when the faults from step 1 are cleared.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464 UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes

Table 9-484. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status station** or **status trunk** command to determine when the port is available for testing.
1002	ABORT	The test was aborted because the system could not allocate time slots for the test. The system might be under heavy traffic conditions, or it might have time slots out of service due to TDM-BUS errors. (The **status health** command may be used to determine whether the system is experiencing heavy traffic.) 1. If the system has no TDM-BUS errors, is not handling heavy traffic, and the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-484. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port has been seized by a user for a valid call. Use **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	The test was disabled via translation. 1. You may want to determine why the test has been disabled before you enable it. 2. To enable the test for the particular analog station being tested, enter the 'change station extension' command, and then change the 'Test' field on the 'Station' form from 'n' to 'y.'
1020	ABORT	The test did not run due to an already existing error on the specific port or due to a more general error on the circuit pack. 1. Examine the error log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error. (Error code 1793 indicates a problem with the DS1 interface board, and any problems on the associated DS1-BD or UDS1-BD should be resolved first.)
2000	ABORT	The test was aborted because response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test aborts with error code 2000 again, run short test sequence on the associated DS1-BD or UDS1-BD. If tests 138 through 145 on the associated DS1-BD or UDS1-BD are also aborting with error code 2000, hyperactivity on the board or facility is indicated. In this case, the hyperactivity problem should be dealt with first.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-484. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This can cause noisy and unreliable connections. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later. The error log may have error type 1281 entries. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the far-end PBX. Make sure that the near-end and far-end switches and any NTCE equipment (the CSUs) have the correct administration. 6. Replace the circuit pack. **NOTE:** If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.

Continued on next page

Table 9-484. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: line type, dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk as kept in the DS1 Interface circuit pack and in the switch software.

Table 9-485. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	The test was aborted because system resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
1006	ABORT	The test was aborted because the station is out of service. This condition may be accompanied by an error type 18 entry in the error log. You may want to determine why the station was taken out of service. (When stations are taken out of service by maintenance software, the problems that preceded that point must be cleared.) 1. Use the **status station** command to check the service state of the port. If the port is indeed out of service, enter the **release station** command to bring the station back into service. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-485. TEST #36 Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7 or 8	FAIL	Test failed due to internal system error. Do not replace port board. ■ Error code 7: the failure occurred during station translation download (to DS1 Interface circuit pack). ■ Error code 8: the failure occurred during station ringer update. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run but will return PASS. To verify that the station is in-service: 1. Enter the **status station** command to verify that the station is in-service. If the station is in-service, no further action is necessary. If the station is out-of-service, continue to step 2. 2. Enter the **release station** command to put the station back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

DS1 OPS Switchhook Inquiry Test (#312)

This test initiates the Switchhook Audit Test. The test queries the switchhook state of the Off-Premises-Station in switch software. If the state in switch software disagrees with the state on the DS1 Interface circuit pack, then the state in the switch software is updated to match the state on the DS1 Interface circuit pack.

Table 9-486. TEST #312 DS1 OPS Switchhook Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status station** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Test failed due to incompatible configuration administered in station administration. 1. Using the **display station** command, verify that the station is not the 24th port of the DS1 Interface circuit pack while common channel signaling is specified. Use the **display ds1** command to check the signaling type of the DS1 circuit pack.
1006	ABORT	The test was aborted because the station is out of service. This condition may be accompanied by an error type 18 entry in the error log. You may want to determine why the station was taken out of service. (When stations are taken out of service by maintenance software, the problems that led up to that must be cleared.) 1. Use the **status station** command to check the state of the port. If the port is indeed out of service, enter the **release station** command to bring the station back into service. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for DS1-BD/UDS1-BD errors in Hardware Error Log. If present, refer to the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Interface Circuit Pack) Maintenance documentation. 2. Retry the command.
2000	ABORT	The test was aborted because response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test aborts with error code 2000 again, run short test sequence on the associated DS1-BD or UDS1-BD. If tests 138 through 145 on the associated DS1-BD or UDS1-BD are also aborting with error code 2000, hyperactivity on the board or facility is indicated. In this case, the hyperactivity problem should be dealt with first.

Continued on next page

Table 9-486. TEST #312 DS1 OPS Switchhook Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	The test was aborted due to a system error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1	FAIL	Internal system error. 1. Look for DS1-BD/UDS1-BD errors in the Hardware Error Log. If present, refer to the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Interface Circuit Pack) Maintenance documentation. 2. If a channel multiplexer is used as the remote DS1 endpoint to which the station connects, refer to the multiplexer vendor's maintenance document for diagnosis. 3. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The station hook states in both switch software and DS1 Interface circuit pack are consistent.
0 2012	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

PDATA-BD (Packet Data Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PDATA-BD	MINOR	test board UUCSS	PDATA Board Maintenance

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The TN553 Packet Data Line (PDATA-BD) circuit pack supports the connection of twelve (12) asynchronous EIA RS-232C endpoints to the packet bus. Functions of this circuit pack are described in the PDATA-PT section.

Error Log Entries and Test to Clear Values

Table 9-487. PDATA Board Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level[1]	On/Off Board	Test to Clear Value
0[2]		Any	Any	Any	test port UUCSSpp sh r 1
1(a)		None	MINOR	ON	
18(b)		Busyout Board	WARNING	OFF	release board UUCSS
257(c)		CC Loop Test (#52)	MINOR	ON	test board UUCSS r3
513(d)					
769(e)					
1025(f)	4363	NPE Audit Test (#50)			
1293(g)	46088 to 46089		MINOR	ON	
1538(h)	46082		MINOR	ON	
1793(i)	46080		MINOR	ON	
2306(j)	46081				
3330(k)	46083		MINOR	ON	
3840(l)	4096 to 4101				
3843(m)	46097				
3999(n)	Any	None			

1. Major or Minor alarms may have been downgraded to Warning alarms based on the values used in the **set options** command.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Error type 1 indicates the circuit pack has stopped functioning or has been physically removed from the system. This error type does not apply to ANN-BD, DETR-BD, S-SYN-BD, M/T-BD, or CLSFY-BD. The alarm is logged approximately 11 minutes after removal of the circuit pack or failure of the SAKI Sanity Test (#53).

Check for the physical presence of the circuit pack in the slot indicated by the alarm. If the circuit pack is not present, insert one of the proper type. If the circuit pack is present and its red LED is lit, see *LED Alarm Without Alarm Log Entry* in Chapter 7, ''LED Interpretation''.

b. The circuit pack has been busied out via the **busyout board UUCSS** command.

c. This error indicates communication problems between the switch and this circuit pack. Execute the **test board UUCSS** command and refer to the repair procedures for Control Channel Loop-Around Test (#52).

d. An on-board hardware failure has been detected by the circuit pack. Reset the circuit pack by executing **busyout board UUCSS** and **reset board UUCSS** commands. If there is a problem, it will be detected during initialization and will cause the circuit pack to lock up and appear insane to the system. See the repair procedure in footnote (a).

e. This error is reported by the circuit pack when it detects a program logic error. While no action is required, this error may lead to errors of other types being reported against this circuit pack.

f. This error is reported by the circuit pack when it cannot update NPE memory and read it back. This error type can be ignored, but may lead to errors of other types being reported against this circuit pack.

g. A critical hardware failure (one or both of the data processors are insane) has been detected on the circuit pack. Reset the circuit pack via the **busyout board UUCSS** and **reset board UUCSS** commands. If the circuit pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm via the **test board UUCSS long clear** command. If the circuit pack Restart Test (#594) fails, replace the circuit pack.

This error is also caused when the buffers on the board receive data faster than they can transmit to the endpoints (Receive FIFO Overflow). Use the above steps to repair the problem.

h. Circuit pack is hyperactive; i.e., it is flooding the switch with messages sent over the control channel. The circuit pack is taken out-of-service when a threshold number of these errors is reported to the switch. Clear the alarm via the following commands: **busyout board UUCSS, reset board UUCSS, test board UUCSS long clear, release board UUCSS**. if the error recurs within 10 minutes, then replace the circuit pack.

i. This error indicates that parity errors are detected when transmitting data to the Packet Bus. Reset the circuit pack via **busyout board UUCSS** and **reset board UUCSS** commands. Also clear the alarm via **test board UUCSS long clear**. If the error returns within 10 minutes, then replace the circuit pack.

j. This error occurs when the circuit pack detects and error in a received frame from the packet bus. These errors are most likely caused by a packet bus problem, but may be due to a circuit pack fault.

   Perform a LANHO Receive Parity Error Counter Test (#595) via **test board UUCSS l** to determine if the condition has cleared. Also refer to PKT-BUS Maintenance documentation to determine if the problem is isolated to this circuit pack or if the problem is caused by Packet Bus faults.

k. A critical failure has been detected in the Packet Bus interface of the circuit pack. This failure may be due to an on-board fault or a Packet Bus fault. If the Packet Bus is alarmed, refer to the PKT-BUS Maintenance documentation for recommended repair procedures.

   If the Packet Bus is not alarmed, reset the circuit pack via **busyout board UUCSS** and **reset board UUCSS** commands. If the circuit pack Restart Test (#594) passes, then the on board circuitry is healthy. Retire the alarm via the **test board UUCSS long clear** command. If the circuit pack Restart Test (#594) fails, replace the circuit pack.

l. This error is not service affecting. No action is required. This error is reported by the circuit pack when it receives a bad control channel message from the switch.

m. This error is not service-affecting. No action is required. A bad translation RAM has been detected, but call continues by using another translation RAM location.

n. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Control Channel Looparound Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop-Around Test (#52) (a)	X	X	ND
SAKI Sanity Test (#53) (a)		X	ND
LANHO Receive Parity Error Counter Test (#595)		X	D

1. D = Destructive; ND = Nondestructive

Note:

a. For Control Channel Loop-Around Test (#52), and SAKI Sanity Test (#53) refer to the respective repair procedures described in "XXX-BD (Common Port Circuit Pack)."

LANHO Receive Parity Error Counter Test (#595)

This test reads and clears the LANHO Receive Parity Error Counter on the circuit pack. This counter is incremented by the circuit pack firmware each time it detects a parity error in the data received from the Packet Bus.

These errors may be indicative of a circuit pack problem, Packet Bus problem, or a problem with another circuit pack on the bus. This test is useful for verifying the repair of the problem.

Table 9-488. Test #595 LANHO Receive Parity Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack via the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-488. Test #595 LANHO Receive Parity Error Counter Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1-10	FAIL	The circuit pack is still detecting errors of this type. The error code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, verify the validity of the Packet Bus. Run the Packet Bus maintenance test with the **test pkt port-network port-network-number long** command. If any Packet Bus tests fail, refer to the Packet Bus Maintenance documentation for recommended repair procedures. 3. If the Packet Bus test passes, check the validity of the circuit pack. Execute a test that involves data transmission onto the Packet Bus. For example, the PDATA Port Local Loop-Around Test (#602). This test can be run by executing **test port UUCSSpp** command. 4. Other circuit packs on the Packet Bus may be the cause of the parity error. Use the **display alarms** command to check the Error Log for other circuit packs that are alarmed. If any alarms are present for other circuit packs, retire those alarms also. Then, rerun the LANHO Receive Parity Error Counter Test (#595) via **test board UUCSS long** on this circuit pack.
	PASS	No errors detected by the circuit pack.

PDATA-PT (Packet Data Line Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PDATA-PT	MINOR	test port UUCSSpp	PDATA Port Maintenance
PDATA-PT	WARNING	release port UUCSSpp	PDATA Port Maintenance

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

System Ports and the PDATA Circuit Pack

The Packet Data Line Circuit (PDATA TN553) port board supports the connection of asynchronous EIA RS-232C endpoints to the packet bus. Each PDATA circuit pack has twelve (12) ports. PDATA ports are used solely to support the System Ports feature. System ports provide a means for the SPE to communicate with data applications via the TDM bus, something the SPE cannot otherwise do, since it has no direct circuit-switched access to the TDM bus. Each system port consists of a PDATA circuit pack port and a Data Line (TN726B) circuit pack port which are cross-connected at the wall field. The PDATA side of the pair provides an interface to the Packet Bus for Mode 3 packet data coming from the SPE via the Packet Interface circuit pack. The PDATA converts the Mode 3 packet data into EIA data which the Data Line circuit pack then converts to Mode 2 data and places on the TDM bus. The data stream can then be directed to any external application having an EIA interface by routing it through another Data Line port (See the figure below.) System ports allow the following applications to communicate with the SPE:

- Save/Restore of Announcement Circuit Pack Recorded Announcements
- Call Detail Recording (CDR)
- Journal Printer for the Property Management System (PMS)
- Wakeup Log Printer for the Property Management System (PMS)
- System Printer
- Data Terminals
- Remote G3-MT terminals

Although the paired PDATA and Data Line circuit packs used for system ports may be located independently and in any port network, they are usually placed in adjacent slots in the PPN.

Data Applications and System Port Connectivity

As part of each data application, the SPE connects itself to the application device through a system port. The application device may be an external terminal, printer, or data-module, or it may be circuitry internal to the switch, as is the case for the Announcement Circuit pack data-module used to save and restore recorded announcements. The figure below is an example of a system port connection using a second Data Line circuit pack (DAT-LN-BD) port to provide dial-in access for a remote terminal.

A feature may not have a permanent connection to a system port. For example, the announcement feature uses the system port when it is saving or restoring announcement data to or from the Mass Storage System. The rest of the time it does not use a system port. This makes troubleshooting these links more difficult, since the symptoms may appear on one side of the link while the problem is on the other. If the link is no longer up, there is no way to determine which system port experienced the problem.

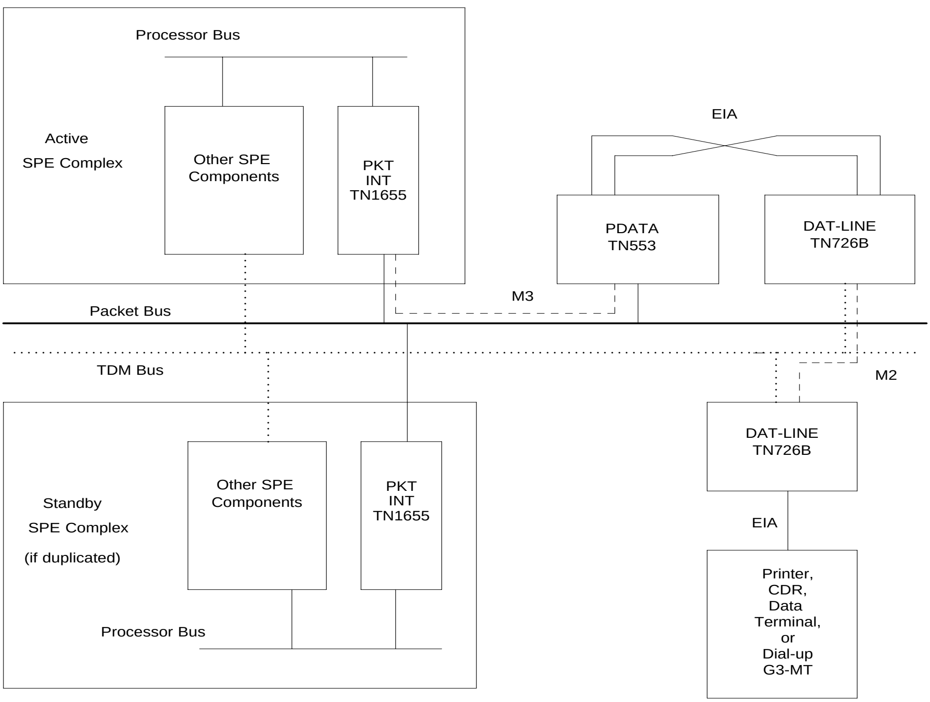

Figure 9-66. Typical System Port Connection

Testing the System Port Pool

This section describes a method for isolating a bad system port when its location is not known. A pool of system ports is used to service the set of application features listed above. The system supports a maximum of 10 system ports. Since each Data Line Circuit pack provides 8 ports and each PDATA provides 12 ports, 2 Data Line Circuit packs and one PDATA Circuit pack are required if all 10 system ports are to be administered. If a link failed due to a faulty system port and that port is not currently connected to the feature, you will need to test the entire pool to isolate the bad system port. Follow these steps to isolate a bad port or exonerate the pool of system ports.

1. Enter **list data-module** and record the extension for each system port. Note: **list data-module name** option can be used to match on the name of the system ports if they are all named similarly.
2. For each system-port enter **display data-module ext** to find the Data Line (DAT-LINE) and PDATA ports administered. Each system port has a single extension that applies to both the Data Line and PDATA port. For historical reasons the PDATA is considered the **associated port**.
3. Check each port for alarms and errors using **display alarms** and **display errors**.
4. Check for SYS-LINK error or alarms for SAP-type links using **Display alarms** and **errors**.
5. Follow the repair procedures for any ports with errors.

Identifying Components of an Application Link

Use this procedure to locate the maintenance objects that make up a given application link. You can then follow the repair procedures for each MO. In the steps given below all the MOs in a link are located before any ports are tested.

Problems with the application adjunct links are reported in two ways:

- The data application experiences problems.
- Errors or alarms are logged against a port or extension.

Locating MOs When the Data Application Link Fails

This sequence of steps should be used if the application is experiencing problems and the health of the ports is unknown.

1. Using column three of the commands table below, find the command to display the status of the application link. Enter the command to confirm the health of the link. If the command requires a data-module extension, enter **list data-module** to determine the extension.
2. If column two of the table below shows there is a link MO for the application, enter **display alarms** and **display errors**. If there are alarms or errors against the MO, follow the repair procedures for that MO.
3. Using column 4 of the table below, find the command to display the extension of the application link. Enter the command and record the extension.
4. Enter **status data-module** ext for the extension found in the previous step. Record any connected ports.
5. If there are connected ports enter **display port** UUCSSpp and record the extension for each port. The equipment type displayed should be `SYSTEM PORT DATA MODULE`. Run **status data-module** ext for the connected port. Record the associated PDATA port.
6. If there are no connected ports, follow the steps in *Testing the System Port Pool* above to isolate or exonerate the system ports.
7. For each port, application extension, and connected Data Line and PDATA ports, check the alarm and error logs for entries against these ports. Follow the repair procedures for each port with problems.
8. Enter **list sys-link** and look for a SAP-type link with a port location that matches the PDATA port. Check the alarm and error logs for entries against the SYS-LINK. Follow repair procedures for SYS-LINK problems.

Locating MOs When Only a Problem Port Is Known

A system port problem may originate in any of the following three components. You may not know at first which is causing the problem.

- The application port
- The PDATA port
- The Data Line port

1. Enter **display port** UUCSSpp to find out what kind of port this is. Record the extension and the identification field. The identification field likely indicates a system-port or another type of data-module.
2. *If the port is a system port,* enter **status data-module** ext. Record the Data Line or PDATA port. If there is a connected port do the following:

a. Record the location of the connected port.

b. Run **display port** UUCSSpp for the connected port and record the identification and extension for the port.

c. *If the port is an announcement port,* skip this step. Otherwise, determine whether the port's extension is administered as an application extension. Do this by executing each command in column 4 of the table below, checking the extension administered for that application against the port's extension.

For each port and application located, check the alarm and error logs for entries against these MOs. Follow repair procedures for MOs with log entries. In situations where no connected ports were listed, test each application link to ensure that more than one problem wasn't involved.

3. If the port is not a system port, enter **status data-module ext** and record the connected ports, if any are present.
4. Locate the application affected by entering each command in column 4 of the table below and checking the administered extension. The extension might be used as a remote G3-MT or data terminal.
5. If the status data-module display indicates no connected ports, follow the steps in *Testing the System Port Pool* above to verify that the system ports are working. If connected ports were displayed, enter **display port UUCSSpp** using the connected port displayed. Record the associated PDATA port.
6. For each port and application located, check the alarm and error logs for entries against these MOs. Follow the repair procedures for MOs with log entries. In situations where no connected ports were listed, test each application link to ensure that more than one problem wasn't involved.
7. Enter **list sys-link** and look for a SAP type link with a port location that matches the PDATA port. Check the alarm and error logs for entries against the SYS-LINK. Follow repair procedures for SYS-LINK problems.

Table 9-489. Data Application Commands

Application Name	Application MO Name	Command to Display Link Status	Command to Locate the Extension
Announcement Circuit Pack	Not Applicable	Not Applicable	display announcements
CDR	CDR-LNK	status cdr-link	display sys-param cdr
Wakeup Log Print er for the PMS Journal Printer for the PMS	JRNL-LNK	status journal-link wakeup-log	display system-parameters hospitality

Table 9-489. Data Application Commands

Application Name	Application MO Name	Command to Display Link Status	Command to Locate the Extension
System Printer	SYS-PRNT	status sp-link	display system-parameters features
Data Terminals	Not Applicable	status data-module ext	list data-module
Remote G3-MT terminals	Not Applicable	status data-module ext	list data-module

System Port Wiring Scheme

If you find that you are having trouble with a PDATA port and you do not know which extensions are being affected or which Data Line port is attached, enter **display port** UUCSSpp with the PDATA port number to display the extension of the System Port. With this extension you can run **display data-module** ext, which will in turn identify the Data Line port. The PDATA and Data Line ports are wired together in a manner similar to a null-modem. The figure below illustrates the wiring scheme for the EIA ports. The subsequent table gives the full wiring sequence for eight Data Line ports attached to eight PDATA ports.

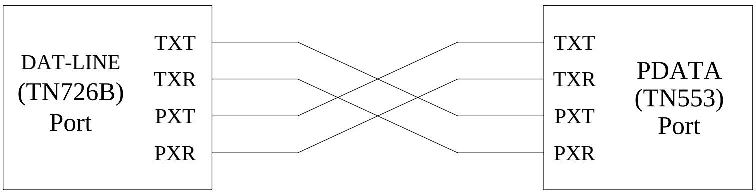

Figure 9-67. System Port Wiring Scheme

Table 9-490. Wiring Table for the System Ports Feature (eight ports)

2049(g)		System Port Connectivity Test (#603)	MINOR	OFF	test port UUCSSpp
3842* 3843* 3844*	37914				test port UUCSSpp sh l

1. Major or Minor alarms on this MO may have been downgraded to Warning alarms based on the values used in the **set options** command.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error occurs if the LAPD Connectivity test fails. If this test fails repeatedly, a MINOR alarm is raised. This alarm indicates the failure to establish a LAPD link with the port and to send and receive test data over that port. See the repair procedure for LAPD Connectivity Test (#558).

b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. These three counters are incremented for errors which may or may not be caused by the PDATA port itself. For example, the Invalid LAPD Frame counter (error type 513) could exceed threshold due to a large number of "bad CRC" errors. The errors could be caused by packets arriving from the "other end" which have a bad CRC, in which case the PDATA port is behaving properly and should not be alarmed. On the other hand, the error could be caused by faulty CRC-checking hardware on the PDATA board, in which case the PDATA board should be alarmed.

   Since these error counters do not necessarily indicate problems with the PDATA port itself, no alarms are raised when the counters exceed threshold. Instead, testing escalates to the LAPD Connectivity Test. If the LAPD Connectivity test fails repeatedly, then the PDATA port is the source of the problem and will be alarmed. More exhaustive tests can be run with the **reset board UUCSS** command.

d. This error occurs if the switch has trouble in writing the translation data into memory. A MINOR alarm is raised if this error occurs. This alarm indicates the failure of either the Angel hardware or the RAM on the board. If the Angel is the cause of the failure, similar alarms should be raised against all other ports on the board. If the RAM is the cause of the failure, then only the port is affected-other ports may function normally.

   No associated test can retire this alarm. The repair procedure for this alarm is as follows. First, reset the circuit pack (i.e. use *busyout board UUCSS* and *reset board UUCSS* commands). If the circuit pack comes back into service after the reset (the red LED on the circuit pack is off), then execute the *test port UUCSSpp long clear* command to clear the alarm. If the PDATA circuit pack fails to reset properly (i.e. the red LED on the circuit pack is on.), replace the circuit pack.

   Notice that the corresponding Translation RAM test always passes because it issues a translation write command but does not wait around for the failure up-link message from the board.

e. This error occurs when the receive FIFO RAM buffers on a circuit pack overflow, i.e., the circuit pack receives data from the bus faster than it can distribute the data to its endpoints. If this error occurs frequently, however, it may indicate a LAPD parameter mismatch. LAPD should be able to recover from this problem, but it may degrade the performance of the Packet Bus. No alarm is raised for this error.

f. This error occurs if the PDATA Port Local Loop-Around test fails. If this test fails, a MINOR alarm is raised. This alarm indicates the failure of the UART device on the port. The circuit pack should be replaced if this alarm cannot be cleared. See the repair procedure for PDATA Port Local Loop-Around Test (#602) for more details.

g. This error occurs if the System Port Connectivity Test (#603) fails or if the System Port connection fails in the call set-up procedure. This error is only applicable to ports used as a System Port. If this test fails repeatedly, a MINOR alarm is raised.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *PDATA Port Local Loop-Around Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
PDATA Port Local Loop-Around Test (#602)	X	X	ND
LAPD Connectivity Test (#558)	X	X	D
System Port Connectivity Test (#603)	X	X	D

1. D = Destructive; ND = Nondestructive

LAPD Connectivity Test (#558)

This test is destructive.

This is a connectivity test which checks if a specific PDATA port is capable of establishing a Level 2 LAPD link. The SPE will assign a LAPD bearer link between the SPE Packet Bus interface (i.e. the Packet Interface, also called PKTINT, TN1655) and the PDATA port. The SPE will send a test packet from the PKTINT to the PDATA port and it will expect to receive a reply from the PDATA port. Failure of this test may indicate an on-board fault associated with the port hardware on the PDATA circuit pack.

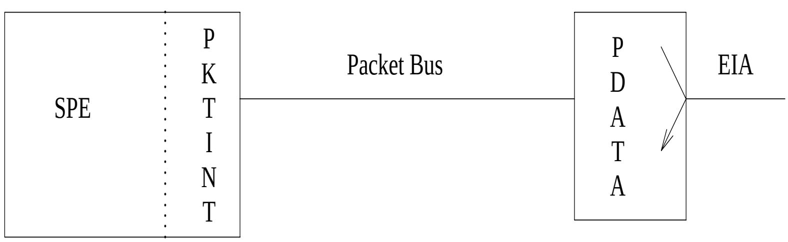

Figure 9-68. Configuration for LAPD Connectivity Test

Table 9-492. TEST #558 LAPD Connectivity Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port is in use for a call. Use **status data-module extension** command to determine when the port is available for testing. 1. Retry the command when the port is idle. The port may be forced to the idle state by executing **busyout port UUCSSpp**. This command is destructive causing all calls and links associated with the port to be torn down.
1137	ABORT	The test link could not be created. 1. If the PDATA port is in an EPN, this is probably caused by Center Stage maintenance interactions. The Center Stage includes the Switch Node Interface (SNI), Expansion Interface (EI) and DS1C boards. Clear any problems in these boards before continuing. 2. Retry at one minute intervals for a maximum of 3 times.
1139	ABORT	The Packet Bus in this port network is out-of-service. 1. Retire the alarm associated with the Packet Bus. Please refer to the maintenance section on the packet bus for details. 2. Retry the command when the alarm associated with the Packet Bus is retired.
1141	ABORT	The Packet Interface, PKTINT, Circuit Pack (TN1655) is out-of-service. 1. Refer to the repair procedures for the PKTINT circuit pack to put the circuit pack back into service. 2. Retry the command when the alarm associated with the Packet Interface is retired.
1144	ABORT	The Packet Bus in the Port Processor Network (Network 1) is alarmed. 1. Retire the alarm associated with the Packet Bus in the Port Processor Network. Please refer to the maintenance section on the packet bus for details. 2. Retry the command when the alarm associated with the Packet Bus is retired.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 3 times.

Continued on next page

Table 9-492. TEST #558 LAPD Connectivity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Response to the test was not received for the PDATA circuit pack within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. **Reset board UUCSS** if the other ports on the board are not in use (Yellow LED is off or run **status data-module extension**). 3. Retry the command at 1-minute intervals a maximum of 3 times. 4. Replace the circuit pack.
2	FAIL	The received test packet from the PDATA port is different than the test packet transmitted to it. 1. If the test fails 3 times, **reset board UUCSS** if the other ports on the board are not in use (yellow LED is off or run **status data-module extension**). 2. If the test continues to fail, replace the circuit pack.
	PASS	The PDATA port is able to terminate a LAPD link.

PDATA Port Local Loop-Around Test (#602)

This test is destructive.

This test verifies the per port circuitry on the PDATA circuit pack. This test is executed by the PDATA circuit pack on command by the switch. The loop-back is done internal to the circuit pack at point "A" in the figure. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack.

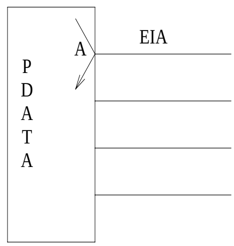

Figure 9-69. Configuration for Port Local Loop-Around Test

Table 9-493. TEST #602 PDATA Port Local Loop-Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port is in use for a call. Use **status data-module extension** command to determine when the port is available for testing. 1. Retry the command when the port is idle. The port can be made idle by executing the **busyout port UUCSSpp** command. This command is destructive causing all calls and links associated with the port to be torn down.
1006	ABORT	Port is out-of-service. 1. Run **status data-module extension** to check if the port is busied out. Run **release port UUCSS** to free it, re-run the test. 2. Refer to the PKT-BUS maintenance section and fix any problems that are related to the packet bus.

Continued on next page

Table 9-493. TEST #602 PDATA Port Local Loop-Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received for the PDATA circuit pack within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. **reset board UUCSS** if the other ports on the board are not in use (Yellow LED is off or run the **status data-module extension** command). 3. Retry the command at 1-minute intervals a maximum of 3 times. 4. Replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The PDATA circuit pack has detected a failure in the execution of the test. 1. If the test fails 3 times, **reset board UUCSS** if the other ports on the board are not in use (Yellow LED is off or run the **status data-module extension** command). 2. If the test fails again, replace the circuit pack.
	PASS	The PDATA on-board loop-around test for the port has passed verifying the integrity of the per port circuitry.

System Port Connectivity Test (#603)

This test is destructive.

This test verifies the capability to communicate between the PDATA and the Data Line (TN 726B) ports of a System Port member. A System Port requires the PDATA port and the Data Line port to be wired together. Failure of this test may indicate faults with the wiring on PDATA port. Thus an off-board alarm is raised.

Since this test is applicable only to ports that are configured as a System Port, the switch aborts the test if the port is not configured as a System Port.

The switch aborts this test if calls associated with the port are in progress. If the ports are in use but tests must be run, the port can be busied out using the **busyout port UUCSSpp** command. Release the port when the tests are done. If a problem is fixed, the associated alarms will not be resolved until the port is released.

Table 9-494. TEST #603 System Port Connectivity Test

Error Code	Test Result	Description/ Recommendation
11	ABORT	The Data Line port could not be setup for this test.
2100	ABORT	Could not allocate Data Line resources 1. Determine the Data Line port associated with the PDATA port. 2. Run **test port UUCSSpp**. If any of the Data Line port tests fail, resolve these problems first. 3. If the problem persists, check the port admin and wiring 4. Verify that the Data Line port is not busied out (**status data-module extension**) or not installed.
1000	ABORT	The PDATA or Data Line port is in use for a call or maintenance tests are already running on these ports. 1. Retry the command when the port is idle. The port may be forced to the idle state by executing the **busyout port UUCSSpp** command. This command is destructive causing all calls and links associated with the port to be torn down.

Continued on next page

Table 9-494. TEST #603 System Port Connectivity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The configuration for this test is incorrect. 1. This is the expected test result for PDATA ports which have not been administered as a System Port. 2. If the PDATA port is supposed to be configured as System Port, make the necessary modifications on the port administration form **change data-module extension**.
1115	ABORT	The PDATA port resources could not be allocated. 1. Run the **busyout port UUCSSpp** 2. Run the test again 3. Retry the command at 1-minute intervals for a maximum of 3 times. 4. Release the port when done.
2012	ABORT	System Call Failed
2031	ABORT	Uplink messages software failed.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 3 times.

Continued on next page

Table 9-494. TEST #603 System Port Connectivity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	Wiring does not match administration.
8	FAIL	Invalid test message sequence.
10	FAIL	Data Line port did not reset correctly.
11	FAIL	PDATA port Data Terminal Ready (DTR) did not reset correctly.
12	FAIL	PDATA port did not reset correctly.
2000	FAIL	Test timed out, most probably the administered ports are not connected correctly. For the above failure codes, use the following steps to correct the problem. 1. Enter the commands **list data-module** and **status data-module extension** on the G3-MT to find the corresponding Data Line port number and PDATA port number. Check the wiring between the PDATA port and the Data Line port. Look for loose connections, mis-wiring or broken wires. 2. Retry test a maximum of 2 times, no need to wait between tests. 3. If the test still fails, and the other ports on the circuit pack are not in use, enter **reset board UUCSS**. (Use **status data-module** extension or LED indicators to determine if other ports are idle). 4. Retry test a maximum of 2 times. 5. Replace the PDATA board. 6. Retry test a maximum of 2 times. 7. Replace the Data Line circuit pack. 8. Retry test a maximum of 2 times.
	PASS	The PDATA port and the Data Line port of the System Port feature are wired together as administered.

PDMODULE (Processor Data Module) TDMODULE (Trunk Data Module)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PDMODULE[2]	MINOR	test port *UUCSSpp* l	Processor Data Module
PDMODULE	WARNING	test port *UUCSSpp* s	Processor Data Module
TDMODULE [2]	MINOR	test port *UUCSSpp* l	Trunk Data Module
TDMODULE	WARNING	test port *UUCSSpp* s	Trunk Data Module

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. Digital Terminal Data Modules (DTDM), and Data Adaptors (DA) in linked mode are considered part of the Digital Line maintenance object. See the the DIG-LINE section for maintenance of these devices. DAs in stand-alone mode are included in PDMODULE.

   Some of the alarms that are logged due to PDMODULE and TDMODULE test failures may be related to circuit pack problems reported during DIG-BD testing. Refer to "XXX-BD (Common Port Circuit Pack)" for information on testing digital line circuit packs.

The PDMODULE and TDMODULE maintenance objects monitor and test Digital Line circuit pack ports that are connected to Data Communications Equipment (DCE) or Data Terminal Equipment (DTE). DCE include processor data modules (MPDM) and Data Adaptors (DA). DTE include trunk data modules (DTE). These stand-alone data modules provide interfaces between DCP ports on the Digital Line circuit packs and data equipment such as terminals, host computers , and data modems. (See the following list and figure.) Data modules are used for dial-up and permanent circuit-switched data calls.

Digital Line circuit packs also connect to digital terminal data modules (DTDMs), which work in conjunction with a voice terminal. Those configurations are covered by the DIG-LINE maintenance object. Circuit pack-level maintenance is covered by DIG-BD whose strategy is described in the "XXX-BD (Common Port Circuit Pack)."

Digital line circuit packs include the TN754, TN754B, TN413, TN2136. See DIG-LINE for more information on the characteristics of these circuit packs.

Stand-Alone DCP Data Modules

There are two types of stand-alone DCP data modules:

Table 9-495. Stand-Alone DCP Data Modules

Type	Name[1]	Interfaces to:
MPDM	Modular Processor Data Module	DTE (data terminals, host computers, printers, etc)
MTDM	Modular Trunk Data Module	DCE (modems, data modules, etc)

1. Early versions of these data modules were referred to as PDMs and TDMs, respectively. Later models are designed to provide a variety of interfaces by using interchangeable modules and are thus called modular data modules. Both types are supported by the tests described in this section

Data Adapters

TN2136 circuit packs use IDCP signaling and a DAA2 Data Adaptor (DA) to interface to DTE. DAs can operate in either of two modes which are covered by different maintenance objects:

Table 9-496. Data Adaptor Modes

DA Mode	Administered as:	Endpoint	Maintenance Object
Stand-Alone	PDM	data endpoint only	PDMODULE
Linked	DTDM	IDT1/2[1] and optional data terminal	DIG-LINE

1. IDT1/2: Italtel Digital Telephone, Model 1 or 2 (also known as Digital Telephones TD7210 and TD7206).

Configurations and Maintenance

In the following discussion, the general term data module refers to MPDMs, MTDMs, and DAs. The PBX loop or digital link between a data module and the Digital Line port supports two logical information channels and one signaling channel. Data modules generally use the primary information channel for data communications and the signaling channel for dialing and call supervision. With 4-wire DCP, the secondary information channel can be used to support a second data module on a shared port.

Besides being used for data calls between terminals, computers, and data communications equipment, data modules also serve as interfaces to equipment associated with system features such as System Administration, Station Message Detailed Recording, Message Center Service, Automatic Call Distribution, Distributed Communications System, and Audio Information Exchange. Maintenance for data modules associated with these latter services are covered by other maintenance objects such as PMS-PRNT, JNL-PRNT, and PMS-LINK.

Maintenance of data modules is closely related to and interacts with Digital Line circuit pack maintenance, and test results for data modules can be affected by the health of the Digital Line circuit pack. Keep this interaction in mind when investigating customer-reported problems with data modules.

Data modules provide a variety of option switches to allow the customer to select data rates, parity, keyboard dialing, local, and remote loop back, etc. (The DAA2 Data Adaptor has an AT (Hayes) type interface that allows selection of the above parameters as well as mode — linked or stand-alone.) An incorrect selection will not necessarily cause errors, alarms or test failures, but it can result in service disruption. Refer to the installation manual provided with the data module for more information about those options.

This discussion occasionally refers to a station's service state, which is defined as follows:

Out-of-Service	The port, and thus the data module, have been removed from service. Causes for this include busyout of the port, removal of the Digital Line circuit pack and failure of the NPE Crosstalk Test (#9).
Disconnected	The port is administered but the associated digital link does not respond. An administered port is put in a disconnected state after a system reboot or circuit pack insertion. This state persists until a link-reset-pass message is received from firmware on the circuit pack.
In-Service	When switch software receives a link-reset-pass message from the port, the port is placed in service. If the link-reset-pass message is missed, and an off-hook message is received while the port is in the disconnected state, maintenance software will run an ID request test and put the port into service upon receiving a correct response.

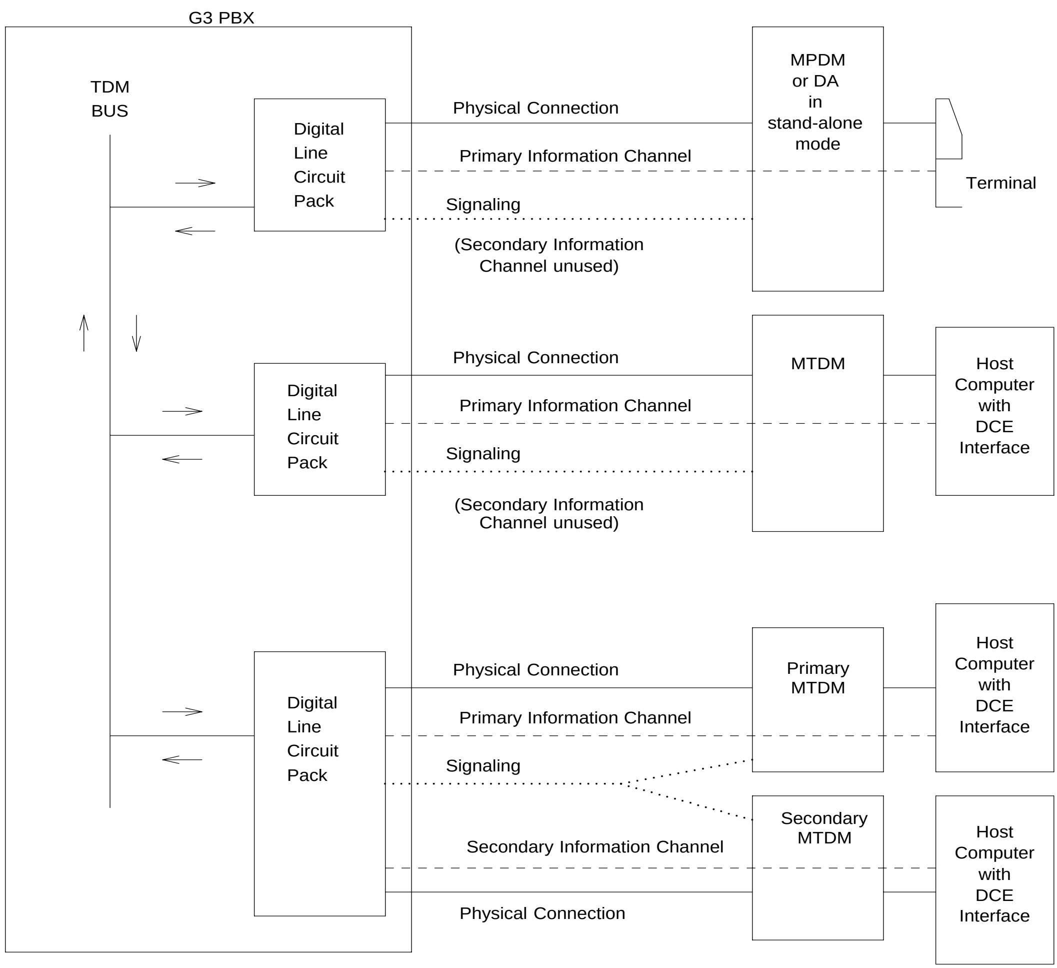

Figure 9-70. Typical Data Module Configurations

Error Log Entries and Test to Clear Values

Table 9-497. PDMODULE, TDMODULE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0(a)	0	None			
1(b,n)	40987	None	WARNING	OFF	
1(c,n)	1 to 20	None	WARNING	OFF	
15(d)	Any	None			
18(e)	0	busyout port *UUCSSpp*	WARNING	OFF	release port *UUCSSpp*
257(f)	40971	None			
513	0	Data Module Audits (#17)	WARNING	OFF	test port *UUCSSpp* sh r 6
769(g,n)	40988	None	WARNING	OFF	
1281	Any	Data Module Audits (#17)	WARNING	OFF	test port *UUCSSpp* sh r 4
1537(h,n)	40968	None	WARNING	OFF	
1793		Information Channel and Control Channel Looparound (#13)	MINOR	ON	test port *UUCSSpp* l r 3
2049		NPE Crosstalk (#9)	MINOR	ON	test port *UUCSSpp* l r 3
2304(i)		None			
2305(j)	32770	None			
2305(k)	40967	None			
2561(l)	Any	Data Module Internal Looparound (#175)	WARNING	OFF	test port *UUCSSpp* l r 5
2817 (m)		Link GPP Loop (183) Against Links	MAJOR	ON	
3841 n)		NONE			
3841(o)		None			

Notes:

a. Error type 0 appears in the Error Log only if a Digital Line circuit pack that has ports administered has been removed since the Error Log was last cleared. Make sure that the circuit pack has been re-inserted.

b. Error type 1 with aux data 40987 indicates an off-board problem detected by the port circuit, and may result in a noisy port or link. See note *n* for recommendations.

c. Error type 1 with aux data of 1 to 20 is logged when at least 15 off-board problems have been detected with the link to the data module. Each error detected increments an on-board counter. The aux data gives the value of this counter divided by 15. The user could experience a noisy port or link. See note ‘‘n’’ for recommendations.

d. Error type 15 is an internal that occurs when an audit request fails.

e. Error type 18 is logged when the port in question is demand busied out Make sure that the port is released from busy out.

f. Error type 257 indicates problems with transmitting to the data module. This is usually an on-board problem and can be ignored if no user complaints are received. Otherwise, check for faulty wiring.

g. Error type 769 indicates that EPF has been turned off due to the overcurrent condition at the data module. See the recommendations in note *n*. This may also be caused by the the PTC being in the ‘‘tripped’’ position due to a short on the power line. You can correct this by removing the short, unplugging the data module from the wall for about 30 seconds, and plugging it back in.

h. Error type 1537 indicates that an in-line maintenance error has generated an off-board warning due to some problem with the link to the data module. This can be ignored if no user complaints are received. Otherwise, see note *n* for recommendations.

i. Error type 2304 indicates an internal error. No action is necessary.

j. Error type 2305 with aux data 32770 indicates that the data equipment went off-hook while the associated link was being initialized (in a disconnected state). Use the **status data-module** command to determine the state of the data module. The off-hook should have changed the service state to in-service. No action is necessary.

k. Error type 2305 with aux data 40967 indicates that the link between the circuit pack and the data module has been reset successfully. The link is normally reset when the circuit pack associated with an administered port is first plugged in (assuming that the data module is already in place and connected to the associated port), when a port is first administered (assuming the associated circuit pack is plugged in and that the data module is connected to the associated port), or when a data module is first connected to an administered port. No system technician action is necessary.

l. Error type 3841 indicates that the downlink buffer on the circuit pack has overflowed. No action is necessary.

m. A DCP endpoint may have been disconnected.

n. Make sure the data module is connected and operating properly. Check for faulty wiring. If necessary, reduce the length of the cable between the data module and the switch to 5000 ft for 24-gauge wire or 4000 ft for 24-gauge wire. Refer to *DEFINITY Communications System Generic 1 and 3 - Installation and Test*, 555-230-104.

If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired in 60 minutes (90 min for error 1537). (These error counters use the leaky bucket mechanism.)

The DA module is not phantom-powered from the port. Thus when it is in linked mode, its range is limited by the Italtel digital phone's limit: 0.7 Km (2300) ft on 26-gauge wire or 1.8 Km (5900) ft on 22-gauge (0.6 mm) wire. If in stand-alone mode, it is limited by the maximum length of loop allowed from the Digital Line Interface (DLI) component: up to 3.5 Km (2 miles) on 22-gauge (0.6 mm) wire.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Data Module Internal Looparound Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Data Module Internal Looparound Test (#175)		X	ND
Digital Port Board Network Processing Element Crosstalk Test (#9)		X	ND
Port Circuit Information Channel and Control Channel Looparound Test (#13)		X	ND
Data Module Audits Test (#17)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#9)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. If a secondary data module is assigned, it is tested after the primary data module. If either test fails, both data modules are taken out of service. This test usually run only during the long test sequence and takes about 20 to 30 seconds to complete.

Table 9-498. TEST #9 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the extension of the data module port. Use the **status data-module** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the extension of the data module port. Use the **status data-module** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	Test disabled via background testing. Use **status data-module** command to determine when the data module is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-498. TEST #9 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1, 2	FAIL	The NPE of the tested port was found to be transmitting in Error Log. This will cause noisy and unreliable connections. Failure code 1 indicates that the Crosstalk Test failed on the primary channel. Failure code 2 indicates that the Crosstalk Test failed on the secondary channel. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times and verify that it continues to pass. 2. If complaints still exist, examine the data module, connections, and wiring.

Information and Control Channel Local Loop Test (#13)

This is a set of four tests that check the operation of the information and control channels used between the SPE and the Digital Line port circuit. This is an Internal Looparound test only and does not check building wiring. See Test #175 for external loop around tests to the data module.

The SPE first sends a message to the on-board microprocessor to loop around both the information and control channels for the port. Then, the primary information channel loop back test is run. The test is performed by sending a digital count from the Tone/Clock circuit pack on the primary channel time slot and receiving the same digital count with a General Purpose Tone Detector. The digital count looks like transparent data to the on-board microprocessor.

With the port still in loop-around mode, the S channel Looparound Test is performed next. This test consists of sending four different transparent patterns to the on-board microprocessor, receiving them back, and comparing them.

The third test is a Looparound Test for the secondary information channel. It is performed only if a secondary data module is assigned to the port.

The fourth test is a Conference Test of the primary channel. This test is the same as the Analog Line Conference Test #6.

Only one result is reported for the three tests run. If any test fails or aborts, the sequence is stopped.

Table 9-499. TEST #13 Information and Control Channel Local Loop Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the data module extension. Then use **status data module** command with the extension number to determine the service state of the data module. If the service state indicates that the data module is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-499. TEST #13 Information and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 retries.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the data module extension. Then use **status data module** command with the extension number to determine the service state of the data module. If the data module is in use, wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 9-499. TEST #13 Information and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	Conference test failed on the primary information channel. In some cases, user may not notice disruption in service. In extreme cases, conferencing feature may not work at all.
14	FAIL	The primary information channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port.
15	FAIL	The control channel between the processor and Digital Line circuit pack is not transmitting properly. This can cause a wide range of effects. The user may notice nothing or the port may be totally unusable. This could also disrupt other users. 1. Run circuit pack tests to check the Tone Generator and the Tone Detector circuit packs using the **test board UUCSS short** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Digital Line circuit pack.
16	FAIL	The secondary information is not transmitting properly. This can cause a wide range of effects. The user may notice nothing or the port may be totally unusable. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist (poor data transmission), examine the data module, connections, and wiring.
	PASS	Information and Control Channel Local Loop Test passed. All channels are transmitting properly

Data Module Audits Test (#17)

This is a series of six tests that are classified as hardware audits. The processor sends messages to the on-board microprocessor to perform the following tests:

- Switchhook Inquiry — This is an update of the processor's software records based on the on-hook/off-hook status of the data module.
- Bad Scan Inquiry — A message is sent uplink that contains a count generated by certain events relating to the digital loop's (link) conditions. This could be an indication of communication problems between the processor and digital port board.
- EPF inquiry — The status of the Electronic Power Feed is sent uplink. EPF is not used for data modules.
- ID Request — A request is made to the data module for its status. The data module sends its configuration information and health information back. This information is checked and a pass/fail result is provided.
- Ringer Update — This updates the data module's ringer state according to processor records.
- Translation Update — This is a message normally used with digital stations to refresh the default value that causes the station to send touch tones only in the primary information channel. This test is not used with data modules.

Table 9-500. TEST #17 Data Module Audits Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switchhook audit timed out. 1. Verify the data module is connected to the PBX and repeat the test. 2. If the test aborts, replace the data module and repeat the test. 3. If the test continues to abort, replace the circuit pack and repeat the test.
2	ABORT	ID request fails, health bit is defective, or no response from on-board microprocessor. 1. Verify that the correct data module type (PDM versus TDM) is administered. 2. If the test aborts, replace the data module and repeat the test. 3. If the test aborts, replace the circuit pack and repeat the test.
3	ABORT	No response from EPF audit.

Continued on next page

Table 9-500. TEST #17 Data Module Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4	ABORT	Internal system error 1. Resolve any outstanding circuit pack maintenance problems. 2. Retry the command at 1-minute intervals a maximum of 5 times.
5	ABORT	Ringer update aborted (data module not in the in-service state) 1. Verify that the data module is powered (power LED on). 2. Make sure data module is connected to the building wiring, check for faulty wiring, check for faulty data module. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. Replace the Data Module and repeat the test. 5. If the test continues to abort, replace the Digital Line circuit pack and repeat the test.
6	ABORT	Data module translation update aborted. 1. Verify the data module is connected to the PBX. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
2000	ABORT FAIL	Response to the test was not received within the allowable time period. Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Data Module Audits passed. This digital port circuit pack is functioning properly. 1. If complaints still exist, investigate by using other port tests, and by examining the data module options, wiring, and connections.

Data Module Internal Looparound Test (#175)

This test verifies that a data message can be sent from the PBX, through the building wiring, through an internal loop-around path in the data module, and back to the PBX. This path is illustrated below.

For this test to run, the "Remote Loop-Around Test" field on the Data Module administration form must be set to "y," indicating that the data module endpoint supports the test.

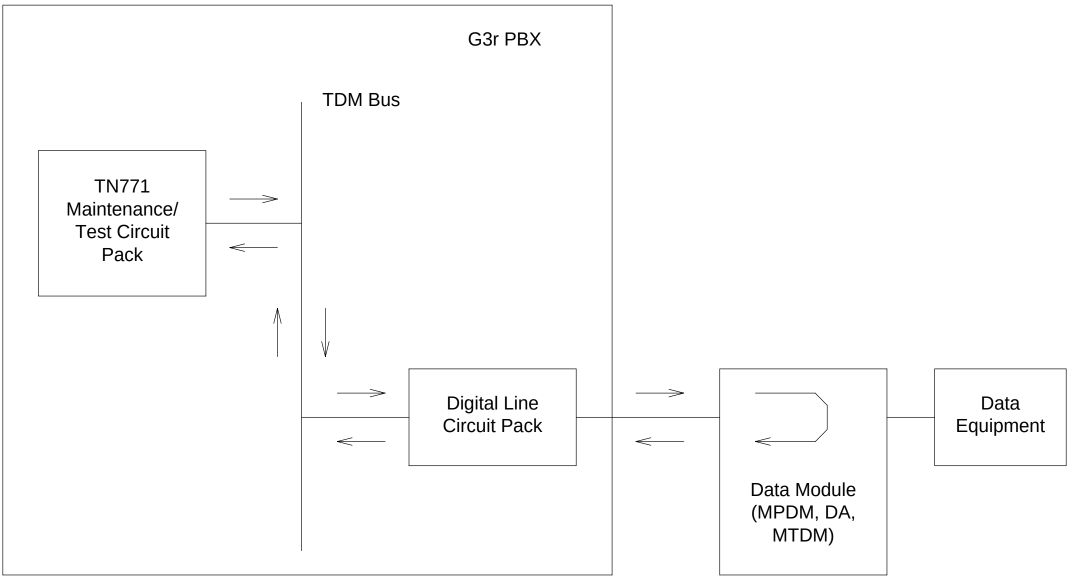

Figure 9-71. Internal Looparound Test

A signaling message is sent through the digital port circuit pack to the data module, requesting it to enter loop-around mode. A test pattern is then sent from the TN771 Maintenance/Test circuit pack, over the path illustrated above, and back to the TN771 where it is checked for consistency.

The test aborts if any of the following local PBX resources are not available: a digital port on the TN771 (there are two such digital ports, but only one may be used at a time), two TDM time slots and an idle digital port connected to the data module.

Table 9-501. TEST #175 Data Module Internal LoopAround Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Loop around testing is not enabled on the data module administration form. 1. Set "Loop-Around Test" field to "y" on the data module administration form.
1042	ABORT	The port under test is a TTI port and thus has only default translations and no assigned extension. The test requires an extension assigned to the port being tested. 1. If there is a need to execute the test on this particular port, then you must fully administer the port so that is has an assigned extension.
1180	ABORT	A Maintenance/Test Circuit pack digital port is not available to carry out the test. 1. Check to see if the Maintenance/Test digital ports are present (use the **list config board** command and look for ports 02 and 03). 2. If the digital ports (02 and 03) on the M/T-BD are not present, refer to the "M/T-DIG (Maintenance/Test Digital Port)" section. 3. If the digital ports are present, try the command again at 1-minute intervals up to 5 times.
1181	ABORT	No time-slots available to connect digital ports for the test. 1. Try the command again at 1-minute intervals up to 5 times.
1182	ABORT	Internal system error. Failed to connect the digital ports with time-slots. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-501. TEST #175 Data Module Internal LoopAround Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1340	ABORT	No Maintenance/Test digital port is currently available to perform this test. 1. Use **list config** to determine whether any Maintenance/Test digital ports (ports 02 and 03 on the Maintenance/Test circuit pack) are present in the system. Because at least one Maintenance/Test circuit pack must always be present in the PPN of any G3r system, there should be at least two such ports present. If the ports are present, proceed to step 2. Otherwise, determine why no ports appear in the **list config** display. Refer to "M/T-DIG (Maintenance/Test Digital Port)" and M/T-BD maintenance documentation. 2. Look for M/T-DIG errors in the Error Log. If present, refer to M/T-DIG maintenance documentation. 3. If the ports are present and no errors are logged against them, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, replace the Maintenance/Test circuit pack.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a "t" for the port). 2. If either **list config** or **display port** indicate that the port is **not** a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct for the test, and no action is necessary.
2005	ABORT	The handshake between the Maintenance/Test digital port and the Data Module failed. 1. Look for M/T-DIG errors in the Error Log. If present, refer to "M/T-DIG (Maintenance/Test Digital Port)" section. 2. If test still aborts on retry, check physical connection of data module under test. Make sure the switches are on NORM, OFF (between REM_LP and LOC_LP), 9600, and ASYN. 3. If the test still aborts, replace the Data Module.

Continued on next page

Table 9-501. TEST #175 Data Module Internal LoopAround Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2312	ABORT	The Looparound Test did not complete, failed to receive loop-back data. 1. Check for M/T-DIG error in the Error Log. If present, refer to M/T-DIG section. 2. Retry the test, if still aborts, replace the Data Module. 3. If the test aborts again, replace the Digital Line Circuit Pack.
2313	ABORT	The Maintenance/Test digital port allocated for this test did not respond to downlinked message. 1. Look for M/T-DIG errors in the Error Log. If present, refer to "M/T-DIG (Maintenance/Test Digital Port)" section. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, replace the MTB.
2314	ABORT	Data Module did not respond to downlinked message. 1. Check the wiring of the Data Module under test. 2. Verify that the Data Module is powered (power LED on). 3. Make sure the switches are on NORM, OFF (between REM_LP and LOC_LP), 9600, and ASYN. 4. If the test still aborts, replace the Date Module. 5. If the same abort code appears, replace the Digital Line Circuit Pack which is connect to the Data Module.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Data received from remote loop back does not match data sent. 1. Check for faulty wiring. 2. Replace the data module and repeat the test. 3. If the test fails, replace the Digital Line circuit pack associated with the data module and repeat the test.
	PASS	Data Module Looparound Test passed.

PE-BCHL (PRI Endpoint Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PE-BCHL[1]	MINOR	test port *UUCSSpp* l	PRI Endpoint Port
PE-BCHL	WARNING	test port *UUCSSpp* sh	PRI Endpoint Port

1. For additional repair information, see also UDS1-BD and *Troubleshooting Wideband Problems* in Chapter 5, ''Alarms, Errors, and Troubleshooting''.

A PRI Endpoint provides ISDN-PRI (Primary Rate Interface) connections application equipment or terminal adapters that terminate ISDN-PRI. The equipment or terminal adapters are connected to the switch via the TN464C/D UDS1 interface circuit pack. This maintenance object monitors the PRI endpoint port hardware on the UDS1 circuit pack by logging hardware errors, running tests for port initialization, and running periodic and scheduled maintenance and demand tests.

Wideband Switching

Wideband switching supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. DEFINITY switching capabilities are extended to support wideband calls comprised of multiple DS0s that are switched end-to-end as a single entity.

Wideband switching is designed for ISDN application equipment such as ISDN video codecs, but can also interface to non-ISDN application equipment by using PRI terminal adapters. In the same sense that a DEFINITY data module acts as a DCP or BRI terminal adapter between endpoint data such as V.35 and dialing interfaces such as RS-366 and a DCP interface, a PRI terminal adapter acts as a wideband terminal adapter between endpoint data and dialing interfaces and DEFINITY's line-side ISDN PRI interface. Wideband switching introduces PRI endpoints on DEFINITY line-side interfaces.

A PRI endpoint has a unique extension number and consists of one or more contiguous B-channels on a line-side T1 or E1 ISDN PRI facility. Endpoints initiate and receive calls via ISDN SETUP messages indicating the data rate and specific B-Channels to be used, and communicate all other call status information via standard ISDN messages. Any DEFINITY ISDN signaling set such as Lucent, CCITT, or ECMA may be used for a line-side ISDN PRI facility.

Multiple PRI endpoints on one line-side facility are separate and distinct within the facility. Non-overlapping contiguous sets of B-Channels are associated with each PRI endpoint, and the endpoint equipment is expected to initiate calls within these boundaries. The endpoint application equipment must:

- Use standard ISDN-PRI signaling
- Adhere to the administered PRI endpoint boundaries when initiating calls
- Handle incoming calls appropriately, based on the originating PRI endpoint

Signaling and B-Channel States

PRI ports use a separate channel called the D-channel for call control and signaling messages. This is called out-of-band signaling. The D-channel associated with the set of B-channels is an ISDN-PRI signaling link port (ISDN-LNK). The signaling protocol used on the ISDN-PRI signaling link port D-channel is defined by one of the four selectable ISDN-PRI Specifications: Lucent, CCITT, ECMA, and ANSI.

The ISDN-PRI Specification defines the possible service states for a B-channel. The service state is negotiated with the far-end terminal adapter, changes over time, and can have a far-end and near-end components. The service state is initialized to Out-Of-Service/Far-End, and an attempt is made to negotiate it to In-Service. The service state of a particular PRI endpoint port B-channel can be displayed with the **status pri-endpoint** extension command.

If a call is present, the Specification defines the permissible call statES as well. There are tests in the short and long test sequences for the PRI endpoint port designed to audit these states and ensure agreement between both ends of the PRI wideband connection.

Alarming Based on Service States

A PRI endpoint port B-channel logs a warning alarm when it is placed in a Maintenance/Far-End or Out-Of-Service/Far-End state. While in such a state, the port is unusable for calls to the terminal adapter. However, the user can still use the other remaining ports in the PRI endpoint to make calls to and from the terminal adapter. When a warning alarm is raised, use the **status pri-endpoint** extension command to determine the exact state of the port. Other alarms can be diagnosed by using the short and long test sequences. Note that a PRI endpoint port B-channel can be placed in a far-end service state by direct action by the far-end terminal adapter or by inaction of the far-end terminal adapter. For example, if it does not respond to a Remote Layer 3 Query (see Test #260 for ISDN-LNK) the associated PRI endpoint port B-channels will be placed in the Maintenance/Far-End service state.

A PRI endpoint port is a port on a UDS1 interface circuit pack and thus depends on the health of the circuit pack for proper operation (see the following figure). A problem on the associated ISDN-PRI Signaling Link Port D-channel (ISDN-LNK) can also affect the PRI endpoint. The ISDN-PRI Signaling Link Port in turn depends on the SYS-LINK (System Link) to the Packet Interface. Keep this hierarchy of dependencies in mind when diagnosing problems.

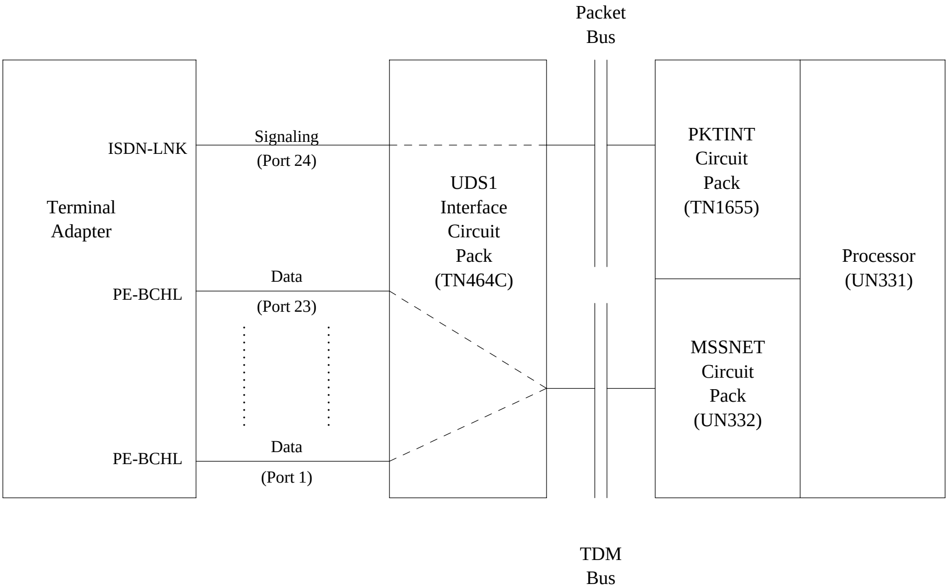

Figure 9-72. PRI Endpoint Port Interactions

PRI Endpoint Port Service States

The **status pri-endpoint** extension command displays the following possible service states for PRI endpoint ports. The table that follows gives recommended procedures for each state. The figure following that shows typical progressions from one service state to another. Refer also to *Troubleshooting Wideband Problems* in Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’ for a layered approach to addressing PRI endpoint problems.

- In-Service (INS)

  The B-channel is in its normal operating state.

- Out-of-Service/Far-End (OOS/FE)

  A B-Channel is initialized to this state when first administered. The switch then sends messages to the far-end terminal adapter to negotiate the B-channel into service. If the far-end terminal adapter does not respond to the messages within a certain time period, the port remains out of service, and maintenance will periodically resend the messages. The port is unusable for incoming and outgoing calls, although other ports in the PRI endpoint can still be used.

- Out-of-Service/Near-End (OOS/NE)

  This is the state of the port when a hardware failure exists on the signaling link, the NPE Crosstalk Test fails, or when the port is busied out by command. In this state, the port is unusable for calls coming in to the switch or going out to the terminal adapter, although other ports in the PRI endpoint can still be used for incoming and outgoing calls. No messages are sent to the far-end terminal adapter until the signaling link comes back into service or the port is released by command.

- Maintenance/Far-End (MTC/FE)

  This state is reached when the far-end terminal adapter does not respond to messages sent over the signaling link for a particular port within a certain amount of time. This state is different from OOS/FE since the signaling link must have initially been up and the B-Channels in service. The switch will periodically send messages to the far-end terminal adapter to try to negotiate the port (B-channel) into service. The port is unusable for outgoing calls to the terminal adapter but will service incoming call requests from the far-end. Other ports of the PRI endpoint can still to place outgoing calls to the terminal adapter. Transitions into MTC/FE do not drop stable calls. If the service state changes from in-service to MTC/FE, stable calls are unaffected.

- Maintenance/Near-End (MTC/NE)

  The signaling link (SYS-LINK) is busied out by the **busyout**, **test port l** or **test pri-endpoint l** commands. Transitions into MTC/NE do not drop stable calls. The **busyout link lnk-no** command does not drop stable wideband calls. In this state, the B-Channel is not usable for new incoming calls to the switch or new outgoing calls to the terminal adapter.

- Pending States (PEND)

  If the near-end is expecting a timed response from the far-end for a request to change the service state of a port, a *pending* state is in effect. For example, if the port is out-of-service/far-end and an in-service message was sent to the far-end, then the service state of the port is OOS/FE-PEND/INS meaning out-of-service/far-end, pending/in-service. The service state will reflect this pending state until the far-end responds or the timer expires.

Table 9-502. PRI Endpoint Port Service States

Service State[1]	Alarm	Possible Cause	Possible Solution
OOS/NE	Warning	Port has been busied out by command.	Enter **release pri-endpoint** extension.
	Minor	NPE Crosstalk Test (#6) failed.	Replace UDS1 circuit pack.
		UDS1 circuit pack lost its signal.	Is the UDS1 circuit pack removed? Is the UDS1 cable disconnected? Is the far-end terminal restarting or experiencing problems? Check circuit pack using procedures UDS1-BD.
OOS/FE	Warning	Far-end problems or incompatibility	Check administration and status of the corresponding port on the terminal adapter.
	Warning	The far-end port is busied out.	Check the status of the far-end terminal adapter.
OOS/FE PINS		Service message was sent and the switch is waiting up to 2 min. for a reply from the far-end terminal adapter.	Wait 2 min. and check service state after the PINS state has cleared.
MTC/NE		System link demand busied out	Check link status. Release with **release link** link#.
MTC/FE	Warning	Signaling channel has been down for over 90 sec.	Consult ISDN-SGRP, ISDN-LNK and/or SYS-LINK. Far-end terminal adapter may currently be restarting.
	Warning	Repeated failure of far end to respond to messages.	Maintenance software will periodically try to resend messages. You can speed the process with **test port** UUCSSpp (Test #256).
	Warning	The far-end port is being tested.	Check status of the far-end terminal adapter.
MTC/FE PINS		Service message was sent and the switch is waiting up to 2 min. for a reply from the far-end terminal adapter.	Wait 2 min. and check service state after the PINS state has cleared.

3585(l)	Any	None			None

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. These error types indicate a disagreement between this switch and the terminal adapter at the other end of the connection with regard to the ISDN *call* state of the PRI endpoint port. This switch will automatically try to recover by clearing the call (the call will be torn down). Use the **status pri-endpoint** extension command to determine the state of the port.

   When running the Short Test Sequence of tests, pay close attention to the results of the Call State Audit Test (#257).

b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors.

c. The PRI endpoint port has been busied out by **busyout pri-endpoint** extension or **busyout port UUCSSpp**. No wideband calls can be made to this port, although wideband calls can still be made to other ports within this PRI endpoint if they are in service.

d. The far-end terminal adapter changed its ISDN *service* state to either out-of-service or maintenance. This may be a temporary condition due to testing of this port by the far-end terminal adapter *or* a hardware problem with the port. Outgoing calls to the terminal adapter will not be allowed over the port, although calls can still be made to other ports that are in service within the same PRI endpoint. To investigate the status of the port, enter **status pri-endpoint** extension.

e. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

f. These error types indicate a disagreement between this switch and the terminal adapter at the other end of the connection with regard to the ISDN service state of the PRI endpoint port. The switch will automatically try to recover by performing a service state audit. Use **status pri-endpoint** extension to determine the state of the port.

   When running the Short Test Sequence, pay close attention to the results of the Service State Audit Test (#256).

g. This port is not recognized by the far-end terminal adapter. Investigate the PRI endpoint administration for both the switch and the terminal adapter, and make sure they agree.

h. The Conference Circuit Test (#7) failed on this port. See Test #7 for repair procedures.

i. The NPE Crosstalk Test (#6) failed on this port. See Test #6 for repair procedures.

j. This error indicates a failure of the UDS1 Interface circuit pack. The results of the Signaling Link State Check Test (#255 in the short sequence) are important.

k. Two Service State Audit attempts have failed (see Test #256). The port will not be usable for any outgoing calls to the terminal adapter until the test passes and the port state is changed to in-service. Incoming calls from the terminal adapter *will* be accepted over this port, and other ports in the PRI endpoint can still be used for both incoming and outgoing calls to and from the terminal adapter.

l. Error Type 3585 appears when the switch receives an ISDN RESTART message for an ISDN port that is not idle. Since calls are not typically cleared with the RESTART message, this error type may be associated with a dropped call report from a user.

The following Aux Data values for Error Type 3585 represent the port's ISDN call state at the time the unexpected RESTART request was received from the terminal adapter. This information can be useful if dropped calls are being reported by users of the PRI endpoint. Aux values that do not appear below can be ignored.

PE-BCHL Error 3585 Aux Data

Aux Data	Meaning
10	A call in a stable, talking state (the *active* state) was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.
4 7 8 260 263	A call that has not reached the active state, but has at least reached a ringing state, was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.
1 3 6 265	A call that has not yet reached a ringing state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.
11 12 19 531 267 268	A call that was already in the process of clearing has been cleared by the far-end terminal adapter with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far-end terminal adapter is attempting to clear ports that it thinks are in a ''hung'' state. The RESTART message puts the port in an idle condition.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Audit and Update Test (#36)	X	X	ND
Signaling Link State Check Test (#255)	X	X	ND
Service State Audit Test (#256)	X	X	ND
Call State Audit Test (#257)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of a port's long test sequence and takes about 20 to 30 seconds to complete.

Table 9-504. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status pri-endpoint** extension commands to determine when the port is available for testing. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-504. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-Bus errors. Use the **status health** command to determine if the system is experiencing heavy traffic. Investigate and resolve any errors against TDM-BUS. 1. If system has no TDM-Bus errors and is not handling heavy traffic, repeat test at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. The **list measurements tone-receiver** command will display information on the system's tone receiver. 1. Resolve any errors against TTR-LEV. 2. Resolve any errors against TONE-PT. 3. If neither of the above exists, retry the test at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use **status pri-endpoint** extension to determine when the port is available for testing. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1117	ABORT	A service state audit message is outstanding. 1. Wait 2 minutes and then try again.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2020	ABORT	The test did not run due to an existing error on the specific port or a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack and follow recommended procedures.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-504. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. The PE-BCHL is moved to out-of-service/near-end state. 1. Replace the circuit pack.
	PASS	The port is able to communicate over the TDM Bus.

Conference Circuit Test (#7)

The Conference Circuit test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 9-505. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status pri-endpoint** extension commands to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use **status pri-endpoint** extension to determine when the port is available for testing. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.

Continued on next page

Table 9-505. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Replace the circuit pack. Even though wideband calls do not use the conferencing feature on the NPE, this failure indicates problems with the circuit pack hardware.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and examining terminal adapter or external wiring.

Audit and Update Test (#36)

This test sends port level translation data from switch processor to the UDS1 interface circuit pack to assure that the port's translation is correct. The port audit operation verifies the consistency of the current state of port kept in the UDS1 interface circuit pack and in the switch software.

Table 9-506. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Test failed due to internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	Port translation has been updated successfully. The current port states kept in the UDS1 interface circuit pack and switch software are consistent. If the port is busied out, the test will not run, but will return PASS. To verify that the port is in-service: 1. Enter **status pri-endpoint** extension to verify that the port is in-service. If the port is in-service, no further action is necessary. If the port is out-of-service, continue to Step 2. 2. Enter **release pri-endpoint** extension or **release port** UUCSSpp command to put port back into in-service. 3. Retry the test command.

Signaling Link State Check Test (#255)

As noted in the preceding general description, operation of the PRI endpoint port depends on the health of the UDS1 interface circuit pack and System Link for proper operation. This test checks the status of those critical elements.

Table 9-507. TEST #255 Signaling Link State Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this PRI endpoint extension is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. 1. Either reconnect the disconnected PRI terminal adapter or disable the rollabout video feature on this circuit pack. To do the latter, enter **change ds1 UUCSS** and set the field labeled ‘‘Alarm when PRI Endpoint Detached?” to “y.’’
4	FAIL	There is a problem with the Signaling Channel and/or with the System Link. 1. Consult procedures for the ISDN-GRP and SYS-LINK. See also ISDN-LNK for useful information.
8	FAIL	There is a problem with the UDS1 interface circuit pack. 1. Consult procedures for UDS1-BD.
	PASS	The signaling link hardware is OK.

Service State Audit (#256)

As noted in the general description for PRI endpoint port, these ports may be in one of several service states as defined by the ISDN-PRI Specification. This test performs a service state audit with the far-end terminal adapter to ensure both sides agree on the service state.

A PASS for this test simply means that an audit message was successfully composed and sent out to the far-end terminal adapter. The ISDN Specification allows up to 2 minutes for a reply. If no reply is received within that 2 minute window, this switch will automatically try once again. If that attempt fails, an error will be logged (Error Type 3073) and the switch will then attempt recovery by automatically retrying approximately every 15 minutes. If the port was initially in the INS (in-service) state, it will now be placed in the MTC/FE (maintenance state, far-end problem) state. Until a Service State Audit attempt is successful, no outgoing calls will be placed over this port, but incoming calls will be accepted. The service state of this port does not affect the service state of other ports in the PRI endpoint. If an incoming call that uses this port is presented while in such a state, a Service State Audit attempt will immediately be attempted (that is, the switch will not wait for the 15-minute cycle, but will instead try to recover immediately). To investigate the status of this PRI endpoint port, issue the **status pri-endpoint** extension command.

Table 9-508. TEST #256 Service State Audit Test

Error Code	Test Result	Description/ Recommendation
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this port. 1. Check the results of Test #255 (Signaling Link State Check).
1117	ABORT	A service state audit message is outstanding. 1. Wait 2 minutes and then try again.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this PRI endpoint extension is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. 1. Either reconnect the disconnected PRI terminal adapter or disable the rollabout video feature on this circuit pack. To do the latter, enter **change ds1 UUCSS** and set the field labeled “Alarm when PRI Endpoint Detached?” to “y.”
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-508. TEST #256 Service State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	Wait 4 minutes and then check the Error Log for any new errors of type 3073. If there are none, then both sides of the ISDN connection agree on the service state; the negotiation succeeded. If there is a new 3073 error, then the negotiation failed (the far-end terminal adapter twice failed to respond within the mandatory 2-minute window). This switch will automatically retry approximately every 15 minutes. If the port was initially in the INS (in-service) state, it will now be placed in the MTC/FE (maintenance, far-end problem) state (refer to the ‘‘Service States’’ section which precedes the PE-BCHL ‘‘Hardware Error Log Entries and Test to Clear Values’’ table); incoming calls will be accepted, but no outgoing calls will be originated this port. If an incoming call is presented, another Service State Audit will be immediately performed in an attempt to bring the PRI endpoint port the proper state.

Call State Audit Test (#257)

If a call is active on the port, the switches on both sides of the connection should agree on the ISDN state of the call as defined in the ISDN Protocol Specification. This test audits internal call state data by querying the far-end terminal adapter as to the ISDN state of the call. It can be helpful when trying to clear a hung call. If the internal call state data on the near-end switch is different than that of the far-end terminal adapter, **the call will be torn down.**

As with Test #256 (Service State Audit), a PASS simply means that an appropriate message was composed and sent to the far-end terminal adapter. The ISDN Specification allows up to 2 minutes for a reply. If a reply is not received within the 2 minute window, a protocol time-out violation will be recorded in the error log against the associated signaling channel (ISDN-PRI Signaling Link Port, which is listed in the Error Log as ISDN-LNK; the Error Type is 1).

Table 9-509. TEST #257 Call State Audit Test

Error Code	Test Result	Description/ Recommendation
1019	ABORT	An audit is already in progress. 1. Wait 2 minutes and try again.
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this port. 1. Check the results of Test #255 (Signaling Link State Check).
1116	ABORT	The port is in an out-of-service ISDN service state. 1. A call cannot be present if the port is in an ISDN out-of-service state, so a call state audit would be inappropriate. No action necessary. (Use the **status pri-endpoint** extension command to investigate the ISDN state of the port).
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this PRI endpoint extension is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. 1. Reconnect the disconnected PRI terminal adapter or disable the rollabout video feature on this circuit pack. To do the latter, enter **change ds1 UUCSS** and set the field labeled "Alarm when PRI Endpoint Detached?" to "y."
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	This switch sent a call state auditing message to the far-end terminal adapter to verify the state of the call active on this port. If a call state mismatch is found, then the call will be torn down within two minutes. If no call was active, then no message was sent.

PGATE-BD (Packet Gateway Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PGATE-BD	MINOR	test board UUCSS long	Packet Gateway Circuit Pack
PGATE-BD	WARNING	test board UUCSS short	Packet Gateway Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Packet Gateway Circuit Pack

The TN577 Packet Gateway is a packet port circuit pack that provides connectivity between synchronous communication links and Packet Bus endpoints.

A LAPD signaling link is established between the Packet Gateway and the SPE for passing call control and other management information. Since one link serves all the ports on the circuit pack, maintenance of the signaling link is part of the Packet Gateway circuit pack maintenance.

Three external cabling arrangements allow port configurations supporting four RS423 connectors. External ports on Packet Gateways running the X.25 application provide switch connectivity to BX.25 adjuncts : AUDIX, CMS, ISDN Gateway, other PBXs in a DCS network, and 3B2 Message Server Adjuncts.

Packet Gateway Congestion Controls

Congestion controls are activated on Packet Gateway when the number of buffers reach a specified threshold (high buffer mark). The switch releases its congestion controls when the Packet Gateway reports that it has recovered from congestion, i.e., its utilized buffer level has returned to normal levels.

A MINOR on-board alarm is raised if congestion persists on the affected Packet Gateway for a 15 minute interval or is raised immediately if the congestion controls fail to prevent all buffers from being exhausted. When congestion abates, the MINOR alarm is not retired until the Packet Gateway is free of congestion for 30 minutes.

Error Log Entries and Test to Clear Values

Table 9-510. PGATE-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1 (a)	0		MINOR	ON	
18 (b)			WARNING	OFF	release board UUCSS
23 (c)	0		WARNING	OFF	add pgate UUCSS
257	65535	Control Channel Loop Test (#52)	MINOR	ON	test board UUCSS l r 20
257 (d)					
513 (e)	4352 to 4357		MINOR	ON	
769 (f)	4358

Table 9-510. PGATE-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3841 3843 (r)					
3842 (s)					
3999 (t)	Any	None			

Notes:

a. This error indicates that the circuit pack has stopped functioning or was physically removed from the system. Check too see whether the circuit pack is present in the slot indicated by the error. If the circuit pack is there, then reset it with **reset board UUCSS**. If the error persists, than replace the circuit pack.

b. Packet Gateway circuit pack has been busied out by command.

c. Packet Gateway circuit pack has not been administered for the slot in which it is inserted.

d. This error indicates transient communication problems between the switch and this circuit pack. This error is not service affecting and can be ignored unless repeated failure of the Control Channel Loop-Around Test indicates a hardware failure of the circuit pack.

e. A hardware failure on the circuit pack has been detected and reported by the circuit pack. These errors are detected by initialization or background tests which run on the circuit pack. The detection of one of these errors causes the circuit pack to "lock up" and appear insane to the system See error type 1.

   The reported aux data values correspond to the following detected errors:

4352:	External RAM error
4353:	Internal RAM error
4355:	ROM Checksum error
4357:	Instruction set error

f. This error is reported by the circuit pack when it detects a program logic error. This error can be ignored, but may lead to errors of other types being reported against this circuit pack.

g. This error is reported by the circuit pack when it cannot update NPE memory and read it back. This error type can be ignored, but may lead to errors of other types being reported against this circuit pack.

h. A critical hardware or firmware failure has been detected on the circuit pack. The switch resets the circuit pack upon the report of one of these errors. If three of these errors are received in 15 minutes, a MINOR alarm is raised on the circuit pack. Try clearing the alarm by executing the **reset board UUCSS** command. The circuit pack should be replaced if this alarm cannot be resolved.

The reported error types correspond to the following detected errors:

1291:	Contents of translation and application program memory corrupted
1292:	Internal hardware component failure
1293:	On-board auxiliary processor insane
1294:	Internal memory access error
1296:	Call aborted due to bad translation RAM locations

i. The circuit pack is hyperactive (flooding the switch with messages sent over the control channel) and is taken out of service when a threshold number of these errors are reported to the switch. Reset the circuit pack via the **reset board UUCSS** command to clear the alarm. If the error happens again within 15 minutes, then replace the circuit pack.

j. These errors are detected and reported by the circuit pack when transmitting frames to the packet bus. The switch raises a MINOR alarm on the circuit pack when these errors are received by the switch at a defined rate.

These errors are reported when the following errors are detected:

1793:	Parity errors are detected when transmitting frames to the packet bus
1794:	Overflow of packet bus transmit buffers has occurred
1795:	Circuit pack cannot find end of frame when transmitting to packet bus

Reset the circuit pack via the **reset board UUCSS** command to clear the alarm. If the error happens again within 15 minutes, then replace the circuit pack.

k. This error is reported when the "Packet Interface Test" has failed. A threshold number of these failures cause a MINOR alarm to be raised on the circuit pack. If the alarm cannot be cleared, try resetting the circuit pack to clear the problem. If the circuit pack reset is successful, execute the "Packet Interface Test" several times again. Replace the circuit pack if the "Packet Interface Test" continues to fail.

l. This error occurs when the circuit pack detects an error in a received frame from the packet bus. These errors are most likely caused by a packet bus problem, but may be due to a circuit pack fault.

These error types are reported when the following errors are detected:

2305:	Invalid LAPD frame received
2306:	Parity error detected on received frame

An Invalid LAPD frame error occurs if the frame contains bad CRC, is greater than the maximum length, or violates the link level protocol.

When invalid LAPD frame errors are reported, the ‘‘Invalid LAPD Frame Error Counter Test’’ should be executed to determine if the condition has cleared. When bus parity errors are reported, the ‘‘LANBIC Receive Parity Error Counter Test’’ should be performed to determine if the condition has cleared. Execution of the Packet Interface Test should be performed if this problem persists to verify the integrity of the circuit pack. If the Packet Interface Test passes, then the repair procedure for the packet bus should be consulted.

m. These errors occur when the Packet Gateway reports that it is congested or the ‘‘Congestion Query Test’’ fails. A Packet Gateway enters a congested state when the number of utilized buffers on the board exceeds a specified threshold.

The error types associated with congestion are defined as follows:

2817:	Utilized buffers have exceeded high buffer mark
2819:	All buffers exhausted

See description of ‘‘Congestion Query Test’’ for correct repair procedure to follow.

n. This error is reported when the call control signaling link fails or when the Link Status Test fails for an X.25 Packet Gateway circuit pack. The call control signaling link is considered failed when it is disconnected at the link level and cannot be reconnected quickly. If the link cannot be reconnected quickly, a MINOR off-board alarm is raised against the circuit pack. This failure may be due to circuit pack problems, packet bus problems, or packet interface circuit pack problems.

o. A critical failure has been detected in the Packet Bus interface of the circuit pack. The switch resets the circuit pack upon the report of one of these errors. If two of these errors are received in 15 minutes, a MINOR alarm is raised on the circuit pack. Try clearing the alarm by executing the **reset board UUCSS** command. The circuit pack should be replaced if this alarm cannot be resolved.

p. The circuit pack is hyperactive (flooding the switch with messages sent over the control channel) and is taken out of service when a threshold number of these errors are reported to the switch. It may exhibit one or more of the following symptoms:

   1. Tests run on the ports of this circuit pack return NO-BOARD.
   2. **List configuration** shows that the circuit pack and ports are properly installed.
   3. A busyout/release of the circuit pack brings the board back into service.
   4. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 3586 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 3586 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

   This condition should clear itself within 30 minutes. It is recommended that the error be allowed to clear itself. If this error reoccurs within 15 minutes of being cleared, replace the circuit pack. If the same error occurs on a different circuit pack, follow normal escalation procedures.

   The circuit pack can be manually brought back into service in the following ways.

   — Busyout and release the circuit pack.

   — Busyout, reset and release the circuit pack.

q. These errors are not service-affecting and can be ignored.

These errors are reported by the circuit pack when it receives a bad control channel message from the switch. The auxiliary data identifies the following error events:

4096:	Bad major heading
4097:	Bad port number
4098:	Bad data
4099:	Bad sub-qualifier
4100:	State inconsistency

r. By themselves, these errors are not service-affecting and can be ignored. They may cause other errors which are service-affecting to be reported.

The error type indicates the following:

3841:	Internal firmware error
3843:	Bad translation RAM detected, but call continues by using another translation location

When it begins to affect service, error type 3843 escalates to error type 1296.

s. This error is reported when the receive buffers for the packet interface overflow. Frequent occurrence of this error may be indicative of a congested circuit pack. See description of ''Receive FIFO Overflow Error Counter Test.''

System Technician-Demanded Tests: Descriptions and Error Codes

When inspecting errors in the system and deciding which ones to address, always investigate errors in the order they are presented in the table below.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop-Around Test #52	X	X	ND
Invalid LAPD Frame Error Counter Test #597		X	ND
LANBIC Receive Parity Error Counter Test #595		X	ND
Receive FIFO Overflow Error Counter Test #596		X	ND
Packet Interface Test #598	X	X	ND
Congestion Query Test #600	X	X	ND
Link Status Test #601	X	X	ND

1. D = Destructive; ND = Nondestructive

Circuit Pack Restart Test (#252)

This destructive test is used to reset the circuit pack. This test is not part of either short or long demand test sequence and is executed only on detection of PPCPU errors. The circuit pack is reset via the SAKI Sanity Test (#53).

Control Channel Loop-Around Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

This test is non-destructive.

Table 9-511. TEST #52 Control Channel Loop-Around Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The circuit pack failed to return the circuit pack code or vintage. 1. Retry the command a few times for a maximum of 5 times. 2. If the problem continues to fail, and if the circuit pack is one of the Port circuit packs, reseat the circuit pack. Otherwise, if the circuit pack is one of the Processor Complex circuit packs, see *Replacing SPE Circuit Packs* in Chapter 5, ''Alarms, Errors, and Troubleshooting'' for how to pull out and reinsert the circuit pack. 3. Retry the command a few times for a maximum of 5 times. 4. If the problem continues to fail, and if the circuit pack is one of the Port Circuit Packs, replace the circuit pack. Otherwise, if the circuit pack is one of the Processor Complex Circuit Packs, see *Replacing SPE Circuit Packs* in Chapter 5, ''Alarms, Errors, and Troubleshooting'' for how to replace the circuit pack. 5. Retry the command a few times for a maximum of 5 times.
	PASS	Communication with this circuit pack is successful.

Circuit Pack Restart Test (#252)

This test is destructive.

This test is used to reset the circuit pack. This test is not part of either short or long demand test sequence and is executed only on detection of PPCPU errors. The circuit pack is reset via the SAKI Sanity Test (#53).

The SAKI Sanity Test resets the circuit pack. This test fails if the circuit pack does not return to a sane state after being reset.

Table 9-512. Test #252 Circuit Pack Restart Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack. 2. Execute command again.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1	FAIL	The circuit pack failed to reset. 1. Execute command again. 2. If the problem persists, then pull out and reinsert the circuit pack. 3. If the problem persists, replace the circuit pack.
2	FAIL	The circuit pack failed to restart. 1. Execute command again. 2. If the problem persists, then pull out and reinsert the circuit pack. 3. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the short test sequence.

LANBIC Receive Parity Error Counter Test (#595)

The test reads and clears the LANBIC Receive Parity Error Counter on the Packet Gateway circuit pack. This counter is incremented by the circuit pack when it detects a parity error with a received frame from the packet bus.

These errors may be indicative of a circuit pack problem, packet bus problem, or a problem with another circuit pack on the bus. This test is useful for verifying the repair of the problem.

This test is non-destructive.

Table 9-513. TEST #595 LANBIC Receive Parity Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test fails repeatedly, attempt to reset the circuit pack. 2. If the test fails again, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1-10	FAIL	The circuit pack is still detecting errors of this type. The error code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, execute the “Packet Interface Test.”. 3. If “Packet Interface Test” passes, see repair procedures for Packet Bus.
	PASS	No errors detected by circuit pack.

Receive FIFO Overflow Error Counter Test (#596)

The test reads and clears the Receive FIFO Overflow Error Counter on the Packet Gateway circuit pack. This counter is incremented by the circuit pack when it detects its packet bus receive buffers overflow.

These errors can occur occasionally due to the statistical sizing of the buffers. Persistent occurrence of these errors may be indicative of a congested circuit pack. Distribution of a portion of the traffic load on the circuit pack to other circuit packs in the system may be necessary.

This test is non-destructive.

Table 9-514. TEST #596 Receive FIFO Overflow Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test fails repeatedly, attempt to reset the circuit pack. 2. If the test fails again, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1-10	FAIL	The circuit pack is still detecting errors of this type. The error code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, perform the “Packet Interface Test.” 3. If “Packet Interface Test” passes, see repair procedures for Packet Bus.
	PASS	No errors detected by circuit pack.

Invalid LAPD Frame Error Counter Test (#597)

The test reads and clears the Invalid LAPD Frame Error Counter on the Packet Gateway circuit pack. This counter is incremented by the circuit pack when it receives an invalid LAPD frame on its packet interface. An invalid frame is detected when a CRC error is detected on a received frame, an unrecognizable frame is received, or a recognizable frame is received in an unexpected state.

These errors may be indicative of a circuit pack problem, packet bus problem, or a problem with another circuit pack on the bus. This test is useful for verifying the repair of the problem.

This test is non-destructive.

Table 9-515. TEST #597 Invalid LAPD Frame Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test fails repeatedly, attempt to reset the circuit pack. 2. If the test fails again, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1-10	FAIL	The circuit pack is still detecting errors of this type. The error code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, execute the "Packet Interface Test". 3. If "Packet Interface Test" passes, see repair procedures for Packet Bus.
	PASS	No errors detected by circuit pack.

Packet Interface Test (#598)

The test checks the packet bus interface circuitry on the Packet Gateway circuit pack. Failure of this test is indicative of a faulty circuit pack.

This test is non-destructive.

Table 9-516. TEST #598 Packet Interface Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test fails repeatedly, attempt to reset the circuit pack. 2. If the test fails again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Circuit pack has detected a failure of the Packet Interface Test. 1. Retry the command 5 times. 2. If the test continues to fail, reset the circuit pack. 3. If the test continues to fail, replace the circuit pack.
	PASS	The Packet Interface Test passes.

Congestion Query Test (#600)

This test determines the state of congestion on the Packet Gateway circuit pack based on the number of utilized buffers on the board. The test passes if the Packet Gateway is operating normally, used buffers are at a normal level. This test fails if the Packet Gateway is in a congested state, i.e., utilized buffers are approaching exhaust or are exhausted.

The switch automatically throttles new calls to a congested Packet Gateway. New outgoing calls are redirected to another Packet Gateway if available. New incoming calls are denied. Normal call handling is resumed when the Packet Gateway reports that it has recovered from congestion.

This test is non-destructive.

Table 9-517. TEST #600 Congestion Query Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test fails repeatedly, attempt to reset the circuit pack. 2. If the test fails again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-517. TEST #600 Congestion Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The Packet Gateway is congested. Its buffer level is approaching exhaust. 1. Retry command 5 times at 1-minute intervals. 2. If command continues to fail, it may be necessary to shed load from the affected Packet Gateway if congestion persists. Examine the Packet Gateway port measurements to determine which ports are heavily utilized and the processor occupancy of the circuit pack. 3. A low processor occupancy when Packet Gateway congested indicates a failure of the circuit pack. Try resetting the circuit pack. If congestion reoccurs, replace the circuit pack. 4. A high processor occupancy validates that the Packet Gateway is actually congested due to traffic load. In the short term, congestion may be relieved by selectively busying out ports on the Packet Gateway or by busying out BRI endpoints assigned to the affected Packet Gateway. In the long term, replacement of ports on the affected Packet Gateway by new ports on existing other or new Packet Gateways or redistribution of D-Channels to existing other or new Packet Gateways has to be considered.

Continued on next page

Table 9-517. TEST #600 Congestion Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The Packet Gateway is congested. No buffers are available at the current time. 1. Retry command 5 times at 1-minute intervals. 2. If command continues to fail, it may be necessary to shed load from the affected Packet Gateway if congestion persists. Examine the Packet Gateway port measurements to determine which ports are heavily utilized and the processor occupancy of the circuit pack. 3. A low processor occupancy when Packet Gateway congested indicates a failure of the circuit pack. Try resetting the circuit pack. If congestion reoccurs, replace the circuit pack. 4. A high processor occupancy validates that the Packet Gateway is actually congested due to traffic load. In the short term, congestion may be relieved by selectively busying out ports on the Packet Gateway or by busying out BRI endpoints assigned to the affected Packet Gateway. In the long term, replacement of ports on the affected Packet Gateway by new ports on existing other or new Packet Gateways or redistribution of D-Channels to existing other or new Packet Gateways has to be considered.
3	FAIL	The Packet Gateway circuit pack is operating normally and is not congested.
	PASS	Hardware setting and attached cable type match Packet Gateway circuit pack administration.

Link Status Test (#601)

This test determines the state of the call control signaling link for X.25 Packet Gateways.

This test determines if the signaling link is connected or disconnected. If the link is connected, this test causes a test frame (called an XID frame) to be sent to the Packet Gateway circuit pack over the signaling link. The test passes if the signaling is connected and a test frame response is received by the switch. The test fails if the signaling link is disconnected or no response if received from the circuit pack.

This test is non-destructive.

Table 9-518. TEST #601 Link Status Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	The necessary system resources to execute the test could not be allocated. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2	FAIL	The X.25 call control signaling link is disconnected. 1. Reexecute the test 5 times at 1-minute intervals. 2. If the test continues to fail, execute the "Packet Interface Test" to determine if the problem is due to the circuit pack. If the test fails, see repair procedures for Packet Interface Test. 3. If the Packet Interface Test passes, then see repair procedures for Packet Control circuit pack and Packet Bus.
3	FAIL	No response was received to transmitted test frame for Call control link. 1. Repeat the test 5 times. 2. If the test continues to fail for this reason, try resetting the circuit pack. 3. If test continues to fail for this reason, try replacing the circuit pack.
	PASS	The X.25 call control signaling link is connected and a correct response was received by the switch to a test packet.

PGATE-PT (Packet Gateway Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PGATE-PT	MAJOR	test port UUCSSpp long	X.25 Port Maintenance
PGATE-PT	MINOR	test port UUCSSpp long	X.25 Port Maintenance
PGATE-PT	WARNING	test port UUCSSpp	X.25 Port Maintenance

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The TN577 Packet Gateway circuit pack provides connectivity from the switch to adjuncts or to other switches in a Distributed Communications System (DCS).

Ports on the TN577 perform statistical multiplexing of data connections based on the X.25 data communication protocol standard. An X.25 Access Link must be established between the Packet Gateway port and the adjunct or DCS switch prior to the connection of any data sessions on the port. Such data connections consist of X.25 packet-data streams which entering the Packet Gateway port and are transported by Packet Gateway circuitry to the packet bus and then to other endpoints on the bus. An X.25 Access Link is illustrated in the description of the Link Status Test (#614).

Packet Gateway Applications

The following applications and adjuncts use packet gateway ports:

- AUDIX
- Call Management System (CMS)
- Distributed Calling System (DCS)
- ISDN Gateway Adjunct
- Message Server

Packet Gateway Configurations

X.25 links connect to the SPE via the packet bus and the TN1655 Packet Interface circuit pack. In addition to the configurations shown, a long distance modem can connect directly to one of the external ports on the Packet Gateway circuit pack to connect to data networks including private lines, Dataphone II networks, and Digital Data Service (DDS) networks. Disregard the references to notes in the following figures.

Adjuncts can directly connect to one of the external ports on the Packet Gateway circuit pack using a null modem or limited-distance modem. This is the preferred method for connecting adjuncts located near the switch. Similar configurations are used to connect to CMS, Message Server, and ISDN Gateway.

The RS-423 interface on the Packet Gateway circuit pack can be switched via administered connection to any DCP Mode 2 digital endpoint on the switching network. Similar configurations are used to connect to CMS, Message Server, and ISDN Gateway. In this configuration, the BX.25 link is switched over the TDM bus to a DS1 port and over a DS1 facility to another G3r switch. The Packet Gateway can use only DMI Mode 1 on the TDM bus.

DCS systems that use ISDN-PRI signaling use a TN464 Universal DS1 circuit pack and do not require a Packet Gateway.

Link-Associated Maintenance Objects

Each link is made up of a chain of several different maintenance objects. The **list sys-link** and **status sys-link** commands can be used to identify the specific components that make up a specific link. All X.25 links use the following MOs:

— PKT-INT

— The PPN PKT-BUS

— The PKT-BUS of the port network housing the packet gateway

— PGATE-BD

— PGATE-PT

Certain configurations may also use some of the following:

— TDM-BUS

— DS1-BD

— UDS1-BD

— TIE-DS1

— ISDN-LNK

— ISDN-TRK

When investigating link problems, first resolve any problems existing at higher levels such as PKT-INT and PKT-BUS, and then proceed to problems at lower levels such as ISDN-TRK.

Identifying Maintenance Objects That Make Up a Link

When the location of the port and the channel number of an X.25 link is known, the **status sys-link** command can be used to identify all of the components in the path traveled by the link. Refer to the SYS-LINK section in this chapter for more guidance in troubleshooting links.

Service problems may be reported in several different ways. Generally a problem will be associated with a local adjunct, an alarmed link that involves hop channels, or an alarmed port or trunk. The following procedures show how to locate components of a link starting with:

— The adjunct or DCS link name

— An associated hop channel number

— A port or trunk

Once the MOs making up the link are known, inspect the alarm and error logs or run tests for each maintenance object located on a suspect link. These procedures do not include isolating problems located on adjuncts or other switches. The steps sometimes require logins on different switches or adjuncts. In this discussion, the term machine refers to a switch or an adjunct.

The packet interface (PKT-INT), packet bus (PKT-BUS), and TDM-BUS are not covered by these procedures because they are part of the fabric for the connections. These components should be tested first if they are alarmed or reporting errors.

Tracing a Link to a Given Adjunct or DCS Link

1. **display adjunct-names**

   Locate and record the adjunct name that was reported and the application type. If the problem is with DCS this step can be ignored. DCS will probably be called DCS.

2. **display communications-interface processor-channels**

   - Find the row with the application name found in the previous step. The application name if it is listed will be in the identification field.
   - Record the processor-channel number, application, interface link and channel, adjunct name and machine ID. For the message server adjunct there may be more than one processor link.

3. **display communications-interface links**

   - Find the line that has the link found in the previous step.
   - Record the link, extension, destination number or TAC and the identification field. The TAC may be combined with a remote extension. Run **display dialplan** if there are questions as to valid TAC numbers.

     If the destination number is a local extension, then it is probably a local data-module. This can be verified by running **display data-module ext**.

4. **display communications-interface hop-channels**

   Check if the link and processor channel found in the previous steps is listed in this form. If it isn't, then the major pieces of the link on this switch have been located. If the link is connected to another link, copy down all the information for that hop-channel. With the link and channel that are connected repeat steps 2 - 4. This should be repeated until there are no more links that are connected to any of the links uncovered to this point. For each link that goes to another machine follow the next instructions in the next section to obtain the MOs on the other machines. If the machine is not a Generic 3, consult the repair procedures for that machine.

5. For each extension located run **display data-module ext** to find the port and the board. The port and board should then be tested to find out if this MO is having problems. The repair section for each MO should be consulted to understand and fix the problem.

6. For each TAC located, run **display trunk-group tac** tac# to find the trunk group. The alarm and error logs should be checked for entries against this trunk group. Alternatively, the trunk group can be tested using **test trunk-group** trunk number. Refer to the repair section for that trunk type if problems are found.

Tracing a Link When a Hop-Channel Is Involved

This problem may be reported in several different ways. Typically a given application on switch "A" in a DCS configuration is down. Using the steps in the section following this one, you find that the application connects to switch "B" over channel "x." This section shows how to continue the tracing procedure on switch B. The extension on switch B that terminates the physical link may or may not be known. If the number of the channel to B is not known, begin at the second step.

1. **display communications-interface hop-channels**

   Find the link that uses the known channel. Record the link/channel pairs

2. **display communications-interface links**

   Look at the links found in the previous step. One of the links should point back to the other switch or adjunct. Record the X.25 extension, destination number and identification field for each link.

   If a destination number is specified, verify that it is a valid extension on the other machine. If the other machine is a DEFINITY Generic 3, follow the procedure in the section that follows this one. If not, refer to the maintenance maintenance documentation for the other machine.

   If the link or channel is not known, scan the identification field for the known machine name that has link connectivity to this machine. For each line of data that matches, record the entire line. For links with remote destination numbers, remove the TAC and verify that the number is valid on the other machine. For Generic 3 machines this can be done using the procedure in the section following this one. If there are no matches, you must go back to the other machine and find out the channel number or the application that uses the channel before continuing.

3. **display station** extension

   Record the port associated with the extension.

4. If the destination number field is not "external," then the number is a valid extension on another machine. The destination number can also be combined with a TAC. Run **list trunk-group** to find if a TAC is prepended to the destination number. Record the trunk-group if a TAC has been prepended.

5. Check the alarm and error logs for each extension, trunk-group or link. If alarms or errors are present follow the repair procedures for that MO.

6. If the link continues to another machine, Use the channel number, application, and identification field to continue the trace there. Repeat this procedure for Generic 3 machines.

Tracing a Link Given a Port or Trunk

1. **display port UUCSSpp**

   a. Find out if the port connects to a data module or a trunk.

   b. Record its extension or trunk group.

   c. If it is a trunk group, run **display trunk** group#/member#. Record the trunk access code (TAC) and go to the next step.

2. **display communications-interface links**

   a. Find the link that has the extension, destination number or TAC located in the previous step. The TAC may be combined with a remote extension.

   b. Record the link, X.25 port, destination # or TAC and identification field.

If the administration was done according to the documentation guidelines, the identification field may contain what application is running. This will give you some idea as to what other problems might be related and the priority for fixing this problem.

If the destination number is a local extension, then it is probably a local data-module. If the number is remote or the word "external", look at the comment field for an indication of the data-module's extension or administered connection. More information on the local extension can be obtained by running **display data-module extension**.

3. **display communications-interface processor-channels**
   a. Find the row with the link number found in the previous step.
   b. Record the processor-channel number, application, interface link and channel, adjunct name and machine ID. For the Message Server Adjunct there can be more than one link.
4. **display communications-interface hop-channels**
   a. Check if the link and processor channel found in the previous steps is listed in this form. If it isn't, then the major pieces of the link on this switch have been located. If the link is connected to another link, copy down all the information for that hop-channel. With the link and channel that are connected, repeat steps 2 - 4. This should be repeated until there are no more links that are connected to any of the links of concern.
   b. For each extension located run **display data-module ext** to find the port and the board. The port and board should then be tested to find out if this MO is having problems. The repair section for each MO should be consulted to understand and fix the problem.
   c. For each TAC located, run **display trunk-group tac tac#** to find out the trunk group. The trunk group should then be tested using **test trunk-group E4trunk number**. The repair section should be consulted to understand and fix problems found for an MO.

X.25 Protocol Errors

All of the X.25 port errors are generated as part of error procedures specified by the X.25 protocol. The reader is referred to the X.25 specification for more detailed explanation of these errors and their implications. These errors are logged as a result of errors detected by the far end and received by the port in X.25 packets, and as a result of errors detected by the near end and sent by the port in X.25 packets to the far end.

All of these errors are conveyed in three types of X.25 packets:

- Restart Request (Indication) Packets
- Reset Request (Indication) Packets

Restart packets cause reinitialization of the X.25 packet layer (Level 3) causing all links to be reset which are associated with the X.25 link. These packets are sent when the packet layer is first initialized or when certain errors are detected. Reset packets are sent to reinitialize a virtual circuit in the data transfer state when specified errors are detected on the virtual circuit.

Errors are conveyed in the Cause and Diagnostic fields of these packets. The Cause Field indicates the reason for the error and the Diagnostic Field provides a further explanation of the error. Cause and diagnostic codes can be generated by either a network (DCE) or a network user (DTE). Code values are segmented such that those generated by a DTE or a DCE can be distinguished. Cause codes are further segmented to distinguish between causes delivered to a DTE which were generated by a private or public network. Essentially, a private network utilizes the PDN cause code values by offsetting the PDN value by 128. DEFINITY G3 assumes the role of a private network when generating the causes whether its side of the interface is administered as a DTE or a DCE.

A port administration option allows logging of X.25 errors to be selectively turned on or off for individual ports. A customer may choose to turn on error logging only for important network interfaces and hosts in order to capture a complete error history about these ports. For less critical interfaces, a customer may choose to turn off error logging to prevent cluttering the system error log. In this case, error logging can be turned on as needed to diagnose trouble reports with the interface. Error logging is not turned on as the administrative default for this option on X.25 Packet Gateway ports.

Error Log Entries and Test to Clear Value

Table 9-519. PGATE Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp s
1 (a)	0	Packet Gateway Port Local Loop-Around (#610)	MINOR	ON	test port UUCSSpp l r 3
18	0	busy port UUCSSpp	WARNING	ON	release port UUCSSpp
257 (b)	0				
513 (c)	1, 2	Level 1 State Query Test (#613)	MINOR	OFF	test port UUCSSpp r 2
769 (d)	0		WARNING	OFF	(d)
1024 to 1289 (e)	0, 3, 35768, 35769				
1537 (l)	Any	Session Status Query Test (976)	WARNING	OFF	
1538 (l)	0	Session Status Query Test (976)	MINOR	OFF	
2049 to 2303 (f)	1-64				
2305 to 2364 (g)	1, 129				
2305 to 2364 (h)	57, 185

Continued on next page

Table 9-519. PGATE Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
2560 to 2815 (j)	1-4156, 39865-39924				
2817 (k)		Link Status Test (#614)	MINOR	OFF	test port UUCSSpp r 2
3585	0-1	Packet Gateway Switched Port Loop-Around Test (#599)	MAJOR	ON	test port UUCSSpp l r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error occurs when the Packet Gateway Port Local Loop-Around Test (#610) fails. Execute the **test port UUCSSpp long** command and see the repair procedures for test #610.

b. This error occurs when a Packet Gateway port detects an overrun or an underrun condition that may be indicative of a hardware problem on the port. The Packet Gateway Port Local Loop-Around Test (#610) should be executed via the **test port UUCSSpp long** command to determine if a hardware problem exists. See the repair procedures for test #610.

c. This error occurs when the Level 1 State Query Test (#613) fails or when the Packet Gateway port detects that the Clear To Send (aux data 1) or Data Carrier Detect (aux data 2) lead is "low" in the RS423 cable connected to the port. This problem can be caused by cabling, data set, or transmission facility faults. For an RS423 connection, execute the **test port UUCSSpp long** command and see the repair procedures for Packet Gateway Port Remote Loop-Around Test #611.

   If the port speed is administered as a switched port then the CTS will always be high but the DCD will be low only if there are transmission problems with the far-end. If this occurs, execute the **test port UUCSSpp long** command and see the repair procedures for Packet Gateway Switched Port Loop-Around Test #599.

d. This error occurs when the port receives an invalid frame. A frame is invalid if it is greater than the maximum length, contains CRC errors, or violates the link level protocol. If this error occurs repeatedly, an off-board WARNING alarm is raised against the port. The Packet Gateway Port Remote Loop-Around Test (#611) can be used to isolate the problem. Before executing the **test port UUCSSpp long** command, refer to the repair procedures for test #611 for special instructions regarding the execution of this test. Once the repair has been verified as described in the repair procedures for test #611, the alarm can be cleared by executing the **test port UUCSSpp long clear** command.

e. These errors occur when an X.25 Restart packet is received or sent by the switch due to a Local Procedure error or Network Congestion. Restarts are sent to initialize the packet layer interface and cause all calls on the interface to be cleared. A Local Procedure error usually indicates that one side of the interface has detected a protocol procedural error. Network Congestion normally indicates that the attached network is severely overloaded and has taken a control measure which entails restarting the X.25 interface. The value of the X.25 diagnostic code (0 to 255) contained in each packet is used to offset the base (1024) to produce unique error types. The auxiliary data value indicates the cause of the error and whether the error was sent or received. The auxiliary data value is encoded as follows:

0	Local Procedure Error received.
3	Network Congestion received.
35768	Local Procedure Error sent.
35771	Network Congestion sent.

f. These errors are reported for processor/hop channels and is consistent with the 1984 CCITT X.25 Recommendation. This error is reported when an X.25 reset packet is received due to an DTE Originated Error (i.e., cause value). The value of the diagnostic code (1 to 255) contained in each packet is used to offset the base (2048) to produce unique error types. Note the diagnostic code of "0" (No Additional Information) is not logged as this is considered a normal resetting circumstance. Only nonzero diagnostics are logged in this case - indicating resetting due to a detected error. The auxiliary data field of the log entry contains the affected logical channel number.

g. These errors are reported only for PVCs and indicate loss of end-to-end communication on the PVC. This error indicates that the PVC is "Out Of Order" due to a network or remote DTE problem (e.g., the remote DTE is unattached). These errors are consistent with the 1984 CCITT X.25 Recommendation. The logical channel number (1 to 64) associated with the PVC is used to offset the the base (2304) to produce unique error types. The auxiliary data field for errors of this type contain "1" when a Public Network code has been received. The auxiliary data field contains "129" if a Private Network cause code has been received.

h. These errors are reported only for PVCs and indicate loss of end-to-end communication on the PVC. This error indicates that the PVC is "Network Out Of Order" due to a network problem. These errors have error types 2305 through 2364 and are consistent with the 1984 CCITT X.25 Recommendation. The logical channel number (1 to 64) associated with the PVC is used to offset the the base (2304) to produce unique error types. The auxiliary data field for errors of this type contain "57" when a Public Network code or "185" when a Private Network code has been received.

i. These errors are only reported for PVCs and indicate the loss of end-to-end communication on the PVC. This error indicates that no response is received from the endpoint when the switch attempts to reset a PVC. This error is reported to the switch by the Packet Gateway port every 6 minutes if no response continues to be received. Errors of this type normally indicate an administrative mismatch for the PVC between the switch and the attached endpoint/network. These errors have error types 2305 through 2364. These errors are consistent with the 1984 CCITT X.25 Recommendation. The logical channel number (1 to 64) associated with the PVC is used to offset the base (2304) to produce unique error types. The auxiliary data field of the log entry contains "35768" for errors of this type.

j. This error is reported when an X.25 Reset packet is received or sent due to a Local Procedure Error (i.e., cause value 5 for Public Network or 133 for Private Network Causes). A Local Procedure error usually indicates that one side of the interface has detected a protocol procedural error. The value of the diagnostic code (0 to 255) contained in each packet is used to offset the base (2560) to produce unique error types. The auxiliary data field indicates whether the error was sent or received by the switch, which logical channel number was affected by the error, and whether a Private or Public Network cause value was used. The auxiliary data value is encoded as follows:

1-64	The corresponding Public Network cause value is received over the indicated logical channel number.
4097-4156	The corresponding Private Network cause value is received over the indicated logical channel number. The logical channel number (1-64) is offset by the value 4096.
39865-39924	The corresponding Private Network cause value is sent over the indicated logical channel number. The logical channel number (1-64) is offset by the value 39864. The switch does not generate any Public Network causes.

k. This error occurs when the Link Status Test (#614) fails. An X.25 Access Link is considered failed if it is disconnected at the link level and cannot be quickly reconnected. This failure is usually related to faults in the external port cabling, data set, transmission facility, or due to a far-end equipment failure. If the link fails, a MINOR off-board alarm is raised against the port. Execute the **test port UUCSSpp long** command and see the repair procedures for test #611.

l. These errors occur when at least one session associated with this port is down. Error 1537 is posted when at least one but not all sessions are down. Error 1538 is posted when all the sessions on the link associated with this port are down, but the link itself is not down. The commands **status pgate-port** or **status link** can be used to isolate the session(s) that are down. Once the session information is available, appropriate actions related to the session involved may be followed.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *PDATA Port Local Loop-Around Test* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-520. System Technician-Demanded Tests: PGATE-PT

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Packet Gateway Port Local Loop-Around Test (#610)		X	D
Packet Gateway Switched Port Loop-Around Test (#599)		X	D
Level 1 State Query Test (#613)	X	X	ND
Link Status Test (#614)	X	X	ND
Packet Gateway Port Remote Loop-Around Test (#611)		X	D
(Local Loopback, Digital and Remote Loopbacks)			
Session Status Query Test (#976)	X	X	ND
Session Restart Test (#977)		X	D

1. D = Destructive, ND = Non-destructive

Packet Gateway Switched Port Loop-Around Test (#599)

This test is destructive.

This test verifies that the Packet Gateway port can send and receive data on the TDM bus.

Failure of this test indicates a possible failure of the Packet Gateway circuit pack, the TDM Bus, or the digital port on the Maintenance/Test circuit pack.

This test aborts when calls are in progress on the port, or if the signaling link the port is connected to the port. This test also aborts when executed on a port whose administered speed is other than “switched.

Table 9-521. TEST #599 Packet Gateway Switched Port Loop-Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port is in use for a call or the X.25 Access Link is connected. Execute **status packet-gateway-port** UUCSSpp to determine when the port is available for testing. 1. Retry the command when the port is idle. The port may be forced to the idle state by executing a **busyout port UUCSS** command. The **busyout port** command is destructive causing all calls and links associated with the port to be torn down.
1005	ABORT	The configuration for this test is incorrect. 1. Verify that the port under test is configured as a switched port. This error code will result when the port under test is configured as an RS423. 2. If this is supposed to be a switched port and it is not administered that way change the configuration using **change data-module ext**. The “baud” field should display “switched”.
1340	ABORT	The Maintenance Test Board digital port was not available.
1341	ABORT	Allocation of timeslots failed.
1342	ABORT	Connection of ports to timeslots failed.
2000	ABORT	Uplink message not received before time limit.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-521. TEST #599 Packet Gateway Switched Port Loop-Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	FAIL	Received data test pattern does not match transmitted data test pattern. 1. Retry command at 1-minute intervals a maximum of 3 times. 2. If it still fails, eliminate that the problem is with PKT-BUS and M/T-DIG by following the repair procedures for those MOs. 3. If they pass, replace the board. Deciding when to replace the board must be balanced against traffic on the other ports.
	PASS	The circuitry of the port tested, and its connectivity across the packet bus, is functioning properly.

Packet Gateway Port Local Loop-Around Test (#610)

This test is destructive.

This test verifies the functionality of a port circuit on the Packet Gateway circuit pack. When the switch sends the test request, the Packet Gateway circuit pack automatically loops back the signal at the port as shown in the the figure below. Failure of this test indicates the existence of a fault in the port hardware on the circuit pack.

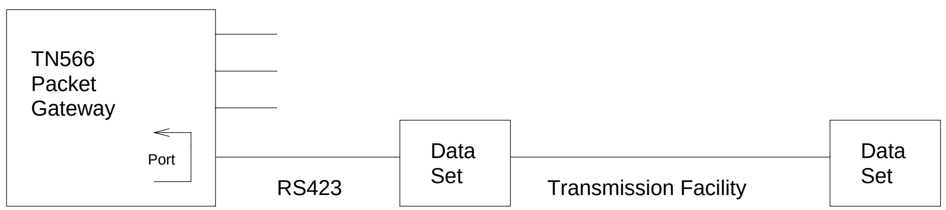

Figure 9-74. Packet Gateway Port Local Loop-Around Test

This test aborts if calls are using the port or if the X.25 Access Link associated with the port is connected. To avoid this, first enter **busyout data-module** extension or **busyout port** UUCSSpp or **busyout link** link#, which will cause all calls and links using the port to be torn down.

Table 9-522. TEST #610 Packet Gateway Port Local Loop-Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The X.25 Access Link is connected or the port is in use for a call. Execute **status packet-gateway-port UUCSSpp** to determine when the port is available for testing. 1. Retry the command when the port is idle. The port may be forced to the idle state by executing a **busyout port UUCSSpp** command. This command is destructive causing all calls and links associated with the port to be torn down.
2000	ABORT	Response to the test was not received from the Packet Gateway circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use (Yellow LED is off). Reset the circuit pack by issuing the **busyout board UUCSS** and the **reset board UUCSS** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The Packet Gateway circuit pack has detected a failure in the execution of the test. 1. If the test fails repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use (Yellow LED is off). Reset the circuit pack by issuing the **busyout board UUCSS** and the **reset board UUCSS** commands. 2. If the test fails again, replace the circuit pack.
	PASS	The circuitry of the port tested is functioning properly.

Packet Gateway Port Remote Loop-around Test (#611)

This test is destructive.

This test checks the integrity of cabling and devices external to the Packet Gateway port hardware. Packet Gateway firmware executes this test on demand by sending a test frame which is looped back to the Packet Gateway by a loop-around that has been externally activated or installed at one of several points in the external connectivity (see loopbacks A, B and C in the figure below). The test passes when the sent and received test frames are identical. The test fails if the sent and received test frames do not match, or if no test frame is received prior to a time out.

If you suspect a problem in cabling or external devices, then repeat this test at points that are progressively further from the PGATE port until either a failure point is identified or the integrity of the entire path is verified. Certain site configurations may require teamwork with those who maintain the off-site transmission facilities.

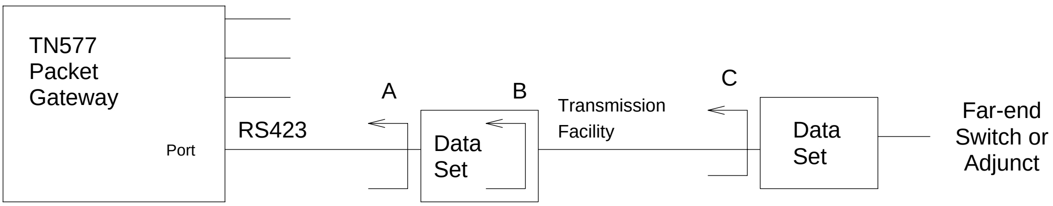

Figure 9-75. Packet Gateway Port Remote Loop-Around Test

Manual activation of the loopback is required for this test. If available, the Local Loopback (B in the above figure), Digital Loopback (C), and Remote Loopback (D) capabilities of external data sets may be used in conjunction with this test for fault isolation. Execution of this test with the data set in the Local Loopback mode verifies the integrity of the external port cabling. Execution of this test with the data set in the Digital Loopback mode verifies the integrity of the data set. Execution of this test with the far-end data set in the Remote Loopback mode verifies the integrity of the transmission facility.

For this test to run, the port or link must be busied out and the “Remote Loopback” field on the data-module form must be set to “y.” This field should only be set to “y” when the external loopback switch has been activated for the test, and should be changed back to “n” when testing is completed and the external loopback has been deactivated.

To test to an MPDM attached to a Packet Gateway port:

1. Enter **busyout data-module** extension or **busyout port UUCSSpp** or **busyout link** link#.
2. Set the switch on the MPDM to local loopback.
3. Enter **change data-module** extension and set the "Remote Loop-Around Test" field to "y."
4. Enter **test data-module** extension **long** or **test port UUCSSpp long** or **test link** link# **long**.
5. When finished testing, enter **change data-module** extension and set the "Remote Loop-Around Test" field to "n."
6. Enter **release data-module** extension or **release port UUCSSpp** or **release link** link#.

To test through an administered connection to an MPDM attached to an adjunct (see "Packet Gateway Configurations" at the beginning of the PGATE-PT section):

1. Enter **busyout data-module** extension or **busyout port UUCSSpp** or **busyout link** link#.
2. Enter **change data-module** extension and set the "Remote Loop-Around Test" field to "y."
3. Set the switch on the MPDM to local loopback.
4. Enter **disable administered-connection** adm-conn#.
5. Attach a loopback plug to the MPDM and set the switch on the MPDM to remote loopback.
6. Enter **enable administered-connection** adm-conn#.
7. When the administered connection becomes established at the MPDM, set remote loopback to normal.
8. Enter **test data-module** extension **long** or **test port UUCSSpp long** or **test link** link# **long**.
9. When finished testing, enter **change data-module** extension and set the "Remote Loop-Around Test" field to "n."
10. Enter **release data-module** extension or **release port UUCSSpp** or **release link** link#.

If a loopback plug is not available, one can be made using a break-out box or hand-made connector. To loop back an RS232 cable, tie the following pins together:

RS232 Cable Loopback

Pins to Join	Pin Names
2-3	Transmit-data, Receive-data
4-5	Request-to-send, Clear-to-send
8-20	Carrier-detect, data-terminal-ready
15-17-24	Transmit-clock, Receive-clock, Transmit-clock

To loop back an RS449 cable (often used to connect AUDIX to an IDI), connect the following pins.

RS449 Cable Loopback

Pins to Join	Pin Names
4-6	SD-A’, RD-A
5-8-17	ST-A, RS-A’, TT-A’
7-9	RS-A’’, CS-A
12-13	TR-A’, RR-A
22-24	SD-B’, RD-C
23-26-35	ST-C, RT-C, TT-B’
25-27	RS-B’, CS-C
30-37	TR-B’, SC

Table 9-523. TEST #611 Packet Gateway Port Remote Loop-Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port is in use for an X.25 Access Link call or a call is connected. Execute **status packet-gateway-port UUCSSpp** to determine when the port is available for testing. 1. Retry the command when the port is idle. The port may be forced to the idle state by executing a **busyout port UUCSSpp** command. This command is destructive causing all calls and links associated with the port to be torn down. 2. If the test fails again, replace the circuit pack.
1005	ABORT	The configuration for this test is incorrect. 1. Verify that the external loopback has been installed or activated. 2. Enter **change data-module** extension and verify that the "Remote Looparound Test" field displays "y". 3. Repeat the test. 4. When testing is complete, deactivate the external loopback and change the "Remote Loop-Around Test" field back to "n." 5. If the test aborts with this code while the port administration is correctly configured, escalate the problem.
2000	ABORT	Response to the test was not received from the Packet Gateway circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use (Yellow LED is off). Reset the circuit pack by issuing the **busyout board UUCSS** and the **reset board UUCSS** commands. 2. Consult the repair procedures for the Packet Gateway Local Loop-Around test (#610).
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	The necessary system resources to execute the test could not be allocated. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-523. TEST #611 Packet Gateway Port Remote Loop-Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Packet Gateway circuit pack has detected a failure in the execution of the test. 1. Verify that the Packet Gateway Local Loop-Around test (#610) passes. Follow repair procedures for that test first if it fails. 2. Run test #611 for each external loopback position. If any test fails, then take the action specified for that point: a. Local Loopback (Loopback "B"): Replace the external port cabling. b. Digital Loopback (Loopback "C"): Replace the data set. c. Remote Loopback (Loopback "D"): Investigate potential transmission line problems. If necessary, escalate the problem to the party responsible for maintaining the off-premise transmission network.
	PASS	Passing of this test for the following loopbacks indicates the integrity of the following pieces of equipment: 1. Local Loopback (Loopback "B"). Packet Gateway port hardware plus cabling. 2. Digital Loopback (Loopback "C"). Packet Gateway port hardware plus cabling plus data set. 3. Remote Loopback (Loopback "D"). Packet Gateway port hardware plus cabling plus data set plus transmission line. 4. If all the above tests pass, place the port in-service (release port UUCSSpp). Execute the **status packet-gateway-port UUCSSpp** command and verify that the transmission-related error counters are not increasing. Execute the "Link Status Test (#614)" via the **test port UUCSSpp** command. Check out equipment at far-end if this test fails.

Level 1 State Inquiry Test (#613)

This test is non-destructive.

This test determines the state of the transmission facility at the physical layer (Level 1). This test is executed by the Packet Gateway circuit pack for a port on a command from the switch. The test passes when the current status of the Data Carrier Detect (DCD) and Clear To Send (CTS) If either of these leads are low, the test fails.

If the port speed is administered as a switched port then the CTS will always be high but the DCD will be low only if there are transmission problems with the far-end and the link had been up. If this occurs, execute the **test port UUCSSpp long** command and consult the repair procedures beginning at Packet Gateway Switched Port Loop-Around Test #599.

Table 9-524. TEST #613 Level 1 State Inquiry Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the Packet Gateway circuit pack X.25 port within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use (Yellow LED is off). Reset the circuit pack by performing the **busyout board UUCSS** and the **reset board UUCSS** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	The necessary system resources to execute the test could not be allocated. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	The Clear To Send lead is ‘‘low’’ indicating a problem with the data set or the cable attached to the port. 1. Repeat the test. 2. If the test still fails, verify that the data set and the Packet Gateway port are properly attached to the cable and the data set is powered on. 3. Place the data set in the ‘‘Local Loopback’’ mode. Consult the repair procedures for the Packet Gateway Port Remote Loop-Around test (#611).

Continued on next page

Table 9-524. TEST #613 Level 1 State Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The Data Carrier Detect lead is “low” indicating a problem on the transmission side of the data set. 1. Repeat the test. 2. If the test still fails, verify the integrity of the wiring on the transmission side of the data set. Make sure that the data set is properly attached to the transmission line. 3. If the local transmission wiring is intact, notify the authority responsible for resolving off-premise transmission facility problems. The Packet Gateway Port Remote Loop-Around Test (#611) may be useful in diagnosing this problem.
	PASS	The Level 1 interface is healthy, both the DCD and CTS leads in the RS423 cable or TDM bus are “high.”

Link Status Test (#614)

This test is non-destructive.

This test determines if the X.25 Access Link is connected or disconnected. The switch determines the state of the X.25 Access Link by sending a query to the Packet Gateway circuit pack. This test passes if the X.25 Access Link is connected and fails if it is disconnected.

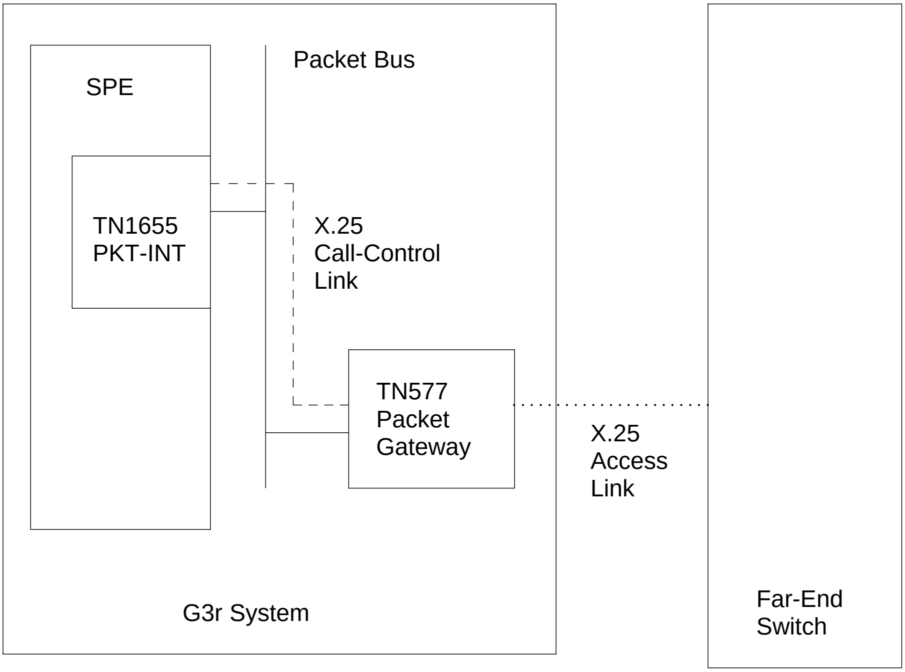

Figure 9-76. Packet Gateway Links

Table 9-525. TEST #614 Link Status Test

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The port is out of service, either due to a hardware failure or the **busyout port UUCSSpp** command. 1. Check if the port has been busied out. If the error log (**display errors** command) contains error type 18 and the alarm log (**display alarms** command) contains an active WARNING alarm for this port, the port has been busied-out. This is a NORMAL abort. 2. If the port has not been busied-out and aborts with this result, execute the Packet Gateway Port Local Loop-Around Test (#610) and the Level 1 State Query Test (#613) via the **test port UUCSSpp long** command. Consult the repair procedures for these tests.

Continued on next page

Table 9-525. TEST #614 Link Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1151	ABORT	The X.25 Call Control Link has failed. It is not possible at the moment to send a message to the Packet Gateway circuit pack to activate this test. 1. Execute the **test board UUCSS** command and see the repair procedures for the X.25 Call Control Link Test (#601). 2. Repeat this test once the X.25 Call Control Link has been re-established, i.e., test #601 passes.
2000	ABORT	Response to the test was not received from the Packet Gateway circuit pack within the allowable time period. 1. If this same result occurs repeatedly, begin by executing the tests as detailed in the earlier section. Consult the individual repair procedures for a specific test if problems are found. 2. If this result continues to occur, attempt to reset the circuit pack if the other ports on the board are not in use (Yellow LED is off). Reset the circuit pack by executing the **busyout board UUCSS** and **reset board UUCSS** commands. 3. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	The necessary system resources to execute the test could not be allocated. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Received data test pattern does not match transmitted data test pattern. Same recommendation as for error code 2 above.

Continued on next page

Table 9-525. TEST #614 Link Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The X.25 Access Link is disconnected. 1. Execute the Packet Gateway Port Local Loop-Around Test (#610) and the Level 1 State Query Test (#613) via the **test port UUCSSpp long** command. Consult the repair procedures for these tests. 2. If all tests pass, check far-end switch equipment. Execute the Packet Gateway Port Remote Loop-Around Test (#611) via the **test port UUCSSpp long** command. Consult the repair procedures for this test. 3. If test #611 passes, see the repair procedures for the Packet Control circuit pack and the Packet Bus.
	PASS	The X.25 Access Link is connected.

Session Status Query Test (#976)

This test is non-destructive.

This test determines the state of the sessions on the X.25 Access Link associated with the Packet Gateway port.

This test determines if all the sessions associated with the channels using the X.25 Access Link is up or down. This test passes if the all the sessions are up and fails otherwise.

Table 9-526. TEST #976 Session Status Query Test

Error Code	Test Result	Description/ Recommendation
1124	ABORT	The X.25 access link associated with this Packet Gateway Port is not enabled. 1. Check if the X.25 access link is enabled for this Packet Gateway Port. If the "enable" field on "display communication-interface link" form is "n" for the link entry which contains the data module extension associated with the Packet Gateway Port, then the X.25 access link is not enabled. Set the field to "y" using **change communication-interface link** command and repeat the test. This is a NORMAL abort.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
1	FAIL	At least one (but not all) sessions on the X.25 access link associated with the Packet Gateway Port are down. Same recommendation as for error type 1537.
2	FAIL	All sessions on the X.25 access link associated with the Packet Gateway Port are down. Same recommendation as for error type 1538.
	PASS	All sessions on the X.25 access link associated with the Packet Gateway Port are up.

Session Restart Test (#977)

This test is destructive.

This test destroys and attempts to restart all the sessions on the X.25 Access Link associated with the Packet Gateway port.

The test attempts to restart all the sessions as long as there is at least one session down on the link. This test aborts if the all the sessions are up.

Table 9-527. TEST #977 Session Status Query Test

Error Code	Test Result	Description/ Recommendation
	ABORT	All sessions are up. This is a NORMAL abort.
1124	ABORT	The X.25 access link associated with this Packet Gateway Port is not enabled. 1. Check if the X.25 access link is enabled for this Packet Gateway Port. If the "enable" field on "display communication-interface link" form is "n" for the link entry which contains the data module extension associated with the Packet Gateway Port, then the X.25 access link is not enabled. Set the field to "y" using **change communication-interface link** command and repeat the test. This is a NORMAL abort.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The X.25 Access Link associated with the Packet Gateway Port is down. Same recommendation as for test type 611.
	PASS	All sessions on the X.25 access link associated with the Packet Gateway Port are restarted.

PKT-BUS (Packet Bus)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PKT-BUS	MAJOR	test pkt P l r 2[1]	Packet Bus
PKT-BUS	MINOR	test pkt P l	Packet Bus
PKT-BUS	WARNING	test pkt P l	Packet Bus

1. where P is the port-network number indicated in the PORT field from the Alarm or Error Log.

The packet bus consists of a single bus, and one such bus appears in each port-network. The packet bus in each port-network is physically independent from those in other port-networks, so each port-network has a separate PKT-BUS maintenance object. This bus supports the following types of connections:

- Logical control links between the SPE and all Expansion Port-Networks (EPN)
- ISDN-BRI D-channel transport (signaling)
- ASAI D-channel transport (signaling)
- ISDN-PRI D-channel (signaling)
- X.25 system adjunct signaling and traffic
- System Access Ports

The TN1655 Packet Interface circuit pack provides the SPE interface to the packet bus. Packet Bus testing depends on the TN771D Maintenance/Test circuit pack, the TN1655 Packet Interface circuit pack, TN570 Expansion Interface circuit pack, and the Packet port circuit packs (TN556 ISDN-BRI Line, TN553 Packet Data Line, TN464 Universal DS1, and TN577 Packet Gateway). Packet Bus tests may abort if some of these are not present in the system. The tests may yield inconsistent results if any of this hardware is defective. The individual test descriptions provide more information.

The interactions between the packet bus and the circuit packs that use the bus are complex. Circuit pack failures can alarm the packet bus, while Packet Bus faults can alarm or interrupt service to one or more circuit packs and their ports and endpoints. The ''Packet Bus Fault Isolation and Repair'' section in Chapter 5, ''Alarms, Errors, and Troubleshooting'' describes Packet Bus maintenance and interactions circuit packs. That section should be referenced for all troubleshooting and repairs. The flowchart is the normal starting point for experienced technicians. Technicians unfamiliar with the packet bus and its implementation in R*X*r should study the introductory material (for example, ''What is the Packet Bus?'') before using the flowchart to diagnose and repair packet bus faults.

This section on the PKT-BUS maintenance object is limited to a description of the Error and Alarm Log entries and the test sequence for the packet bus. The following list summarizes some of the important points to consider when working with the packet bus.

- The Maintenance/Test circuit pack (TN771D) is a critical tool for isolating packet bus faults. This circuit pack is present in each port network of a Critical Reliability system (duplicated SPE *and* PNC). In a Standard Reliability system, the circuit pack may be included as a customer option. If a TN771D is not present, *one must be taken to the customer site* to allow for proper fault isolation. The *''Packet Bus Fault Isolation and Repair''* section in Chapter 5, ''Alarms, Errors, and Troubleshooting'' describes the packet bus testing facilities of the TN771D and when one must be taken to the customer site.
- Certain catastrophic packet bus failures have an effect on maintenance software activities relating to Packet circuit packs, ports, and endpoints:
  - — Packet circuit pack (BRI-BD, PGATE-BD, PDATA-BD, UDS1-BD) in-line errors indicating possible Packet Bus failures are logged in the error log, but are not acted upon.
  - — Port-level (BRI-PORT, ABRI-PORT, PGATE-PT, PDATA-PT) in-line errors on Packet circuit packs which indicate possible Packet Bus failures *are not logged or acted upon*.
  - — Circuit pack and port in-line errors that are not relevant to the Packet Bus, or that indicate a circuit pack failure, are acted upon in the normal fashion.
  - — Periodic and scheduled background maintenance are not affected.
  - — Foreground maintenance (for example, a **test board** command executed at a terminal) is not affected.

  The actions in the previous list serve to reduce the system load, which could become excessive if many maintenance objects are affected by a packet bus failure. However, such an excessive load should in no way impede the isolation and the correction of the faults.

  When the above actions are implemented, Error Type 3329 is logged against PKT-BUS, and a Warning alarm is raised. Other Packet Bus errors may raise more severe alarms, thereby overriding the Warning alarm.
- Since all packet traffic requires communication with the Packet Interface, circuit pack in the SPE , a packet bus failure in the Processor Port-Network (PPN) causes packet traffic in the Expansion Port-Networks (EPNs) to fail. Due to this requirement, a PPN packet bus failure must be investigated first whenever packet bus failures occur in multiple port-networks.

Hardware Error Log Entries and Test to Clear Value

Table 9-528. PKT-BUS Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board[1]	Test to Clear Value
0[2]	0	Any	Any	Any	test pkt port-network
1 (a)	1-2	Packet Circuit Pack Audit Test (#570)	MAJOR	ON	test pkt port-network P l r 2
513 (b)	1-24	Maintenance/Test Circuit Pack Query Test (#572)	MAJOR	ON	test pkt port-network P l r 2
1793 (c)	Any	None			
2049 (d)	1-3	Maintenance/Test Circuit Pack Query Test (#572)	MINOR	ON	test pkt port-network P l r 2
2305 (e)	1-24	Maintenance/Test Circuit Pack Query Test (#572)			test pkt port-network P l
3329 (f)	1-7	none	WARNING	ON	test pkt port-network P l
3585 (g)	Any	none	MINOR	ON	test pkt port-network P l
3841 (h)	Any	none	MINOR	OFF	

1. ON-BOARD indicates a problem with the packet bus itself.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Within the last minute, packet circuit packs have reported errors that indicate a possible packet bus failure. The Aux Data value is 1 or 2, indicating that only one or more than one Packet circuit pack (respectively) have reported a possible packet bus failure.

b. The Maintenance/Test packet bus port (M/T-PKT) for this port-network has determined that there are more packet bus faults than the port can correct. The Aux Data value indicates the number of faulty leads.

c. Packet circuit packs have detected possible packet bus failures via in-line error or via background test failure. Examine the Error and Alarm logs for more specific PKT-BUS errors.

d. The Maintenance/Test packet bus port (M/T-PKT) has detected a Packet Bus fault and taken corrective action by swapping to spare leads. This error appears only in Critical Reliability systems (duplicated SPEs and PNC). The Aux Data value indicates the number of faulty leads. If this is the only active error against the packet bus, *the packet bus is still in service*. Due to the disruptive nature of the packet bus Fault Isolation and Correction procedures, repairs should be deferred until a time when the least interruption in service will result. This should be determined by consultation with the customer. However, do not delay repairs for too long, since the switch will not be able to recover from another packet bus failure until the existing one is resolved. *Packet Bus Fault Isolation and Correction* in Chapter 5, ''Alarms, Errors, and Troubleshooting'' contains a sub-section, *A Special Precaution Concerning the TN771D* that describes how to ensure that the TN771D is providing correct information. A new TN771D may need to be taken to the customer site.

e. The Maintenance/Test packet bus port (M/T-PKT) has detected open leads on the packet bus. The Aux Data value indicates the number of open leads.

f. Packet circuit pack, port, and endpoint maintenance has been disabled due to a packet bus failure. The Aux Data value indicates the cause:

Aux Data	Cause
1	In-line errors from packet circuit packs
2	Uncorrectable packet bus fault reported by the
	Maintenance/Test packet bus port (M/T-PKT)
3	Both of the above
100*x*	Packet-related circuit pack, port, and endpoint maintenance in the EPN has been disabled due to a packet bus failure in the PPN. The last digit has the same meaning as the single digits listed above.

Keep in mind that although only packet circuit packs can detect and report packet bus problems, such problems can be caused by any circuit pack.

g. Packet circuit pack, port, and endpoint maintenance has been disabled due to more than one circuit pack reporting in-line errors. If this occurs more than three times in 15 minutes a Minor alarm is raised against the packet bus. This happens when maintenance is disabled due to errors and is then re-enabled because no more errors are reported.

This error may still be present in the error log even though the Packet Circuit Pack Audit Test (#573) indicates that only one circuit pack is reporting a problem. This happens when more than one circuit pack has reported errors in any one-minute interval since the packet bus fault occurred.

h. The Maintenance/Test packet bus port (M/T-PKT) for this port-network is not in service. This alarm does not appear for EPNs in Standard or High Reliability systems since a TN771 is not required there. The error indicates one or more of the following:

- The packet bus port has been busied out (indicated by Error Type 18), and a Warning alarm is active against M/T-PKT in the same port-network. Release the port by entering **release port UUCSS04**.
- The packet bus port has failed. Look for alarms against M/T-PKT, and attempt to resolve these alarms.
- The Maintenance/Test circuit pack was not recognized by the system at the last system restart. Replace the Maintenance/Test circuit pack.
- There is no Maintenance/Test circuit pack in this port-network. One must be installed.

The TN711 must be installed before other packet bus alarms can be resolved. (Alarms against a given maintenance object are not resolved until all alarm-generating conditions have been cleared).

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables. By clearing error codes associated with the *Packet Circuit Pack Audit Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Packet Circuit Pack Audit Test (#573)	X	X	ND
Maintenance/Test Circuit Pack Query Test (#572)	X	X	ND

1. D = Destructive; ND = Nondestructive

Maintenance/Test Circuit Pack Query Test (#572)

This test queries the Maintenance/Test packet bus port about the state of health of the packet bus. If the Maintenance/Test circuit pack indicates that the packet bus has faults, the test fails. The corresponding failure code describes the severity, type, and number of faults. The test passes if the packet bus is fault-free.

NOTE:
A Maintenance/Test circuit pack is usually not present in any EPN of a system without duplicated PNC (Critical Reliability). Customers may optionally install a Maintenance/Test circuit pack in order to make use of its analog trunk and digital line test capabilities, and to enhance the system's analog trunk and digital line test capabilities, system's ability to quickly recognize a packet bus failure.

Table 9-529. Test #572 Maintenance/Test Circuit Pack Query Test

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The packet bus port of the Maintenance/Test circuit pack is out of service. 1. Determine if the port is busied out. If so, release it with the **release port UUCSS04** command. Then retry the test command. 2. If there are alarms active against the packet bus port (MT-PKT), refer to M/T-PKT Maintenance documentation to resolve them. Then retry the test command.

Continued on next page

Table 9-529. Test #572 Maintenance/Test Circuit Pack Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1142	ABORT	No Maintenance/Test circuit pack packet bus port is in service in this port-network. 1. If this port-network is required by configuration guidelines to have a Maintenance/Test circuit pack (i.e., it is either a PPN or else an EPN in a system having both SPE and PNC duplication) either a. the Maintenance/Test circuit pack for this port-network has failed, and should be replaced, b. the Maintenance/Test circuit pack has been busied out, and should be released, or c. there is no Maintenance/Test circuit pack in this port-network, and one must be installed. 2. In an EPN of a system without both SPE and PNC duplication, the Maintenance/Test packet bus Port is not required and may not be present. If it is present, and is busied out, or has failed, release or replace the circuit pack. If there is no Maintenance/Test circuit pack, ignore the results of this test for this port-network.
2000	ABORT	The test timed-out while waiting for an uplink CCMS response from the Maintenance/Test packet bus port. 1. Re-enter the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, check for problems with the Maintenance/Test packet bus port (look for M/T-PKT in the Error and Alarm Logs).
2059	ABORT	The Maintenance/Test packet bus port has reported a hardware failure. 1. Refer to M/T-PKT Maintenance documentation to correct the problem. 2. Re-enter the test command.

Continued on next page

Table 9-529. Test #572 Maintenance/Test Circuit Pack Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2077	ABORT	The Maintenance/Test Circuit Pack Query located more than one Maintenance/Test packet bus port in the port-network. **NOTE:** The software should not allow this to occur. This is an internal system error. Escalate the problem, but also attempt the following work-around steps. 1. Remove all Maintenance/Test circuit packs from the port-network. 2. Insert one Maintenance/Test circuit pack (there should not be more than one in a port-network). 3. Re-enter the test command.
2100	ABORT	Maintenance could not allocate all of the necessary system resources to perform this test.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Re-enter the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-529. Test #572 Maintenance/Test Circuit Pack Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Maintenance/Test packet bus port has detected faults on the Packet Bus. The error codes are interpreted as follows:
1*xxx*		The Maintenance/Test packet bus port has reconfigured the packet bus around the faulty leads. This action only occurs in Critical Reliability systems (duplicated SPE and PNC).
2*xxx*		The Maintenance/Test packet bus port is unable to correct all of the Packet Bus faults it has detected.
x**0***xx*		None of the packet bus faults are open faults.
x**1***xx*		At least some of the packet bus faults are open faults. Look for error type 2305 in the Error Log. The Aux Data value indicates the number of open leads.
xxyy		The last two digits of the error code indicate the total number of faulty packet bus leads detected. Examples: Error Code 2003 FAIL: The Maintenance/Test packet bus port has detected 3 faulty leads. None of them are opens. At least one was unable to be corrected. Error Code 1103 FAIL: The Maintenance/Test Packet Port has detected 3 faulty leads. At least one is an open. The Maintenance/Test circuit pack was able to correct all of them by reconfiguring. 1. Refer to the "Packet Bus Fault Isolation and Repair" section in Chapter 5, "Alarms, Errors, and Troubleshooting"
	PASS	No faults have been detected on the packet bus by the Maintenance/Test circuit pack. This is an indication that the packet bus is operating correctly.

Packet Circuit Pack Audit Test (#573)

This test determines whether Packet circuit packs have reported Packet Bus-related in-line errors within the last minute. If so, the failure code indicates whether one or more than one circuit pack has reported such failures.

If the test has failed within the last 5 minutes, there is a 15 second delay before the result is returned. This prevents a repeated sequence of this test from always reporting the same result. If the test passes and a FAIL has not occurred within the last five minutes, a PASS is returned immediately.

Table 9-530. Test #573 Packet Circuit Pack Audit Test

Error Code	Test Result	Description/ Recommendation
2500	ABORT	An internal operation failed; the test could not be repeated. 1. Re-enter the command at one-minute intervals a maximum of five times.
1	FAIL	One Packet circuit pack has reported packet bus-related in-line errors within the last minute.
2	FAIL	More than one Packet circuit pack has reported packet bus-related in-line errors within the last minute.
	PASS	No Packet circuit packs have reported packet bus-related in-line errors within the last minute. This indicates that the packet bus is healthy, or that a packet bus fault is transient or is being caused by a faulty Packet circuit pack. If this test passes, but there are other signs of a packet bus failure (for example, logged errors or alarms, or other test failures), refer to the "Packet Bus Fault Isolation and Repair" section in Chapter 5, "Alarms, Errors, and Troubleshooting".

PKT-INT (Packet Interface Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PKT-INT	MAJOR[2]	reset packet-interface CS	Packet Interface Circuit Pack
PKT-INT	MINOR	test packet-interface CS l	Packet Interface Circuit Pack
PKT-INT	WARNING	test packet-interface CS l	Packet Interface Circuit Pack

1. C is the carrier location (a or b), S is the position number of the Packet Interface circuit pack (1, 2, or 3). The carrier location is required only for duplicated SPEs.
2. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.

The Packet Interface (PKT-INT) circuit pack (TN1655) serves as an interface between the Switch Processing Element (SPE) and the Packet bus in the Processor Port Network (see the figure in the following pages).

The PKT-INT supports links used for call setup of all ports located in Expansion Port Networks (EPNs). Therefore, if the PBX system is equipped with the Standard Reliability configuration (without duplicated SPEs), a failure of the Packet Interface circuit pack will prevent call origination and tear-down from telephones and trunks connected to EPNs. In addition to affecting telephone service, a failure of the Packet Interface circuit pack will affect service provided by the following circuit packs that connect to the Packet bus:

- TN464C Universal DS1 circuit pack — ISDN PRI service
- TN553 Packet Data Line circuit pack — System Port feature used for connectivity to features such as Call Detail Recording and dial-up administration.
- TN556 ISDN-BRI Line circuit pack — ISDN BRI service
- TN577 Packet Gateway circuit pack — BX.25 links used for services requiring BX.25 links such as AUDIX and Distributed Communications Systems

If the PBX system is equipped with the High Reliability or Critical Reliability option (i.e. with duplicated SPEs), and if a failure of the Packet Interface circuit pack on the active SPE causes a MAJOR alarm, a SPE interchange will occur if the state of health of the standby SPE is high enough to permit an interchange. A MAJOR alarm caused by a failure of a Packet Interface circuit pack on the standby SPE will drop the state of health of the standby SPE which prevents any attempt to interchange SPEs.

The links that pass through the Packet Interface circuit pack are identified as application links and system links as follows:

1. Application links
   a. EIA endpoints requiring connectivity to the SPE.

      These links pass over the Packet bus, through the System Ports, and over the TDM bus to provide connectivity from the SPE to endpoints on the TDM bus (see figure below).

      The following system features use application links of this type.

      - Call Detail Recording (CDR)
      - Dial-up administration
      - Property Management System (PMS)
      - Journal printer
      - Wake-up log printer
      - Announcement circuit pack upload/download of recorded messages

   b. BX.25 links supported by the Packet Gateway.

      The following system features use application links of this type.

      - Distributed Communication System (DCS)
      - Audio Information Exchange (AUDIX)
      - Messaging Service Adjunct (MSA)
      - Call Management System (CMS)
      - Outgoing Call Management (OCM)
      - Adjunct Switch Application Interface (ASAI)
2. System links
   - Expansion Archangel links (signaling links for call setup of endpoints in an EPN)
   - Center Stage Control Network (CSCN) links
   - ISDN PRI D channel signaling links
   - Packet Gateway call control links (signaling links to the Packet Gateway circuit pack)

- ISDN BRI D channel broadcast and point-to-point signaling links
- Adjunct Switch Application Interface (ASAI) links

The PBX has been designed for a maximum of three Packet Interface circuit packs but only one Packet Interface circuit pack is required for the current PBX hardware configuration. The Packet Interface circuit pack will normally be inserted in the first Packet Interface slot provided in the control carrier although it will operate in any one of the three slots provided. If more than one Packet Interface circuit pack is inserted, an alarm will be generated. For a system equipped with duplicated SPEs, the slot used for the Packet Interface circuit pack on the standby SPE must be the same slot position as that used on the active SPE or an alarm will be generated against the Packet Interface circuit pack in the standby SPE.

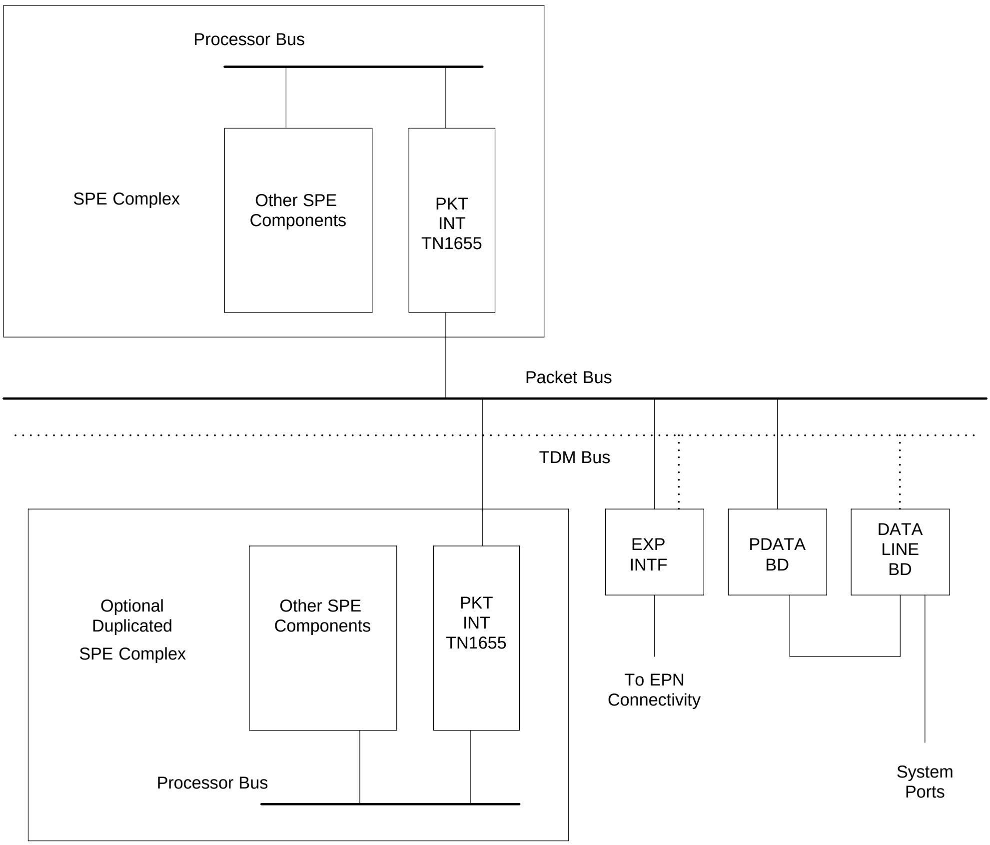

Figure 9-77. Packet Interface Connectivity

Packet Interface Service Operations

The following sections provides more background information about Packet Interface service operations.

Administration

There are no **add** or **remove** commands associated with the Packet Interface circuit packs. Instead, Packet Interface fields (*Packet Intf1, Packet Intf2, Packet Intf3*) that appear under the SPE Optional Boards category on the second page of the System Parameters Maintenance Form are provided to indicate whether the Packet Interface circuit pack is administered.

If a Packet Interface circuit pack is physically present, the corresponding Packet Interface field is set to “y” when the system boots, and no change to that field is allowed. (If the system is equipped with duplicated SPEs, a Packet Interface field is set to “y” when either SPE carrier contains a Packet Interface circuit pack in the corresponding position.) If a Packet Interface circuit pack is not present, then the value for the Packet Interface field is read from translation data stored on disk or removable media. If the field is set to “n,” a Packet Interface circuit pack may be administered by changing the corresponding Packet Interface field to “y.”

Packet Interface Circuit Pack Replacement

When replacing a Packet Interface circuit pack, follow the procedure used for replacing any circuit pack in the SPE carrier. The SPE carrier must be powered down before a Packet Interface circuit pack is removed or added and then the SPE carrier must be powered back up after the circuit pack is inserted.

Packet Interface circuit packs should not be plugged in or removed from a running system since configuration tables in software need to be updated at system restart time. This is also true for Packet Interface circuit packs in the standby SPE carrier when the system is equipped with duplicated SPEs. Refer to *Replacing SPE Circuit Packs* in Chapter 5, “Alarms, Errors, and Troubleshooting” for more information on the procedures for replacing circuit packs in a standby SPE carrier.

Demand Reset of a Packet Interface Board

A demand reset of a Packet Interface circuit pack on an active SPE via the entry of a **reset packet-interface** command will be denied by system software if the Packet Interface is in service (has not been placed in an out-of-service state by background maintenance software). Otherwise, a reset of an in-service Packet Interface circuit pack would cause severe service disruption including the loss of all existing calls and dropped links to adjuncts such as AUDIX. The software that controls Packet Interface maintenance puts a Packet Interface circuit pack in the out-of-service state if that circuit pack has been reset three times within the last 15 minutes. as part of the automatic recovery action that is initiated when a hardware fatal fault condition is detected.

A demand reset of a Packet Interface circuit pack on the standby SPE is not disruptive and is allowed regardless of the service state of the associated maintenance software. When a standby Packet Interface circuit pack is reset, memory shadowing is turned off and then back on. A memory refresh is then performed to update the state of the standby Packet Interface circuit pack and to refresh the standby's memory. It takes several minutes after a Packet Interface circuit pack on the standby SPE is reset before memory refresh of the standby SPE is complete. During that time, demand tests of the standby Packet Interface circuit will abort.

Service States

Packet Interface maintenance software maintains a state variable that keeps track of the in-service/out-of-service state of each Packet Interface circuit pack. In a system equipped with a single SPE, if maintenance software detects that a Packet Interface circuit pack has a "fatal fault", it will automatically attempt to reset that circuit pack as quickly as possible. An extensive set of diagnostic tests are run when the circuit pack is reset.

If the circuit pack diagnostic tests do not pass in a system without duplicated SPEs, the failing Packet Interface circuit pack is placed in an out-of-service state. All links handled by that circuit pack will go out of service. This is a disruptive action since established calls associated with telephones connected to Expansion Port Networks are dropped as a result of the EPNs being taken out of service.

If the system is equipped with duplicated SPEs and if the standby SPE has an acceptable state-of-health, an SPE interchange will occur instead of a reset of the Packet Interface circuit pack. This is less disruptive than a reset since stable calls are not disconnected.

A Packet Interface circuit pack will also be put in the "out-of-service" state if the circuit pack has reported a fatal fault at system initialization time or if the circuit pack has been reset by background maintenance three times within the last 15 minutes, whether or not the Reset test passes. The state of a Packet Interface circuit pack can be determined by using the **status packet-interface** command.

Duplication Impact

The Packet Interface circuit pack is a single point of failure in a system that is not equipped with duplicated SPEs. If this is not acceptable, customers have the option of upgrading to a configuration with a duplicated SPE processor complex as part of the High Reliability or Critical Reliability Configuration. the previous figure shows the configuration with duplicated processors. The following concepts apply only when the processors are duplicated.

- Configuration Mismatch

  The number and position of Packet Interface circuit packs on the standby SPE must match exactly the number and position of Packet Interface circuit packs on the active SPE. If this is not the case, a MAJOR alarm is raised against a missing Packet Interface circuit pack on the standby SPE and a WARNING alarm is raised against extra Packet Interface circuit packs on the standby SPE.

  The system is provided with 3 slots for a maximum of 3 Packet Interface circuit packs. Only one Packet Interface circuit pack is required. This circuit pack is typically plugged into the first slot but it may be plugged into any of three slots. A WARNING alarm will be raised if more than one Packet Interface circuit pack is present in an SPE carrier.

  The version of firmware on a standby Packet Interface circuit pack must also match the version of firmware on the corresponding active Packet Interface circuit pack. If this is not the case, the standby Packet Interface circuit pack enters a fatal fault state and the standby Packet Interface circuit pack maintenance software sets its corresponding in-service/out-of-service state to out-of-service.

  The configuration checks are only made if the active SPE can communicate with the standby SPE. If the standby SPE is locked off-line by setting the SPE-SELECT switches on the DUPINT circuit packs to the position of the active SPE, the mismatch test is not run and therefore, the mismatch is not detected.

- Packet Bus Connection

  In a system equipped with duplicated SPEs, the Packet Interface circuit packs in the Standby SPE can not access the Packet Bus to write data except during the time of a planned SPE interchange and when the Peer Link Test (#888) is run. Consequently, the Maintenance Looparound Test (#886) that requires access to the Packet Bus is not run on Packet Interface circuit packs on the Standby SPE.

- SPE Interchange

  Severe Packet Interface circuit pack faults which cause system and application links to go down will be detected within 1 second. A fatal fault error message will be generated and the Packet Interface maintenance software will attempt to run the Packet Interface Reset test. In systems equipped with the High Reliability or Critical Reliability Configuration this will result in a request for an SPE interchange instead of a reset of the Packet Interface circuit pack since stable calls are preserved across an SPE interchange.

- Clearing Alarms on Standby Packet Interface Circuit Packs

  Alarms for Packet Interface circuit packs on the standby SPE are not cleared automatically when handshake communication with the standby SPE goes down. Handshake communication will go down when the standby SPE is powered down (as part of the repair procedures) or when the SPE-SELECT switches on the DUPINT circuit packs are set to the position of the active SPE. Packet Interface alarms remain after an SPE interchange. This means that memory shadowing will not turn on after an SPE interchange if a Packet Interface circuit pack on the standby SPE had a Major alarm before the interchange. If the Packet Interface circuit pack is replaced, the alarm will still be present. A demand reset of the standby PKT-INT is required to clear the alarm.

Maintenance Object Interactions

- Packet Bus Maintenance

  The Packet Interface circuit pack physically interacts with the PKT-BUS (Packet Bus). For certain types of Packet Interface circuit pack errors, it may be difficult to isolate the fault to one of these two components. In these cases, Packet Interface maintenance will forward the error report to the Packet Bus maintenance, thus causing Packet Bus maintenance to record a Packet Bus fault in the hardware error log and to run appropriate Packet Bus tests.

- Packet Circuit Pack Maintenance

  The operation of the Packet Interface circuit pack affects the operation and maintenance of other circuit packs connected to the Packet bus. This includes:

  1. Expansion Interface circuit pack maintenance (EXP-INTF)
  2. Packet Data Line as part of the System Port (PDATA-BD)

     A System Port is used for connectivity to endpoints connected to the TDM bus such as CDR and dial-up G3-MTs.

  3. BRI applications (BRI-PT)
  4. Packet Gateway applications (PGATE) for X.25 interfaces
  5. Universal DS1 applications (UDS1) for ISDN/PRI applications

Some errors of Packet Circuit Packs may require examination of the Packet Interface operating status. To obtain this information, examine the Error and Alarm Logs for PKT-INT entries. Also issue the **status packet-interface** command to determine the service state of the Packet Interface circuit packs (e.g., in-service/out-of-service) and information about the total number of Packet Interface links assigned to a Packet Interface circuit pack. For a Packet Interface circuit pack in the standby SPE in a system equipped with duplicated SPEs, a Packet Interface is shown to be a "standby" mode if it is not out of service due to a failure condition. The number of links for a standby Packet Interface is always zero.

In general, if all links for a Packet Interface circuit pack on an Active SPE are shown in the "Failed Links" category, there may be a fault on the Packet Interface circuit pack or on the Packet Bus that caused all links to go down. If only a small percentage of the links are shown as "Failed Links," then the Packet Interface circuit pack is probably not the source of the problem. Examples of the source of individual link failures include the failure of a BRI telephone set, a disconnect of the cord to a BRI set, and a failure or removal of an Expansion Interface circuit pack in an Expansion Port Network, The disconnect of a BRI set causes three link failures and the removal of a EI board in an EPN causes one link failure. Refer to Chapter 8, "Maintenance Commands", for more information on the **status packet-interface** command.

For the case where not all links are in the "Failed Links" category, examine the alarm log and error log for failures of the following circuit pack types and follow the repair procedures for those circuit packs before considering replacing the associated Packet Interface circuit pack:

- Expansion Interface circuit pack (EXP-INTF)
- Switch Node Interface circuit pack (SNI-BD)
- Switch Node Clock circuit pack (SNC-BD)
- Packet Data Line circuit packs and ports (PDATA-BD, PDATA-PT)
- ISDN-BRI Line circuit packs, ports, and stations (BRI-BD, BRI-PORT, BRI-SET)
- Packet Gateway circuit packs and ports (PGATE-BD, PGATE-PT)
- Universal DS1 circuit packs and ports (UDS1-BD, TIE-DS1)

Error Log Entries and Test to Clear Values

Table 9-531. Packet Interface Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	ON	test packet-interface CS l r 2
1 (a)	Any	None	MAJOR[2]	ON	reset packet-interface CS[3]
10 (b)	0	None			
23 (c)	0	None	MAJOR[2]	OFF	
23 (d)	0	None	MINOR	OFF

3841 (x)	Any	None	MAJOR[2]	OFF	reset packet-interface CS[3]

1. Indicates that an alarm was raised but an associated error was not entered into the hardware error log due to a momentary overload condition caused by a burst of hardware or software error reports. Run the long test sequence. Refer to the appropriate test descriptions for any failures and follow the recommended procedures.
2. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.
3. A Packet Interface circuit pack on an active SPE can only be reset if it has been taken out of service by background maintenance software. A Packet Interface circuit pack on a standby SPE can be reset independent of its service state.

Notes:

a. Error 1 occurs when background maintenance software has reset the Packet Interface circuit pack as a fault recovery action. It is used to keep track of the number of times that the Packet Interface circuit pack is reset, independent of whether or not the Reset test passed. Once three of these errors have occurred in the last 15 minutes, maintenance will place the Packet Interface circuit pack into an out-of-service state, and a MAJOR on-board alarm will be raised on the Packet Interface circuit pack.

   1. Check to see if error codes 257, 513, 769, 1025, 1281, or 3841 are present in the hardware error log. If one or more of those error codes are present, refer to the information associated with those errors for the appropriate repair procedures.

   2. If no other Packet Interface errors appear in the error log, and if the Packet Interface circuit pack is not in a held reset state as indicated by the absence of a MAJOR alarm with a Service State of OUT, no action should be taken. If a Packet Interface MAJOR alarm is present and no other Packet Interface error codes are in the hardware error log, execute a demand reset by entering **reset packet-interface CS** and refer to the repair procedures for Test # 889.

b. Error 10 indicates that the Packet Interface maintenance software caused an escalating system WARM restart as part of a recovery action for certain Packet Interface circuit pack failures. A SYSTEM error type 10 should also be present, indicating that a software initiated WARM restart occurred.

   1. Check to see if error types 513, 1025, or 3074 are present in the hardware error log. If they are present, refer to the repair procedures for those errors for further action.

c. Error 23 along with an associated MAJOR alarm indicates that (a) Packet Interface circuit pack translation data was loaded from the removable media or disk at boot time but the Packet Interface circuit pack was not detected to be physically present or (b) a Packet Interface circuit pack is on the active SPE but a corresponding Packet Interface circuit pack on the standby SPE is missing.

   1. If the Packet Interface circuit pack is physically present, replace the circuit pack. The SPE must be rebooted to resolve the alarm.

   2. Otherwise, insert the missing Packet Interface circuit pack into the system or use the **change system-parameters maintenance** command to change the entries for Packet Interface circuit packs to match the circuit packs actually present. If a Packet Interface circuit is added to the system, the SPE must be rebooted to resolve the alarm.

d. Error 23 along with an associated MINOR alarm occurs when a user logically administers a Packet Interface circuit pack using the **change system-parameters maintenance** command when the Packet Interface circuit pack is not physically present.

1. Use the **display system-parameters maintenance** command to determine the number of Packet Interface circuit packs logically or physically present.
2. Insert the missing Packet Interface circuit pack into the system or use the **change system-parameters maintenance** command to change the entries for Packet Interface circuit packs to match those actually present.

e. Error 50 indicates that the SPE is sending more downlink messages than the Packet Interface can keep up with. This is an in-line error not produced by any test. When this error is reported, application software is slowed down to allow the Packet Interface to process existing downlink messages. If there is a hardware problem, the Packet Interface test will normally cause other errors to be logged. In the rare case where there are no other PKT-INT errors logged but error 50 occurs more than 10 times in the last hour, follow normal escalation procedures.

f. Error 100 indicates that the SPE requested a reset of Packet Interface circuit packs on the active SPE as part of a Packet Interface circuit pack recovery action. In a High Reliability or Critical Reliability system, an SPE interchange will occur instead of a Packet Interface circuit pack reset, if the health of the standby SPE allows an interchange.

1. If no other PKT-INT errors except error code 1 are present, this means that that the Packet Interface circuit pack was in a fatal fault state at the time of system initialization or SPE interchange and it was reset successfully. No other actions are required.
2. If PKT-INT error codes other than error code 1 are present, refer to the repair procedures for those errors to correct the failure.

g. Error 150 indicates that a SPE interchange occurred and that the Packet Interface circuit pack was the cause of the spontaneous interchange.

1. If other PKT-INT errors are present, investigate those errors.
2. If no other PKT-INT errors are present, run the **test packet-interface long clear** command and investigate any failures.

h. Error 200 indicates that memory shadowing was turned off in preparation for resetting a Packet Interface circuit pack on the active SPE in a system with the High Reliability or Critical Reliability Configuration. No action should be taken based on this error code. Normally, when the state of health of the standby SPE allows an SPE interchange, an SPE interchange will be requested instead of a Packet Interface reset. However, if the state of health of the standby SPE does not permit an SPE interchange, the Packet Interface circuit pack on the active SPE will be reset. As part of that reset action, memory shadowing is turned off so that the Packet Interface circuit pack on the standby SPE will be refreshed after the active Packet Interface circuit pack is reset.

i. Error 257 indicates that the circuit pack detected a fatal failure. This error is a very serious and when it occurs, maintenance software immediately escalates testing to the destructive reset test (#889).

   1. If the Packet Interface circuit has a MAJOR alarm:

      a. Reset the Packet Interface circuit pack using the **reset packet-interface CS** command.

      b. Refer to the repair procedures for the Packet Interface Reset Test (#889).

   2. If the Packet Interface circuit pack is not alarmed, no action is required.

j. Errors 267 and 217 indicate that the number of Packet Interface circuit packs detected as being physically present exceeds number of Packet Interface circuit packs supported by the software configuration or, if the SPEs are duplicated, that a Packet Interface circuit pack is detected as being physically present on the standby SPE but the corresponding Packet Interface circuit pack on the active SPE is not present.

   1. If more than one Packet Interface circuit pack is inserted in the active or standby SPE carrier, remove the extra circuit pack(s).

   2. If the SPE is duplicated, visually check that the number and location of Packet Interface circuit packs in the standby SPE carrier match the number and location of Packet Interface circuit packs in the active SPE carrier. If there is a mismatch, insert Packet Interface circuit packs in the standby SPE to match the Packet Interface circuit packs in the active SPE.

k. Error 513 is called Message Handshake failure. It indicates that a failure with the message protocol between the SPE software and the Packet Interface circuit pack was detected.

   1. If the Packet Interface circuit has a MAJOR alarm:

      a. Reset the Packet Interface circuit pack using the **reset packet-interface CS** command.

      b. Refer to the repair procedures for the *Packet Interface Reset Test (#889)*.

2. If the Packet Interface circuit pack is not alarmed, no action is required.

l. Error 769 indicates that there was a failure in the *Packet Looparound test*. A maintenance looparound link cannot be established or the Packet Interface circuit pack cannot send and receive data correctly as part of the looparound test (Test #886). If the number of errors exceeds a defined threshold, a Major alarm will be raised.

   In a system equipped with duplicated SPEs, a failure of the Maintenance Looparound test may have caused an SPE interchange which would result in an alarm associated with error code 769 being reported against a Packet Interface circuit pack that is currently on the standby SPE. If so, it may be necessary to force the standby SPE to go active by using the SPE-SELECT switches on the DUPINT circuit packs to run the Maintenance Looparound test to make sure the problem is cleared.

   For more information, refer to the repair procedures of Test #886.

m. Error 1025 indicates a failure of the private Level 3 looparound test (Test # 885).

   1. If the Packet Interface circuit has a MAJOR alarm:

      a. Reset the Packet Interface circuit pack using the **reset packet-interface CS** command.

      b. Refer to the repair procedures for the *Packet Interface Reset Test (#889)*.

   2. If the Packet Interface circuit pack is not alarmed, no action is required.

n. Error 1281 indicates that the Packet Interface circuit pack has Translation RAM failures. PKT-INT Translation RAM is used to convert the addresses of a packet to the destination endpoint address.

   1. If the Packet Interface circuit has a MAJOR alarm:

      a. Reset the Packet Interface circuit pack using the **reset packet-interface CS** command.

      b. Refer to the repair procedures for the *Packet Interface Reset Test (#889)*.

   2. If the Packet Interface circuit pack is not alarmed, no action is required.

o. Error 1537 indicates a Boot PROM memory failure. The Packet Interface circuit pack may still be operational if no other errors are reported. However the circuit pack may report a fatal fault during board initialization. This may occur during a system recovery level more severe than a WARM restart. For more information, refer to Test #884.

p. Error 1793 indicates a FLASH Memory test failure. The Packet Interface circuit pack may still be operational if no other errors are reported. However the circuit pack may report a fatal fault during board initialization. This may occur during a system recovery level more severe than a WARM restart. For more information, refer to the repair procedures of Test #884.

q. Error 2049 indicates a LAPD Received Buffer Overflow error. The Packet Interface circuit pack Packet bus receive buffer overflowed. For more information, refer to the repair procedures of Test #887.

r. Error 2305 indicates a Packet Bus Interface Detected Parity failure. The Packet Interface circuit pack received packets with parity error from the Packet bus.

   1. Check for errors logged against the Packet bus and Maintenance/Test circuit pack. Refer to the appropriate repair procedures to clear those errors first.
   2. Check all other circuit packs connected to the Packet bus in the same cabinet. Packet Bus failures are likely to be caused by a faulty circuit pack connected to the backplane or bent pins on the back plane.
   3. If steps 1 and 2 above do not clear the problem, execute the **test packet-interface** command and follow repair procedures described for Test #887.

s. Error 2561 indicates a Active-Standby Peer Link test failure indicating a possible failure of the Packet Interface circuit pack on the active SPE or a failure of the corresponding Packet Interface circuit pack on the standby SPE. If the number of errors exceeds a defined threshold, a Minor alarm will be raised. For more information, refer to the repair procedures of Test #888.

t. Error 2817 indicates a Standby Packet Interface circuit pack Translation RAM failure. A MINOR alarm is raised when there are 1 to 5 bad locations and a MAJOR alarm is raised when there are 5 or more bad locations. Execute the **test packet-interface** command and follow repair procedures described for Test #887.

u. Errors 3074, 3073, and 3072 indicate PKT-INT Transmit Buffer Overflow, which means that the number of transmit buffers required by software exceeded the number available. A 3074 error is generated when the PKINT sends an in-line hardware error to maintenance software indicating transmit buffer overflow. As part of the background recovery action for this error, maintenance software will automatically run the Maintenance Looparound test (#886). If that test fails, maintenance software generates error codes 3073 and 3072, and it requests a system WARM restart. If, after the WARM restart, transmit buffer overflow errors continue to be reported, maintenance software generates error code 100 and it resets the PKT-INT. These errors may be the result of system overload due to a problem with communication between the PKT-INT and the EPNs.

1. Check for errors logged against the Expansion Interface circuit pack, the Switch Node Interface circuit pack, Packet Gateway circuit pack, the Packet Data Line circuit packs associated with the System Ports, BRI Line circuit packs and BRI endpoints, and the Universal DS1 circuit packs supporting PRI service. Errors against those components should be cleared first.
2. Enter the **test packet-interface short** command against the Packet Interface circuit pack associated with the error. If the Maintenance Looparound test (#886) test passes, the alarm will clear. If the test fails, repeat the test 5 times. If it continues to fail, follow normal escalation procedures.

v. Error 3329 indicates that the TDM clock has failed. The Tone Board should have been alarmed (TONE-BD, TDM-CLK). Refer to TDM-CLK and/or TONE-BD for further action. The Packet Interface circuit is taken out of service when this failure occurs. Execute the **reset packet-interface** command to bring the Packet Interface circuit back into service.

w. Error 3585 indicates that a Packet bus failure has been detected and that the Packet bus is alarmed. Refer to the Packet Bus maintenance documentation for further action.

x. Error 3841 indicates that the Packet Interface circuit pack has reported a fatal fault failure condition that may be caused by a Packet Bus failure on the Processor Port Network.

1. If error 3585 has also been reported, refer to the maintenance documentation for PKT (Packet Bus) maintenance. After the Packet Bus failure has been corrected, execute the **reset packet-interface** command to bring the Packet Interface circuit back into service.
2. If error 3585 has not been reported, enter the **reset packet-interface** command and follow the repair steps associated with test #889.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Packet Interface Private Looparound* test for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Packet Interface Reset Test (#889)			X	D
Packet Interface Private Looparound Tests (#885)		X		ND
Packet Interface Maintenance Looparound Test (#886) (a)	X	X		ND
Packet Interface Memory Checksum Test (#884)		X		ND
Packet Interface Error Counter Read and Clear Test (#887)	X	X		ND
Packet Interface Active-Standby Peer Link Test (#888) (b)	X	X		ND

1. D = Destructive; ND = Nondestructive

Notes:

a. This test is run only on a Packet Interface circuit pack on an active SPE.

b. This test is run only on a Packet Interface circuit pack on a standby SPE.

Memory Checksum Test (#884)

This test involves sending a message to the Packet Interface circuit pack to run private non-destructive memory checksum tests on the firmware text residing in Boot PROM and FLASH memory. If the test fails during background testing, the circuit pack will remain operational until a reset is executed on the circuit pack. Then the initialization firmware will fail and will put the circuit pack in an out-of-service state.

Table 9-532. TEST #884 Memory Checksum Test

Error Code	Test Result	Description/ Recommendation
1006 1137	ABORT	Packet Interface circuit pack is in the out-of-service state so normal maintenance tests will not run on that circuit pack. 1. Request a Packet Interface circuit pack reset using the **reset packet-interface CS** command. Refer to the Packet Interface Reset Test (#889) repair procedures for further action.
1334	ABORT	The Packet Interface circuit pack command queue is full. This should be a temporary condition caused by a high rate of commands being sent to a Packet Interface circuit pack. Continued operation with a full command queue will cause a system WARM restart that may escalate to more severe restart levels. 1. Retry the command at 10-second intervals, a maximum of 5 times.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. A planned interchange may be caused by 24 hour scheduled testing. During this time the terminal will be held out of service but it should recover automatically after three minutes. 1. Wait three minutes and retry the command.
1339	ABORT	The test could not run on the standby Packet Interface circuit pack because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the setting the SPE-SELECT switches on the DUPINT circuit packs to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE, The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if the SPE-SELECT switches are in the a or b position, respectively.
1347	ABORT	The test could not run because refresh of the standby SPE's memory is not complete. 1. Enter **status spe** and verify that refresh is not complete. Wait until the status screen indicates that refresh is complete and try the command again. The status screen should indicate that shadowing is on. If some event such as a major alarm on a Packet Interface circuit pack on the standby SPE causes shadowing to turn off, refresh cannot complete and abort code 1350 will be returned when **test packet-interface** is entered.

Continued on next page

Table 9-532. TEST #884 Memory Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1350	ABORT	The test could not run because memory shadowing has not started. 1. Enter **status spe** and verify that shadowing has not started. The SPE is locked when the SPE-SELECT switches on the DUPINT circuit pack are set to the position of the active SPE. Return the switches to the neutral position. If the SPE is not locked, verify that there are no alarms active for the standby SPE. If there are, enter "display alarms" and verify that there are no major alarms against the standby Packet Interface circuit packs. If there are, clear those alarms first.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2500	ABORT	Internal system error 1. Retry the command.
	NO BOARD	The Packet Interface circuit pack is administered but it is not detected as being physically present. 1. If the Packet Interface circuit pack is present, replace it. 2. If the Packet Interface circuit pack is not physically present, use the **display system-parameters maintenance** command to check if the Packet Interface circuit pack is administered as being present. If it is administered, use the **change system-parameters maintenance** command to change the Packet Interface circuit packs administered to be those actually present.

Continued on next page

Table 9-532. TEST #884 Memory Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1537	FAIL	The Boot PROM memory checksum test failed. The circuit pack may still be operational. 1. Retry the command. 2. If the same error code occurs a. If the system is not equipped with the High Reliability or Critical Reliability Configuration replace the circuit pack at a time that would cause the least disruption of service. The circuit pack is still functional but should be replaced since it may not operate after a system reboot and it will enter a fatal fault state if it is reset for other reasons. b. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, replace that circuit pack. c. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the active SPE, perform a planned SPE interchange by entering the command **reset system interchange**. Use the **status spe** command to determine when refresh is complete (between 2 to 10 minutes, depending on system size) and retry the test command. If the test of the circuit pack on the standby SPE continues to fail, replace that circuit pack.

Continued on next page

Table 9-532. TEST #884 Memory Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1793	FAIL	The Flash memory checksum test failed. The circuit pack may still be operational but it will fail if a reset is executed. 1. Retry the command. 2. If the same error code occurs a. If the system is not equipped with the High Reliability or Critical Reliability Configuration replace the circuit pack at a time that would cause the least disruption of service. The circuit pack is still functional but should be replaced since it may not operate after a system reboot and it will enter a fatal fault state if it is reset for other reasons. b. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, replace that circuit pack. c. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the active SPE, perform a planned SPE interchange by entering the command **reset system interchange**. Use the **status spe** command to determine when refresh is complete (between 2 to 10 minutes, depending on system size) and retry the test command. If the test of the circuit pack on the standby SPE continues to fail, replace that circuit pack.
	PASS	The circuit pack's firmware is in a proper state. If problems are still reported on the circuit pack, check for errors on the Private Looparound test (#885) and Maintenance Looparound Test (#886).

Private Looparound Tests (#885)

This test requests the Packet Interface circuit pack to execute its three private looparound tests: Level 2 looparound, Broadcast path looparound, and Level 3 looparound. These tests verify the health of the circuit pack's Packet Bus interface, as well as the translation RAM, inward and outward bound data paths, parity indications and CRC calculations, and the Level 3 processing firmware.

- Level 2 (LAPD) Link Looparound

  LAPD is a link level protocol that is used for all system links. This test verifies the health of the processing of these links.

- Broadcast Link Looparound

  Each ISDN BRI port has two associated broadcast signaling links, one for call control and one for maintenance and management. Since these links have separate routing circuitry from the Level 2 Looparound, this test forces a CRC error to verify the CRC hardware associated with the broadcast data path.

- Level 3 Link Looparound

  Level 3 Links support the X.25 Data Phase protocol used with the Packet Gateway to support X.25 links such as those used for AUDIX. This test verifies the health of the Level 3 firmware. Since soft errors are possible, the Packet Interface circuit pack retries the test before reporting an error.

These tests are also run as part of the reset tests. If the Level 2 or Level 3 looparound test fail as background tests, a "fatal error" message will be sent to the Packet Interface maintenance software and the Packet Interface circuit pack will be put in the "out-of-service" state. Therefore, it is expected that the repair procedures associated with Abort Code 1137 (out-of-service) would normally be followed when failures with the Level 2 and Level 3 tests occur.

Table 9-533. TEST #885 Private Looparound Tests

Error Code	Test Result	Description/ Recommendation
1006 1137	ABORT	Packet Interface circuit pack is in the out-of-service state so normal maintenance tests will not run on that circuit pack. 1. Request a Packet Interface circuit pack reset using the **reset packet-interface CS** command. Refer to the Packet Interface Reset Test (#889) repair procedures for further action.
1334	ABORT	The Packet Interface circuit pack command queue is full. This should be a temporary condition caused by a high rate of commands being sent to a Packet Interface circuit pack. Continued operation with a full command queue will cause a system WARM restart that may escalate to more severe restart levels. 1. Retry the command at 10-second intervals, a maximum of 5 times.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. A planned interchange may be caused by 24 hour scheduled testing. During this time the terminal will be held out of service but it should recover automatically after 3 minutes. 1. Wait 3 minutes and retry the command.

Table 9-533. TEST #885 Private Looparound Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2500	ABORT	Internal system error 1. Retry the command.
	NO BOARD	The Packet Interface circuit pack is administered but it is not detected as being physically present. 1. If the Packet Interface circuit pack is present, replace it. 2. If the Packet Interface circuit pack is not physically present, use the **display system-parameters maintenance** command to check if the Packet Interface circuit pack is administered as being present. If it is administered, use the **change system-parameters maintenance** command to change the Packet Interface circuit packs administered to be those actually present.
1	FAIL	The Private Link Broadcast looparound test failed. The circuit pack will enter a fatal fault state when this occurs and the Packet Interface Maintenance software should put the circuit in a out-of-service state. Therefore by the time further action is taken, it is expected that the test will abort with ABORT code 1137 and a demand reset should be used to test the circuit pack. 1. Reset the circuit pack using the **reset packet-interace CS** command. Refer to the repair procedures for the Packet Interface Reset Test (#889) for further action. 2. If the test continues to fail, replace the Packet Interface circuit pack.

Continued on next page

Table 9-533. TEST #885 Private Looparound Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The Private Level 2 looparound test failed. The circuit pack will enter a fatal fault state when this occurs and the Packet Interface Maintenance software should put the circuit in a out-of-service state. Therefore by the time further action is taken, it is expected that the test will abort with ABORT code 1137 and a demand reset should be used to test the circuit pack. 1. Reset the circuit pack using the **reset packet-interace CS** command. Refer to the repair procedures for the Packet Interface Reset Test (#889) for further action. 2. If the test continues to fail, replace the Packet Interface circuit pack.
3	FAIL	The Private Link Level 3 looparound test failed. The circuit pack may still be operational. 1. Retry the command. 2. If the test continues to fail with the same error code: a. If the system is not equipped with the High Reliability or Critical Reliability Configuration replace the Packet Interface circuit pack. b. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, replace the circuit pack on the standby SPE. c. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the active SPE, 3. Perform a planned SPE interchange by entering the command **reset system interchange**. Use the **status spe** command to determine when refresh is complete (between 2 to 10 minutes, depending on system size) and retry the test command. 4. If the test of the circuit pack on the standby SPE continues to fail, replace that circuit pack.

Continued on next page

Table 9-533. TEST #885 Private Looparound Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	All the private looparound tests passed. The circuit pack is functioning properly. If the system is still unable to place calls on cabinets other than the SPE cabinet, then: 1. Display the error log using the command **display errors** and check for errors on the Packet Bus and Maintenance/Test circuit pack. Clear those errors first. 2. Check all other circuit packs connected to the Packet Bus in the same cabinet. Packet Bus failures are likely to be caused by a faulty circuit pack connected to the backplane or bent pins on the back plane. Refer to the PKT-BUS maintenance documentation for repair procedures.

Maintenance Looparound Test (#886)

This test checks whether the Packet Interface circuit pack can send and receive data correctly. It establishes a LAPD link from a Packet Interface circuit pack back to the same Packet Interface circuit pack and transmits and receives test data over that testing link. While timing signals from the Packet Bus are used for the data transfer, the data itself is looped around on the circuit pack at the interface to the Packet Bus and does not get sent over the Packet Bus.

NOTE:
This test is not run if the Packet Interface circuit pack is on a standby SPE in a system equipped with duplicated SPEs. However, a failure of the Maintenance Looparound test may have caused an SPE interchange which would result in an alarm associated with the looparound failure error code 769 being reported against a Packet Interface circuit pack that is currently on the standby SPE. If that is the case, and if all other Packet Interface tests associated with the **test packet-interface CS long** pass, force the standby SPE to go active by using the SPE-SELECT switches. Then enter the **test packet-interface CS** command to run the Maintenance Looparound test to make sure the problem has been cleared.

Table 9-534. TEST #886 Maintenance Looparound Test

Error Code	Test Result	Description/ Recommendation
1006 1137	ABORT	Packet Interface circuit pack is in the out-of-service state so normal maintenance tests will not run on that circuit pack. 1. Request a Packet Interface circuit pack reset using the **reset packet-interface CS** command. Refer to the Packet Interface Reset Test (#889) maintenance documentation for further action.
1139	ABORT	The Packet Bus is alarmed 1. Try to retire the alarm associated with the Packet Bus. Refer to the Alarm Log via the **display alarms** command. Refer to the maintenance documentation for Packet Bus Maintenance for further action. 2. Retry the command when the alarm associated with the Packet Bus is retired.
1335	ABORT	Internal system error. The Packet Interface circuit pack is on the standby SPE and this test is not allowed to execute on a Packet Interface circuit pack on the standby SPE. 1. If you wish to run this test on the standby Packet Interface, you must first make it active with **reset system interchange**. Be sure you understand the implications explained in *Planned SPE Interchange* in Chapter 5, ''Alarms, Errors, and Troubleshooting''.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. A planned interchange may be caused by 24 hour scheduled testing. During this time the terminal will be held out of service but it should recover automatically after 3 minutes. 1. Wait 3 minutes and retry the command.
1373	ABORT	Could not establish the link loop around link to run this test. 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2060	ABORT	Packet link bus went down during maintenance looparound test. 1. Retry the command at 1-minute intervals, a maximum of 5 times. 2. If there are errors associated with the Packet Bus, refer to the maintenance information associated with the Packet Bus.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, a maximum of 5 times.

Continued on next page

Table 9-534. TEST #886 Maintenance Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	NO BOARD	The Packet Interface circuit pack is administered but it is not detected as being physically present. 1. If the Packet Interface circuit pack is present, replace it. 2. If the Packet Interface circuit pack is not physically present, use the **display system-parameters maintenance** command to check if the Packet Interface circuit pack is administered as being present. If it is administered, use the **change system-parameters maintenance** command to change the Packet Interface circuit packs administered to be those actually present.
1-3	FAIL	The test failed. Maintenance was unable to establish a looparound link from the Packet Interface circuit pack back to itself or was unable to receive data that was sent out over one side of the looparound link. 1. Issue the **test packet-interface CS** command to retry the test. If the same error code is observed, background maintenance software will automatically attempt to reset the circuit pack and clear the problem. 2. Retry the command and if the test fails, replace the circuit pack. 3. If the test continues to fail after replacing the circuit pack, run the **test packet P long** command. If any of the tests fail, the fault may be on the Packet Bus. Refer to the PKT-BUS (Packet Bus) Maintenance documentation for recommended repair procedures. 4. If the test continues to fail after the circuit pack is replaced and with no other alarms associated with the Packet Bus or circuit packs connected to the Packet Bus, follow normal escalation procedures.

Continued on next page

Table 9-534. TEST #886 Maintenance Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	This test passed. The circuit pack and its interface with the SPE are functioning properly. If the system is unable to place calls on cabinets other than the SPE cabinet, then: 1. Check for errors on the Packet Bus and Maintenance/Test circuit pack. Solve those errors first. 2. Check all other circuit packs connected to the Packet Bus in the same cabinet. Packet Bus failures are likely to be caused by a faulty circuit pack connected to the backplane or bent pins on the back plane. 3. Check the Packet Interface circuit pack connections to the Packet Bus.

Read and Clear Board Counters (#887)

This test involves sending commands to read on-circuit pack error counters on the Packet Interface circuit pack. It also verifies the message interface between the SPE and the Packet Interface circuit pack.

This test checks different circuit pack counters depending on whether the circuit pack is on the active or standby SPE.

If the Packet Interface circuit pack is on the active SPE, this test reads and clears the Parity Error counter and FIFO Overflow counter. Those counters are not used when a Packet Interface circuit pack is in standby mode.

If the Packet Interface circuit pack is on the standby SPE, this test reads but does not clear a Translation RAM counter. The Translation RAM counter is not cleared since the number of bad translations RAM locations indicates bad locations that cannot be used. For a Packet Interface Circuit Pack on the active SPE, information about the number of bad Translation location is sent to maintenance software as an in-line error from the circuit pack so it is not necessary to read a counter location.

Table 9-535. TEST #887 Read and Clear Board Counters

Error Code	Test Result	Description/ Recommendation
1006 1137	ABORT	Packet Interface circuit pack is in the out-of-service state so normal maintenance tests will not run on that circuit pack. 1. Request a Packet Interface circuit pack reset using the **reset packet-interface CS** command. Refer to the Packet Interface Reset Test (#889) maintenance documentation for repair procedures.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. A planned interchange may be caused by 24 hour scheduled testing. During this time the terminal will be held out of service but it should recover automatically after 3 minutes. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Packet Interface circuit pack because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the setting the SPE-SELECT switches on the DUPINT circuit packs to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE, The *SPE Selected field* on the **status spe** screen will display *spe a* or *spe b* if the SPE-SELECT switches are in the a or b position, respectively.
1347	ABORT	The test could not run because refresh of the standby SPE's memory is not complete. 1. Enter **status spe** and verify that refresh is not complete. Wait until the status screen indicates that refresh is complete and try the command again. The status screen should indicate that shadowing is on. If some event such as a major alarm on a Packet Interface circuit pack on the standby SPE causes shadowing to turn off, refresh cannot complete and abort code 1350 will be returned when the test packet-interface command is entered.

Continued on next page

Table 9-535. TEST #887 Read and Clear Board Counters — *Continued*

Error Code	Test Result	Description/ Recommendation
1350	ABORT	The test could not run because memory shadowing has not started. 1. Enter **status spe** and verify that shadowing has not started. The SPE is locked when the SPE-SELECT switches on the DUPINT circuit pack are set to the position of the active SPE. Return the switches to the neutral position. If the SPE is not locked, verify that there are no alarms active for the standby SPE. If there are, enter **display alarms** and verify that there are no major alarms against the standby Packet Interface circuit packs. If there are, clear those alarms first.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2500	ABORT	Internal system error 1. Retry the command.
	NO BOARD	The Packet Interface circuit pack is administered but it is not detected as being physically present. 1. If the Packet Interface circuit pack is present, replace it. 2. If the Packet Interface circuit pack is not physically present, use the **display system-parameters maintenance** command to check if the Packet Interface circuit pack is administered as being present. If it is administered, use the **change system-parameters maintenance** command to change the Packet Interface circuit packs administered to be those actually present.

Continued on next page

Table 9-535. TEST #887 Read and Clear Board Counters — *Continued*

Error Code	Test Result	Description/ Recommendation
256 512 768	FAIL	The Packet Interface circuit pack on the active SPE has an error counter set. The following error codes are possible: 256: Parity error 512: FIFO overflow 768: Parity error and FIFO overflow error 1. If error code 256 or 768 is reported the Packet Interface circuit pack received a parity error off the Packet Bus. a. First check for alarms logged against the Packet Bus. Refer to the PKT-BUS maintenance documentation to clear those errors first. b. Then check for alarms and errors logged against other circuit packs connected to the Packet bus in the Processor Port Network cabinet. A list of packet circuit packs is presented in the first section of this repair procedure. Refer to the repair procedures for those circuit packs, in this manual, to clear those errors first. c. If the system is not equipped with the High Reliability or Critical Reliability Configuration, replace the circuit pack at a time that would cause the least disruption of service. The circuit pack is still functional but should be replaced. d. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, replace that circuit pack. e. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the active SPE, perform a planned SPE interchange by entering the command **reset system interchange**. Replace the circuit pack on the standby SPE.

Continued on next page

Table 9-535. TEST #887 Read and Clear Board Counters — *Continued*

Error Code	Test Result	Description/ Recommendation
256 512 768	FAIL *(cont'd.)*	2. If error code 512 or 768 is reported for a Packet Interface on an **active SPE**, the receive FIFO in the PKT-INT has overflowed. This may be an indication that additional Packet Interface circuit packs are required. For the current hardware configuration, only one Packet Interface circuit pack is allowed so the problem should be escalated if the repair steps presented below do not correct the problem. Retry the command after a one minute delay and if the test continues to fail: a. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the active SPE, perform a planned SPE interchange by entering the command **reset system interchange**. Replace the circuit pack b.) Otherwise, (the system is not equipped with the High Reliability or Critical Reliability Configuration) replace the circuit pack at a time that would cause the least service disruption. 3. If error code 512 or 768 is reported for a Packet Interface on a standby SPE, replace the Packet Interface circuit pack.
1024-1096	FAIL	The Packet Interface circuit pack on the standby SPE has bad Translation RAM locations. A MINOR alarm is generated when the number of bad locations is from 1 and 4. A MAJOR alarm is generated if the number of bad locations is 5 or more. The MAJOR alarm prevents a planned SPE interchange. (A planned interchange may be administered to occur automatically every 24 hours or it may be requested by using the **reset system interchange** command.) 1. If a MAJOR alarm is associated with this error, replace the alarmed Packet Interface circuit pack. 2. If a MINOR alarm is associated with this error, replace the alarmed Packet Interface circuit pack at a time that would cause the least disruption to service.
	PASS	The SPE is able to communicate with the Packet Interface circuit pack. If problems are still reported on the circuit pack, check for failures using the Private Looparound test (#885) and Maintenance Looparound test (#886).

Active-Standby Peer Link Test (#888)

The Active-Standby Peer Link Test is only run in a system equipped with the High Reliability or Critical Reliability Configuration. It verifies that the Peer Link can be set up between the active and standby SPEs. The Peer Link is a link set up across the Packet Bus between the Packet Interface circuit pack on the active and standby SPEs. It is used for forwarding data and control messages between the active and standby SPE in preparation for a planned SPE interchange. This test not only checks the operation of setting up a Peer Link but it also verifies that the active and standby Packet Interface circuit packs can communicate over the Packet Bus.

This test is run against the standby Packet Interface circuit pack although it checks functionality on both the active and standby Packet Interface Circuit Packs.

Table 9-536. TEST #888 Active-Standby Peer Link Test

Error Code	Test Result	Description/ Recommendation
1006 1137	ABORT	Packet Interface circuit pack is in the out-of-service state so normal maintenance tests will not run on that circuit pack. 1. Request a Packet Interface circuit pack reset using the **reset packet-interface CS** command. Refer to the Packet Interface Reset Test (#889) repair procedures for further action.
1139	ABORT	The Packet Bus is alarmed. 1. Try to retire the alarm associated with the Packet Bus. Refer to the Alarm Log via the **display alarms** command. Refer to the PKT-BUS Packet Bus maintenance documentation for further action. 2. Retry the command when the alarm associated with the Packet Bus is retired.
1336	ABORT	Internal system error. 1. If you wish to run this test on the standby Packet Interface, you must first make it active with **reset system interchange**. Be sure you understand the implications explained in *Planned SPE Interchange* in Chapter 5, ''Alarms, Errors, and Troubleshooting''.
1337	ABORT	The test is not allowed to run since a PNC (Port Network Connectivity) interchange is in progress. A PNC interchange may be initiated on demand with the use of the **reset pnc interchange** command or as a result of a recovery action. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-536. TEST #888 Active-Standby Peer Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. A planned interchange may be caused by 24 hour scheduled testing. During this time the terminal will be held out of service but it should recover automatically after 3 minutes. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Packet Interface circuit pack because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by a variety of reasons such as the setting the SPE-SELECT switches on the DUPINT circuit packs to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected field* on the **status spe** screen will display *spe a* or *spe b* if the SPE-SELECT switches are in the a or b position, respectively.
1347	ABORT	The test could not run because refresh of the standby SPE's memory is not complete. 1. Enter **status spe** and verify that refresh is not complete. Wait until the status screen indicates that refresh is complete and try the command again. The status screen should indicate that shadowing is on. If some event such as a major alarm on a Packet Interface circuit pack on the standby SPE causes shadowing to turn off, refresh cannot complete and abort code 1350 will be returned when the test packet-interface command is entered.
1350	ABORT	The test could not run because memory shadowing has not started. 1. Enter **status spe** and verify that shadowing has not started. The SPE is locked when the SPE-SELECT switches on the DUPINT circuit pack are set to the position of the active SPE. If the SPE is licked, return the switches to the neutral position. If the SPE is not locked, verify that there are no alarms active for the standby SPE. If there are, enter **display alarms** and verify that there are no major alarms against the standby Packet Interface circuit packs. If there are, clear those alarms first.

Continued on next page

Table 9-536. TEST #888 Active-Standby Peer Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2500	ABORT	Internal system error 1. Retry the command.
	NO BOARD	The Packet Interface circuit pack is administered but it is not detected as being physically present. 1. If the Packet Interface circuit pack is present, replace it. 2. If the Packet Interface circuit pack is not physically present, use the **display system-parameters maintenance** command to check if the Packet Interface circuit pack is administered as being present. If it is administered, use the **change system-parameters maintenance** command to change the Packet Interface circuit packs administered to be those actually present.
1	FAIL	Peer link setup between the active and standby Packet Interface circuit packs failed. 1. Use the **display alarms** command to display the active alarms. If there are any errors associated with the Packet Bus, refer to the PKT-BUS maintenance documentation to clear the Packet Bus problems first. 2. Retry the test command after a one minute delay. 3. If the test continues to fail, replace the Packet Interface circuit pack on the standby SPE.

Continued on next page

Table 9-536. TEST #888 Active-Standby Peer Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 *(cont'd.)*	FAIL	4. If the test continues to fail: a. Use the **display alarms** command to display the active alarms. Verify that there are no alarms on the standby SPE components other than the PKT-INT alarms for the Peer Link failure. If there are other alarms for SPE components, clear those alarms first.Enter the **status spe** command and verify that refresh is complete. If it is not, refer to the repair procedures for STBY-SPE for further action. b. Initiate an SPE interchange by moving the SPE SELECT switches on the DUPINT circuit packs to the position corresponding to the carrier location of the standby SPE. This will cause an SPE interchange using a WARM restart, assuming refresh is complete. Established calls will not be disconnected. c. Replace the Packet Interface circuit pack on the standby SPE and restore the SPE SELECT switches to their neutral position. (Refer to Replacing SPE Circuit Packs in Chapter 5, ''Alarms, Errors, and Troubleshooting'' for procedures for replacing circuit packs in a standby SPE carrier.) d. Enter the **status SPE** command at on minute intervals up to 10 minutes to check for completion of memory refresh.

Continued on next page

Table 9-536. TEST #888 Active-Standby Peer Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	No response from the active Packet Interface circuit pack to a request to the Packet Interface on the active SPE for peer link setup between the active and standby Packet Interface circuit pack. 1. Retry the test command after a one minute delay. 2. If the test continues to fail: a. Use the **display alarms** command to display the active alarms. Verify that there are no alarms on the standby SPE components other than the alarm for the Peer Link failure. If there are, clear those alarms first. b. Initiate an SPE interchange by moving the SPE SELECT switches on the DUPINT circuit packs to the position corresponding to the carrier location of the standby SPE. This will cause an SPE interchange using a WARM restart. Established calls will not be disconnected. c. Replace the Packet Interface circuit pack on the standby SPE and restore the SPE SELECT switches to their neutral position. (Refer to Replacing SPE Circuit Packs in Chapter 5, ''Alarms, Errors, and Troubleshooting'' for procedures for replacing circuit packs in a standby SPE carrier.) d. Enter the **status SPE** command at on minute intervals up to 10 minutes to wait for memory refresh to complete.
	PASS	The SPE is able to communicate with the Packet Interface circuit pack. If problems are still reported on the circuit pack, check for errors on the Private Looparound Tests (#885) and Maintenance Looparound Tests (#886).

Reset Test (#889)

The reset action initializes the Packet Interface circuit pack and causes the firmware on the Packet Interface circuit pack to run a comprehensive set of diagnostic tests.

The demand reset action will abort if the specified Packet Interface circuit pack is on an active SPE (versus a standby SPE) and if that Packet Interface circuit pack is in the in-service state.

A Packet Interface circuit pack is put in the out-of-service state automatically if it has been reset 3 times by background maintenance within the last 15 minutes, independent of the results of the reset action.

If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, the demand reset action will run if handshake is up, independent of the service state of the circuit pack. Shadowing is turned off automatically when a standby PKT-INT is reset. Memory refresh can then take up to 10 minutes to complete.

Table 9-537. TEST #889 Reset Test

Error Code	Test Result	Description/ Recommendation
1334	ABORT	The Packet Interface circuit pack command queue is full. This should be a temporary condition caused by a high rate of commands being sent to a Packet Interface circuit pack. Continued operation with a full command queue will cause a system WARM restart that may escalate to more severe restart levels. 1. Retry the command at 10 second intervals, a maximum of 5 times.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. A planned interchange may be caused by 24 hour scheduled testing. During this time the terminal will be held out of service but it should recover automatically after 3 minutes. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Packet Interface circuit pack because the standby SPE is unavailable. 1. Refer to “STBY-SPE” for information on why a standby SPE may be unavailable and what repair actions should be taken. The **status spe** screen should indicate that handshake is down. This may be caused by setting the SPE-SELECT switches on the DUPINT circuit packs to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE, The *SPE Selected field* on the **status spe** screen will display *spe a* or *spe b* if the SPE-SELECT switches are in the a or b position, respectively.

Continued on next page

Table 9-537. TEST #889 Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1347	ABORT	The Packet Interface circuit pack on the standby SPE is in an uninstalled state even though it is physically present. This can be caused by replacing that circuit pack without following the ‘‘lock-and-power-down’’ procedure for replacing SPE circuit packs. 1. Use the **status packet-interface** command to determine the service state of the Packet Interface circuit pack. If the state is not "uninstalled", follow normal escalation procedures. 2. Remove and restore power to the standby SPE carrier. 3. Enter **status spe** and wait until that screen indicates that memory refresh is complete. 4. If refresh does not complete, check the alarm log for alarms against a shadowing-relevant component and follow recommendations for that component. 5. If there is an alarm against PKT-INT, replace the Packet Interface circuit pack and retry the command.
1362	ABORT	The Reset test is not allowed to run because the Packet Interface circuit pack is in service. Resetting a Packet Interface circuit pack that is in-service on an active SPE is not allowed since this is a destructive test (existing phone calls involving telephones connected to Expansion Port Networks would be disconnected). 1. Use the **status packet-interface** command to determine the service state of the Packet Interface circuit pack. If the state is "out-of-service", try the Reset command again.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Packet Interface circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2500	ABORT	Internal system error 1. Retry the command.

Continued on next page

Table 9-537. TEST #889 Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Packet Interface circuit pack is administered but is not detected as being physically present. 1. If the Packet Interface circuit pack is present, replace it. 2. If the Packet Interface circuit pack is not physically present, use the **display system-parameters maintenance** command to check if the Packet Interface circuit pack is administered as being present. If it is administered, use the **change system-parameters maintenance** command to change the Packet Interface circuit packs administered to be those actually present. **NOTE:** If the system is equipped with the High Reliability or Critical Reliability Configuration, the Packet Interface entry on the system-parameters maintenance screen will show "y" if translation data is present for a Packet Interface circuit pack on either the active or standby SPE or if a Packet Interface circuit pack is present on either the active or standby SPE. The corresponding entry on the screen can only be changed from "y" to "n" if a Packet Interface circuit pack is not physically present in the active SPE. However, if the system is restarted with a restart level equal or greater than a WARM restart, the Packet Interface circuit pack maintenance software will automatically detect any Packet Interface circuit pack physically present on the active or standby SPE and the corresponding field on the system-parameters maintenance screen will show a "y."
5001	FAIL	The TDM clock on the Processor Port Network has failed. 1. Refer to the "TDM-CLK" to clear this failure.
5002	FAIL	The Packet Bus on the Processor Port Network has failed. 1. Refer to "PKT-BUS" to clear this failure.

Continued on next page

Table 9-537. TEST #889 Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any Other Than Those Listed Above	FAIL	The Packet Interface circuit pack diagnostic tests failed. If the system is equipped with the High Reliability or Critical Reliability Configuration, the reset will run only on demand if the Packet Interface circuit pack is on the standby SPE or if Packet Interface circuit pack is in an out-of-service state on the active SPE (which means an SPE interchange was not allowed because the standby SPE is not healthy). If the latter case is true, also refer to the repair procedures for STBY-SPE for clearing the problem on the standby SPE. 1. Retry the command **reset packet-interface** 2. If the reset fails, replace the circuit pack. (Refer to Replacing SPE Circuit Packs in Chapter 5, ''Alarms, Errors, and Troubleshooting'' for procedures for replacing circuit packs in a standby SPE carrier.) 3. If the Packet Interface circuit pack is on the standby SPE, enter the **status SPE** command at one minute intervals up to 10 minutes after the circuit pack is replaced to check for completion of memory refresh.
	PASS	The Packet Interface circuit pack diagnostic software passed. The Packet Interface circuit pack is put back into service automatically. If the Packet Interface on the standby SPE continues to report an in-line fatal fault code (error 257) and as a result goes into the out-of-service state even though the demand reset test passes, the firmware version of the Packet Interface circuit pack on the standby SPE may not be the same as the firmware version of the Packet Interface circuit pack on the active SPE. Use the **list configuration control** command to determine if the vintage of the Packet Interface circuit packs on the active and standby SPEs is the same.

PMS-LINK (Property Management System Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
PMS-LINK	MINOR	test pms l	PMS Link
PMS-LINK	WARNING	test pms	PMS Link

Property Management System (PMS) is a stand-alone computer system that environments such as hotels or hospitals use for services such as reservations, registration, messaging, housekeeping, night audit, billing, and inventory. The PMS Link provides a communications channel between the switch and the customer-owned PMS so that the PMS can interrogate the system for information related to the following features:

- Message Waiting Notification
- Controlled Restriction
- Housekeeping Status
- Check-in/Check-out
- Room Change/Room Swap

Refer to *DEFINITY Communications System Generic 3 Feature Description,* 555-230-204, for details of the PMS feature. The PMS device connects to the system via a data module (PDM, MPDM, DTDM) connected to a port on a TN754 Digital Line circuit pack which is administered as a data extension. A PMS device can also be connected through an ADU to a port on TN726B. The PMS link to the processor is via a system port. A system port is comprised of a port on the TN726B Data Line circuit pack and a port on the TN553 Packet Data circuit pack connected to each other in a null-modem fashion. Refer to the PDATA-PT section for information on the system port connectivity.

PMS Link maintenance provides a strategy for maintaining the link between the switch and a PMS device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Link Maintenance uses a ‘‘try-and-wait’’ mechanism for maintaining the PMS Link. If a PMS Link is torn down due to an error, PMS Link Maintenance attempts to bring up the link immediately. If the Link Setup fails, PMS Link Maintenance will wait for five minutes before the next retry. If the number of retries reaches a threshold (12), a Minor alarm is raised for service attention.

PMS Link Maintenance does not cover the maintenance of the elements composing the PMS physical link (the external PMS device, Data Module (PDM/MPDM/DTDM), Digital Line Port of a TN754 Digital Line circuit pack, ADU, or Data Line Port of TN726B Data Line circuit pack). If PMS Link Maintenance cannot restore the PMS Link, then the maintenance tests of these individual components of the PMS Link must be executed to diagnose faults. If the **test pms-link** command fails, no alarm will be generated.

The **list pms-down** command lists all events that have meaning to the PMS that have occurred while the link between the switch and the PMS was down. For example, any room status codes entered by hotel housekeeping staff during a time of PMS outage would be shown in this report.

Procedures for Restoring the PMS Link

1. Determine the status of the PMS Link.

   Enter **status pms** command and make sure that the PMS Link is not busied out for maintenance. If the link is “down,” then continue with the next step.

2. Where does the PMS Link connect?

   Enter **display system hospitality** and find out the destinations of the PMS Link.

3. Determine the status of the data extension.

   Enter **status data** extension command and verify whether the data extension is in in-service/idle state. If the data extension is NOT available, then look for the extension number in Alt Name field of Hardware Error Log. Refer to the "XXX-BD (Common Port Circuit Pack)" section for resolutions.

4. Is the external PMS device available?

   Make sure that the PMS device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the PMS device.

5. If the problem is not found in the above steps, check the system port for any problems. Refer to the PDATA-PT section for for description about system port and its connectivity.

When restoring the PMS link it is necessary to execute maintenance test on different objects that comprise the PMS link It is recommended that you busy out the PMS link before trying to restore the link. When the PMS Link is busied out, all PMS Link maintenance actions are deactivated, and interference with tests of other MOs is prevented.

Hardware Error Log Entries and Test to Clear Values

Table 9-538. PMS Link Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test pms sh r 1
18 (a)	0	busyout pms-link	WARNING	OFF	release pms-link
257 (b)	Any	Link Retry Test (#215)	MINOR/[2] WARNING	OFF	test pms-link l
513 (c)	Any	None			test pms-link
769 (d)	Any	None			
1025 (e)	40-49	None			
1281 (f)	10-19	None			
1537 (g)	N0-N9	None			
1793 (h)	Any	None			test pms-link
2049 (i)	Any	None			
2305 (j)	50-59	None			release pms-link or test pms-link
2561 (k)	Any	None			test pms-link
2817 (l)	100-109 200-209 300-309	None			
3073 (m)	70-79	None			
3841 (n)	20-29	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. The PMS Link has been busied out with the **busyout pms-link** command. The link is torn down. Enter the **release pms-link** command to restore the link.

b. The Link Retry Test (#215) fails. An error was detected when setting up the link. Refer to the *Procedures for Restoring the PMS Link* above.

c. The PMS physical link is down for one of the following reasons:

- Cable to the PMS device is disconnected.
- The PMS device is powered off.
- The data extension to which the PMS device connects has been busied out.

Check the connectivity of wire and cable among wall jacket, data module, and the PMS device. Enter **status data <extension>** and verify that the data extension of the PMS device is in in-service/idle state. If the data extension is not available, then refer to *Procedures for Restoring the PMS Link* above.

d. There has been no communication between the switch and the PMS for a period of time specified in ‘‘system hospitality’’ administration. The PMS Link is torn down. To clear this error, refer to *Procedures for Restoring the PMS Link* above.

e. The link was taken down because the switch could not receive an incoming message from the PMS. The message from the PMS repeatedly had corrupted data or the switch received requests for acknowledgment but never received a message to be processed. If this error type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

f. The link was taken down because the switch could not send an outgoing message. The message, which was sent but not acknowledged, was flushed. If this error type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

g. The PMS has been busied out for maintenance at the request of the PMS. The PMS Link is torn down. The reason code (N), if present, is that supplied by the PMS in the request message. If this error type recurs frequently (that is, more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. No alarm is raised against this error.

h. Due to either heavy call traffic, or the PMS protocol message rate being faster than the PMS/PBX protocol specifications allow, the PMS Link is torn down. PMS Link maintenance software will wait for five minutes before attempting to set up the link again. If this error type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. The PMS should be checked for adherence to message rate defined in the PMS/PBX protocol specifications. No alarm is raised against this error.

i. The attempt to swap the database between PBX and PMS failed three times consecutively due to excessive PMS/PBX protocol violations, buffer overflows, or PMS Link outages. The PMS Link is NOT torn down. If this error type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. No alarm is raised against this error.

j. The PMS Link has been busied out with the **busyout pms-link** command or has been brought down with the **test pms-link long** command. The PMS Link is torn down, and PMS Link maintenance will stop attempting to reestablish the link in the case where the **busyout pms-link** command has been used. When the **test pms-link long** command has been used, PMS Link maintenance will continue to try to reset the link. To restore the PMS Link after use of the **busyout pms-link** command, issue the **release pms-link** command. To restore the PMS Link after use of the **test pms-link long** command, issue the **test pms-link** command.

k. The PMS Link is physically established, but the protocol has not been started by the PMS before the protocol timer expires. The PMS Link is NOT torn down. If this error type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. The PMS should be checked to make sure that it will attempt to start the protocol according to the PMS/PBX protocol specifications. No alarm is raised against this error.

l. For Error Type 2817 look for the following AUX data:

10x	The PMS violated the application protocol. The first message after a request to initiate a database exchange was not the start of a database exchange. The message is processed. If this error type with this aux data value occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.
20x	The PMS violated the application protocol. The start of a database exchange was received in a state in which it was not expected. The message is ignored. If this error type with this Aux data value occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.
30x	The PMS violated the application protocol. The end of a database exchange was received when no exchange was in progress. The message is ignored. If this error type with this Aux Data value occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. No alarm is raised against this error.

The PMS should be assessed for adherence to the PMS/PBX protocol specifications.

m. The link was taken down by the switch because the threshold for application protocol violations has been exceeded by the PMS. The protocol never started and messages were received and/or messages were received in a state in which they were not expected. (Refer to Error Type 2817 for recommended strategy.)

n. Link was taken down by the switch because the threshold for link protocol violations has been exceeded by the PMS. PMS is sending ‘‘garbage’’ to the switch.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND

1. D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external PMS device. If the link has been disconnected already, then this test just returns ‘‘PASS.’’ All resources allocated for a PMS Link are released after this test.

Table 9-539. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40 50	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
1010	ABORT	The PMS Link has been busied out and placed in the out-of-service state. 1. Enter **release pms-link** command to release the PMS Link from busyout state. 2. Retry **test pms long** command to execute the test.
2012	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	FAIL	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	PASS	The PMS Link is torn down.

Link Retry Test (#215)

This test sends a message to the PMS software process to make a data call to the extension where the PMS device connects. If the PMS Link is already up, then this test passes without making any data call.

Table 9-540. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10 20	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
30	ABORT	Internal system error. 1. Refer back to the "Procedures for Restoring the PMS Link" section for resolution.
1010	ABORT	The PMS Link has been busied out and placed in the out-of-service state. 1. Enter **release pms-link** command to release the PMS Link from busyout state. 2. Retry **test pms** command to execute the test.
2012	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	FAIL	The PMS Link CANNOT be established. 1. Refer back to the "Procedures for Restoring the PMS Link" section for restoring the PMS Link.
	PASS	The PMS Link is up.

PMS-PRNT/JNL-PRNT (PMS Printer Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
PMS-PRNT/JNL-PRNT	MINOR	test journal [pms-log | wakeup-log] l	PMS Printer/ Journal Printer
PMS-PRNT/JNL-PRNT	WARNING	test journal [pms-log | wakeup-log]	PMS Printer/ Journal Printer

A journal printer is a printer to which Emergency Access to Attendant, Wakeup and Property Management System (PMS) events are printed as they occur. The PMS-log printer is used as a backup of the PMS output device to print an audit trail of all PMS transactions and Housekeeping Status Change events when the PMS Printer Link is not available. There may be one or two journal printers. If there is one, all events are printed there. If there are 2, then emergency access, wakeup events, and scheduled reports are printed on one printer (JNL-PRNT), and PMS events are printed at the other (PMS-PRNT).

The scheduled report printer is where summaries of daily wakeup activity and emergency access activity are printed. If the customer requests a summary report, the report will be printed exactly once per day.

The distinction between Journal and Scheduled report printers is logical rather than physical. Whether or not there are two printers, the scheduled reports are always sent to the printer that journals the wakeup and emergency access events. A scheduled report will temporarily suspend the journal activity. Upon completion of the scheduled report, journaling will be resumed after the printing of all the withheld events.

The journal printer device connects to the system via a data module (PDM, MPDM, DTDM) connected to a port on a TN754 Digital Line circuit pack that is administered as a data extension. A journal printer device can also be connected through an ADU to a port on TN726B Data Line circuit pack. The journal printer link to the processor is via a system port. comprised of a port on the TN726B Data Line circuit pack and a port on the TN553 Packet Data circuit pack connected to each other in a null-modem fashion. Refer to the PDATA-PT Maintenance Service Description for information on the system port connectivity.

PMS/JOURNAL Printer Link Maintenance provides a strategy for maintaining the link between the system and a PMS device (an external Journal Printer device). The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Printer Link Maintenance uses a try-and-wait mechanism. If a PMS Printer Link is torn down due to an error, PMS Printer Link Maintenance will try to bring the link up immediately. If the link setup fails, PMS Link Maintenance will wait for five minutes before the next trial. If the number of retries reaches a threshold (15), a Minor alarm is raised for service attention.

PMS Printer Link Maintenance does not cover the maintenance of the elements composing the journal printer physical link (for instance, the external printer device, Data Module (PDM/MPDM/DTDM), Digital Line Port or ADU and Data Line Port). If PMS Printer Link maintenance cannot restore the PMS Printer Link, then the maintenance tests of individual components of the PMS Link must be executed to diagnose faults.

The **list pms-down** command lists all events that have meaning to the PMS that have occurred while the link between the switch and the PMS was down. For example, any room status codes entered by hotel housekeeping staff during a time of PMS outage would be reflected in this report.

Procedures for Restoring the PMS Printer Link

1. Determine the status of the PMS Printer Link.

   Enter **status journal-printer wakeup-log|pms-log** and make sure that the journal printer link is not busied out for maintenance. If the link is down, then continue to the next step.

2. Where does the journal printer link connect?

   Enter **display system hospitality** and find out the destinations of the PMS Printer Link.

3. Determine the status of the data extension.

   Enter **status data extension** command and verify that the data extension is in the in-service/idle state. If the data extension is *not* available, look for the extension number in the Alt Name field of the Hardware Error Log. Refer to "XXX-BD (Common Port Circuit Pack)" for resolutions.

4. Is the external printer device available?

   Make sure that the printer device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the printer device.

5. If the problem is not found in the above steps, check the system port for any problems. Refer to “PDATA-PT” for a description of system ports.

It should be noted that when restoring the PMS printer link, it is necessary to execute tests on different maintenance objects that comprise the link; it is recommended that you busy out the PMS printer link before trying to restore the link. If the PMS printer Link is busied out, then all PMS printer Link maintenance actions are deactivated, and interference with tests of other MOs is prevented.

Error Log Entries and Test to Clear Values

Table 9-541. PMS-PRNT/JNL-PRNT Link Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test journal wakeup-log|pms-log sh
18 (a)	0	busyout journal wakeup-log/pms-log	WARNIN G	OFF	release journal wakeup-log|pms-log
257 (b)	Any	Link Retry Test(#215)	MINOR/[2] WARNIN G	OFF	test journal wakeup-log|pms-log l
513 (c)	Any				test journal wakeup-log|pms-log
769 (d)					

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures. Both PMS Printer and Journal Printer are administered to the same extension, and the printer is not connected. Refer to the *Procedures for Restoring the PMS Printer Link* above for resolution.
2. Minor alarms may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. Craft busied out the Journal Printer Link. The link is torn down. Enter **release** command to restore the link.

b. Link Retry Test (#215) fails. Physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. Refer to “Procedures for Restoring the PMS Printer Link” above.

c. Physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. The PMS Printer Link physical link is down due to the following causes: cable to the printer device is disconnected, the printer device is powered off, or the data extension where the printer device connects to has been busied out. Check the connectivity of wire and cable among wall jacket, data module, and the printer device. Enter **status data <extension>** and verify that the data extension of the printer device is in the in-service/idle state. If the data extension is not available, then refer to the ‘‘Procedures for Restoring the PMS Printer Link’’ above.

d. Link idle timer; link comes down. This indicates that the printer device is in an off-line state, for example, paper jam or paper out. Check the printer device and act promptly to put it back to on-line state. Enter **test journal wakeup-log|pms-log** command to set up the printer link.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND

1. D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external printer device. If the link has been disconnected already, this test just returns PASS. All resources allocated for a PMS Printer Link are released after this test.

Table 9-542. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40	ABORT	Internal system error.
50	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.

Table 9-542. TEST #213 Link Tear Down Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1010	ABORT	The link has been busied out to out-of-service. 1. Enter **release journal wakeup-log|pms-log** command to release the link from busyout state. 2. Retry **test journal wakeup-log|pms-log l** command to execute the test.
2012	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	FAIL	Internal System error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	PASS	The link is torn down.

Link Retry Test (#215)

This test sends a message to the journal printer management software process to make a data call to the extension where the printer device connects to. If the journal printer link is already up, this test passes without making any data call.

Table 9-543. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10	ABORT	Internal system error.
20	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
30	ABORT	Internal system error. 1. Refer to the “Procedures for Restoring the PMS Printer Link” section for instructions.
1010	ABORT	The PMS Printer Link has been busied out to out-of-service. 1. Enter **release journal wakeup-log|pms-log** command to release the link from busyout state. 2. Retry **test journal wakeup-log|pms-log l** command to execute the test.
2012	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	FAIL	The link CANNOT be established. 1. Refer to the “Procedures for Restoring the PMS Printer Link” section for instructions.
	PASS	The link is up.

PNC-DUP (PNC Duplication)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
PNC-DUP	NA	status pnc	PNC duplication

In systems with the Critical Reliability option, the following components, which together comprise the Port Network Connectivity (PNC), are duplicated:

- Expansion Interface (EI) TN570 circuit packs in the port networks (PNs)
- Switch Node Interface (SNI) TN573 circuit packs in switch nodes
- DS1 Converter (DS1C) TN574 circuit packs for remote EPN connections
- Fiber-optic cables (metallic in certain cases) connecting the above circuit packs
- DS1 facilities between the DS1Cs
- Switch Node Clock (SNC) TN572 circuit packs

Although not part of the PNC, Tone-Clock circuit packs are also duplicated in each PN. The PNC is available in two different configurations: direct connect, in which each port network is connected directly by fiber optic links to each other PN; and Center Stage Switch (CSS) which utilizes one or two switch nodes to interconnect the PNs. All systems have one Processor Port Network (PPN). Direct connect systems can have up to two Expansion Port Networks (EPNs). CSS systems with one switch node can have up to 15 EPNS. CSS systems with two switch node can have up to 21 EPNS. See the following figures.

PNC duplication architecture utilizes an active/standby duplication scheme, in which one complete set of PNC components supports call processing, while the duplicate PNC is held in reserve. All calls on the active PNC are simultaneously set up, or shadowed, on the standby PNC in order for it to be capable of instantly assuming active status when necessary, allowing for interchanges without service disruption (in the case of single faults).

The PNC-DUP maintenance object tracks the health of the active and standby PNCs, controls planned and spontaneous interchanges, and manages related functions such as double call refresh and unrefresh, antithrashing, and so on. The main responsibility of PNC-DUP is to recover the system to full service in the event of a fault. In the event of multiple faults PNC-DUP will do its best to maximize service continuity.

PNC duplication does not introduce any additional types of hardware or hardware faults, and there are no tests associated with the PNC-DUP MO. Instead, it's error log entries are used to log useful information about the occurrence and causes of interchanges in order to facilitate diagnosis of problems which can then be addressed by using the documentation for the individual maintenance object involved.

PNC-DUP Related Commands

The following commands and their output screens are fully described in Chapter 8, "Maintenance Commands".

`status pnc`	This command displays information about the operational status of both PNCs including state of health, alarms, busyouts and locks, and so on.
`reset pnc interchange`	This command is used to initiate a demand PNC interchange. If the standby is healthy (state of health indexes all zero), there is no effect on service. Otherwise, calls may be dropped.
`set pnc`	This command is used to lock or unlock the active PNC, preventing interchanges. It does not interfere with double call setup.
`busyout pnc`	This removes the standby PNC from service. See also the following section on busyout of PNC components.

Busyouts and PNC-DUP

Busyout pnc puts the standby PNC in the busyout state. In this condition:

1. Double call set up is turned off.
2. The standby PNC is unrefreshed; existing duplicate call connections are removed.
3. PNC interchanges are prevented.

Upon release, interchanges are re-enabled and a global refresh of double call setup on the standby is performed.

When PNC duplication is in effect:

- An active PNC component cannot be busied-out.
- A standby PNC component can only be busied-out when the standby PNC is first busied-out.
- The standby PNC cannot be released unless all standby PNC components are released.

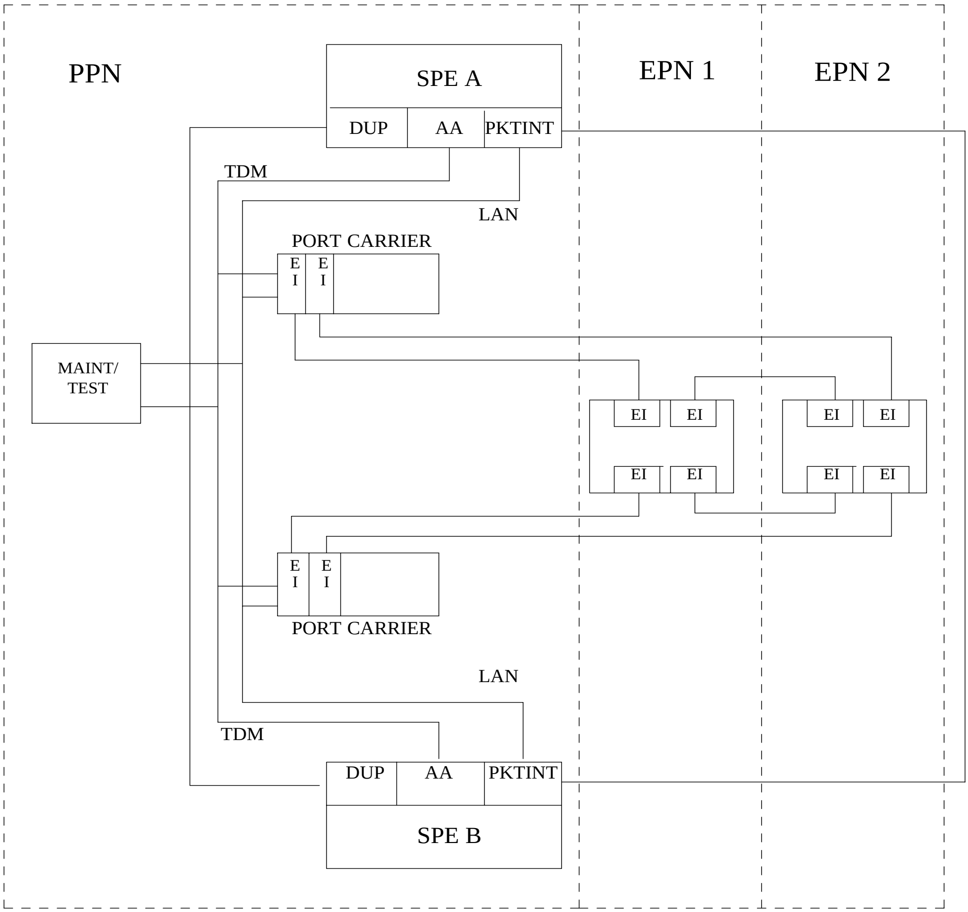

Figure 9-78. Duplicated Direct Connect PNC Connectivity

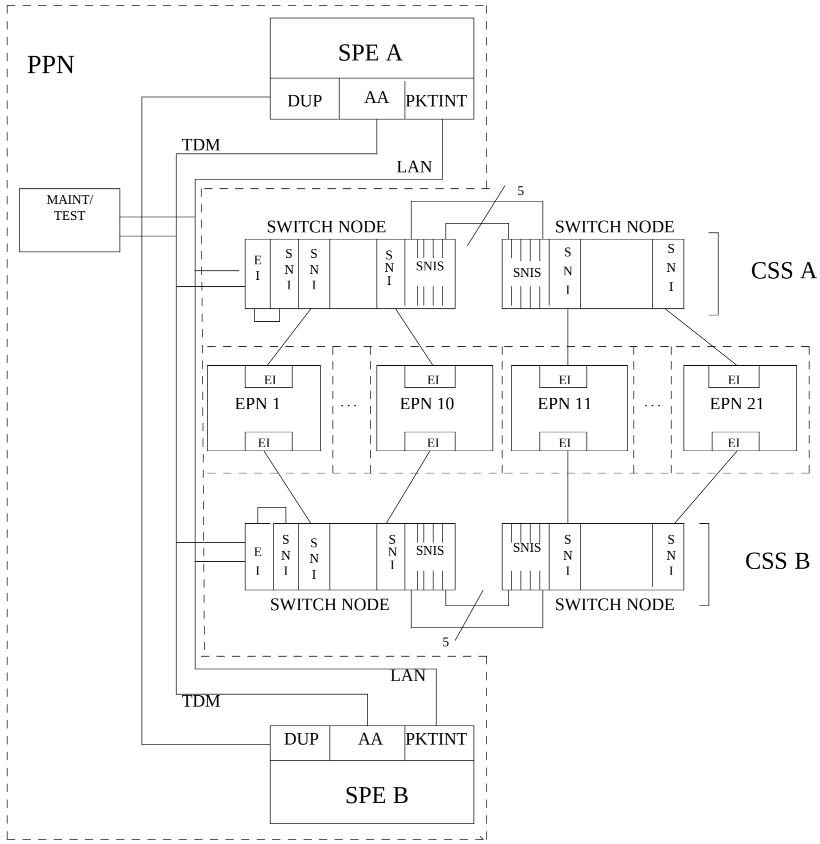

Figure 9-79. Duplicated PNC with Center Stage Switch

Enabling and Removing PNC Duplication

To enable PNC duplication perform the following sequence of steps:

1. Enable PNC-DUP on the **change system-parameters customer-options** form.
2. Fully administer duplicate fiber link connectivity. Verify by **list fibers**.
3. Trun on PNC-DUP via the **change system-parameters duplication** form. This is note allowed if any component of either PNC (A or B) is busied out.
4. The system must insert all connectivity-related components for both standby and active PNC. For CSS configurations this takes up to 5 minutes depending upon CSS circuit pack insertion. For Direct Connect configurations this is declared complete at 5 minutes after the first appearance of the terminal login prompt.

5. The PNC-DUP initialization anti-thrashing timer must expire (this occurs 5 minutes after completion of board insertion, PNC interchange, or system reset of level 2 or higher).

To disable PNC duplication perform the following sequence of steps:

1. Verify that the A-PNC is active. A forced interchange may be required. See **reset pnc** in Chapter 8, "Maintenance Commands".
2. Busyout the standby PNC (B-PNC).
3. Turn off the system parameter for PNC-DUP via **change system-parameters duplication**.

   After PNC duplication has been removed, configuration audits will generate the alarm shown below and possibly others. To clear this alarm, the B-PNC fibers, circuit packs in switch node carriers (EIs, SNIs, SNCs, and DS1Cs), and switch node carriers must be removed as outlined in the following steps.

   ```
   01D   SN_CONF     5000  255
   ```

   In this case, 01D is the B-PNC switch node from which uplication was removed.
4. Remove the B-PNC fibers by removing the Endpoint Board Locations on the **change fiber** form for all fibers. For fibers using DS1Cs, remove the B-PNC DS1C Board Locations on page 3 of the **change fiber** form.
5. Remove the B-PNC circuit packs starting with the switch node carrier most distant from the SPE complex. Use **change circuit pack UUC**, page to the B-PNC carrier and remove all of the circuit packs there. Remove all circuit packs in the other B-PNC switch node carriers.

   If the Expansion Interface circuit pack associated with the PPN is located in the switch node carrier closest to the SPE, it cannot be removed from translation until it has been busied-out and disconnected from the carrier slot.

   When SNI, SNC, or DS1C circuit packs are removed from a B-PNC carrier, any alarms against them should be resolved.
6. Remove the B-PNC switch node carriers. Use **change cabinet UUC** and enter **not-used** for B-PNC carriers.

   Any alarm against the carrier such as 01D SN-CONF should be resolved. The B-PNC carriers and associated circuit packs should not be alarmed.

7. Disable PNC duplication on the **change system-parameters customer-options** form by changing “PNC Duplication” to “no.”

   If an alarm exists against any Expansion Interface circuit pack connected to a B-PNC carrier, attempt to use **test board UUCSS long clear** to clear the alarm.

Alterations to PNC which involve only the *addition* of fiber connectivity can be done with PNC-DUP operational. Alterations requiring the *removal* of fiber connectivity must be done with PNC-DUP removed. PNC-DUP must be removed and translations should be saved before any hardware changes are made.

Steady State LEDs

The LEDs of PNC components in a stable duplicated system should appear as follows:

- The *active* EIs in the EPNs are functioning as archangels. Their LEDs flash in a pattern of 2 seconds on 200 milliseconds off.
- The EPN standby EIs yellow LEDs are off.
- The PPN active EI yellow LED is on solid.
- The PPN standby EI yellow LED is off.
- The SNIs on the active switch node(s) have yellow LEDs on solid.
- The SNIs on the standby switch node(s) have yellow LEDs off.
- Active DS1Cs yellow LEDs are on solid.
- Standby DS1Cs yellow LEDs are off.
- DS1C facility green LEDs are on if the corresponding facility is equipped.

PNC State of Health

PNC-DUP software monitors the health of the two PNCs as determined by their state of health (SOH) vectors, and initiates an interchange when the health of the active falls below that of the standby (unless prevented from doing so by a PNC lock, busyout, or antithrashing mechanism). Potentially service-disrupting faults which occur in PNC components are reported to PNC-DUP and incorporated in the state of health for the affected PNC. The SOHs of both PNCs are displayed on the **status pnc** screen.

```
status pnc                                                          page 1 of 1
                              PORT NETWORK CONNECTIVITY

                                Duplicated? yes
                           Software Locked? no
                            Standby Busied? no
                            Direct Connect? no
                         Standby Refreshed? yes
                      Interchange Disabled? no

              A-PNC                                 B-PNC

           Mode: active                          Mode: standby
State of Health: functional           State of Health: functional

```

Screen 9-3. Status PNC Screen with Standby PNC Fully In-Service

PNC State of Health Indexes

The Inter-PN and Inter-SN Indexes form the state of health vector, which is used to track and compare the states of health of both PNCs. The fields making up the indexes are two digit numbers separated by periods (.), with each field representing a different class of faults. The fault class fields are arranged in order of decreasing importance from left to right. In other words, each field in the index supersedes the following fields in determining which PNC is healthiest. A fault class drives an interchange only when all of the higher priority fault classes are equal. A zero entry indicates no faults in that class. Increasing numbers indicate increasingly higher numbers of faults present in that class.

The Inter-PN Index contains five fields (XX.XX.XX.XX.XX), and the Inter-SN Index has two (XX.XX). The Inter-PN Index reports faults in connectivity between port networks and supersedes the Inter-SN Index, which reports faults in connectivity between switch nodes. (The Inter-SN Index is only meaningful for systems with a center stage switch having 2 switch nodes, each of which is duplicated).

The meaning of each fault class field is given in the following table. A zero entry indicates that there are no such faults reported. Higher numbers indicate increasing number of faults. All zeros indicates perfect state of health. Unless the PNCs are locked, the active PNC’s state of health should always be equal to or better than the standby’s. (Otherwise, the system would perform a spontaneous interchange.)

After a PNC-related alarm is cleared, the system performs a partial refresh of the standby PNC. The corresponding fault class field is not updated to reflect the improved state of health until the refresh is done. The state of health indexes will not agree with the current alarm status during this period.

Inter SN Index: FC_SNIL s11.s10 FC_SNIHW

Table 9-544. PNC State of Health Fault Classes

Fault Class	Priority	Description	MOs
FC_EAL	1	Number of PNs with EALs down	EXP-PN
FC_INL	2	Number of PNs with LINL, RINL, or EI-SNI neighbor link faults	EXP-PN SN-CONF
FC_HW	3	Number of PNs affected by hardware faults in a link having an EI as an endpoint (Endpoints can be determined with **list fiber-link**.)	EXP-INTF SN-CONF FIBER-LK SNI-BD DS1C-BD
FC_PER	4	Number of PNs affected by SNI peer link faults for SNIs connected to EIs	SNI-PEER
FC_DS1	5	Number of PNs affected by DS1C facility faults	DS1FAC
FC_SNIL	6	Number of inter-switch-node fibers affected by peer or neighbor link faults	SNI-PEER
FC_SNIHW	7	Number of inter-switch-node fibers affected by hardware faults	SN-CONF SNI-BD FIBER-LK

In multinode CSS configurations FC_DS1 is considered less critical that FC_SNINL since DS1C constraints affect only one EPN and indicate restricted bandwidth. However FC_SNINL can indicate problems for all EPNs on the far end switch node (the one downlink from the PPN) If the DS1C problem is critical (for example, loss of all bandwidth to the affected EPN) a constraint with a higher order fault class will be reported to PNC DUP.

Resolving Poor State of Health

When the SOHs for both PNCs are not all zeros (perfect health), use the following steps to identify and repair the problem.

1. Look for PNC component alarms (major or minor) for the PNC side whose SOH is not all zero. The standby PNC should be repaired first.
2. Busy-out the standby PNC.

3. Follow the appropriate diagnostic and repair procedures for the alarmed PNC components just as with a simplex PNC. Both the alarm and error logs should be examined to isolate the fault.
4. Verify that the related PNC SOH is restored to all zeros.
5. Release the standby PNC for busy-out.

Refresh and Unrefresh of the Standby PNC

In a fully functional PNC with healthy standby and active sides, the standby PNC has a complete set of call connections corresponding to those in the active PNC. If, however, the state of health of the standby PNC degrades, a selective unrefresh of those connections which utilize the faulted component(s) is performed. If the health of the standby PNC improves, a selective refresh of connections on the affected route is performed. so that call setup is consistent between the active PNC and the healthy parts of the standby PNC.

The `Standby Refreshed?` field on the **status pnc** screen does *not* refer to the selective type of refresh. It refers only to a global refresh which is performed when:

- The system is initialized and PNC duplication is enabled.
- There has been a spontaneous PNC interchange.
- The standby PNC has been released from busy-out.
- A system reset of level 2 or higher has taken place.

The refreshed field may display `yes` when in fact the standby is partially unrefreshed. An interchange into an incompletely refreshed standby will result in dropped calls. This can happen when a more severe fault occurs on the active PNC, or when **set pnc interchange** is used with the override option.

PNC Interchanges

PNC spontaneous interchanges occur when PNC duplication software determines that the SOH of the standby PNC is better than that of the active PNC. PNC-DUP executes a spontaneous interchange only when a message from a PNC component maintenance object sends a message indicating that either a fault has occurred on the active PNC, or a fault has been resolved on the standby PNC such that the state of health of the active PNC is now lower than that of the standby.

This message will usually indicate the type and location of the failed connectivity component. A corresponding major or minor alarm is logged by the reporting MO, stimulating an alarm report.

In the less common situation when the resolution of a fault on the standby renders it more healthy than a simultaneously faulted active PNC, the message will indicate the type and location of the *improved* component.

Once the interchange completes, the failed component will be on the standby PNC. A demand interchange can be requested in the presence or absence of standby PNC faults. The following sequence of actions can be observed during a fault-free interchange:

1. The Expansion Interfaces currently acting as archangels in the EPNs are deactivated as indicated by the yellow LEDs going from flashing to on solid.
2. The PPN EIs are interchanged as indicated by the new standby EI yellow LED off and the new active EI yellow LED on solid.
3. One by one the EPN EIs are interchanged as indicated by new standby EI yellow LED turning off and the new active EI yellow LED flashing (2 seconds on, 200 milliseconds off). At this point the interchange is functionally complete.
4. The SNIs yellow LEDs are updated. so that the SNIs on the active SN have yellow LEDs on, while the standby SN's SNIs yellow LEDs turn off.

Certain conditions may interfere with the normal execution of the interchange:

1. In a faulted spontaneous interchange it is possible the EPN/EPNs directly affected by the fault will be the last to interchange.
2. A user directly affected by the single fault instigating a PNC interchange can experience a momentary outage of voice path connectivity during the switch.
3. If faults exist on both the standby and active PNC, it is possible to have some EPNs go out of service while others are returned to service.
4. The new standby SNIs yellow LED my not be off due to a fault in the line of communication path to the standby SNIs. In a multi-fault interchange, LEDs on the new active SNIs may not be on for the same reason.

In any multifault situation, rely on **status pnc** to determine which is the active PNC.

PNC duplication informs Timing Synchronization maintenance when a PNC interchange has been completed and indicates which PNC is active. This will cause Synchronization to audit and insure that the primary source for synchronization of Tone-Clocks in each PN is supplied by a path associated with the active PNC.

Antithrashing and PNC Interchanges

Following a spontaneous PNC interchange, subsequent PNC interchanges are prevented for 5 minutes. This condition is indicated by a 'yes" in the Interchange Disabled? field of the status pnc screen. After 5 minutes, the antithrashing, timer expires, interchange decisions are re-enabled, and the field displays “no.” *Should a catastrophic failure occur on the active PNC during the period when "Interchange Disabled?" is set to "yes" there will be no spontaneous PNC interchange.* Demand PNC interchanges also invoke anti-thrashing, but only for a period of 30 seconds. During antithrashing mode, demand interchanges are also prevented unless the override option is specified. Use of this option will cause a service disruption.

Repairs on the Standby PNC Components

⚠ **CAUTION:**

If there is a TDM-CLK alarm, system timing may be routed through part of the standby PNC, and circuit switched data may be affected by the following repair procedures. This can happen, for example, when a slave tone/clock circuit pack experiences a loss of signal and switches to receive timing from the standby EI. In this case TDM-CLK 2305 error will be logged, and the clock problem should be addressed first, if possible.

To repair PNC components in a duplicated PNC proceed as follows:

1. Most repairs will involve fixing a single fault on the standby PNC. Use **set pnc lock** or **busy-out pnc** to prevent an interchange into the PNC being repaired.
2. If a faulty component exists on the currently active PNC, the standby PNC is more severely faulted. Normally the standby PNC will be fully repaired first since it is the most severely impaired. To repair the active PNC, request an interchange via the **reset pnc interchange override-and-lock** command. The *override-and-lock* option ensures that no subsequent interchange will occur during the repair of the standby PNC. The demand interchange may not be necessary if the following conditions drive a spontaneous interchange:
   - The anti-thrashing period from the last interchange has expired.
   - The global refresh from releasing the standby PNC has completed.

   The standby PNC SOH is better than the active.
3. At this point, the faulty component will be on the standby PNC, and the PNCs are locked in their current active/standby state. Busy-out the PNC. Then fault isolation and component testing procedures for the individual PNC components can be used just as for a simplex PNC. Replacement of components will not disrupt operation of the active PNC.

4. Once the failed component is replaced, test the standby PNC component from the terminal to ensure the replacement is functioning properly.
5. When confident that the problem has been resolved, as indicated by a state of health with all zeros, (**status pnc**), unlock and release the pnc. Note that no further PNC interchange is required since you can test the standby PNC as thoroughly as the active.

Interactions: SPE Resets and PNC Interchanges

- After a system reset 4 (reboot), the A PNC is always the active.
- A system reset of level 1 (warm), 2 (cold2) or 3 (cold1) does not change which PNC is active. If a PNC interchange was in progress when the reset took place, the PNC interchange still goes to completion.
- If a system reset level 1 (warm) takes place during a PNC interchange, the reset is escalated to level 2 (cold2).

Fault Isolation Using Duplicated PNC

PNC duplication, can, in some cases aid in the isolation of faults. PNC interchanges can be used to help indict the faulty hardware. Following are two examples demonstrating this technique.

- There is a fault which can occur in either the PPN EI or the PKT-INT which cannot be readily attributed to one board or the other. If the packet bus transceivers on either the PKT-INT or EI fail, it will be apparent that the two boards cannot communicate, but it will not be clear which board is at fault. In this case, a planned interchange of the PNC can be used to indict one of the two boards. If the interchange cures the problem, the EI was at fault. If the interchange does not cure the problem, the PKT-INT is suspect, provided there are no PKT-BUS faults.
- A similar relationship exists for the EPN Archangel (active EI) and certain TDM bus problems. If the EAA is unable to communicate with a port board over the TDM bus, either the EAA has a fault, the port board has a fault, or there is a problem with the TDM bus itself. If TDM bus maintenance tests find no problems with the bus, then it is either the port board or the EAA. It may be simpler to replace the port board than to request a PNC interchange. However, if it is not clear which port board may be at fault, or maintenance is being performed remotely, verify that the EAA is not at fault by executing a PNC interchange. If the interchange solves the problem, then the EAA is faulty. If the problem persists after the interchange, but TDM bus maintenance finds no problem, then the port board is faulty.

Error Log Entries

Whenever a PNC interchange takes place, an error is logged against PNC-DUP with a code that conveys information about the cause of the interchange and which PNC became active. There are no alarms associated with PNC-DUP errors, but there should be an alarm against the PNC component that drove the interchange. There are no PNC-DUP test sequences, but **status pnc** will provide information regarding the status of the PNCs. The information given in the following tables will help to identify areas of the Alarm Log to be investigated to find the source the problem.

Error Code	Aux Data
00000 (a)	None
10000 to 10021 (b)	1
10100 to 10121 (c)	1
10200 to 10221 (d)	1
10300 to 10321 (e)	1
10400 to 10421 (f)	1
10601 to 10627 (g)	1
10701 to 10727 (h)	1
11000 to 11021 (i)	1
11100 to 11121 (j)	1
11200 to 11221 (k)	1
11300 to 11321 (l)	1
11400 to 11421 (m)	1
11601 to 11627 (n)	1
11701 to 11727 (o)	1
20000 to 20021 (p)	1
20100 to 20121 (q)	1

Error Code	Aux Data
20200 to 20221 (r)	1
20300 to 20321 (s)	1
20400 to 20421 (t)	1
20601 to 20627 (u)	1
20701 to 20727 (v)	1
21000 to 21021 (w)	1

21200 to 21221 (y)	1
21300 to 21321 (z)	1
21400 to 21421 (aa)	1
21601 to 21627 (ab)	1
21701 to 21727 (ac)	1
51000 (ad)	1
52000 (ae)	1
53000 (af)	1
60801 (ag)	1
60800 (ah)	1

1. The Aux Data indicates which PNC became active after the PNC interchange: ‘‘0’’ denotes PNC-A; ‘‘1’’ denotes PNC-B.

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
18	None	busy PNC-DUP	WARNING	ON	release pnc-dup

Notes:

a. An error took place in generating the error code.

b. A spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC_EAL. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (10003 points to port network 4) **List config port-network** gives the cabinet number associated with a port network.

c. A spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC_INL. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (10003 points to port network 4) **List config port-network** gives the cabinet number associated with a port network.

d. A spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC_HW. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (10203 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

e. A spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC_PER. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (10303 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

f. A spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC_DS1. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (10403 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

g. A spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC_SNIL. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. **List fiber-link** gives the location of the fiber.

h. A spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC_SNIHW. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. **List fiber-link** gives the location of the fiber.

i. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC_ EAL. This indicates that one or more Expansion Archangel Links are down. Investigate any EXP-PN alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (11003 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

j. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC_ INL. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (11103 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

k. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC_ HW. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (11203 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

l. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC_ PER. This indicates one or more faults on peer links that connect SNIs to EIs. Investigate any alarms against SNI-PEER. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (11303 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

m. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC_ DS1. This indicates faults on one or more DS1C facilities. Investigate any alarms against DS1-FAC. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (11403 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

n. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC_SNIL. This indicates one or more faults on peer or neighbor links between SNIs on different switch nodes. Investigate any alarms against SNI-PEER. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. **List fiber-link** gives the location of the fiber.

o. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC_SNIHW. This indicates one or more faults on hardware connecting SNIs on different switch nodes. Investigate any alarms against SN-CONF, SNI-BD, FIBER-LK. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. **List fiber-link** gives the location of the fiber.

p. A spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC_EAL. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (20003 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

q. A spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC_INL. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (20103 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

r. A spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC_HW. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (20203 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

s. A spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC_PER. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (20303 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

t. A spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC_DS1. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the retired alarm. (20403 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

u. A spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC_SNIL. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. **List fiber-link** gives the location of the fiber.

v. A spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC_SNIHW. Use **status pnc** to look at the state of health indexes for the PNCs, and investigate any associated alarms. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. **List fiber-link** gives the location of the fiber.

w. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC_EAL. This indicates that one or more Expansion Archangel Links are down. Investigate any EXP-PN alarms. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (21003 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

x. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC_INL. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (21103 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

y. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC_ HW. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (21203 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

z. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC_ PER. This indicates faults on peer links that connect SNIs to EIs. Investigate any alarms against SNI-PEER. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (21303 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

aa. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC_ DS1. This indicates faults on one or more DS1C facilities. Investigate any alarms against DS1-FAC. Adding 1 to the last two digits of the error code gives the PN number of the port network that reported the alarm. (21403 points to port network 4.) **List config port-network** gives the cabinet number associated with a port network.

ab. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC_ SNIL. This indicates faults on peer or neighbor links between SNIs on different switch nodes. Investigate any alarms against SNI-PEER. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the alarm. **List fiber-link** gives the location of the fiber.

ac. A spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC_ SNIHW. This indicates faults on hardware connecting SNIs on different switch nodes. Investigate any alarms against SN-CONF, SNI-BD, FIBER-LK. The last two digits of the error code indicate the fiber-link number (01-27) of the fiber that reported the alarm. **List fiber-link** gives the location of the fiber.

ad. A spontaneous PNC interchange took place upon the expiration of the anti-thrashing timer.

ae. A spontaneous PNC interchange took place upon the unlocking of the PNCs with the **set pnc unlock** command.

af. A spontaneous PNC interchange took place upon the completion of a global refresh of the standby.

ag. A demand interchange was executed with the **reset pnc interchange**command.

ah. A demand interchange was executed with the **reset pnc interchange**command using the **override-and-lock** option.

POWER

Battery and Charger for AC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
POWER	MINOR	test environment *UU*	Battery and Battery Charger

1. *UU* is the cabinet number indicated in the PORT field from the Alarm or Error Log.

DEFINITY Systems support two different cabinet types: multicarrier and single carrier. Single carrier cabinets are used only for EPNs. Both cabinet types may be powered by either AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply.

AC-powered Multi-Carrier Cabinets can be equipped with rechargeable batteries that provide backup power during short power outages. Battery backup is optional on cabinets powered by an Uninterruptible Power Supply (UPS), and is required on those that are not. DC-powered cabinets and single-carrier cabinets do not have battery backup, and this MO is not valid for those cabinets.

The battery backup for the J58890CH unit consists of one battery assembly and charger. The battery backup for the J58890CE unit consists of three 48V batteries and a battery charger. Each cabinet so equipped has its own independent battery backup unit. When power to the cabinet is interrupted, a warning alarm is logged against AC-POWER and the system draws power from the backup batteries. This is known as Nominal Power Holdover (NPH). If power is restored before the NPH time expires, the alarm is resolved. If power does not return, error logs are saved to the Mass Storage System. The nominal power holdover provided is as follows:

PPN Cabinet:

All carriers	10 seconds
Simplex control carrier	10 minutes
Duplicated control carriers	5 minutes

EPN cabinet:

All carriers	15 seconds
Expansion control carrier	10 minutes

When AC power is restored after an outage, the battery charger fully recharges the batteries within 30 hours.

In a multi-carrier cabinet system, the Battery & Battery Charger maintenance object represents the battery charger and the battery which are located in the lower left corner of the cabinet. Should anything go wrong with the battery or charger, they must be replaced using the procedure described in the ''Replacing the Battery and Battery Charger'' section below. The system will detect one of the following three problems with the batteries or charger:

- Reserve Fault: the charger has detected a problem within itself or the batteries and has notified the system.
- High Charge Rate: the batteries have been charging at a high charge rate for an excessively long period of time. This indicates that there is a short in the batteries or the charger.
- Prepare to Disconnect (Low Battery): the batteries are in danger of being drained to a point where the batteries would be damaged. This warning often occurs after multiple power failures.

  The batteries take 30 hours to fully charge after being drained. A fully charged battery pack should bridge two power failures without causing a low battery warning to occur.

Replacing the Battery and Battery Charger (J58890CE)

1. Move the power switch on the battery charger to OFF.

   WARNING:
   Always turn off the battery charger before replacing the batteries. Failure to do so will result in damage to the 397C battery charger.

2. Disconnect the cord from the outlet on the front of the battery charger.
3. Remove the screw at the top left of the cover and open the cover to access the charger.
4. Check the battery voltages at the test points. Check all 3 batteries wired in series (the voltage should be 144 volts, 3 X 48 volts = 144 volts) .

   NOTE:
   An ordinary voltmeter can be used to check battery voltages at the test points, but it may not produce valid results. If the battery voltage readings are below 48 volts (the voltages at test points should read 144 volts, 3 x 48 volts = 144 volts), the battery is probably defective. However, a normal voltage reading does not necessarily mean the battery is good; under load, a defective battery with a normal reading on the voltmeter may discharge rapidly.

5. Check the battery dates and the preventive maintenance log. Replace the batteries if they are more than 2.5 years-old.

   NOTE:
   If any defective batteries are found, replace all of them. Batteries are ordered in sets of three and should be replaced as such.

6. If no defective batteries are found, replace the entire charger.
7. Close the cover and secure it with the screw.
8. Reconnect the cord and move the power switch to ON.

Replacing the Battery Assembly (J58890CH)

The batteries are replaced as an entire assembly.

1. Check the battery voltages at the test points (on the Battery Interface Unit (BIU)).
2. Remove the BIU from the power distribution unit.
3. Disconnect the battery plug from the power distribution unit (J20).
4. Remove the battery assembly from the rear of the cabinet.
5. Install the new battery assembly in the reverse order.
6. Plug the BIU back into the power distribution unit.

Error Log Entries and Test to Clear Values

Table 9-545. Battery & Battery Charger Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment *UU* sh r 1
1	Any	Battery & Battery Charger Query Test (#5) (error code 8)	MINOR	ON	test environment *UU* s r 1
257	Any	Battery & Battery Charger Query Test (#5) (error code 4)	MINOR	ON	test environment *UU* s r 1

Continued on next page

Table 9-545. Battery & Battery Charger Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
769	Any	Battery & Battery Charger Query Test (#5) (error code 2)	MINOR	ON	test environment *UU* s r 1
3840(a)	1005 or 1028	Associated Battery & Battery Charger Query Test (#5)			test environment *UU* s r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Note:

a. Check to see if the battery charger is connected. If the cabinet is powered by a UPS, there is no battery backup, and this error can be ignored.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-546. System Technician-Demanded Tests: POWER

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND [1]
Battery & Battery Charger Query Test (#5)	X	X	ND
AC Power Query Test (#78) (a)	X	X	ND
Power Unit Query Test (carrier E) (#127) (b)	X	X	ND
Power Unit Query Test (carrier D) (#127) (b)	X	X	ND

Continued on next page

Table 9-546. System Technician-Demanded Tests: POWER — *Continued*

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Power Unit Query Test (carrier A) (#127) (b)	X	X	ND
Power Unit Query Test (carrier B) (#127) (b)	X	X	ND
Power Unit Query Test (carrier C) (#127) (b)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Sensors Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1. D = Destructive, ND = Non-destructive

Notes:

a. Refer to AC-POWER (AC Power) for a description of this test.

b. Refer to CARR-POW for a description of this test.

c. Refer to EMG-XFER (Emergency Transfer) for a description of this test.

d. Refer to CABINET (Cabinet Sensors) for a description of this test.

e. Refer to EXT-DEV (External Alarm) for a description of this test.

f. Refer to RING-GEN (Analog Ring Generator) for a description of this test.

Battery & Battery Charger Query Test (#5)

This test queries the SYSAM in the PPN or the EPN Maintenance circuit pack in an EPN for the status of the battery pack and battery charger, and reports the result. During this test, the status LED on the battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

Table 9-547. TEST #5 Battery & Battery Charger Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	The battery charger is not connected. If the system has a UPS and no battery charger and batteries, ignore this error since the batteries and charger are not required with certain UPSs. 1. Verify that the battery charger is switched on. 2. Unplug one battery. 3. Switch off the charger and remove its white power cord. 4. Verify that the power cord has at least 106 VAC. 5. Verify that the connector on the rear of the charger is properly inserted. 6. Re-insert the charger power cord and switch on the charger. 7. Plug the battery back in. 8. Run the test environment. The batteries will probably need charging and may be drained if there were power outages. Reconnect the battery charger to allow the batteries to recharge. If test #5 is run before the batteries are completely charged, the test will fail with Error Code 2. If Abort 1005 occurs again, escalate the problem. 9. Wait 30 hours and rerun the test.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 time. 2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet system. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, check for and resolve all SYSAM errors in a PPN or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test.

Continued on next page

Table 9-547. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2029 2319 2320 2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2	FAIL	The system is in nominal power holdover, and the battery is currently so low that the system will disconnect power very shortly. 1. If power returns, then the port carriers in the PPN should power-up again. All the circuit packs should be reinserted, and the system should continue to operate normally. There will probably be a minor alarm against Battery & Battery Charger due to the fact that the batteries are recharging. 2. If power does not return, the system will shut down to prevent damage to the batteries. Restore power, and the system will reboot. *No manual intervention is required.* 3) Rerun the test. If the test still fails, then the SYSAM in a PPN or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. Resolve all alarms on these MOs and rerun the test. There are failures that can occur on the SYSAM and EPN Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.
4	FAIL	The battery is currently being charged. 1. After 30 hours, the battery should be fully charged, and this error should clear.

Continued on next page

Table 9-547. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
		2. If after 30 hours the battery is still in the high charge rate, an alarm will be raised. Display the Error Log with the **display errors** command and select the category "environ" to display only environment-related errors. Look for POWER errors of type 257. The *first occurrence* of this error indicates the time when the battery started charging. Use this time as the starting point to determine if the battery has been charging for 30 hours. If the battery has been charging for 30 hours, then replace the battery and battery charger. **CAUTION:** *Read the section, "Replacing the Battery and Battery Charger" before proceeding. 3) Rerun the test. If the test still fails, then SYSAM in a PPN or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. There are failures that can occur on the SYSAM and EPN Maintenance circuit pack that will not be detected by their respective maintenance, but which will cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. Resolve all alarms on these MOs, and rerun the test.*
6	FAIL	This indicates that error codes 2 and 4 have occurred. Refer to these descriptions. Also, refer to the description for error code 14 for this test.

Continued on next page

Table 9-547. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
8	FAIL	**NOTE:** For a Global AC MCC (J58890CH) use the procedures outlined in step 3. There is a reserve power fault. A problem exists with the battery charger or, less likely, the batteries. Also, this fault could be generated if the charger is switched off or a battery is unplugged. 1. Replace the battery charger and the battery. The fault should disappear. **WARNING:** *Always turn off the battery charger before replacing the batteries.* 2. Rerun the test. If the test still fails, then SYSAM in a PPN or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. Resolve all alarms on these MOs and rerun the test. There are failures that can occur on the SYSAM and EPN Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. *More information continues.*
8 *(cont'd.)*	FAIL *(cont'd.)*	3. Procedures for a Global MCC (J58890CH): a. Look to see if any "red" LEDs are "on" on any of the rectifier modules or the BIU (Battery Interface Unit) located in the Power Distribution Unit (J58890CH). b. If the BTW (Battery Temp Warning) LED on the BIU is "on" check the batteries for a over temp condition[a] if temp is normal[a] replace the BIU, If the test still fails replace the battery in a small battery system. For a large battery system escalate the problem. c. If the BNA (Battery Not Available) LED is "on" check the battery connections including connector J20.

Continued on next page

Table 9-547. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
		d. If you have an alarm and all LEDs are ok (PWR OK and BOK) on the rectifier modules, and the BIU (Battery Interface Unit), make sure the BIU and the RM0850 rectifiers are seated properly (plugged in). If the BOK LED on the BIU is ok use the following information to check the number of rectifiers serving this cabinet: Number of carriers per cabinet / Number of rectifiers per cabinet 1 — 2 2 — 3 3 — 3 4 — 4 5 — 4 If the number of rectifiers is correct replace the maintenance circuit pack in the EPN or PPN.
10	FAIL	Error codes 2 and 8 have occurred. Refer to these descriptions. Also, refer to the description for error code 14 for this test.
12	FAIL	Error codes 4 and 8 have occurred. Refer to these descriptions. Also, refer to the description for error code 14 for this test.
14	FAIL	Error codes 2, 4, and 8 have occurred. Refer to these descriptions. **NOTE:** This could also indicate that the detection logic on the SYSAM or EPN MAINT (Maintenance) circuit pack is defective. Such an error will not be detected by the respective maintenance. If many environment tests are failing, replace the suspect circuit pack (depending on system configuration).
	PASS	The SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN has reported that the status of Battery & Battery Charger is good.

a The equipment must be installed in a well-ventilated area. Maximum equipment performance is obtained at an ambient room temperature between 40 and 120 degrees Fahrenheit (4 and 49 degrees Celsius) for short term operation (not more than 72 consecutive hours or 15 days in a year) and up to 110 degrees Fahrenheit (43 degrees Celsius) for continuous operation.

Battery and Charger for DC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
POWER	MINOR	test environment *UU*	Battery & Battery Charger

1. *UU* is the cabinet number indicated in the PORT field from the Alarm or Error Log.

NOTE:
This MO applies to the J58890CE and the J58890CH-1 with large battery holdover.

This MO represents the battery backup unit found in AC-powered multi-carrier cabinets. Because the system does not recognize the type of external power, this MO exists in DC-Powered multi-carrier cabinets but serves no functional purpose. In such cabinets, all POWER tests should always either pass or abort, and no POWER alarms should be raised.

DEFINITY Systems support two different cabinet types: multi-carrier and single-carrier. Single-carrier cabinets are used only for EPNs. Both cabinet types may be powered by either AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply.

Error Log Entries and Test to Clear Values

Table 9-548. Battery & Battery Charger Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment UU sh r 1
1	Any	Battery & Battery Charger Query Test (#5) (error code 8)	MINOR	ON	test environment UU s r 1
257	Any	Battery & Battery Charge Query Test (#5) (error code 4)	MINOR	ON	test environment UU s r 1
769	Any	Battery & Battery Charger Query Test (#5) (error code 2)	MINOR	ON	test environment UU s r 1
3840(a)	1005 or 1028	Associated Battery & Battery Charger Query Test (#5)			test environment UU s r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Note:

a. This error occurs is valid only for AC-powered multi-carrier cabinets with battery backup. For DC-powered cabinets, you cannot clear the error and it should be ignored.

Battery Holdover (Large Batteries)

The large batteries are mounted inside a separate battery cabinet and can supply holdover times of 2 to 8 hours depending on the size of the battery. The batteries are circuit breaker protected and are charged by the J58890CH-1. The batteries also contain a thermal sensor that change the charging voltage depending on the battery temperature.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND*
Battery & Battery Charger Query Test (#5)	X	X	ND
AC Power Query Test (#78) (a)	X	X	ND
Power Unit Query Test (carrier E) (#127) (b)	X	X	ND
Power Unit Query Test (carrier D) (#127) (b)	X	X	ND
Power Unit Query Test (carrier A) (#127) (b)	X	X	ND
Power Unit Query Test (carrier B) (#127) (b)	X	X	ND
Power Unit Query Test (carrier C) (#127) (b)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Sensors Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

Notes:

a. Refer to AC-POWER for a description of this test.

b. Refer to CARR-POW for AC- and DC-Powered Systems section for a description of this test.

c. Refer to EMG-XFER for a description of this test.

d. Refer to CABINET for a description of this test.

e. Refer to EXT-DEV for a description of this test.

f. Refer to RING-GEN for a description of this test.

Battery & Battery Charger Query Test (#5)

This test queries the SYSAM in the PPN or the EPN Maintenance circuit pack in an EPN for the status of the battery pack and battery charger, and reports the result. In a DC-Powered system, this test should never fail. During this test, the status LED on the battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

Table 9-549. TEST #5 Battery & Battery Charger Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
1005	ABORT	Battery charger is not connected. DC-powered cabinets do not have battery backup; ignore this error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2028	ABORT	Internal system error prevented the extinguishing of the Battery Charger status LED. 1. Since this test is not relevant for DC-powered systems, an occurrence of this error indicates possible existence of internal system problems.
2029 2319 2320 2500	ABORT	Internal system error 1. Try the command again at 1-minute intervals up to 5 times.
any	FAIL	The SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN is incorrectly reporting a problem with power. If this test fails for a DC-powered cabinet, the circuit pack has a problem. Replace the suspect circuit pack and run the test again.
	PASS	All that can be inferred is that the SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN in an EPN multicarrier cabinet system is working properly for this test.

PPP-PT (Control LAN Packet/Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PPP-PT	MAJOR	**test port UUCSSpp long**	PPP Port Maintenance
PPP-PT	MINOR	**test port UUCSSpp long**	PPP Port Maintenance
PPP-PT	WARNING	**test port UUCSSpp**	PPP Port Maintenance

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The TN799 Control LAN (CLAN) packet port circuit pack provides TCP/IP connection to adjuncts applications such as CMS, Intuity, and DCS Networking. The CLAN circuit pack has 1-10baseT Ethernet connection and up to 16 DS0 physical interfaces for PPP connections. Multiple CLAN circuit packs in a system gives additional TCP/IP capacity.

A remote socket control link (RSCL) links the CLAN and the SPE to pass call control and other management information. Since one link serves all the ports on the circuit pack, maintenance of the RSCL is part of the CLAN circuit pack maintenance.

NOTE:
The CLAN TN799 circuit pack combines the functions of the PGATE and PI circuit packs into one circuit pack. The PGATE or PI can be used with the CLAN to create an X.25 to TCP/IP bridge for adjunct and DCS connectivity.

Control LAN Congestion Controls

The switch activates congestion controls on CLAN when it detects buffers exceeding the threshold. The switch releases the congestion controls when the CLAN reports that its buffer level has returned to normal levels.

If congestion:	Then the switch:
Persists for a 14-minute interval	Raises MINOR alarm
Exhausts buffers	Raises MINOR alarm
Ceases for 12 minutes	Retires MINOR alarm

Error Log Entries and Test to Clear Value

Table 9-550. PPP-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp s
1 (a)	0	SCOTCH Sync Looparound Test (#1275)	MINOR	ON	test port UUCSSpp l r 3
257 (b)	0		WARNING	OFF	
513 (c)	0		MINOR	OFF	
769 (d)	0		WARNING	OFF	
1281 (e)	0				
1537, 1538 (f)	See note	Session Status Test (#1286)	MINOR	OFF	
1793-1920 (g)	See note				
2305-2560 (h)	See note				
2561-2816 (h)	See note				
3329 (i)	35768	TCP/IP Ping Test (#1281)	WARNING	OFF	
3585 (j)	0-1	TDM Looparound Test (#1285)	MAJOR	ON	test port UUCSSpp l r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. **Error Type 001**: SCOTCH Synchronous Looparound Test (#1275) failed.

1. Test the port (**test port UUCSSpp long**).
2. Refer to SCOTCH Synchronous Looparound Test (#1275) repair procedures.

b. **Error Type 257**: CLAN port detected overrun or underrun condition that may indicate a hardware problem.

   1. Test for hardware problem (**test port UUCSSpp long**).
   2. Refer to SCOTCH Synchronous Looparound Test (#1275) repair procedures to verify repair.
   3. Clear the alarm (**test port UUCSSpp long clear**).

c. **Error Type 513**: PPP link lost end-to-end connectivity.

   1. Test for hardware problem (**test port UUCSSpp long**).
   2. Run TDM Looparound Test (#1285) and refer to repair procedures if there is a hardware problem.

      If there is no hardware problem, the switch tries to re-establish PPP link.

d. **Error Type 769**: Port received an invalid frame, which

   - is greater than the maximum length
   - contains CRC errors
   - violates the link level protocol.

   1. Test the port (**test port UUCSSpp long**).
   2. Refer to TDM Port Looparound Test (#1285) to verify repair.
   3. Clear the alarm (**test port UUCSSpp long clear**).

e. **Error Type 1281**: System software received an indication that the far-end has requested a disconnect of a session on this link. This is a log-only error.

f. **Error Type 1537, 1538**: Some or all port sessions (sockets) are down.

If the switch indicates that:	Then it:
Some of the sessions are down	Raises off-board WARNING
All of the sessions are down	Raises off-board MINOR alarm

   1. Test the port (**test port UUCSSpp short**).
   2. Refer to Session Status Test (#1286) repair procedure to verify repair.

g. **Error Type 1793-1920**: system software received an indication that a socket was closed due to an error. Error Type indicates the application associated with this socket.

Error Type	Application
1793	Unused
1794	DCS
1795	AUDIX
1796	CMS
1797	ISDN Gateway
1798-1920	Reserved for future

Aux Data indicates the internal application number.

h. **Error Type 2305-2816**: System software detected a session is down. Aux Data indicates the session number. These are log only errors. Error types 2305-2560 are for session numbers 1-256. Error types 2561-2816 are for session numbers 257-512.

i. **Error Type 3329**: TCP/IP Ping Test failed.

1. Test the port (**test port UUCSSpp short**).
2. Refer to TCP/IP Ping Test (#1281) repair procedures.

j. **Error Type 3585**: TDM Port Looparound Test (#1285) failed.

1. Test the port (**test port UUCsspp long**).
2. Refer to TDM Looparound Test (#1285) repair procedure.

System Technician-Demanded Tests: Descriptions and Error Codes

Investigate errors in the order they appear in the table below.

Table 9-551. System Technician-Demanded Tests: PPP-PT

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND [1]
TDM Looparound Test (#1285)		X	D
SCOTCH Synchronous Looparound Test (#1275)		X	D
TCP/IP Ping Test (#1281)	X	X	ND
Session Status Test (#1286)	X	X	ND
PPP Link Status Test (#1279)	X	X	ND

1. D = Destructive, ND = Non-destructive

TDM Looparound Test (#1285)

NOTE:
This test is destructive.

This test verifies whether the CLAN PPP port can send and receive data on the TDM bus. This test has a tone generator send tones on a timeslot, and it has a tone receiver receive tones on another timeslot. The tones are looped through the ppp port.

If the received tones:	Then:
Match the tones sent	The test passes
Do not match the tones sent	The test fails

Test failure indicates failure of the

- CLAN (TN799) circuit pack
- TDM Bus
- Tone generator / tone receiver circuit pack

Table 9-552. TEST #1285 TDM Looparound Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port is in use. 1. Determine port status (**status clan-port UUCSSpp**). 2. Retry the command when the port is idle. The port may be forced to the idle state by executing a **busyout port UUCSS** command. 3. Escalate if the problem persists. NOTE: The **busyout port** command is destructive, causing all calls and links associated with the port to be torn down.
1002	ABORT	No TDM bus timeslots available for the test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
1003	ABORT	No more tone receivers idle for use in this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. If this problem persists, reset the circuit pack (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). 2. If the problem persists, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.

Continued on next page

Table 9-552. TEST #1285 TDM Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
	FAIL	Received tones do not match transmitted tones. 1. Retry command at 1-minute intervals, up to 3 times. 2. If the problem persists, refer to TDM-BUS, Tone Generator, and Tone Receiver repair procedures. 3. If the problem persists, reset the board (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). Repeat the test. 4. If the problem persists, replace the circuit pack.
	PASS	Port connections across the TDM bus function properly.

SCOTCH Synchronous Looparound Test (#1275)

NOTE:
This test is destructive.

This test verifies the circuit in the datapath of a ppp call. This test fails if the data transmitted on the port does not match the data received in the looparound mode. Failure of this test indicates a port hardware fault on the circuit pack.

This test aborts if calls are using the port, or if the PPP link associated with the port is connected. To avoid this, first enter **busyout data-module *extension***, or **busyout port UUCSSpp**, or **busyout link *link#***, which will cause all calls and links using the port to be torn down.

Table 9-553. TEST #1275 SCOTCH Synchronous Looparound Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port is in use or PPP link is connected. 1. Determine when the port is available for testing (**status clan-port UUCSSpp**). 2. The port may be forced to the idle state by executing a **busyout port UUCSSpp** command. **NOTE:** This command is destructive, causing all calls and links using the port to be torn down.
1002	ABORT	No TDM bus timeslots available for the test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
1963	ABORT	Firmware indicates that the port is in use or ppp link is connected. 1. Determine when the port is available for testing (**status clan-port UUCSSpp**). 2. The port may be forced to the idle state by executing a **busyout port UUCSSpp** command. **NOTE:** This command is destructive, causing all calls and links using the port to be torn down.
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. If this problem persists, reset the circuit pack (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). 2. If the problem persists, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
2100	ABORT	Could not allocate the necessary system resources to run test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.

Continued on next page

Table 9-553. TEST #1275 SCOTCH Synchronous Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	CLAN circuit pack detected test failure. 1. If the problem persists, reset the circuit pack (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). 2. If the problem persists, replace the circuit pack.
	PASS	Port circuitry functioning properly.

TCP/IP Ping Test (#1281)

This non-destructive test fails if the endpoint fails to respond. Use this test to check the circuitry in the data path for a peer-to-peer IP layer connection.

Table 9-554. TEST #1281 TCP/IP Ping Test

Error Code	Test Result	Description/ Recommendation
1, 2, 7, 11	ABORT	Internal error 1. Retry the command at 1-minute intervals up to 3 times 2. Escalate if the problem persists.
1005	ABORT	Test configuration is incorrect. 1. Verity PPP link is in-service (**status clan-port UUCSSpp** or **status link *n***). 2. Repeat the test. 3. Escalate if the problem persists.
1124	ABORT	ppp link is not enabled. 1. Verify that the ppp link is enabled (**status port UUCSSpp**, **status link *n***, or **display data-module**). 2. If the link is not enabled, enable the link (**change data-module**). 3. Repeat the test. 4. Escalate if the problem persists.

Continued on next page

Table 9-554. TEST #1281 TCP/IP Ping Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1125	ABORT	PPP link not in service. 1. Verify whether ppp link is in service (**status port UUCSSpp** or **status link n**). 2. If the ppp link is not in service, release the link (**release link n** or **release port UUCSSpp**). 3. Repeat the test. 4. Escalate if the problem persists.
2000	ABORT	Response to the test was not received from the CLAN circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use (Yellow LED is off). Reset the circuit pack (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
2100	ABORT	Could not allocate the necessary system resources to run test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
1003	FAIL	Ping to the destination failed due to on-board problem. 1. Retry the command at 1-minute intervals, up to 3 times. 2. If the problem persists, reset the circuit pack (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). 3. If the problem persists, re-administer the PPP connection through a different PPP port, if available. 4. If the problem still persists, or if there are no other available PPP ports, replace the circuit pack.

Continued on next page

Table 9-554. TEST #1281 TCP/IP Ping Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1007	FAIL	Ping to the destination failed due to the destination down. 1. A PPP destination or a component in the path (e.g., DS1 trunk) may be down. Check the status of the destination or other components in the path. 2. If the destination and all components in the path are in-service, ping the PPP destinations (**ping ip-address** ***xxx.xxx.xxx.xxx***). 3. Escalate if the problem persists.
	PASS	TCP/IP Ping Test (#1281) is successful.

Session Status Test (#1286)

This non-destructive test determines the status of all PPP port sessions. This test queries the system software on port session status.

If the system software indicates that:	Then the switch:
All port sessions are up (ALL UP)	Raises no alarm, or retires alarm
Some port sessions are up (SOME UP)	Raises MINOR alarm
All port sessions are down (ALL DOWN)	Raises MINOR alarm

Table 9-555. TEST #1286 Session Status Test

Error Code	Test Result	Description/ Recommendation
1124	ABORT	ppp link is not enabled. 1. Verify that the ppp link is enabled (**status port UUCSSpp**, **status link *n***, or **display data-module**). 2. If the link is not enabled, enable the link (**change data-module**). 3. Repeat the test. 4. Escalate if the problem persists.
1125	ABORT	PPP link not in service. 1. Verify whether PPP link is in service (**status port UUCSSpp** or **status link n**). 2. If the PPP link is not in service, release the link (**release link n** or **release port UUCSSpp**). 3. Repeat the test. 4. Escalate if the problem persists.
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. If the problem persists, reset the circuit pack (**busyout port UUCSSpp**, **reset board UUCSS**, and **release board UUCSS**). 2. If the problem persists, replace the circuit pack.
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
1	FAIL	System software indicates at least one PPP link session is down (SOME UP). 1. Isolate downed sessions (**status port UUCSSpp** or **status link n**). Follow actions based on session information.

Continued on next page

Table 9-555. TEST #1286 Session Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	System software indicates all PPP sessions are down (ALL DOWN). 1. Test the port (**test port UUCSSpp**) to verify the SCOTCH Synchronous Looparound Test (#1275) result. 2. If test passes, wait for system software to indicate ALL UP. 3. If the test fails, check the destination and other components in the path. 4. If the destination and other components in the path are in-service, take action based on session information.
	PASS	All sessions up.

PPP Link Status Inquiry Test (#1279)

This non-destructive test determines the state of the PPP link. The test passes only if the link is up.

Table 9-556. TEST #1279 PPP Link Status Inquiry Test

Error Code	Test Result	Description/ Recommendation
1124	ABORT	ppp link is not enabled. 1. Verify that the ppp link is enabled (**status port UUCSSpp**, **status link *n***, or **display data-module**). 2. If the link is not enabled, enable the link (**change data-module**). 3. Repeat the test. 4. Escalate if the problem persists.

Continued on next page

Table 9-556. TEST #1279 PPP Link Status Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1125	ABORT	PPP Link is not in service. 1. Verify whether PPP link is in-service (**status port UUCSSpp** or **status link n**). 2. If the PPP link is not in service, release the link (**release link n** or **release port UUCSSpp**). 3. Repeat the test. 4. Escalate if the problem persists.
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
	FAIL	PPP link is down. 1. Test the port (**test port UUCSSpp long**) to verify the SCOTCH Synchronous Local Loop Around Test (#1275) result. 2. If the test passes, wait for sessions to come up. 3. If the test fails, check the destination and other components in the path (e.g., DS1 trunks). 4. If the destination and other comonents in the path are in-service and the test still fails, execute **busyout port UUCSSpp** and **release port UCCSSpp**, and repeat the test. 5. If the test still fails, reset the circuit pack (**busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS**). Repeat the test. 6. If the problem persists, replace the circuit pack.
	PASS	PPP link is up.

PRI-CDR/SEC-CDR (Call Detail Recording Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
PRI-CDR/SEC-CDR	MINOR	test cdr primary/secondary l	CDR Link
PRI-CDR/SEC-CDR	WARNING	test cdr primary/secondary	CDR Link

The CDR feature records detailed call information on all incoming and outgoing calls on specified trunk groups and sends this information to a CDR output device. The two physical links can be administered for connecting external CDR output devices to the system. They are identified as the primary CDR (PRI-CDR) link and the secondary CDR (SEC-CDR) link. The CDR device connects to the system via a data module (PDM, MPDM, DTDM) connected to a port on a TN754 Digital Line circuit pack that is administered as a data extension. A CDR device can also be connected through an ADU to a port on TN726B. The CDR link to the processor is via a system port. A system port is comprised of a port on the TN726B Data Line circuit pack and a port on the TN553 Packet Data circuit pack connected to each other in a null-modem fashion. Refer to the PDATA-PT section for information on the system port connectivity. External CDR output devices include:

- 94A Local Storage Unit (LSU)
- TELESEER CDR Unit
- Call Accounting System (CAS)
- Call Detail Recording Unit (CDRU)
- Printer
- Host computer
- Personal computer (PC)
- Customer-provided equipment

CDR Link Maintenance provides a strategy for maintaining the link between the system and an external CDR output device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. CDR Link Maintenance uses a try-and-wait mechanism for maintaining the CDR link. If the CDR link is torn down due to an error, CDR Link Maintenance tries to bring the CDR link up. If the Link Setup fails, CDR Link Maintenance will wait for 30 seconds before the next retry. If the number of retries reaches a threshold (two), a Minor alarm is raised for service attention.

CDR Link Maintenance does not cover the maintenance of the elements composing the CDR physical link:

- External CDR output device
- Data Module (PDM/MPDM/DTDM) and Digital Line Port of TN754 Digital Line circuit pack
- ADU and Data Line Port of TN726B Data Line circuit pack

If CDR Link Maintenance cannot restore the CDR link, the maintenance tests of these individual components of the CDR link must be executed to diagnose faults.

Procedures for Restoring the CDR Link

1. Determine the status of CDR links.

   Enter **status cdr** command and make sure that the CDR links are not busied out for maintenance. If the link is down, then continue to the next step.

2. Where does the CDR link connect to?

   Enter **display system feature** and find out the destinations of CDR links. Continue to the next step.

3. Enter the **status data extension** command and verify whether the data extension is in the in-service/idle state. If the data extension is *not* available, then look for the extension number in the Alt Name field of the Hardware Error Log and refer to "XXX-BD (Common Port Circuit Pack)" for resolutions.

4. Is the external CDR output device available?

   Make sure that the CDR output device is on-line and ready for service. Check the physical connectivity between Data Module and the CDR output device.

5. If the problem is not found in the above steps, check the system port for any problems. Refer to the PDATA-PT section for for description about system port and its connectivity.

When restoring the CDR link it is necessary to execute maintenance test on different objects that comprise the CDR link. It is recommended that you busy out the CDR link before trying to restore the link. When the CDR Link is busied out, then all CDR Link maintenance actions are deactivated, and interference to tests of other MOs is prevented.

Error Log Entries and Test to Clear Values

Table 9-557. CDR Link Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test cdr primary|secondary sh
18(a)	0	busyout cdr primary|secondary	WARNING	OFF	release cdr primary|secondary
257(b)	Any	Link Retry Test (#215)	MINOR/[2] WARNING	OFF	test cdr primary|secondary l
513(c)					test cdr primary|secondary
1025(d)					
1281(e)	Any				

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. The CDR link is busied out. The CDR link is torn down.

b. Link Retry Test (#215) fails. An error was detected when setting up the link. Refer to the preceding section ‘‘Procedures for Restoring the CDR Link’’ for resolution.

c. The CDR physical link is down for one of the following reasons:

- Cable to the CDR output device is disconnected.
- CDR output device is powered off.
- The data extension where the CDR output device connects to has been busied out or there is a scheduled daily interchange.

Check the connectivity of wire and cable among wall jacket, data module, and the CDR output device. Enter **status data extension** and verify that the data extension of the CDR output device is in the in-service/idle state. If the data extension is not available, then refer to The preceding section ‘‘Procedures for Restoring the CDR Link’’ for resolution. Issue the **display system-parameters-maintenance** command to see the start time of daily maintenance. If the error occurs and is resolved during of daily maintenance, it can be ignored.

d. This error indicates that the CDR output device is in an off-line state, (for example, due to paper jam or paper out for a printer device). The CDR link is torn down. Check the CDR output device and act promptly to put it back to on-line state. Enter **test cdr primary|secondary** command to set up the CDR link.

e. Software detects an overflow of CDR records generated in the switch due to the heavy trunk traffic and low speed CDR output device. If both primary and secondary links are ON, the secondary link is torn down temporarily for two minutes to speed up the output process to the primary link. No action is necessary for this error type.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND

1. D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external CDR output device. If the link has been disconnected already, this test just returns PASS. All resources allocated for a CDR link are released after this test.

Table 9-558. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40	ABORT	Internal system error.
50	ABORT	Internal system error. 1. Retry the command at one-minute intervals for a maximum of 5 times.
1010	ABORT	The CDR link has been busied out to out-of-service. 1. Enter the **release cdr primary|secondary** command to release the CDR link from busyout state. 2. Retry the **test cdr primary|secondary long** command to execute the test.
2012	ABORT	Internal system error. 1. Retry the command at one-minute intervals a maximum of 5 times.
	FAIL	Internal system error. 1. Retry the command at one-minute intervals for a maximum of 5 times.
	PASS	The CDR link is torn down.

Link Retry Test (#215)

This test sends a message to the CDR software process to make a data call to the extension where the CDR output device connects to. If the CDR link is already up, then this test will be passed without making any data call.

Table 9-559. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10	ABORT	Internal system error.
20	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
30	ABORT	Internal system error. 1. Refer to "Procedures for Restoring the CDR Link" for instructions.
1010	ABORT	The CDR link has been busied out to out-of-service. 1. Enter **release cdr primary|secondary** command to release the CDR link from busyout state. 2. Retry **test cdr primary|secondary long** command to execute the test.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The CDR link CANNOT be established. 1. Refer to the "Procedures for Restoring the CDR Link" for instructions.
	PASS	The CDR link is up.

PROC-SAN (Process Sanity Audits)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
PROC-SAN	none	none	Process Sanity Audits

The Process Sanity Audits maintenance object is responsible for monitoring the sanity of software processes in the system. If the Process Sanity Audits MO detects that a process has gone insane (does not respond to a sanity message within an allotted time period), the process will be restarted. If the Process Sanity Audits MO detects that multiple processes (or a single key process) do not respond to sanity messages within an allotted time period, a system recovery action will be initiated.

The Process Sanity Audits MO has no alarms and no tests. Certain errors are logged to the Hardware Error Log for information purposes only.

Error Log Entries and Test to Clear Values

Table 9-560. Process Sanity Audits Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	none
10 (a)	0	none	none	none	none
204 (a)	any	none	none	none	none

Note:

a. These errors indicate that a system recovery action has been taken because one or more software processes failed to respond to a sanity audit in a timely fashion. As a result of the recovery action, the system may have temporarily suspended service for a period of time surrounding the error.

PROCR (RISC Processor Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
PROCR	MAJOR[2]	test processor UUC l	RISC Processor Circuit Pack
PROCR	MINOR	test processor UUC s	RISC Processor Circuit Pack

1. UU is the cabinet number (always 1, not required). With simplex SPE, carrier designation is not required. With duplicated SPEs, carrier a or b must be specified.
2. After a spontaneous SPE interchange has occurred, the Alarm Log retains for three hours a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.

The UN331B Processor circuit pack executes the system software, including all call processing, maintenance and administration functions. The Processor circuit pack is the most critical component for correct system operation.

Full system operation depends on nearly every circuit pack in the SPE. However, the ability to load and run the maintenance software by the Processor circuit pack depends only on correct Memory, Processor Bus, R-Media-Disk-MSSNET and SYSAM operation.

There are many Processor circuit pack problems (or other SPE problems) that will result in the SPE being unable to load or run software. This condition is indicated by the message "SPE Down" displayed on the terminal. In these cases, refer to the SPE DOWN section of this manual for repair procedures.

The Processor circuit pack contains an instruction cache and a data cache. These caches provide local, high speed memory that is closely coupled with the processing function on the Processor circuit pack. The local nature of the caches speeds up system operation by eliminating many external Memory accesses when reading instructions or data. As the Processor runs, it tries to use information already in the cache so that time will not be wasted going out to memory. If it does not find the information in the cache, it reads it from memory and stores it in the cache for possible future use. Over time, most instruction or data accesses are likely to be satisfied by current information in the cache. Problems in the cache circuits may stop the Processor from running or may only result in reduced system performance.

The Processor circuit pack contains a Burst Read function that transfers multiple words of instructions from memory with each request. This is done to speed up the transfer of information from the Memory to the Processor, and is especially helpful for "filling up" the cache in parallel with internal processing on Processor circuit pack. Most of the circuitry needed to support this function is found on the Memory circuit packs, but part of this function is on the Processor as well. Refer to Memory documentation for test information.

The Processor circuit pack contains a Write Buffer function that helps prevent internal processing operations from being held up by Processor Bus activity. If the Processor needs to write to Memory, it writes to the Write Buffer. If the Processor Bus is in use at this time, the information is transferred to Memory at an appropriate time. Up to 12 processor writes can be pending, waiting for transfer to memory.

The Processor Bus contains parity checking functions. If one address or data bit is corrupted during an access cycle, the error detection logic detects and reports this to Processor circuit pack.

The Processor circuit pack contains interrupt and exception signals that tell the Processor when normal or erroneous events occur in SPE components. An example of a normal event is an interrupt that occurs when data provided by an SPE component such as the SYSAM is available for the Processor. An example of an error-indicating exception is detection of a parity error on the Bus when Processor reads Memory. These types of errors result in system recovery actions which are described in Chapter 4, ‘‘Initialization and Recovery’’.

The Processor circuit pack contains an erasable, programmable read-only memory (BOOTPROM) that contains the system initialization and low-level diagnostic programs. Problems in this hardware may result in difficulties with system start-up, restart, or SPE maintenance testing in general.

If the PBX system is equipped with High Reliability or Critical Reliability option (i.e. with duplicated SPEs), and if a failure of the active Processor circuit pack causes a MAJOR on-board alarm, a SPE interchange will occur if the health of the standby SPE permits the interchange. Refer to Replacing SPE Circuit Packs in Chapter 5 for more information about duplicated SPEs.

Error Log Entries and Test to Clear Values

Table 9-561. PROCR Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test processor UUC s r 1
1		BOOTPROM Checksum Test (#897)	MAJOR[2]	ON	test processor UUC s r 1
150(a)	Any	None	MAJOR†	ON	test processor UUC l c
257		Parity Checker Test (#899)	MINOR	ON	test processor UUC s r 2
513		Write Buffer Test (#900)	MAJOR†	ON	test processor UUC s r 1
1025		Cache Audit (#896)	MINOR	ON	test processor UUC s r 2
1026(b)		Cache Audit (#896)	MAJOR	ON	test processor UUC s r 2
1281		Cache Test (#895)	MAJOR†	ON	test processor UUC l r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display init causes** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.

Notes:

a. This error (150) indicates that a SPE interchange has occurred and that the Processor circuit pack was the cause of the spontaneous interchange.

   1. If other PROCR errors are present, investigate these errors.
   2. If no other PROCR errors are present, run the **test processor a|b long clear** command and investigate any test failures.

b. A parity error was detected in the processor's data cache or instruction cache. In a system with duplicated SPEs, this error can be generated only while the processor is running on the active SPE since the software running on the standby processor does not use the Processor data and instruction caches. Therefore, if PROC error 1026 is present for a processor on the standby SPE, that error must have been generated some time in the past when the processor was running as the active SPE.

   Execute the **test processor long** command for a processor either on the active or standby SPE, and if any tests fail, follow the repair procedures for those failures. It is unlikely that a parity error will occur at the time the

Processor Cache Audit test (#896) is run on demand. However, the processor Cache test (#895) may uncover a failure that can cause cache parity errors.

If no tests fail but a MAJOR alarm is present as a result of the 1026 error, replace the Processor circuit pack since multiple cache parity errors have occurred in the past and will probably occur again which can cause call processing failures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Processor Cache Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequenc e	Reset Board Sequence	D/ND[1]
Processor Cache Test (#895)		X		D
Processor Cache Audit (#896)	X	X		ND
Processor BOOTPROM Checksum Test (#897)	X	X		ND
Processor Parity Checker Test (#899)	X	X		ND
Processor Write Buffer Test (#900)	X	X		ND

1. D = Destructive; ND = Nondestructive

Processor Cache Test (#895)

This test is destructive.

This test overwrites the contents in the Instruction and Data Caches, requiring them to be refilled during normal execution.

This test verifies that the Processor Instruction and Data Caches are functional. Some errors in the caches will cause the Processor to stop functioning, while others simply reduce performance by forcing instructions or data to be read from memory more often than would normally be necessary. In any case, cache problems are serious and the Processor circuit pack must be replaced as soon as possible if they are detected.

Table 9-562. TEST #895 Processor Cache Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Processor circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to “STBY-SPE” for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the high reliability or critical reliability configuration and if the Processor circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mail on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.

Continued on next page

Table 9-562. TEST #895 Processor Cache Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Processor cache is not functioning correctly. 1. Replace the Processor circuit pack immediately. To replace the Processor circuit pack, refer to *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The cache portion of the Processor circuit pack is operating correctly.

Processor Cache Parity Audit (#896)

This audit checks the state of the Cache Parity bit maintained by the R3000 CPU. If this bit is set, there may be problems with either the CPU, the Instruction, or Data Cache. An indication of bad cache parity won't itself mean that the system won't operate, but minor to severe performance degradation may be present. For example, a single bad bit in either cache could cause this bit to be set. If the faulty word is seldom accessed, the impact will be small. If the bit is accessed frequently, there could be serious problems with much, or all, of the cache (stuck data bit) with the only direct indication again being the cache parity error or cache test error.

Table 9-563. TEST #896 Processor Cache Parity Audit

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022	ABORT	Internal system error 1. Retry the command.

Continued on next page

Table 9-563. TEST #896 Processor Cache Parity Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
1335	ABORT	This test is only run on the active SPE since the standby processor does not use the cache memory. Cache failures may cause cause cache parity errors on the active SPE which can be logged against a standby SPE is an SPE interchange has taken place. If a PROC 1026 error code is present in the hardware error log for a processor on the standby SPE: a. Enter the test memory long command to run the Processor Cache test (#895) to verify that the cache has not failed. b. Request an SPE interchange by entering **reset system interchange** and run the short processor test sequence **test processor** while the processor is on the active SPE. c. If all test pass but a MAJOR alarm is present as a result of a 1026 error in the hardware error log, replace the processor circuit pack since multiple cache parity errors have occurred in the past and will probably occur again which can cause call processing failures.
2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Processor circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.

Continued on next page

Table 9-563. TEST #896 Processor Cache Parity Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Processor circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mail on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The Cache Parity Error bit is set, there may be problems with either the CPU or the Instruction or Data Cache. 1. Retry the command. 2. If the test continues to fail, run **test processor a|b long**. 3. If the Processor Cache test (#895) or the Processor Cache Parity Audit (#896) fails, replace the Processor circuit pack. To replace the Processor circuit pack, refer to *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The Processor has not detected any parity errors in the Instruction and Data Caches since the last time this audit was run.

Processor BOOTPROM Checksum Test (#897)

This test computes the checksum of the Processor's bootstrap BOOTPROM and compares it to a predetermined value stored within the BOOTPROM. A failure of this test indicates the BOOTPROM is corrupt.

Table 9-564. TEST #897 Processor BOOTPROM Checksum Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Processor circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Processor circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.

Continued on next page

Table 9-564. TEST #897 Processor BOOTPROM Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2334	ABORT	The hardware mail on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The computed checksum did not match the BOOTPROM checksum. The system may not continue to operate correctly. The system may fail at some future date when the corrupted area the bootstrap BOOTPROM is accessed. 1. Replace the Processor circuit pack. To replace the Processor circuit pack, refer to *Replacing SPE Circuit Packs* in Chapter 5, "Alarms, Errors, and Troubleshooting".
	PASS	The computed checksum matched the BOOTPROM checksum. This part of the Processor will continue to operate normally.

Processor Parity Checker Test (#899)

This test verifies that the Processor can detect parity errors on the bus. If this part of the Processor circuit pack is faulty, the system may continue to operate properly, but may not correctly respond if a bus problem arises later. The Processor reads a special memory location on the SYSAM circuit pack to perform this test. Problems with the SYSAM may also cause this test to fail.

Table 9-565. TEST #899 Processor Parity Checker Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error 1. Retry the command.

Continued on next page

Table 9-565. TEST #899 Processor Parity Checker Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Processor circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Processor circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mail on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The Processor cannot detect bus parity error conditions. 1. Retry the command. 2. If the test continues to fail, replace the Processor circuit pack. 3. If the test continues to fail after replacing the Process circuit pack, replace the SYSAM circuit pack. To replace the Processor circuit pack, refer to *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The Processor Parity Checker is functional.

Processor Write Buffer Test (#900)

This test verifies that the Write Buffer operates properly on the Processor circuit pack. Failure of this test is serious. The Processor circuit pack must be replaced as soon as possible.

Table 9-566. TEST #900 Processor Write Buffer Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1022 1335 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Processor circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the Processor circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.

Continued on next page

Table 9-566. TEST #900 Processor Write Buffer Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2334	ABORT	The hardware mail on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The Processor Write Buffer is not operating correctly. 1. Replace the Processor circuit pack immediately. To replace the Processor circuit pack, refer to *Replacing SPE Circuit Packs* in Chapter 5.
	PASS	The Write Buffer portion of the Processor circuit pack is operating correctly.

R-MEDIA

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
R-MEDIA	WARNING	test removable-media a|b long	MSS Removable Media circuit pack
R-MEDIA	MINOR	test removable-media a|b long	MSS Removable Media circuit pack
R-MEDIA	MAJOR[2]	test removavle-media a|b long	MSS Removable Media circuit pack

1. In a system with a simplex SPE, the carrier need not be specified. In a system with duplicated SPEs, carrier a or b must be specified.
2. This alarm occurs when the system undergoes a reset of level 3, 4, or 5, and the switch cannot load translation from the Removable Media; it also occurs when a program update cannot be applied. See the Error Log Table, error type 3585.

Description

The Mass Storage System (MSS) provides non-volatile storage for system software, translation data, announcement data and program update data. As shown in the figure below, the MSS consists of a Host Adapter circuit on the UN332C MSS-Network Control circuit pack (MSSNET), a Small Computer System Interface (SCSI) bus, a TN2211 Optical Drive circuit pack or a TN1656 Tape Drive circuit pack, and the TN1657 Disk Drive circuit pack. The Disk Drive acts as the primary storage device. The TN2211 Optical Drive or TN1656 Tape Drive serves as a backup device and as a removable medium for system data. The faceplate details are shown in Figure 9-80.

In this document, “removable media” refers to both the tape drive and optical disk drive. Those actions which ar applicable to only the tape drive are indicated as “tape only”.

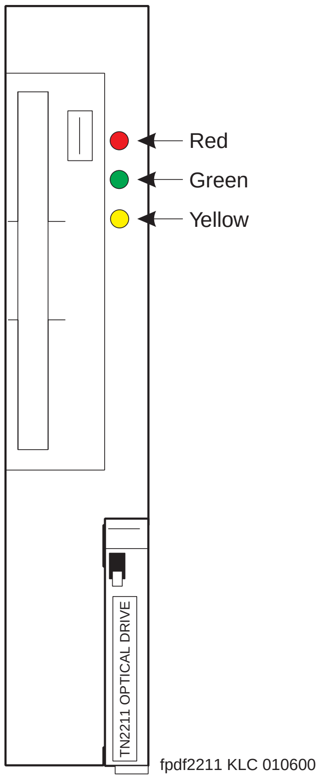

Figure 9-80. TN2211 faceplate

The system is usually booted from the boot image stored on disk. The **save translation** and **save announcements** commands save to disk the memory-resident translation data and TN750-resident announcement data, respectively. The **backup disk** command copies data from the disk to the removable media for backup storage. The **restore disk** command copies data from the removable media back to disk. All MSS components reside in the SPE, or PPN control carrier (carrier A for a simplex SPE, carriers A and B for a duplicated SPE).

The removable media circuit pack contains SCSI bus terminators, a -48V to +12V power converter, an industry standard SCSI-based removable media drive, and interface circuitry to the private bus to control the LEDs, detect the presence of the circuit pack, and identify the vintage of the hardware.

A -48V to +12V converter circuit on the TN2211 Optical Drive circuit pack provides power for both the Optical Drive and the Disk Drive. The presence of +12V on these circuit packs is monitored separately by maintenance software so that a failure of the +12V converter on the Removable Media circuit pack can be identified or ruled out as the source of the problem when the Disk Drive loses +12V power.

The Host Adapter circuit pack, Removable Media Drive circuit pack, and Disk circuit pack are treated as separate, but related, maintenance objects (H-ADAPTR, R-MEDIA, and DISK). Since the Disk circuit pack is controlled by SCSI commands which are generated by the Host Adapter, problems with the Host Adapter can prevent communications with the Disk. Whenever the Host Adapter is taken out of service by the **busy-out host-adapter** command, or due to failure of a critical Host Adapter test, the Removable Media (R-MEDIA) and Disk (DISK) maintenance objects are also placed in a maintenance busyout state.

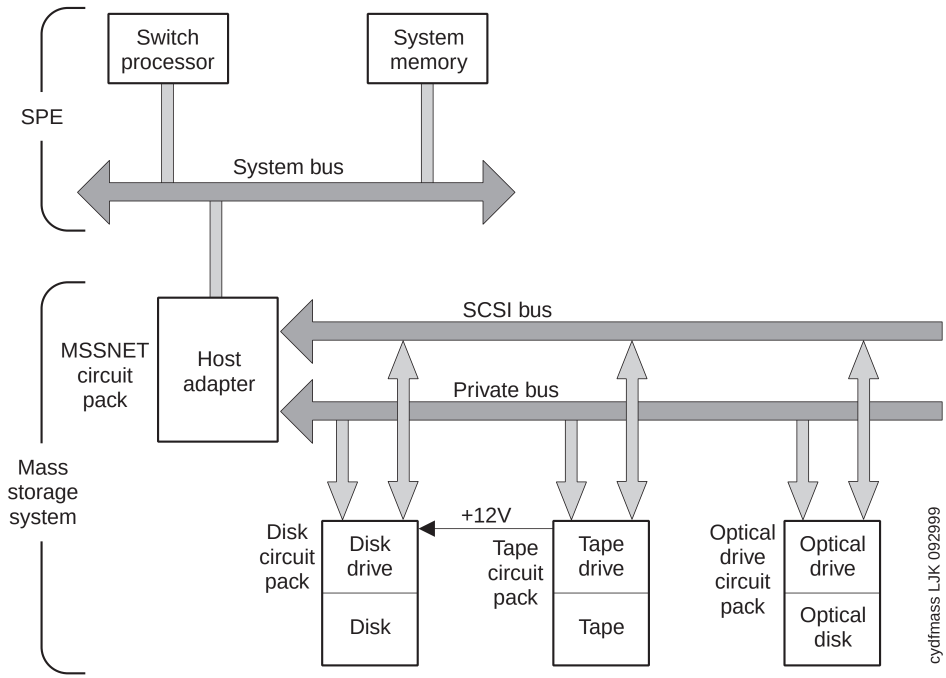

Figure 9-81. Mass Storage System interactions

General repair procedures for R-MEDIA

Use the following guidelines when troubleshooting and resolving R-MEDIA problems.

1. *Avoid saving translations or announcements* on the backup removable drive until all other removable media and Host Adapter problems have been resolved.

   If there is something wrong with the Mass Storage System, an attempt to save translations or announcements could destroy a good copy of the files on the removable media.

2. In a system configured with duplicated SPEs, the tests run on the standby removable media circuit pack are identical to those run on the active removable media circuit pack. Communications between the active and standby SPEs is provided by the DUPINT circuit pack for both the control channel and memory shadowing. Therefore, problems with the DUPINT circuit pack may affect maintenance tests of the standby removable media circuit pack.

3. Check the error log for power related problems and refer to the maintenance documentation on power.

4. The data on the removable media will likely be destroyed if:

   - The optical disk is removed when the amber LED on the removable media circuit pack is on.
   - The removable media circuit pack is removed while the amber LED on the removable media circuit pack is on.
   - Power is removed from the removable media while the amber LED on the removable media circuit pack is on.

5. Since maintenance software cannot always distinguish between errors caused by the removable media and those caused by the removable media drive or Host Adapter, check for removable media errors first.

   - Make sure there is disk in the drive. Optical disks look similar to 1.44Mb floppy disks, but are thicker (see Figure 9-82).

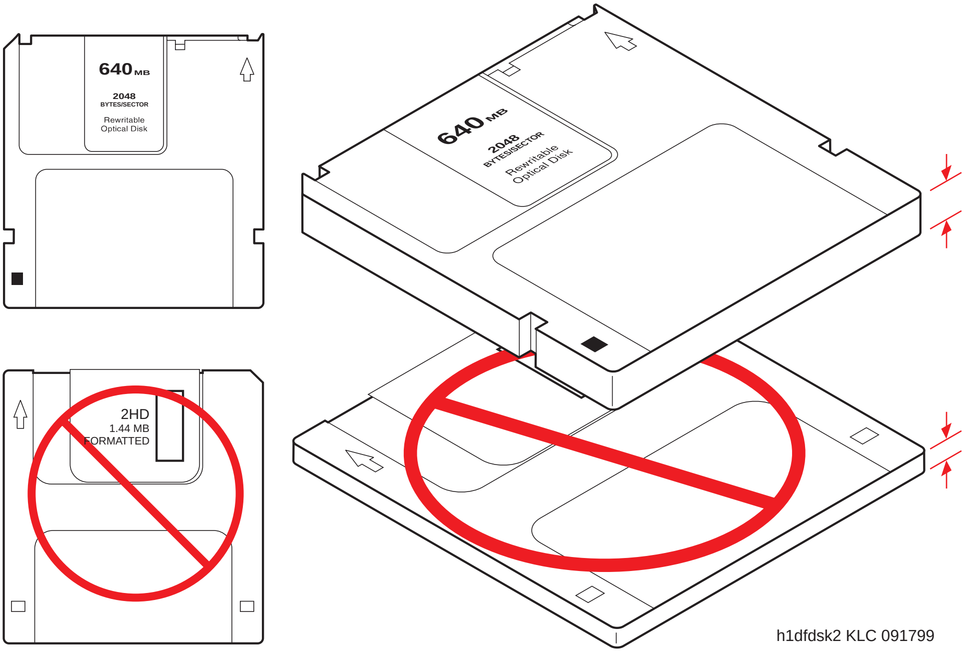

Figure 9-82. Use a 640Mb optical disk only, not a 1.44Mb floppy disk

- Make sure that the write protect lock is not active (see Figure 9-83). To deactivate write protect on a tape cartridge, slide the RECORD switch on the tape cartridge in the direction of the arrow on the switch. To deactivate write protect on a optical disk cartridge, slide the *square* switch on the back of the optical disk so that the hole is covered.

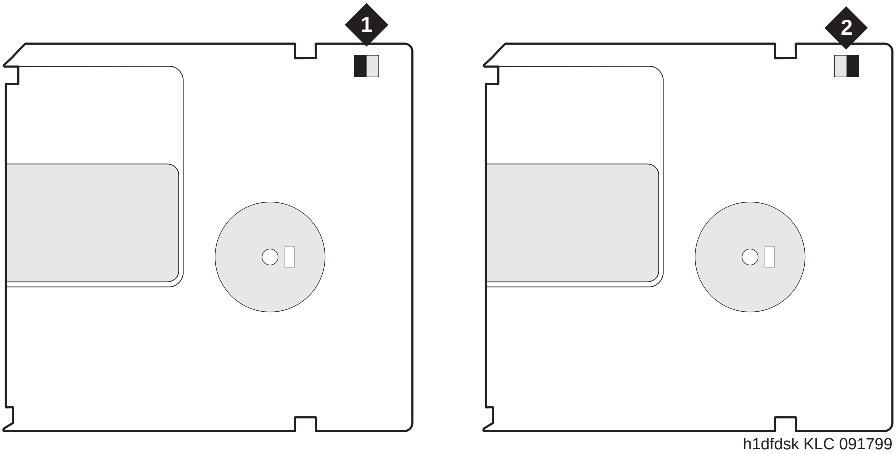

Figure Notes

1. Write-protect disabled
2. Write-protect enabled

Figure 9-83. Optical disk write-protection tab

General repair procedures for tape

The following statement applies to the TN1656 Tape Drive only:

- Cleaning the tape drive head is very important. Dirty tape drive heads may cause problems that appear to be hardware-related. A tape drive head with abrasive particles can permanently damage a new tape. A worn tape may leave abrasive particles in the tape drive head. To clean the tape heads in the Tape Drive, follow the "Tape drive head-cleaning procedure TN1656 Tape Drive ONLY" at the end of this section.

Replacing an removable media cartridge

If the removable media cartridge (tape or optical disk) needs to be replaced, follow the procedure given below:

1. Resolve all other removable media drive circuit pack alarms/problems.
2. Install a removable media cartridge that has the same release number or, if that is not practical, install a removable media disk with the same file layout as the original removable media disk.
   - When a tape cartridge is first inserted, there should be a spinning noise for the TN1656 indicating that the Tape Drive is performing a retension pass (moving the tape forward and then back to the tape mark several times). This may take several minutes.

- When an optical disk is first inserted in a TN2211 Optical Disk Drive, the amber LED should be on (lit) for a few seconds, then off. If the amber LED stays on, the optical disk needs to be re-inserted.

CAUTION:

Be sure not to touch the surface of the optical disk as this can render the disk unusable. (Figure 9-84)

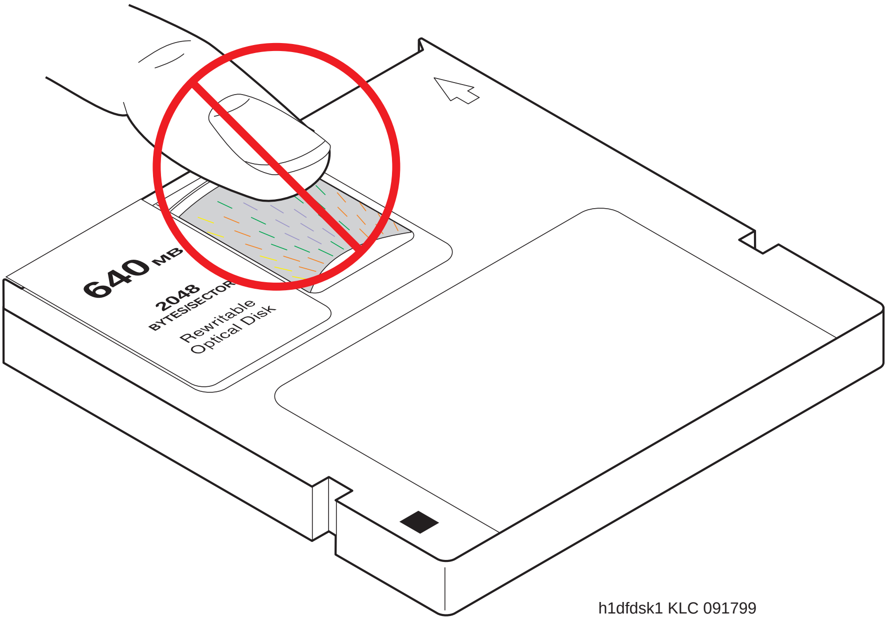

Figure 9-84. Do not touch the surface of the optical disk

3. Verify that the removable media cartridge has an acceptable release number by checking the Software Version (**list configuration software-vintage**).
4. If a new removable media cartridge is not available, but all other removable media alarms/problems have been resolved, then replace the damaged removable media with the backup removable media cartridge. Wait for the retension pass to complete (for tape only).
5. Verify that the removable media has the latest translations (**list configuration software-vintage**).

   If the removable media does not have the latest translation or announcement files, then perform a **backup disk**.

Replacing the TN2211 removable media circuit pack

For a Simplex SPE:

a. Enter **busyout host-adapter**. The Host Adapter should be "busied out" to prevent other applications from trying to access the removable media or the disk. The removable media circuit pack supplies +12V to the Disk circuit pack so when it is removed, the Disk circuit pack will also go out of service.

b. Replace the removable media circuit pack and insert the removable media cartridge into the new removable media circuit pack.

c. Issue the **reset host-adapter** command. This may take up to 3 minutes to complete for a tape since it waits for the tape to retension.

d. Issue the **release host-adapter** command.

e. Issue the **status spe** command and check that the status screen indicates that the removable media and disk are now in service.

For a Duplicated SPE:

a. See "Replacing SPE Circuit Packs" in Chapter 5.

b. After the standby SPE is powered up and fully refreshed, test the standby optical disk using the **test removable-media long** command.

Error Log Entries and Test to Clear Values

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3841 (u)[2]		Miscellaneous	WARNING	OFF	test removable-media a|b long rep 1

1. In a system with a simplex SPE, the carrier does not have to be specified. In a system with a duplicated SPE, the carrier (A or B) must be specified.
2. If error type 1 with aux data of 123 is present. this field will have the out of service cause data. See the MSS Error Actions table (Table 9-575) at the end of this section (R-MEDIA).

The `Service State` field in the Alarm Log refers to the accessibility of the device.

- **IN** (in service) means that users can access the device, and all maintenance tests can run.
- **MTC** (maintenance busy) means that the device is "busied out," and users cannot access it although all demand maintenance tests can run.
- **OUT** (out of service) means that users cannot access the device, but background and demand testing can run.

Notes:

a. **Error type 1**: means that the device is out of service as a result of maintenance tests detecting a critical failure of the removable media drive.

b. **Error type 18**: means that the removable media drive was busied out on demand from the System Access Terminal.

c. **Error type 250**: means that the R-Media Reset Test (#894) failed.

d. **Error type 257**: means that the device could not be accessed.

e. **Error type 513**: means that on-board removable media drive diagnostics tests requested by the Removable Media Diagnostic Test (#813) failed.

f. **Error type 526**: means that the Host Adapter was busied out. This also causes the removable media drive to be busied out.

g. **Error type 529**: means that there was a failure to put the removable media drive in service or to take it out of service.

h. **Error type 769**: means that the removable media Looparound Test (#814) failed.

i. **Error type 1025**: means that a media error was detected when the removable media cartridge was read or written.

1. Replace the removable media cartridge if this error continues.

j. **Error type 1281**: indicates that a hardware failure condition was detected by the Firmware Error Counters Read and Clear Test (#812). See the *MSS Error Actions* table (Table 9-575) at the end of this section.

k. **Error type 1537**: indicates that the removable media cartridge is write protected. Check the write-protect switch on the removable media cartridge (Figure 9-83). It should cover the opening (opposite position).

l. **Error type 1793**: is an in-line error from the removable media control software that indicates there was a problem with the SCSI Bus Access Failure or Memory Access Failure between the Host Adapter circuit pack and the removable media drive circuit pack. See the *MSS Error Actions* table (Table 9-575) at the end of this section.

m. **Error type 2049**: indicates that a bad command was sent to the removable media drive. This may be caused by a software error or a hardware failure.

1. Execute the **test removable-media long** command and fix any failures associated with those tests.

n. **Error type 2306**: means that a block has been reassigned on the removable media or an attempt to reassign a block has failed. This error does not apply to an optical disk cartridge.

1. Replace the removable media as soon as practical.
2. This alarm can be retired by issuing the **reset removable-media** command, but it will reappear each time the Removable Media Firmware Counter Test (#812) is run.

o. **Error type 2561**: indicates that the Data Write-Read Test (#810) failed.

p. **Error 2817**: indicates that the Removable Media Status Test (#815) detected a fault. See the *MSS Error Actions* table (Table 9-575) at the end of the section on R-MEDIA.

q. **Error type 3073**: indicates in-line errors reported by the removable media control software. See the *MSS Error Actions* table (Table 9-575) at the end of the section on R-MEDIA.

r. **Error type 3329**: indicates that the Removable Media Audit Test (#811) detected a corrupted directory file.

   1. Execute the **test removable-media long** command and fix any failures associated with those tests. The Auxiliary Code for this Error Log entry and the failure code for the Removable Media Audit test indicate the directory file that is corrupted.
   2. If Test #811 fails, follow normal escalation procedures.

s. **Error type 3585** with Aux Data 408: indicates that there was an error in reading translation data from the removable media and/or disk (Table 9-575).

   This error only occurs on a system reset 3,4, or 5 (Cold 1, system reboot, or extended system reboot). If a disk is present, the system first tries to read translations from the first and second copies of translation on the disk and, if that fails, it tries to read translation from the first and second copies of translation on the removable media.

   If an error was detected with reading translations from the disk and then the removable media, a 408 error is logged (Table 9-575). This error invokes *Emergency Transfer* on a system with simplex SPE and causes a SPE interchange ion duplicated systems.

   1. To clear this alarm, correct all other removable media errors.

      If the SPE is not duplicated, it may be necessary to use a backup removable media cartridge to first restore translation data to the disk. A new backup removable media cartridge should be obtained as soon as possible.

      If the system is equipped with duplicated SPEs and if the alarm is associated with the removable media on the standby SPE, the active SPE should be running with the most current translation.
   2. After correcting any hardware failures associated with the removable media and disk on the standby SPE, save translations to the disk and removable media on the standby SPE.

t. **Error type 3585** with Aux Data 409 (Table 9-575): means that there was an error in reading the program update file from both the disk and removable media or there was an error in applying the program update file once it was successfully read from the disk or removable media.

   This error only occurs during a system reset 4 or 5 (system reboot or extended system reboot). If a disk is present, the system tries to read the program update file from the disk first and, if that fails, it tries to read the program update file from the Removable Media cartridge. After it succeeds in reading a copy of the program update file, it checks to see if the program update information is appropriate for the software version in memory before it applies it to the software boot image.

   If an error is detected with any part of the process of reading the program update file from the disk or removable media and applying the program update to memory, a hardware error 409 is generated (Table 9-575). This error invokes a MAJOR alarm and *Emergency Transfer* on a system with simplex SPE. It initiates an SPE interchange followed by a MINOR alarm on a system with duplicated SPEs. When this error occurs, the copies of the program update files on the disk and removable media are invalidated so that those files no longer appear when a **list configuration software** command is entered from the System Access terminal.

1. Correct any other removable media and disk alarms.
2. Then restore the two copies of the program update files on the disk and removable media and apply those upgrades using ''Software updates'' in Chapter 6.

u. **Error type 3841**: is used to record miscellaneous data when an out-of-service condition occurs. See the *MSS Error Actions* table (Table 9-575) at the end of the section on R-MEDIA.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Removable Media Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND [1]
Removable Media Reset Test (#809)	X	X		ND
Removable Media Diagnostic Test (#813)	X	X		ND
Removable Media Looparound Test (#814)	X	X		ND
Removable Media Status Test (#815)	X	X		ND
Removable Media Firmware Error				
Counters Read and Clear Test (#812)	X	X		ND
Removable Media Write-Read Test (#810)		X		ND
Removable Media Audit Test (#811)		X		ND
Removable Media Reset (#894)			X	ND

1. D = Destructive; ND = Nondestructive

Removable Media Reset Test (#809 and #894)

The Removable Media Reset Test consists of the following steps controlled by firmware on the Host Adapter Circuit (located on the MSSNET CIRCUIT PACK):

- Removable Media Drive reset

  A SCSI “BUS DEVICE RESET” message is transmitted to the removable media drive to reset it.

- Presence test

  A SCSI “INQUIRY” command is sent to the removable media drive to attempt to query with it. If the removable media drive is present, it returns information about the device type, whether or not its medium is removable, compatibility with established standards, vendor and product IDs, and other miscellaneous information.

- Capacity test

  A SCSI “READ CAPACITY” command is sent to the removable media drive. It returns with the logical block address and the block length of the last logic block on the medium.

  A SCSI “READ DATA BUFFERS” command is sent to the removable media drive. This returns the size of the controller memory data buffers.

  A SCSI “READ DEFECT DATA” command is sent to the removable media drive. This returns the addresses of bad blocks on the tape that must be mapped around.

- Device Diagnostic Tests

  A SCSI “SEND DIAGNOSTICS” command is sent to the removable media drive to initiate a set of device-dependent self-tests that are run as a unit. Failures can be for multiple reasons and the return code which indicates the cause of failure is vendor unique. A failure condition is reported as single failure type since the only repair action is to replace the removable media drive circuit pack.

Table 9-568. TEST #809/#894 Removable Media Reset Test

Error Code	Test Result	Description/ Recommendation
526	ABORT	The Host Adapter has been busied out. 1. Issue the **release host-adapter** command.
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
1335	ABORT	Could not run the test on the Standby SPE; duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE; interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE; handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE; refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby), retry the command.
1350	ABORT	Could not run test on Standby SPE; shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period.

Continued on next page

Table 9-568. TEST #809/#894 Removable Media Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Could not run the test on the Standby SPE; internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
	NO BOARD	The removable media has been placed in the “uninstalled” state. 1. Verify that a removable media cartridge is installed and not write-protected (Figure 9-83) and that the removable media cartridge is fully inserted and powered up. 2. Attempt a demand reset (**reset removable-media**) of the removable media drive.
201	FAIL	The removable media drive is not responding or it may not be present. 1. Verify that the removable media drive circuit pack is present and powered. 2. Replace the removable media drive circuit pack. 3. If the reset continues to fail with this error code, replace the Host Adapter circuit pack.
5124	FAIL	No removable media cartridge is installed. 1. Verify that a removable media cartridge is installed and not write-protected (Figure 9-83). 2. If the reset continues to fail with this error code, continue with the steps below for the general reset failure case.

Continued on next page

Table 9-568. TEST #809/#894 Removable Media Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Varies 1	FAIL	The removable media drive could not be reset successfully. 1. Verify that a removable media cartridge is installed and not write-protected. 2. If the test continues to fail, replace the removable media cartridge. Wait for the retension pass to complete (for TAPE only). If the test succeeds, issue the **backup disk** command. 3. If the test continues to fail, replace the removable media drive circuit pack. 4. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The removable media drive was reset correctly. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table (Table 9-575) at the end of this section.

Removable Media Write-Read Test (#810)

The Removable Media Write-Read Test verifies that data can be written to a specific file on the removable media cartridge and read back successfully. It does not test the integrity of other files on the removable media cartridge. This test consists of the following steps:

1. Maintenance software in the SPE issues a request to the Host Adapter for a transfer of data between SPE memory and a specified block on the removable media cartridge.

   The Host Adapter firmware issues an SCSI **WRITE** command to the removable media drive which results in a transfer of data between the SPE memory and the removable media cartridge.

2. Maintenance software in the SPE issues a request to the Host Adapter to run a checksum on the data previously written to the removable media.

   The Host Adapter reads the data off the removable media cartridge and computes a checksum which is returned to the SPE maintenance software.

3. Maintenance software compares the value of the checksum from the Host Adapter with the checksum it previously calculated on the data it stored on the removable media cartridge.

Multiple failure conditions can occur during this test, since it uses both the software and hardware functions used during normal operations.

Table 9-569. TEST #810 Removable Media Write-Read Test

Error Code	Test Result	Description/ Recommendation
1301 1302	ABORT	Could not run the test—internal MSS error (see Table 9-575) 1. Retry the command.
1304	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (Use the **display system-parameters maintenance** command to display the start time for scheduled maintenance and the option for saving translations).
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
1335	ABORT	Could not run the test on the Standby SPE; duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE; interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.

Continued on next page

Table 9-569. TEST #810 Removable Media Write-Read Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	Could not run the test on the Standby SPE; handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE; refresh not complete. 1. When the standby is restored to service (use **status spe**), retry the command.
1350	ABORT	Could not run the test on the Standby SPE; shadowing not enabled. 1. When standby is restored to service (use **status spe**), retry command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2500	ABORT	Could not run the test on the Standby SPE; internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
	NO BOARD	The removable media has been placed in the “uninstalled” state. 1. Verify that a removable media cartridge is installed and not write-protected and that the removable media drive is fully inserted and powered up. 2. Attempt a demand reset (**reset removable-media**) of the removable media drive.

Continued on next page

Table 9-569. TEST #810 Removable Media Write-Read Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Varies [1]	FAIL	The removable media could not be accessed, the checksum on the data written did not match the checksum in memory or the data read did not match the data written. 1. Verify that a removable media cartridge is installed and not write-protected. 2. ***This step is for a TN1656 Tape Drive only. Do not attempt to clean a TN2211 Optical Drive as this will damage the drive***. If a non-write-protected tape cartridge was inserted, remove it and clean the Tape Heads. 3. If the test continues to fail, replace the removable media cartridge. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the removable media drive circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Removable Media write-read test succeeded. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table (Table 9-575) at the end of this section.

Removable Media Audit Test (#811)

The Removable Media Audit Test verifies the following medium conditions.

- The directory can be read.
- There are no “dirty” files. A file is said to be “dirty” if the data in the file is not complete or if the directory entry for that file was not updated after the data was written to the device.
- ***For tapes only***: A tape has not exceeded the number of passes recommended by the manufacturer. If the tape has exceeded 90% of the manufacturer’s recommended limit of accesses, the tape should be replaced. An alarm indicating this appears nightly after scheduled maintenance is executed. This alarm can be retired by issuing the **reset removable-media** command.

Table 9-570. TEST #811 Removable Media Audit Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
1335	ABORT	Could not run the test on the Standby SPE; duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE; interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE; handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE; refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE; shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.

Continued on next page

Table 9-570. TEST #811 Removable Media Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
	NO BOARD	The removable media cartridge has been placed in the “uninstalled” state. 1. Verify that a removable media cartridge is installed and not write-protected and that the removable media drive is fully inserted and powered up. 2. Attempt a demand reset (**reset removable-media**) of the removable media.
Varies [1]	FAIL	The audit of the removable media directory failed. 1. Verify that a removable media cartridge is installed. 2. Perform a **backup disk**. This may take up to 10 minutes to complete. 3. If the test continues to fail, replace the removable media cartridge and rerun the test. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the removable media drive circuit pack. 5. If the test continues to fail, determine if other R-MEDIA, Disk, or Host Adapter tests fail, and if they do, follow the repair procedures for those failures.
	PASS	The removable media drive directory audit succeeded. Check other results to see if it is operating correctly.

1. See the MSS Error Actions table (Table 9-575) at the end of the section on R-MEDIA.

Removable Media Firmware Error Counters Read and Clear Test (#812)

The Host Adapter firmware is constantly running background tests on each of its devices. When an error is detected by one of these background tests, the appropriate counter in the host adapter dual port RAM is incremented. The Removable Media Firmware Error Counters Read and Clear Test requests that the firmware return these errors to the software and clear the area in dual port RAM. If any counter is non-zero, the software then increments the appropriate software counter. The 16 errors reported by the firmware are:

- Unexpected interrupt from the SCSI Bus Interface Controller Chip (SBICC)
- SBICC timed out during SCSI command
- Error interrupt from the Direct Memory Access Controller (DMAC)
- DMAC timeout without issuing interrupt
- Removable Media self-test failed
- Removable Media external looparound test failed
- Command failed with bad sense key
- Removable Media could not be accessed
- Flaw detected in removable media medium
- Unrecoverable hardware error on removable media
- Invalid parameter in SCSI command
- Media removed or device reset
- Removable Media cartridge is write protected
- Removable Media reached end of medium
- Block reassigned on removable media cartridge
- Block reassignment on removable media failed

Also, this test checks for two other conditions (tape only):

- the presence of grown defects on the tape medium
- whether the tape has been accessed in excess of 90% of the manufacturer’s suggested maximum.

Table 9-571. TEST #812 Removable Media Firmware Error Counters Read and Clear Test

Error Code	Test Result	Description/ Recommendation
1305	ABORT	Could not read firmware error counters.
1306	ABORT	Could not read configuration area for defect information. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
1335	ABORT	Could not run the test on the Standby SPE; duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE; interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE; handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When standby is restored to service (use **status spe** to determine state of standby) retry command.
1347	ABORT	Could not run the test on the Standby SPE; refresh not complete. 1. When standby is restored to service (use **status spe** to determine state of standby) retry command.
1350	ABORT	Could not run the test on the Standby SPE; shadowing not enabled. 1. When standby is restored to service (use **status spe** to determine state of standby) retry command.

Continued on next page

Table 9-571. TEST #812 Removable Media Firmware Error Counters Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2500	ABORT	Could not run the test on the Standby SPE; internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
	NO BOARD	The removable media drive has been placed in the "uninstalled" state. 1. Verify that a removable media cartridge is installed and not write-protected and that the removable media drive is fully inserted and powered up. 2. Attempt a demand reset (**reset removable-media**) of the removable media drive.
7	FAIL	Background tests run by the Host Adapter detected that the removable media drive could not be accessed at some time previous to executing the read-and-clear test. This error may have been caused by removing and reinserting the removable media cartridge. The read-and-clear test or reset test must be run at least once before this error is cleared. 1. Try **test removable-media** again to see if the error has cleared. 2. Verify that the removable media cartridge is present. 3. If the test continues to fail, replace the removable media drive circuit pack.

Continued on next page

Table 9-571. TEST #812 Removable Media Firmware Error Counters Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
11	FAIL	Background tests run by the Host Adapter detected that the removable media drive was reset at some time previous to executing the read-and-clear test. This error may have been caused by removing and reinserting the removable media cartridge. The read-and-clear test or reset test must be run at least once before this error is cleared. 1. Try **test removable-media** again to see if the error has cleared. 2. If the test continues to fail, replace the removable media drive circuit pack.
5504	FAIL	A block has been reassigned to a different location on the removable media as a result of a medium error. This is referred to as a “grown defect.” Removable media performance will be affected since the removable media drive must search ahead to read or write this block and then return to where it left off. Continued testing will not correct the problem. The removable media cartridge should be replaced as soon as practical. 1. Run the STO-DATA tests to verify that the boot images, translations, announcements, and so on, are valid. 2. If errors are detected, run **backup disk full** to restore good copies to the optical disk. 3. If the STO-DATA tests continue to fail, replace the removable media.
5512	FAIL	***For tapes only***: 90% of the manufacturer’s recommended limit for tape accesses has been exceeded. Continued testing will not correct the problem, and the tape needs to be replaced as soon as practical.

Continued on next page

Table 9-571. TEST #812 Removable Media Firmware Error Counters Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	At least one of the firmware error counters was non-zero. 1. Run the **test removable-media** command again to verify that this failure was not from a failure condition which has been cleared as a result of this test clearing the firmware counters. 2. Verify that a removable media cartridge is installed and not write-protected (Figure 9-83). 3. If a non-write-protected removable media cartridge was inserted, retry the command at 1-minute intervals a maximum of 5 times. 4. ***This step is for a TN1656 Tape Drive only. Do not attempt to clean a TN2211 Optical Drive as this will damage the drive***. If the test continues to fail, remove the tape cartridge and clean the Tape Heads. 5. If the test continues to fail, replace the removable media cartridge. If the test succeeds, issue the **backup disk full** command. 6. If the test continues to fail, replace the removable media drive circuit pack. 7. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The firmware error counters were zero. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table (Table 9-575) at the end of this section.

Removable Media Diagnostic Test (#813)

The Removable Media Diagnostic test causes the Host Adapter to send a SCSI “SEND DIAGNOSTICS” command to the removable media circuit pack. This initiates a set of device-dependent self-tests that are run as a unit. Failures can be for multiple reasons. The return code that indicates the cause of failure is vendor unique. A failure condition is reported as single failure type since the only repair action is to replace the removable media circuit pack.

Table 9-572. TEST #813 Removable Media Diagnostic Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
1335	ABORT	Could not run the test on the Standby SPE; duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE; interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE; handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE; refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE; shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2500	ABORT	Could not run the test on the Standby SPE; internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-572. TEST #813 Removable Media Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
	NO BOARD	The removable media has been placed in the “uninstalled” state. 1. Verify that a removable media cartridge is installed and not write-protected and that the removable media drive is fully inserted and powered up. 2. Attempt a demand reset (**reset removable-media**) of the removable media drive.
[1]	FAIL	A Removable Media diagnostic test failed. 1. Verify that a removable media cartridge is installed and not write-protected. 2. ***This step is for a TN1656 Tape Drive only. Do not attempt to clean a TN2211 Optical Drive as this will damage the drive***. If the test continues to fail, remove the tape cartridge and clean the Tape Heads. 3. If the test continues to fail, replace the removable media cartridge. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the removable media drive circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The removable media passed all diagnostic tests. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table (Table 9-575) at the end of this section.

Removable Media Looparound Tests (#814)

This test extends the Host Adapter Looparound test to send data from the Host Adapter to buffers on the removable media drive circuit pack and back to the Host Adapter. It may detect errors related to the Host Adapter, SCSI bus, and the removable media circuit pack. It is intended to functionally test the removable media circuit pack to the extent possible without actually writing data to the removable media cartridge.

This test consists of two sets of tests:

- Removable Media Internal Looparound

  Data is generated in the RAM of the Host Adapter and transferred to its SCSI Data Memory. An SCSI **WRITE DATA BUFFERS** command is sent to the removable media drive circuit pack which causes the removable media circuit pack to copy the data to its buffers. An SCSI **READ DATA BUFFERS** command is then sent by the Host Adapter to the the removable media circuit pack which causes the removable media circuit pack to transfer the data from its buffers back to the Host Adapter's SCSI Data Memory. The Host Adapter then copies the data back to its private RAM, where it compares it with the original test data.

- Removable Media External Looparound

  This test is similar to the Internal Loop-around test except that the data originates in the Host Adapter's Dual Port RAM and it is transferred to and from the SCSI Data Memory using SPE system bus accesses. Only a small amount of data is sent to the removable media circuit pack in order to keep system bus access to a minimum.

Table 9-573. TEST #814 Removable Media Looparound Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).

Continued on next page

Table 9-573. TEST #814 Removable Media Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1335	ABORT	Could not run the test on the Standby SPE; duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE; interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE; handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE; refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE; shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2500	ABORT	Could not run the test on the Standby SPE; internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).

Continued on next page

Table 9-573. TEST #814 Removable Media Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The removable media has been placed in the “uninstalled” state. 1. Verify that a removable media cartridge is installed and not write-protected and that the removable media drive is fully inserted and powered up. 2. Attempt a demand reset (**reset removable-media**) of the removable media drive.
1	FAIL	The Removable Media Looparound test failed. 1. Verify that a removable media cartridge is installed and not write-protected. 2. ***This step is for a TN1656 Tape Drive only. Do not attempt to clean a TN2211 Optical Drive as this will damage the drive***. If the test continues to fail, remove the tape cartridge and clean the Tape Heads. 3. If the test continues to fail, replace the removable media cartridge. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the removable media drive circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Removable Media Looparound test passed. Look at the results of other tests to see if it is operating correctly.

1. See the MSS Error Actions table (Table 9-575) at the end of this section.

Removable Media Status Test (#815)

The Removable Media Status Test verifies that:

- the Host Adapter knows about the existence of the removable media circuit pack.
- the LEDs on the faceplate can be turned on and off correctly.

NOTE:
This only verifies that the control and status logic for the LEDs is operating correctly. The operation of the LEDs may also be tested visually by using the **test led** command.

- +12V from on-board DC-to-DC converters is present.

Table 9-574. TEST #815 Removable Media Status Test

Error Code	Test Result	Description/ Recommendation
1306 1307 1308	ABORT	Internal software error between maintenance software and MSS driver. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
1335	ABORT	Could not run the test on the Standby SPE; duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE; interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE; handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE; refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE; shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2500	ABORT	Could not run the test on the Standby SPE; internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-574. TEST #815 Removable Media Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the option for saving translations).
	NO BOARD	The removable media drive has been placed in the “uninstalled” state. 1. Verify that a removable media cartridge is installed and not write-protected and that the removable media drive is fully inserted and powered up. 2. Attempt a demand reset (**reset removable-media**) of the removable media drive.
[1]	FAIL	The configuration information shows the removable media drive circuit pack is missing or the removable media drive LED test failed. 1. Verify that a removable media cartridge is installed and not write-protected. 2. ***This step is for a TN1656 Tape Drive only. Do not attempt to clean a TN2211 Optical Drive as this will damage the drive***. If the test continues to fail, remove the tape cartridge and clean the Tape Heads. 3. If the test continues to fail, replace the removable media cartridge. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the removable media drive circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Removable Media Status Test passed successfully. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table (Table 9-575) at the end of this section.

Removable Media Reset Test (#894)

The Removable media Reset Test is run on as part of the **reset removable-media** command. The test results for Test #894 are the same as those for Test #809, which is run as part of the **test removable-media** sequence. All optical drive alarms are cleared when Test #894 passes, while only some removable media drive alarms may clear when Test #809 passes. Refer to "Removable Media Reset Test (#809 and #894)" for repair procedures.

Tape drive head-cleaning procedure TN1656 Tape Drive ONLY

NOTE:
Do not attempt to clean a TN2211 Optical Disk Drive. This will result in damage to the drive.

The following procedures should be used to clean the PBX Tape Drive(s). **A Tape Drive should be cleaned once every three months** to reduce the risk of losing information and to prevent unexpected service calls. An entry should be made in the Preventive Maintenance Log when this is done (see Chapter 6).

A DC2000 Series Data Cartridge Tape Drive Cleaning Kit from 3M is used to clean the tape head and the tape capstan. This kit consists of a Cleaning Positioning Cartridge and 20 cleaning wands (Comcode 406622464 or 3M Reorder number DC051111-12947). A refill kit of 20 cleaning wands is also available (Comcode 406622472 or 3M Reorder Number DC051111-12948).

NOTE:
The cleaning wands are flammable. Dispose of properly.

1. Busyout the the Tape circuit pack (**busyout removable-media *c***, where *c* is carrier a or b). This prevents background maintenance tests and other application software from trying to access the tape.
2. Eject the Tape Cartridge from the Tape circuit pack (TN1656). Insert the Cleaning Position Cartridge into the Tape Drive with the *label side to the left*.
3. Prepare the cleaning wand for use as follows: Hold the bristle end down, crush the wand at the "x" area and squeeze to release fluid and saturate the bristles.
4. Insert the wand into **R/W Head Slot** (top of cartridge) with gentle twisting motion. Stop when solid resistance is felt. Rotate the wand 6 turns while raising and lowering end of wand.
5. Remove the used wand and discard.
6. Prepare a second wand as described in step 3 above.

7. Eject the Cleaning Position Cartridge out of the Tape circuit pack and reinsert it. This conditions the tape drive to move the capstan when the cleaning wand is inserted in the next step.
8. Insert the wand into the **Capstan Slot** (middle of cartridge) within 10 seconds after the Cleaning Position Cartridge was reinserted.
9. Apply a gentle forward pressure to the wand for about 15 seconds. You should be able to feel the capstan moving.
10. Remove the used wand and discard.
11. Eject the Cleaning Positioning Cartridge and insert the PBX Tape Cartridge back into the Tape Drive.

> **NOTE:**
> After the Tape Cartridge is inserted back into the Tape Drive, it will run through a retension pass which can take up to 2 minutes to complete. During that time, the **reset removable-media** command entered in the next step causes a "please wait" message to flash on the terminal screen while the tape is retensioning, but the command completes after the retension pass completes.

12. Reset the Tape circuit pack (**reset removable-media *c***, where *c* is carrier a or b). This clears out a tape error that indicates the tape cartridge had been removed and reinserted.
13. Release the Tape from its maintenance busy-out state using the **release removable-media *c*** command, where *c* is the carrier number (a or b).

MSS error list

Table 9-575 lists the Mass Storage System Error Actions.

Table 9-575. MSS Error Actions

Code	Description
0	Unexpected interrupt from SBICC.
1	SBICC timed out during SCSI command.
2	DMAC generated error interrupt.
3	DMAC timed out without interrupt.
4	Removable Media self-test failed.
5	Removable Media external looparound test failed.
6	Command failed with bad SENSE key.

Continued on next page

Table 9-575. MSS Error Actions — *Continued*

Code	Description
7	Removable media could not be accessed.
8	Flaw detected in removable media medium.
9	Unrecoverable hardware failure on removable media drive.
10	Invalid parameter in SCSI command.
11	Media removed or reset.
12	Removable media is write protected.
13	Removable media reached end of medium.
14	Block reassigned on removable media.
15	Block reassignment failed on removable media.
16	Inconsistent capacity data
17	Device busy
18	Device reservation conflict
19	Request sense failed
101	Unrecognized *opcode*.
102	Unrecognized *modifier*.
103	*xlist_length* too long.
104	Invalid transfer address.
105	Intra-device copy ranges overlap.
121	Device invalid for *opcode* requested.
122	Device non-existent.
123	Device is out of service.
124	*to_byte* or *from_byte* is out of range.
125	*to_byte* + *numbytes* is invalid or *from_byte* + *numbytes* is invalid.
126	Type of device is invalid for *opcode* requested.
201	An unexpected interrupt code was returned from the SBICC. This represents a protocol error that could be the result of the HA or the target device. The device may not be present.
251	SBICC timed out. This could be the fault of the HA or target device. The HA will attempt to reset the SBICC.
301	DMAC error. This could be the fault of the HA or the SCSI target device.

Table 9-575. MSS Error Actions — *Continued*

Code	Description
351	DMAC timed out. This could be the fault of the HA or the SCSI target device. The HA will attempt to reset the SBICC.
401	Could not save announcements or program update file.
408	Could not read translation from the Disk and removable media as part of system initialization.
409	Could not apply program update file.
422	Could not save translations.
501	A non-critical diagnostic test failed on the Host Adapter. This includes the USART chip test and the LED tests.
511	A diagnostic test requiring bus mastership failed. This happens only as the result of an MSS_DIAG command. This could be the fault of the HA or the system. Therefore the board does not put itself in held reset state. Rather, the error is reported and counters are incremented.
521	The HA looparound test requiring bus mastership failed. This happens only as the result of an MSS_LOOPAROUND command. This could be the fault of the HA or the system. Therefore the board does not put itself in held reset state. Rather, the error is reported and counters are incremented.
531	Target device **SEND DIAGNOSTICS** self-test indicated a hardware error. This indicates that there are problems with the controller or the device, and it should be taken out of service. This error will not occur if other errors (for example, SBICC) prevent the **SEND DIAGNOSTICS** command from running.
551	The target device internal looparound failed due to data corruption. Other errors (SBICC, SCSI check condition) would cause a different error code to be reported. This failure demonstrates that the target may potentially corrupt data and it should be taken out of service.
552	The target device external looparound failed due to data corruption. Other errors (SBICC, SCSI check condition) cause a different error code to be reported. This failure demonstrates that the target may potentially corrupt data. However, the HA does not take the device out of service as a result of this error. This test is only run following the target device internal looparound which detects actual problems with the target device. This failure implicates the HA bus interface or a system problem.
561	When the MSS_RESET command was issued for a device, it was found not to be present.
562	When the MSS_RESET command was issued for a device, the NQUIRY command failed.

Continued on next page

Table 9-575. MSS Error Actions — *Continued*

Code	Description
563	When the MSS_RESET command was issued for a device, the TEST UNIT READY command failed
564	When the MSS_RESET command was issued for a device, the READ CAPACITY command failed
565	The device reset failed.
566	Device type not supported.
567	Capacity data is inconsistent.
568	Block size doesn't divide into 8K.
601	**REQUEST SENSE** failed.
700	Indicates that there is no specific sense key information for a SCSI target on which a **REQUEST SENSE** was issued. This should never happen because firmware only asks for sense information if errors occurred.
701	SCSI sense information reported a recovered error on a SCSI target where it didn't make sense. Normally recovered errors are filtered by the HA firmware for reads and writes. However, for other commands, this is reported to software.
702	SCSI sense information indicates that the target device cannot be accessed. This will occur if the removable media cartridge is not present.
703	SCSI sense information indicates that a SCSI command terminated with a nonrecovered error condition probably caused by a flaw in the medium or an error in the recorded data.
704	SCSI sense information indicates a nonrecoverable hardware failure occurred. The removable media may be broken.
705	SCSI sense information indicates that there was an illegal parameter in the command descriptor block or in additional parameters supplied. This could be caused by a HA firmware failure or a problem with the target device.
706	SCSI sense information indicates that the target device's removable medium may have been changed or the target controller has been reset.
707	SCSI sense information indicates that reads or writes were attempted for a medium that was protected from this operation.
708	SCSI sense information indicates that a write-once read-multiple device or a sequential-access device encountered a blank block while reading or a write-once read-multiple device encountered a nonblank block while writing. This should never happen; the HA only supports direct access devices.
709	SCSI sense information indicates a vendor-unique sense key.

Continued on next page

Table 9-575. MSS Error Actions — *Continued*

Code	Description
710	SCSI sense information indicates a **COPY**, **COMPARE**, or **COPY AND VERIFY** command was aborted due to an error condition on the source device, the destination device, or both. This shouldn't happen since these commands aren't issued by the HA.
711	SCSI sense information indicates that the target controller aborted the command.
712	SCSI sense information indicates that a **SEARCH DATA** command has satisfied an equal comparison. This should not happen since this command is not issued by the HA.
713	This indicates that a buffered peripheral device has reached the end-of-medium and data remains in the buffer that has not been written to the medium.
714	This indicates that the source data did not match the data read from the medium. This should not happen since the HA does not issue any commands involving comparisons.
715	SCSI sense information returned a reserved sense key. This should not happen.
758	Device returned busy.
764	Device returned reservation conflict status.
801	HA firmware was attempting to process a command requiring system bus access and the NOGOINT interrupt occurred. This probably indicates that system software failed to enable bus access before issuing an MSS command requiring it. It also could indicate a system problem or a HA problem.
802	HA firmware was accessing the system bus and it timed out. This could be a result of MSS command argument errors, system problems, or a HA problem.
803	HA firmware was accessing the system bus and received a data-parity interrupt. This could indicate a system or HA problem.
804	HA firmware was accessing the system bus and received a error detection and correction interrupt. This could indicate a system or HA problem.
805	System bus error test failed.
1001	Firmware error
1002	Cheetah/Pecos error
1003	Both the 68020 and the DMAC tried to access the same location in the SDM concurrently.

Continued on next page

Table 9-575. MSS Error Actions — *Continued*

Code	Description
1004	HA firmware couldn't put a response in the response queue because it was full. This could be the fault of the HA, or system software. However, there is no way to recover, therefore the HA places itself in held reset.
2001	A critical diagnostic test on the Host Adapter failed making it dangerous to continue service.
2002	The Host Adapter internal looparound test failed because of data corruption.
3001	An exception occurred indicating a serious hardware or firmware problem. Additional information will be placed in HA DPRAM about which exception occurred and the address at which it occurred.
3002	An interrupt occurred when it should not have. This includes interrupts that are a normal part of command processing but that occurred unexpectedly.
4001	The checksum of the firmware image in memory prior to FLASH PROM programming failed.
4002	Flash PROM programming failed.
5000	The removable media cartridge has been changed or the removable media drive has been reset by firmware.
5001	Alternate copy of file used—primary could not be accessed.
5113	Device out of service
5124	No removable media cartridge in removable media drive.
5126	Handshake not up
5127	Memory refresh not complete
5200	Kernel call received a notification.
5201	Spurious interrupt from MSSNET.
5202	Message received on an unexpected class.
5203	File system on the device is corrupt.
5204	Driver failed to get parity error interrupt.
5205	Driver failed to get EDC error interrupt.
5206	Driver failed to get timeout interrupt.
5207	Alternate file could not be accessed.
5208	Bad path index on software call.
5209	Driver failed to get bus error interrupt.

5227	File 15 (small config core dump) corrupt.
5228	File 16 (large boot image) corrupt.
5229	File 17 (alternate boot image) corrupt.
5230	File 18 (large core dump on disk) corrupt.
5231	File 19 (large core dump on removable media) corrupt.
5300	Command timed out.
5301	Driver ran out of resources.
5302	Device or host adapter is not ready.
5303	State information is invalid.
5304	Firmware returned unexpected tag.
5305	MSSNET board is not inserted.
5400	Initialization error.
5401	Kernel call failed.

Continued on next page

Table 9-575. MSS Error Actions — *Continued*

Code	Description
5402	Timer call failed.
5403	DUPINT call failed.
5404	DRIP call failed.
5405	Critical path destroyed.
5406	Internal error.
5504	Block reassigned on removable media as a result of a medium error
5505	While running status test, configuration test failed.
5506	While running status test, LED test failed.
5507	Status test found host adapter in “held reset” state.
5508	Unable to obtain path to PAM.
5509	Translations were not locked.
5510	+5V not present
5511	+12V not present
5512	Exceeded 90% of manufacturer’s recommended tape access limit
5513	Disk capacity not sufficient for memory size.
5514	Disk not configured for larger memory size.
30003	Cannot write to removable media, removable media cartridge, or device error.
30004	Cannot read from removable media, removable media cartridge, or device error.
30017	Checksum error in block.
30203	Write-read mismatch error.

RING-GEN

Analog Ring Generator

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
RING-GEN	MAJOR	test environment P	Analog Ring Generator

1. P is the port network number indicated in the PORT field from the Alarm or Error Log.

Analog phones must be provided with a voltage that allows them to ring. The Analog Ring Generator maintenance object represents the device that provides the ringing voltage for all analog phones associated with a given cabinet. In a multi-carrier cabinet, the ring generator resides in the power distribution unit . It is protected by a fuse located next to the main circuit breaker on the front of the unit. In single-carrier cabinets, the ring generator is part of the WP-91153 power supply. Failure of the ring generator results in loss of ringing on analog phones. Ringing on digital and hybrid phones is not affected.

The ringing voltage is monitored by the Tone-Clock circuit pack. In a port network with duplicated Tone-Clocks, it is the active Tone-Clock that performs this function. In an EPN made up of single-carrier cabinets, the Tone-Clock monitors only the ringing voltage in the carrier that contains the tone clock.

The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins. For more information, refer to Chapter 5.

Error Log Entries and Test to Clear Values

Table 9-576. Analog Ring Generator Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment UU
1		Analog Ring Generator Query (#118)	MAJOR	ON	test environment UU r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Analog Ring Generator Initialization* Test, for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-577. Multicarrier Cabinet

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Analog Ring Generator Initialization Test (#117)	X	X	ND
Analog Ring Generator Query Test (#118)	X	X	ND
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
OLS Query Test (Carrier E) (#127) (c)	X	X	ND
OLS Query Test (Carrier D) (#127) (c)	X	X	ND
OLS Query Test (Carrier A) (#127) (c)	X	X	ND
OLS Query Test (Carrier B) (#127) (c)	X	X	ND
OLS Query Test (Carrier C) (#127) (c)	X	X	ND
Emergency Transfer Query Test (#124) (d)	X	X	ND
Cabinet Sensors Query Test (#122) (e)	X	X	ND
External Alarm Lead Query Test (#120) (f)	X	X	ND

1. D = Destructive, ND = Non-destructive

Notes:

a. Refer to POWER for a description of this test.
b. Refer to AC-POWER for a description of this test.
c. Refer to CARR-POW for a description of this test.
d. Refer to EMG-XFER for a description of this test.
e. Refer to CABINET for a description of this test.
f. Refer to EXT-DEV for a description of this test.

Table 9-578. Single-Carrier Cabinet

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Analog Ring Generator Initialization Test (#117)	X	X	ND
Analog Ring Generator Query Test (#118)	X	X	ND
Single-Carrier Cabinet Power Query Test (#79) (a)	X	X	ND
Emergency Transfer Query Test (#124) (b)	X	X	ND
External Alarm Lead Query Test (#120) (c)	X	X	ND

1. D = Destructive, ND = Non-destructive

Notes:

a. Refer to DC-POWER for a description of this test.

b. Refer to EMG-XFER for a description of this test.

c. Refer to EXT-DEV for a description of this test.

Analog Ring Generator Initialization Test (#117)

The TN768, or TN780 will report an error to the system software if the ringing voltage falls to low (only if system software has made a request to the TN768, or TN780 to monitor the voltage). The Analog Ring Generator Initialization Test sends a request to the TN768, or TN780. If there are redundant tone/clock circuit packs in the port network, then the request is sent only to the active tone/clock.

Table 9-579. TEST #117 Analog Ring Generator Initialization Test

Error Code	Test Result	Description/ Recommendation
1 1000 1001 1003 1115 2012 2100	ABORT	The system software is unable to determine the active tone/clock circuit pack, unable to allocated the resources necessary to run the test, or unable to send a down link message. 1. Wait for the green LED on the active tone/clock to go out; use the **status port-network** command to determine the active Tone/Clock circuit pack. 2. Rerun the test. If the test aborts again, refer to TDM-CLK.
2000	ABORT	Response to the request was not received within the allowable time period. 1. Look for TDM-CLK errors and alarms. Resolve all other Tone/Clock problems first. 2. Rerun the test.
	PASS	The active Tone/Clock has successfully been enabled to monitor the ringing voltage level.

Analog Ring Generator Query Test (#118)

The Analog Ring Generator Query Test requests the active Tone/Clock circuit pack to check the ringing voltage. The tone/clock circuit pack replies with PASS if the ringing voltage is adequate to ring the analog phones. If not, the active tone/clock circuit pack replies with a FAIL.

Table 9-580. TEST #118 Analog Ring Generator Query Test

Error Code	Test Result	Description/ Recommendation
1 1000 1001 1003 1115 2012 2100	ABORT	Could not seize the resources to run the test. Other maintenance is running on the active tone/clock circuit pack. 1. Wait for the green LED on the active tone/clock circuit pack to go out; use the **status port-network** command to determine the active Tone/Clock circuit pack. 2. Rerun the test. If the test aborts again, refer to TDM-CLK.
2000	ABORT	Response to the request was not received within the allowable time period. 1. Look for TDM-CLK errors and alarms. Resolve all other tone/clock problems first. 2. Rerun the test.

Continued on next page

Table 9-580. TEST #118 Analog Ring Generator Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The ringing voltage is below acceptable levels. **Procedure for a multicarrier cabinet system:** 1. If this is a duplicated SPE system, then determine the active Tone/Clock circuit pack by issuing a **status port-network** command. Make the Standby Tone/Clock circuit pack active via the **set tone-clock PC** command and rerun the test. a. If the test passes, then the trouble is with the now Standby Tone/Clock circuit pack. Refer to "TONE-BD" for details on replacing the Standby Tone/Clock circuit pack. After the circuit pack is replaced, make this Tone/Clock active again by issuing the **set tone-clock PC** command and rerun the test. b. If the test fails, then proceed with Step 2. 2. Resolve CARR-POW alarms first, and then rerun the test. 3. Check fuse on the power distribution unit. Replace if it is open, and rerun the test. If the test still fails, then an analog line circuit pack could be defective and causing the ring generator and/or fuse to fail. 4. Unseat all analog circuit packs in the affected cabinet, and rerun the test. 5. If the test passes, then the ring generator is healthy, and one of the analog circuit packs is defective. Replace the analog circuit packs one at a time, and rerun the test to determine which circuit pack is causing the problem. When the defective analog circuit pack is found, replace it and rerun the test. If the test still fails, proceed with Step 6.
	FAIL *(cont'd.)*	6. Since the test still fails, the ring generator is defective. a. If the reset button on the ring generator is out, press it in. b. Originate calls to several analog stations on different port circuit packs in different carriers in the affected port network. c. If called stations ring, the fault is cleared. Proceed to Step d. If no stations ring, replace the ring generator. d. Rerun the test. If the test still fails, proceed to Step 7. 7. The active tone/clock may be faulty and incorrectly reporting the level of the ringing voltage. Replace the active tone/clock and rerun the test. Refer to "TONE-BD" for details on replacing the tone/clock. Rerun the test.

Continued on next page

Table 9-580. TEST #118 Analog Ring Generator Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	**Procedure for a single-carrier cabinet system:** This failure indicates that there is no ringing voltage in the carrier where the active tone/clock circuit pack resides. Other carriers may or may not have ringing voltage. 1. If this is a duplicated system, determine the active Tone-Clock circuit pack by issuing a **status system** command. Make the Standby Tone-Clock circuit pack active via the **set tone-clock PC** command and rerun the test. a. If the test passes, then the trouble is with the "new" stand by Tone-Clock circuit pack. Refer to "TONE-BD" for details on replacing the standby Tone-Clock circuit pack. After the circuit pack is replaced, make this Tone-Clock active again by issuing the **set tone-clock PC** command and rerun the test. b. If the test fails, then proceed with Step 2. 2. Unseat all analog circuit packs in the cabinet that contains the Active Tone/Clock circuit pack and rerun the test. 3. If the test passes, then the ring generator is healthy and one of the analog circuit packs is defective. Replace the analog circuit packs one at a time, and rerun the test to determine which circuit pack is causing the problem. Replace the defective analog circuit pack. Rerun the test. If the test still fails, go to Step 4. 4. Replace the WP-91153 power unit for the affected carrier, and rerun the test. If the test still fails, go to Step 5. 5. The active tone/clock may be faulty and incorrectly reporting the level of the ringing voltage. Replace the active tone/clock and rerun the test. Refer to "TONE-BD" for details on replacing the active tone/clock circuit pack. Rerun the test.
	PASS	The analog ringing voltage level is acceptable. For a single-carrier cabinet stack, ringing voltage is acceptable in the cabinet containing the active tone/clock circuit pack.

S-SYN-BD (Speech Synthesis Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
S-SYN-BD	MIN	test board UUCSS sh	Speech Synthesis Circuit Pack
S-SYN-BD	WRN	test board UUCSS sh	Speech Synthesis Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Refer to ''XXX-BD (Common Port Circuit Pack)'' for circuit pack level errors. See also S-SYN-PT (Speech Synthesis Port) for related port information.

S-SYN-PT (Speech Synthesis Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
S-SYN-PT	MAJOR	test port UUCSSpp sh	Speech Synthesis Port
S-SYN-PT	MINOR	test port UUCSSpp l	Speech Synthesis Port
S-SYN-PT	WARNING	test port UUCSSpp sh	Speech Synthesis Port

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The TN725B Speech Synthesis circuit pack provides four independent Speech Synthesis Ports which may be connected to any of the voice time slots on the Time Division Multiplex (TDM) Bus. Each Speech Synthesis Port consists of a speech synthesizer device (SSD) and is managed by a custom-coded programmable speech synthesizer (PSS) controller. The PSS controller is, in turn, controlled by the on-board microprocessor via a command interface specifically designed for this application. The PSS controller's main function is the orderly transfer of encoded speech from the speech vocabulary read-only memory (ROM) to the SSDs. The SSDs decode it and produce 64 kb/s 5-255 PCM (Pulse Code Modulation) speech. The encoded speech is stored in up to 512K bytes of on-board ROM. In addition, each Speech Synthesis Port has an associated dual-tone multifrequency receiver (DTMR) to receive touch-tone digits from a station set connected to the port via a voice time slot. The station set may be connected to the Speech Synthesis Port through either a line or trunk circuit.

When there is an incoming call to a port, the ‘‘listen’’ network time slot is connected to the DTMF receiver input and the ‘‘talk’’ network time slot is connected to the SSD output. This enables the Speech Synthesis Port to support speech synthesis features or touch-tone input with voice response features. Some of the features that use the Speech Synthesis Port's capabilities include Leave Word Calling, Automatic Circuit Assurance, Automatic Wakeup (hotel-motel), and Do Not Disturb (hotel-motel).

The Speech Synthesis circuit pack should not be confused with the Announcement circuit pack. Different voice features are supported by each circuit pack.

Error Log Entries and Test to Clear Values

Table 9-581. Speech Synthesis Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	17672	None			
18	0	busy-out port UUCSSpp	WARNING	OFF	release port UUCSSpp
130(b)		None	WARNING	ON	test port UUCSSpp sh
257		Speech Synthesis PSS Handshake Test (#168)	MAJOR	ON	test port UUCSSpp sh r 2
513	17922	Speech Synthesis Memory Test (#166)	MINOR	ON	test port UUCSSpp sh r 2
769	17664	Speech Synthesis DTMF Receiver Inquiry Test (#164)	MINOR	ON	test port UUCSSpp sh r 2
1025	17670	Speech Synthesis SSD Inquiry Test (#167)	MINOR	ON	test port UUCSSpp sh r 2
1281		Speech Synthesis DSP Tone Test (#165)	MINOR	ON	test port UUCSSpp sh r 2

2305		NPE Crosstalk Test (#6)	MINOR	ON	test port UUCSSpp l r 2
3840(d)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. An in-line failure of the on-board microprocessor/PSS handshake has occurred. Refer to Test #168 for repair procedures.

b. This error type indicates that the circuit pack been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

c. A transient error that does not cause an alarm can occasionally occur during a SPE, TDM BUS, or Tone Clock interchange. Test the port and follow the instructions for conference Test (#7).

d. This error is not service-affecting and no action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Speech Synthesis PSS Handshake Test (#168)	X	X	ND
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Speech Synthesis DTMF Receiver Test (#163)		X	ND
Speech Synthesis Memory Test (#166)	X	X	ND
Speech Synthesis DSP Tone Test (#165)	X	X	ND
Speech Synthesis SSD Inquiry Test (#167)	X	X	ND
Speech Synthesis DTMF Receiver Inquiry Test (#164)	X	X	ND
Speech Synthesis Parameter Update Test (#169)	X	X	ND

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may occur. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-582. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test and the test has been aborted. You must wait until the port is idle (yellow LED is off) before retesting. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-582. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining the Error Log.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 9-583. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test and the test has been aborted. You must wait until the port is idle (yellow LED is off) before retesting. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-583. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. 1. Retry the test. 2. If the Test continues to fail then replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining the Error Log.

Speech Synthesis DTMF Receiver Test (#163)

A series of dual-tone multifrequency (DTMF) tones are conferenced from the TDM Bus into the port's DTMF receiver and checked to see if the correct tones have been detected during the correct intervals. If all the DTMF tones were detected correctly, the test passes. If any of the tones were not detected correctly, the test fails.

Table 9-584. TEST #163 Speech Synthesis DTMF Receiver

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	DTMF tones were not detected. This type of failure may cause features using touch-tone input to the Speech Synthesis Port to malfunction. 1. Verify that the Tone-Clock circuit pack is functioning correctly by checking the Error Log and using the **test tone-clock long** command. 2. If the test fails again, replace the Speech Synthesis circuit pack.
	PASS	The port has detected all DTMF tones correctly. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.

Speech Synthesis DTMF Receiver Inquiry Test (#164)

This test determines the sanity of the port's dual-tone multifrequency (DTMF) receiver. The on-board microprocessor tests the port's DTMF receiver and determines if it is in a sane (test passes) or insane (test fails) condition.

Table 9-585. TEST #164 Speech Synthesis DTMF Receiver Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The DTMF receiver for this port is insane. 1. If the test fails again, replace the circuit pack.
	PASS	The DTMF receiver for this port is sane. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.

Speech Synthesis DSP Tone Test (#165)

The digital signal processor (DSP) associated with each port can generate a 440-Hz tone whose presence can be detected by TN748 General Purpose Tone Detector circuit packs. A 440-Hz tone is generated for 500 ms on a specified time slot which is being listened to by the detector circuit. If the detector determines the tone is present on the time slot, the test passes; otherwise, it fails.

Table 9-586. TEST #165 Speech Synthesis DSP Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle retry the command at 1-minute intervals a maximum of 5 times.
1001 1002 1003	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1021	ABORT	The 440-Hz tone was not detected by the Tone Detector circuit and inter-digit time-out has occurred on the Tone Detector circuit. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify all Tone Detector circuit packs in the system are functioning correctly by checking the Error Log and using the **test board UUCSS long** command. Replace any faulty Tone Detector circuit packs and repeat the test. 3. If the test continues to abort, replace the Speech Synthesis circuit pack.
2000 2100	ABORT ABORT	Response to the test request was not received within the allowable time period. Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The 440-Hz tone was not detected by the Tone Detector circuits. 1. If the test fails again, verify all Tone Detector circuit packs in the system are functioning correctly by checking the Error Log and using the **test board UUCSS long** command. Replace any faulty Tone Detector circuit packs and repeat the test. 2. If the test fails again, replace the Speech Synthesis circuit pack.
	PASS	The 440-Hz tone has been detected correctly. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.

Speech Synthesis Memory Test (#166)

The encoded speech for the Speech Synthesis circuit pack is stored in on-board read-only memory (ROM). A checksum is computed for each 32K speech memory block and compared against a known checksum value. If all computed checksum values are successfully compared against the stored checksum values, the test passes. If, while testing the speech complex memory, the on-board microprocessor finds a memory error, the test is terminated and a failure is reported. This type of failure may affect other ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port.

Table 9-587. TEST #166 Speech Synthesis Memory Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
1019	ABORT	Test is already running on a different port, possibly due to background maintenance activity. Only one of these tests may be active on a circuit pack at a time. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The computed checksum from the speech vocabulary ROM did not compare correctly with the stored checksum. This type of failure may cause features using the Speech Synthesis Port's speech services to malfunction and result in degradation of synthesized speech quality ranging from insignificant to major. 1. Replace the circuit pack.
	PASS	The computed checksum values were successfully compared against the stored checksum values. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.

Speech Synthesis SSD Inquiry Test (#167)

This test determines the sanity of the specified port's speech synthesis device (SSD). The on-board microprocessor tests the port's SSD and determines if it is in a sane (test passes) or insane (test fails) condition. Other ports on the Speech Synthesis circuit pack will continue to function correctly during this type of failure.

Table 9-588. TEST #167 Speech Synthesis SSD Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The SSD is insane. 1. Replace the circuit pack.
	PASS	The SSD is sane. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.

Speech Synthesis PSS Handshake Test (#168)

This test verifies control functionality between the on-board microprocessor and programmable speech synthesizer (PSS) controller. A failure occurs if either of the following events occur:

- The on-board microprocessor times out while waiting for the PSS controller to respond.
- An invalid command is received by the on-board microprocessor from the PSS controller.

This type of failure will affect all four ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port.

Table 9-589. TEST #168 Speech Synthesis PSS Handshake Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The on-board microprocessor has timed out while waiting for the PSS controller to respond or an invalid command has been received by the on-board microprocessor from the PSS controller. This type of failure may cause features using the Speech Synthesis Port's speech services to malfunction. 1. Replace the circuit pack.
	PASS	The on-board microprocessor/PSS handshake is working correctly. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.

Speech Synthesis Parameter Update Test (#169)

This test updates the dual-tone multifrequency (DTMF) interdigit time-out parameter used by the Speech Synthesis circuit pack so that it is consistent with that specified by the switch processing element (SPE).

Table 9-590. TEST #169 Speech Synthesis Parameter Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED is off) before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	An internal system error has occurred.
	PASS	The DTMF interdigit time-out parameter has been updated. 1. User-reported troubles should be investigated using other tests and by verifying that other ports on this circuit pack are working correctly.

The SEC-CDR (SEC-CDR Link) maintenance strategy is covered in the PRI-CDR/SEC-CDR (PRI-CDR Link) Maintenance documentation.

SN-CONF (Switch Node Configuration)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SN-CONF	MAJOR	test board UUCSS s	Switch Node Configuration
SN-CONF	MINOR	test board UUCSS[2]	Switch Node Configuration

1. UU is the universal cabinet number (1 for PPN, 2 — 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. If the error and alarm logs display the switch node carrier location UUC, (cabinet and carrier only), run the *long* test sequence on the active SNC in the carrier, (slot 10 or 12). If the error and alarm logs display a circuit pack location, UUCSS, run the *short* test sequence on the alarmed SNI.

A switch node carrier contains:

- Up to 16 Switch Node Interface (SNI) TN573 circuit packs in slots 2 through 9 and slots 13 through 20
- One or two Switch Node Clock (SNC) TN572 circuit packs in slots 10 and 12
- An Expansion Interface (EI) TN570 circuit pack, a DS1 Converter (DS1C) TN574 circuit pack, or no circuit pack in slot 1
- An optional DS1 CONV circuit pack in slot 21

SN-CONF errors and alarms are generated for two types of failures:

1. Failure of a board in the switch node carrier to insert (be detected by software).
2. A problem found by running the Configuration Audit (test #759). Test 759 is executed for either an SNI or SNC circuit pack during scheduled maintenance or as part of the **test board UUCSS s** command.

   For SNI circuit packs, test 759 queries the SNI for SNCs in the same switch node carrier, SNI peers, DS1 CONVs, and EI or SNI neighbors that the SNI can communicate with and compares this data to the administered data.

   For SNC circuit packs, test 759 queries the SNC for SNCs and SNIs in the same switch node carrier that the SNC can communicate with and compares this data to the administered data.

Switch node carriers are part of port network connectivity (PNC). For background information about PNC, refer to the Maintenance Architecture and Hardware Configurations chapters and related maintenance objects.

Error Log Entries and Test to Clear Values

SN-CONF Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS sh r 1
5000(a)	Any	processor route audit (#760)	MINOR	OFF	test board UUCSS l rep 1
6000(b)	1	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6000(b)	2	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6001(c)	Any	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6002(d)	1	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6002(d)	2	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6003(e)	Any	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6004(f)	Any	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6005(g)	Any	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6005(g)	1	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6005(g)	2	configuration audit (#759)	MAJOR	OFF	test board UUCSS rep 1
6006(h)	Any	configuration audit (#759)	MINOR	OFF	test board UUCSS rep 1
6007(i)	Any	configuration audit (#759)	MINOR	OFF	test board UUCSS rep 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. At least one administered circuit pack in this switch node carrier was not inserted, or one or more administered circuit packs in this switch node carrier did not respond to Test 760 with an up-link board insertion message.

   To resolve this error, run test 760 via **test board UUCSS l** for an SNC in the same switch node carrier that has this error.

b. No neighbor link is administered but the SNI has one. If the aux data is 1, the type of neighbor connected is an EI. If the aux data is 2, the type of neighbor connected is an SNI.

   To resolve error type 6000 with aux data 1, refer to FAIL code 133 for test 759. To resolve error type 6000 with aux data 2, refer to FAIL code 134 for test 759.

c. No neighbor link exists between the SNI and its neighbor, but a neighbor link, i.e. fiber link, is administered.

   To resolve this error, refer to FAIL code 135 for test 759.

d. The physical neighbor type does not match administration. If the aux data is 1, the type of neighbor administered is an SNI and the type of neighbor connected is an EI. If the aux data is 2, the type of neighbor administered is an EI and the type of neighbor connected is an SNI.

   To resolve error type 6002 with aux data 1, refer to FAIL code 136 for test 759. To resolve error type 6002 with aux data 2, refer to FAIL code 137 for test 759.

e. The neighbor location does not match administration.

   To resolve this error, refer to FAIL code 138 for test 759.

f. A peer link does not exist to another equipped SNI. The aux data equals the slot number of the SNI to which this SNI or SNC does not have a peer link. To resolve this error, refer to the FAIL code for test 759 corresponding to the aux data on the following table:

Aux Data (slot no.)	Test 759 FAIL Code
2	102
3	103
4	104
5	105
6	106
7	107
8	108
9	109
13	113
14	114
15	115
16	116
17	117
18	118
19	119
20	120

g. A link does not exist to one of the SNCs. If the aux data is not 1 or 2, the link from this SNI to the active SNC does not exist. If the aux data is 1, the link from this SNC to the active SNC does not exist. If the aux data is 2, the link from this SNC to the standby SNC does not exist.

   To resolve this error, refer to FAIL code 112 for test 759.

h. The SNI is administered to be connected to a DS1C but is not.

To resolve this error, refer to FAIL code 139 for test 759.

i. The SNI is connected to a DS1C, but no DS1C is administered.

To resolve this error, refer to FAIL code 140 for test 759.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Configuration Audit* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Configuration Audit (#759)	X	X		ND
Processor Route Audit (#760)		X		ND

1. D = Destructive, ND = Non-destructive

Configuration Audit (#759)

This test is non-destructive.

NOTE:
For descriptions of result codes for this test refer to:

- SNC-BD when the circuit pack tested is a Switch Node Clock (circuit pack slots 10 or 12).
- SNI-BD when the circuit pack tested is a Switch Node Interface (circuit pack slots 2-9 or 13-20).

This test is run via the **test board short** or **test board long** command for SNI circuit packs or SNC circuit packs.

For SNI circuit packs, this test queries the SNI for SNCs in the same switch node carrier, SNI peers, DS1Cs, and EI or SNI neighbors that the SNI can communicate with and compares this data to the administered data.

For SNC circuit packs, this test queries the SNC for SNCs and SNIs in the same switch node carrier that the SNC can communicate with and compares this data to the administered data.

Failures of this test cause entries in the error and alarm logs against Switch Node Configuration (SN-CONF) with the board location of the SNI or SNC.

Incorrectly Connected Administered Fibers

Some physically connected fibers that do not match fiber administration can cause port network problems that are not detected and alarmed by PNC test. The symptoms will usually be phone calls not working correctly, and port network component alarms because of translation mismatches.

This test is unable to detect the case where an SNI is connected to the same type of board (EI or SNI) as administered but located in a different cabinet but the same carrier and same slot as the administered fiber endpoint. The administered fiber endpoint can be viewed with the **list fiber-link** command. This test can only detect if the fiber endpoint connected to the SNI is in a different carrier, slot location than the administered fiber endpoint.

Incorrectly Connected Administered SNI-EI Fibers

If the SNI is connected to the same type of fiber endpoint as the administered fiber endpoint, but the location is the same as administered except for the cabinet, all phone calls will not work correctly; some phone calls will not go through and some phone calls will ring the wrong phone.

The **test led** command can be used in this case to check connectivity.

1. Run the **test led port-network** command on each administered port network and verify that the LEDs on the correct port network are lit.
2. If they are not lit, check that the fiber connections to the port network are consistent with the administered fibers (**list fiber-link**) that does not light the LEDs as expected.
3. Run **test led switch-node** on each administered switch node carrier and verify that the LEDs on the correct carrier are lit.
4. If they are not, check the connectivity to the switch node carrier that does not light the LEDs as expected.

Incorrectly Connected SNI-SNI Fibers between 3 Switch Nodes

If the system has more than 2 switch nodes, SNI-SNI fibers administered between 2 switch nodes could be incorrectly connected to a third switch node. This is a problem that could occur during installation or when inter-switch node fibers are changed. For multiple fibers to a distant switch node (not the PPN switch node), an incorrect connection would not appear as a problem unless this fiber is used for a system-link to a port network connected to the distant switch node. The **status system-link** command can be used to determine the boards in the path from the PPN to a specific port network. A specific SNI-SNI fiber connection must be in the system-link path to be checked with the port network LED test.

Forcing SNI-SNI Fiber Connection

To force an SNI-SNI fiber connection to be used as a system-link remove all SNI-SNI connections except the fiber-link being tested at the distant switch node by removing SNI boards in the distant switch node.

1. Use the **status system-link** command to verify that the fiber selected for test is in the path to the EPN connected to the distant switch node that will be used for the LED test.
2. Run the **test led** sequence to a port network as described above to verify this fiber connection.
3. Repeat the above procedure for each of the SNI-SNI fibers terminating on the distant switch node.

Testing Multiple Fiber Connections

To test multiple fiber connections to a distant switch node:

1. Use the **list fiber-link** command to determine the number of SNI-SNI fibers that are administered and terminate on the distant switch node.
2. Run the **test led port-network** command on a port network connected to the distant switch node and verify the LEDs on the correct port network are lit.
3. Use the **status system-link** command and select the active EI in the port network connected to the distant port network under test. This display will show the path from the PPN and the SNI-SNI fiber being used.
4. If the port network LEDs are not lit, verify that the fiber connections to the port network are consistent with the administration assignments by using the **list fiber-link** command.
5. If the port network LEDs are lit and there are multiple fibers to the distant switch node, remove the SNC that is listed by the **list fiber-link** command for this path.
6. Use the **status system-link** command to determine the new path from the PPN to the distant switch.
7. Run the **test led port-network** command on a port network connected to the distant switch node and verify that the LEDs on the correct port network are lit.
8. Repeat steps 5 — 7 until all SNI-SNI fiber connections to the distant switch have been tested.

Processor Route Audit Test (#760)

This test is non-destructive.

This test sends processor routes to all SNIs and SNCs in the same carrier as the SNC that the **test board UCSS** command was run for. The processor route is used for the boards to send uplink messages to the SPE and gives a sequence of boards for the message to get routed through so that the message ends up at the SPE. If the SNI and SNC boards do not have processor routes, they will not be able to send any in-line errors to the SPE.

When each individual board receives the processor routes, it sends a board insertion message uplink and software inserts that board if it has not already been inserted. Each board is sent either one or two processor routes depending on the configuration.

The **test led** or **list config carrier** command can be used to see whether boards are inserted.

The processor route test is run as part of the long test sequence for SNC boards.

Table 9-591. TEST #760 Processor Route Audit Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-591. TEST #760 Processor Route Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2306	ABORT	None of the circuit packs in this switch node carrier are responding to the processor route messages sent by software. 1. Run the **test led switch-node** for the switch node that this switch node carrier resides in to verify whether the LEDs on any of the boards light. 2. If none of the LEDs light for the boards in this carrier, fix any problems associated with the connectivity of this carrier to the SPE. Use **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	If this test fails, not all of the administered circuit packs in this switch node carrier responded with an up-link board insertion message. Check to see that administered SNI and SNC boards match the physically installed SNI and SNC boards by entering **list config carrier UUC**. The command output will show "NO BOARD" for every board that is administered, but not inserted. ■ If all administered boards are inserted, run this test again. ■ If administration does not match the physical configuration, and is *correct*, insert the missing circuit packs in this switch node carrier. ■ If administration does not match the physical configuration, and is *incorrect*, change the administration and run this test again. ■ If *none* of the administered boards in this switch node carrier were inserted, fix any other SN-CONF errors by following the associated repair procedures for SN- CONF. Use **display errors** with category **pnc** to view SN-CONF errors. Next check if any INLs, LNLs, or RNLs are down with **list sys-link**. If any INLs, LNLs, or RNLs are down, refer to the SYS-LINK section for fixing link problems.
	PASS	If this test passes, all of the administered circuit packs in this switch node carrier were inserted.

SNC-BD (Switch Node Clock Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SNC-BD	MAJOR	test board UUCSS s	SNC Circuit Pack
SNC-BD	MINOR	test board UUCSS s	SNC Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (10 or 12).

The Switch Node Clock (SNC) TN572 circuit pack is part of the Center Stage Switch (CSS) configuration. It resides in a switch node carrier that alone or with other switch nodes make up a CSS. In a high reliability system (duplicated SPE, simplex PNC), each SNC is duplicated such that there are two SNCs on each switch node carrier. In a critical reliability system (duplicated SPE and PNC), each switch node is fully duplicated, and there is one SNC on each switch node carrier. SNCs are placed in slots 10 and 12 of the switch node carrier.

The active SNC communicates with each circuit pack in the switch node carrier over the serial channel bus on the backplane. In addition, the active SNC provides timing to the circuit packs in the switch node carrier via the clock busses. The active SNC uses Timing Priority Number (TPN) links with each Switch Node Interface (SNI) and the other SNC to receive and distribute TPNs. TPNs are used for setting up the correct timing distribution for the switch node carrier. The active SNC receives timing for the switch node carrier from each SNI circuit pack in the carrier and chooses the SNI with the best timing reference for the switch node carrier timing signal the SNC puts out on the clock busses. The timing reference for each SNI is derived from the fiber signal to each SNI. The active SNC chooses the SNI to receive timing from by choosing the SNI with the lowest numbered TPN which means that the SNI is closest to the system timing source. The active SNC also verifies that the SNI reference signal is good before using that SNI as the timing reference for the switch node carrier. The active SNC then supplies this timing over the clock busses on the backplane to all the SNI and SNC circuit packs in the carrier. For more information on timing synchronization including how the SNC fits into the overall synchronization configuration, see the SYNC section.

The SNC circuit packs are associated with three maintenance objects:

- The SNC-BD MO covers general SNC board errors and errors with the serial communication channel between the active and standby SNCs.
- The SNC-LINK MO covers errors between the active SNC and SNIs over the serial channel (aux data is 1). Also, the SNC-LINK MO covers TPN Link errors between the active SNC and SNIs (aux data is 2).
- The SNC-REF MO covers errors the active SNC detects with SNI reference signals.

SNC circuit packs are part of port network connectivity (PNC). For background information about PNC, refer to the Maintenance Architecture and Hardware Configurations chapters.

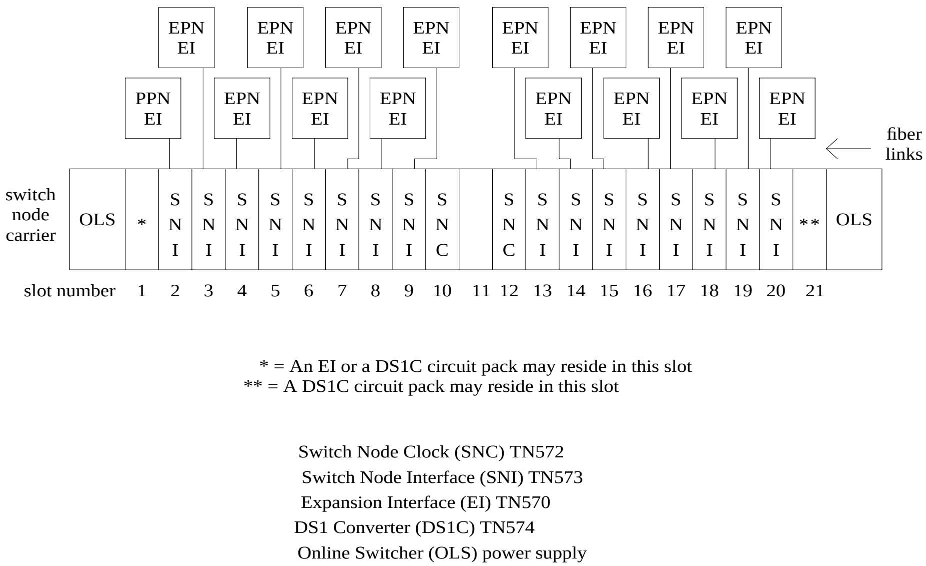

Figure 9-85. A Center Stage Switch Configuration

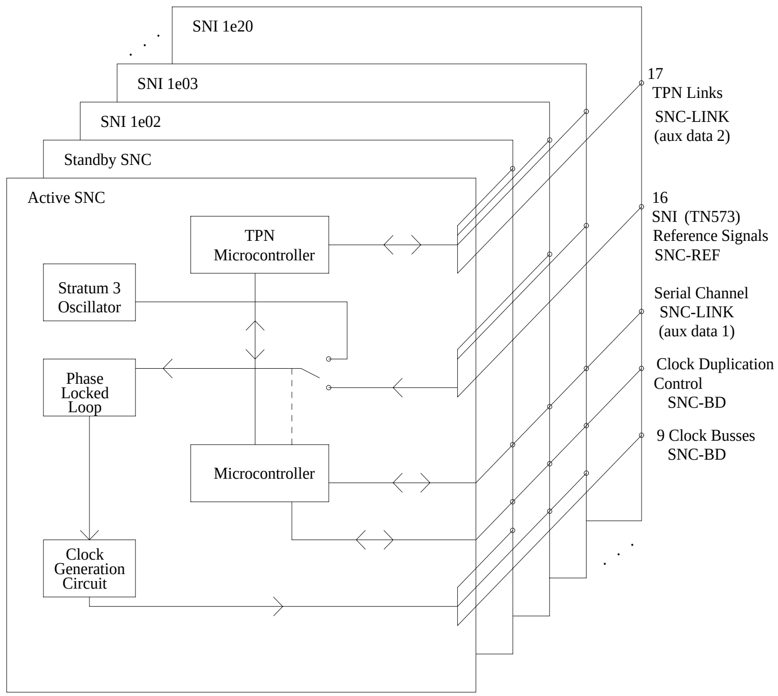

Figure 9-86. SNC Functions

SNC LEDs

SNC circuit packs have the standard red, green and yellow LEDs. The red and green LEDs operate as usual: red means an alarm condition and green indicates maintenance testing in progress. If the yellow LED is lit this indicates that the SNC is the active circuit pack, supplying timing to the carrier. In a high reliability system (duplicated SPE, simplex PNC), the standby SNC on a carrier will be unlit. In a critical reliability system (duplicated PNC), an SNC on a standby switch node carrier will be lit since it is providing timing for the standby carrier.

Clear Firmware-Counters Command

SNC firmware generates error reports independently of technician-demanded tests. Therefore, the **test board** UUCSS clear command will not affect the error status reported by firmware. The **clear firmware-counters** command will clear all firmware-generated errors unconditionally.

The **clear firmware-counters** UUCSS command sends a downlink message to the SNC circuit pack, causing it to clear out its firmware error counters and failure database. Once the firmware failure database is cleared, the failure audit test (#777) will pass. If problems still exist, the firmware will increment its error counters and the failure audit test will begin failing again.

This command should not be used as a replacement for the repair procedures associated with the hardware error log entries. This command may be useful if a problem has been fixed and off-board alarms associated with the problem are still active.

Replacing SNC Circuit Packs

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack. Replacing an SNC on a system with unduplicated SNCs disrupts service.

Standard Reliability System (Simplex SPE, PNC and SNCs)

This procedure is destructive. Any links through the switch node carrier will go down.

1. Pull out the SNC circuit pack to be replaced.
2. Insert a new SNC circuit pack.
3. Wait for the SNC to reset. (The red and green LEDs light and then go out. The yellow LED should be on solid.)
4. **Test alarm long clear** category **exp-intf**. **Do not busyout the Expansion Interface circuit packs.**
5. Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1 CONV-BD alarms to clear, or enter **clear firmware-counters**.

High Reliability System (Duplicated SPE and SNCs, Simplex PNC)

This procedure is non-destructive.

1. If the SNC circuit pack to be replaced is the active SNC in the switch node carrier (yellow LED is on solid), first set the standby SNC to active via the **set switch-node-clock** command.
2. When the SNC circuit pack is in standby mode (yellow LED is off), pull out the SNC circuit pack to be replaced.

3. Insert a new SNC circuit pack.
4. Wait for the SNC to reset. (The red and green LEDs light and then go out.) The yellow LED should be off since the SNC circuit pack is in standby mode.

Critical Reliability System (Duplicated SPE and PNC)

WARNING:

On a system with duplicated PNC, synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WARNING alarm against TDM-CLK with error type 2305. Repairs to standby PNC in this state may disrupt service. Otherwise, if the active PNC is functional, replacement of a standby component will not disrupt service.

STEPS:

Enter **status pnc**	Verify that the component to be replaced is on the standby PNC.
Enter **busyout pnc**	
Enter **busyout board UUCSS**	UUCSS represents the cabinet-carrier-slot address of the circuit pack to be replaced.
Replace the circuit pack	
Enter **release board UUCSS**	**CAUTION:** *Do not busyout any Expansion Interface circuit pack after this point.*
Enter **test alarms long clear** for category **exp-intf**	
Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C alarms to clear, or enter **clear firmware counters <a-pnc or b-pnc>**	Use the letter designation of the pnc which holds the replaced component (the standby pnc).
Enter **status pnc**	If either PNC state-of-health is not "functional", consult the ''PNC-DUP (PNC Duplication)'' section.
Enter **release pnc**	

Error Log Entries and Test to Clear Values

Table 9-592. SNC Board Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS r 1
1(a)	Any	Failure Audit (#777)	MAJOR	ON	test board UUCSS r 1
18(b)	0	busyout board UCSS	WARNING	OFF	release board UCSS
257(c)	Any	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
513(d)	Any	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
769(e)	Any	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
1025(f)	Any	Failure Audit (#777)	MAJOR	ON	test board UUCSS r 1
1281(g)	Any	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
1537(h)	Any	Failure Audit (#777)	MINOR	ON	test board UUCSS r 1
1793(i)	Any	Failure Audit (#777)	MAJOR	ON	test board UUCSS r 1
2049(j)	Any	Failure Audit (#777)	MAJOR	ON	test board UUCSS r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Error type 1 indicates SNC on-board microcontroller error. (This occurs whenever the microcontroller sanity test fails, the ROM has problems, the processor internal or external RAM is faulty, or the firmware instruction test fails. In addition, this error indicates problems with the interrupt capabilities, the dual port RAM and the RTM (Real Time Monitor) interface on the faceplate of the SNC.)

   Replace the SNC circuit pack.

b. This error indicates that the SNC circuit pack has been busied out via the **busyout board UCSS** command. To resolve this error, release the SNC circuit pack via the **release board UCSS** command.

c. These errors occur whenever firmware detects failure of the phase-locked loop, inability to lock, or failure of the clock drivers and the problem is off-board.

   1. Enter **display errors** and if SNC-BD error type 1793 exists in the hardware error log, follow the associated repair procedures for SNC-BD error 1793.

2. Enter **display errors** and if no SNI-BD 1025 errors exist in the error log, replace the active SNC.
3. Enter **display errors** and if any SNI-BD 1025 errors exist in the error log, follow the associated repair procedure in the SNI-BD section for these errors.

d. This error occurs whenever the active SNC determines that there is a problem communicating with the standby SNC via the connecting serial channel.

If the switch node carrier is administered with duplicate SNCs:

1. If the standby SNC (the one with its yellow LED off) has this error, escalate the problem. (**Status switch-node** will also display the active and standby SNCs.)
2. If the system originally had duplicate SNCs and the standby SNC was removed and never replaced and the active SNC has not been reset after the standby SNC was removed, this error will occur.

   If you do not intend to replace the SNC:

   a. Remove the standby SNC from circuit pack administration via **change circuit-pack**.
   b. If the problem persists, replace the active SNC circuit pack.

   Otherwise:

   a. Insert an SNC circuit pack.
3. Check the error log via **display errors**. If SNIs in the switch node carrier also have problems communicating with the active SNC, i.e. error code 257 is logged against SNI-BD, then replace the active SNC.
4. Replace the standby SNC circuit pack.
5. Retry the **test board** command. Check the error log via **display errors**. If this error is still in the error log, replace the active SNC.

If the switch node carrier is administered with only one SNC:

1. If step 2 above does not apply, replace the SNC.

e. This error occurs whenever the standby SNC determines that there is a problem communicating with the active SNC via the connecting serial channel.

1. If the active SNC (the one with its yellow LED on) has this error, escalate the problem. (**Status switch-node** will also display the active and standby SNCs.)
2. Check the error log via **display errors**. If more than one SNI in the switch node carrier has problems communicating with the active SNC, i.e. error code 257 is logged against SNI-BD, then replace the active SNC.

3. If a single SNI has SNI-BD error 257, replace the SNI circuit pack.
4. Replace the standby SNC circuit pack.
5. Retry the **test board** command. Check the error log via **display errors**. If this error is still in the error log, replace the active SNC.

f. This error occurs when the firmware detects problems with the various hardware circuit monitors (e.g. loss of reference monitor) that verify correct operation of the reference links.

   Replace the SNC circuit pack.

g. This error occurs when the firmware detects problems with the interface used to track the status of both SNCs when there are duplicated SNCs in a switch node carrier. When this error occurs, software may have incorrect information from SNC firmware for which SNC is active. Therefore, the yellow LEDs on the SNCs must be checked in the following repair procedure and the **status switch-node** command should not be used when this error type occurs.

   If the switch node carrier has duplicate SNCs:

   1. Replace the SNC that does not have its yellow LED lit.
   2. Retry the **test board** command. Check the error log via **display errors**. If this error is still in the error log, replace the SNC that has its yellow LED lit.

   If the switch node carrier has only one SNC, replace the SNC.

h. This error occurs whenever a loss of signal from the SNC on-board Stratum 3 oscillator is detected by the firmware.

   Replace the SNC circuit pack.

i. These errors occur whenever firmware detects failure of the phase-locked loop, inability to lock, or failure of the clock drivers and the problem is on-board.

   Replace the SNC circuit pack.

   If the error persists, follow normal escalation procedures.

j. This error occurs when the firmware detects problems with the microcontroller used for Timing Priority Number processing.

   Replace the SNC circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *configuration audit* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Configuration Audit (#759)	X	X		ND
Failure Audit(#777)	X	X		ND
Processor Route Audit(#760)		X		ND
SNC On-Board Test(#778)	X	X		ND
TPN Test(#779)	X	X		ND
Switch Node Clock Reset Test(#780)			X	D

1. D = Destructive, ND = Non-destructive

NOTE:
Test #983 is not an actual demand maintenance test. This test number is used to report results of executing of the **clear firmware-counters** command. Refer to error codes for Test #777.

Configuration Audit (#759)

This test is non-destructive.

This test is run via the **test board short** or **test board long** command for SNC circuit packs.

For SNC circuit packs, this test queries the SNC for SNCs and SNIs in the same switch node carrier that the SNC can communicate with and compares this data to the administered data.

Failures of this test cause entries in the error and alarm logs against Switch Node Configuration (SN-CONF) with the board location of the SNC.

Table 9-593. TEST #759 Configuration Audit

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNC circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that this board resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNC may be service interrupting. Refer to the SNC-BD section for the procedure for replacing an SNC. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Check **list fibers** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Table 9-593. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
102	FAIL	The SNC circuit pack cannot communicate with the SNI in slot 2. 1. If a standby SNC (one with its yellow LED off) was tested and resulted in this error code, follow normal escalation procedures. (**status switch-node** will also display the active and standby SNCs.) 2. Use **list configuration carrier** to determine whether an SNI is physically present in slot 2. If the `Vintage` field indicates that a circuit pack is present, proceed to step 3. If the `Vintage` field reports `no board`, do one of the following: ■ If an SNI is not supposed to be installed in slot 2: a. This failure will not affect service. The missing SNI can be removed from administration with **change circuit-pack**. b. If the error persists, reset the active SNC circuit pack with **reset board** UUCSS. If the error still persists, replace the active SNC circuit pack. ■ If an SNI is supposed to be installed in slot 2, insert one. 3. **Display errors** for category **pnc**. If the SNC has SNC-BD error 513, or SNC-LINK errors with aux data 1 pointing to other SNIs besides the one in slot 2, replace the active SNC circuit pack. 4. If SNIs in the same carrier have SNI-BD error 257 logged, (indicating they are having trouble communicating with the SNC), replace the active SNC circuit pack. 5. If the SNC being tested has SNC-LINK error type 1, replace the SNI in slot 2. Replacing an SNI may interrupt service. Refer to the SNI-BD section for the procedure for replacing an SNI. 6. If the SNC being tested still has SNC-LINK error type 1, replace the SNC circuit pack.

Table 9-593. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
112	FAIL	The SNC circuit pack cannot communicate with the other SNC. **If this test was run on the active SNC and if the switch node carrier is administered with duplicate SNCs:** 1. If the system originally had duplicate SNCs and the standby SNC was removed and never replaced, this error will occur. *If you do not intend to replace the SNC:* a. Remove the standby SNC from circuit pack administration via **change circuit-pack**. b. If the problem persists, reset the active SNC circuit pack via **reset board UUCSS**. If the problem persists after the reset, replace the active SNC circuit pack. 2. Check the error log via **display errors**. If SNIs in the switch node carrier also have problems communicating with the active SNC, i.e. error code 257 is logged against SNI-BD, then replace the active SNC. 3. Replace the standby SNC circuit pack. 4. Retry the **test board** command. If this test continues to fail, replace the active SNC. **If this test was run on the active SNC and if the switch node carrier is administered with only one SNC:** 1. Replace the SNC.
112	FAIL *(cont'd.)*	**If this test was run on the standby SNC:** 1. Check the error log via **display errors**. If more than one SNI in the switch node carrier has problems communicating with the active SNC, i.e. error code 257 is logged against SNI-BD, then replace the active SNC. 2. Replace the standby SNC circuit pack. 3. Retry the **test board** command. Check the error log via **display errors**. If this error is still in the error log, replace the active SNC.

Table 9-593. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
113	FAIL	The SNC circuit pack cannot communicate with the SNI in slot 13. 1. If a standby SNC (one with its yellow LED off) was tested and resulted in this error code, follow normal escalation procedures. (**status switch-node** will also display the active and standby SNCs.) 2. Use **list configuration carrier** to determine whether an SNI is physically present in slot 13. If the `Vintage` field indicates that a circuit pack is present, proceed to step 3. If the `Vintage` field reports `no board`, do one of the following: If an SNI is not supposed to be installed in slot 13: a. This failure will not affect service. The missing SNI can be removed from administration with **change circuit-pack**. b. If the error persists, reset the active SNC circuit pack with **reset board** UUCSS. If the error still persists, replace the active SNC circuit pack. If an SNI is supposed to be installed in slot 13, insert one. 3. **Display errors** for category **pnc**. If the SNC has SNC-BD error 513, or SNC-LINK errors with aux data 1 pointing to other SNIs besides the one in slot 13, replace the active SNC circuit pack. 4. If SNIs in the same carrier have SNI-BD error 257 logged, (indicating they are having trouble communicating with the SNC), replace the active SNC circuit pack. 5. If the SNC being tested has SNC-LINK error type 2049, replace the SNI in slot 13. Replacing an SNI may interrupt service. Refer to the SNI-BD section for the procedure for replacing an SNI. 6. If the SNC being tested still has SNC-LINK error type 2049, replace the SNC circuit pack.

<tr><td></td><td>PASS</td><td>The administered data and the circuit packs the SNC can communicate with match.</td></tr>
</table>

Continued on next page

Table 9-593. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	No board was detected by the test. 1. Check that SNC board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use the **reset board** command if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Processor Route Audit Test (#760)

This test is non-destructive.

This test sends processor routes to all SNIs and SNCs in the same carrier as the SNC that the **test board UCSS** command was run for. The processor route is used for the boards to send uplink messages to the SPE and gives a sequence of boards for the message to get routed through so that the message ends up at the SPE. If the SNI and SNC boards do not have processor routes, they will not be able to send any in-line errors to the SPE.

When each individual board receives the processor routes, it sends a board insertion message uplink and software inserts that board if it has not already been inserted. Each board is sent either one or two processor routes depending on the configuration.

Use **test led** or **list config carrier** to see whether boards are inserted.

Table 9-594. TEST #760 Processor Route Audit Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	None of the circuit packs in this switch node carrier are responding to the processor route messages sent by software. 1. Run the **test led switch-node** for the switch node that this switch node carrier resides in to verify whether the LEDs on any of the boards light. 2. If none of the LEDs light for the boards in this carrier, fix any problems associated with the connectivity of this carrier to the SPE. Use the **list fiber link** command to obtain a list of the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	If this test fails, not all of the administered circuit packs in this switch node carrier responded with an up-link board insertion message. Check to see that administered SNI and SNC boards match the physically installed SNI and SNC boards by entering **list config carrier** UUC. The command output will show "NO BOARD" for every board that is administered, but not inserted. ■ If all administered boards are inserted, run this test again. ■ If administration does not match the physical configuration, and is correct, insert the missing circuit packs in this switch node carrier. ■ If *none* of the administered boards in this switch node carrier were inserted, fix any other SN-CONF errors by following the associated repair procedures for SN-CONF. Use **display errors** with category **pnc** to view SN-CONF errors. Next check if any INLs, LNLs, or RNLs are down, refer to the SYS-LINK section for fixing link problems.

Continued on next page

Table 9-594. TEST #760 Processor Route Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	If this test passes, all of the administered circuit packs in this switch node carrier were inserted.
0	NO BOARD	No board was detected by the test. 1. Check that SNC board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use the **reset board** command if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Failure Audit (#777)

This test is non-destructive.

This test queries the SNC for any existing failures and any unacknowledged cleared failure messages. Each failure generates an error and alarm entry against SNC-BD, SNC-LINK, or SNC-REF. An unacknowledged cleared failure message is a message the SNC circuit pack sent to software indicating a previous failure is now gone and the SNC circuit pack did not receive a message from software indicating that the failure message was received by software.

If no failures are detected by the SNC circuit pack, this test will pass.

If this test reports failures, the results screen for the **test board** command will show **FAIL** with no FAIL code. The error log must then be displayed via **display errors** with category PNC to view all SNC related errors: SNC-BD, SNC-LINK, and SNC-REF.

Table 9-595. TEST #777 Failure Audit

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNC circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that this board resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNC may be service interrupting. Refer to the SNC-BD section for the procedure for replacing an SNC. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use the **list fiber link** command to obtain a list of the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.

Continued on next page

Table 9-595. TEST #777 Failure Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The SNC circuit pack reported failures or retransmitted a cleared failure message. 1. Check the error and alarm logs for SNC-BD, SNC-LINK, or SNC-REF entries. Use the **display errors** and **display alarms** commands with category PNC. Fix any problems found by referring to the SNC Board, SNC Link, or SNC Reference Error Log Entries tables in this section and follow the associated repair procedures. 2. If no SNC-BD, SNC-LINK, or SNC-REF errors exist in the error and alarm logs, retry the command.
	PASS	No problems are detected on the board.
0	NO BOARD	No board was detected by the test. 1. Check that SNC board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use the **reset board** command if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

SNC On-Board Test (#778)

This test is non-destructive.

This test queries the SNC circuit pack for status of the background tests run on-board. These background tests include an SNC on-board microcontroller test, clock test, an SNC on-board Stratum 3 oscillator test, and TPN microcontroller test.

Table 9-596. TEST #778 SNC On-Board Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2303	ABORT	The SNC circuit pack responded that the software test requested is not valid. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNC firmware is not able to run the test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNC circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that this board resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNC may be service interrupting. Refer to the SNC-BD section for the procedure for replacing an SNC. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use the **list fiber link** command to obtain a list of the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Table 9-596. TEST #778 SNC On-Board Test — *Continued*

Error Code	Test Result	Description/ Recommendation
101	FAIL	The SNC circuit pack has on-board microcontroller failure.
128	FAIL	The SNC circuit pack has a problem with its clock; firmware has detected a phase-locked loop failure, an inability to lock, or a failure of the clock drivers.
129	FAIL	The SNC circuit pack has a problem with the SNC on-board Stratum 3 oscillator.
130	FAIL	The SNC circuit pack has a problem with the TPN microcontroller. 1. Replace the SNC circuit pack.
	PASS	No problems exist with the on-board functions verified by this test.
0	NO BOARD	No board was detected by the test. 1. Check that SNC board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use the **reset board** command if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

TPN Test (#779)

This test is non-destructive.

This test queries the SNC circuit pack for status of the ROM and internal RAM background tests for the TPN microcontroller.

Table 9-597. TEST #779 TPN Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2302	ABORT	Software received unexpected message data from the SNC circuit pack. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2303	ABORT	The SNC circuit pack responded that the software test requested is not valid. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNC circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-597. TEST #779 TPN Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2306	ABORT	The SNC circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that this board resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNC may be service interrupting. Refer to the SNC-BD section for the procedure for replacing an SNC. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use the **list fiber link** command to obtain a list of the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.
	FAIL	The test failed. Replace the SNC circuit pack.
	PASS	No problems exist with the TPN microcontroller.
0	NO BOARD	No board was detected by the test. 1. Check that SNC board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use the **reset board** command if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Switch Node Clock Reset Test (#780)

This test is destructive.

This test resets the SNC circuit pack via the **reset board UUCSS** command when an SNC circuit pack location is entered. If the system has PNC duplication, the active SNC on the active PNC cannot be reset.

If the SNC is active and the **reset board** command is executed, an SNI in the same carrier as the SNC will be told by software to reset the SNC via the TPN link. If no inserted SNIs in the same carrier as the SNC can successfully reset the SNC, software will send a reset message directly to the SNC. Software first tries to reset the SNC via an SNI in case the SNC is insane because the latter method (sending the reset message directly to the SNC) will not work if the SNC is insane.

If an active SNC is reset and a standby SNC exists in the same switch node carrier, the standby SNC will become active. The **reset board** command should not be used to make a standby SNC active. Instead, the **set switch-node-clock UUCSS** command should be used.

If the SNC is standby and the **reset board** command is executed, the active SNC is told by software to reset the standby SNC via the TPN link.

An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use the **reset board** command if the SNC circuit pack gets into a mode where it cannot communicate with software.

Table 9-598. TEST #780 Switch Node Clock Reset Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2302	ABORT	Software received unexpected message data from the SNC circuit pack. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-598. TEST #780 Switch Node Clock Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2303	ABORT	The SNC circuit pack responded that the software test requested is not valid. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNC circuit pack reponded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNC circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that the SNC resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNC may be service interrupting. Refer to the SNC-BD section for the procedure for replacing an SNC. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Use the **list fiber link** command to obtain a list of the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-598. TEST #780 Switch Node Clock Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The reset message was sent out successfully to the active SNC or to an SNI. A PASS does not necessarily mean the SNC circuit pack was successfully reset. The reset can be verified by checking that the red and green LEDs turn on and then turn off. If an SNC circuit pack fails one of the firmware tests run during its reset sequence, the red LED will stay on and the circuit pack should be replaced.
0	NO BOARD	No board was detected by the test. 1. Check that SNC board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use the **reset board** command if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Clear Firmware Counters (#983)

This test number is used to report unsuccessful results of the **clear firmware-counters** command. This is not an actual demand maintenance test. If the command aborts, refer to the error codes listed for Test #777.

SNC-LINK (Switch Node Clock Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SNC-LINK	MINOR	test board UUCSS s	SNC Link

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (10 or 12).

The SNC-LINK maintenance object reports errors in communications between the active Switch Node Clock and Switch Node Interfaces over the serial channel (aux data 1) and the TPN link (aux data 2). SNC-LINK errors are described on the following pages. For a complete description of SNCs and SNIs, including circuit pack replacement instructions, see maintenance objects SNI-BD and SNC-BD.

Error Log Entries and Test to Clear Values

Table 9-599. SNC-LINK Hardware Error Log Entries

Error Type	Aux Data	SNI Slot[1]	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[2]	0		Any	Any	Any	test board UUCSS r 1
1	1 (a)	2	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
1	2 (b)	2	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
257	1 (a)	3	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
257	2 (b)	3	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
513	1 (a)	4	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
513	2 (b)	4	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1

2561	2 (b)	15	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
2817	1 (a)	16	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
2817	2 (b)	16	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
3073	1 (a)	17	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
3073	2 (b)	17	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
3329	1 (a)	18	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1

Continued on next page

Table 9-599. SNC-LINK Hardware Error Log Entries — *Continued*

Error Type	Aux Data	SNI Slot[1]	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3329	2 (b)	18	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
3585	1 (a)	19	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
3585	2 (b)	19	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
3841	1 (a)	20	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1
3841	2 (b)	20	Failure Audit (#777)	MINOR	OFF	test board UUCSS r 1

1. The location of the SNI with which the SNC cannot communicate.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error occurs whenever the active SNC determines that there is a problem communicating with an SNI circuit pack in the same carrier via the connecting multiprocessor serial channel used for transmitting CSCN messages. The slot location of the SNI with which the SNC cannot communicate is given in Table 9-599.

   1. Check the error log via **display errors**.
   2. If any SNI-PEER errors exist in the hardware error log, follow the associated repair procedures for SNI-PEER errors.
   3. If the SNC has SNC-LINK errors with aux data of 1 against other SNIs and/or has SNC-BD error 513, replace the SNC circuit pack.
   4. If SNIs in the same carrier have SNI-BD error 257 logged indicating they are having trouble communicating with the SNC, replace the SNC circuit pack.
   5. Use **list configuration carrier** to determine whether an SNI is physically present in the slot pointed to by the SNC-LINK error. If the `Vintage` field indicates that a circuit pack is present, proceed to step 6. If the `Vintage` field reports `no board`, do one of the following:
      - If an SNI is not supposed to be installed in this slot:
      - Remove the SNI from circuit pack administration with **change circuit-pack**.
      - If the error remains, readminister the SNI circuit pack and then remove it from administration again.

- If the error still remains, replace the active SNC circuit pack.
- If an SNI should be installed in this slot, but is missing, insert an SNI circuit pack.

6. Replace the SNI that the SNC is complaining about.
7. Retry the command. If this error is still in the error log, continue with the following steps.
8. Replace the SNC circuit pack.
9. If a standby SNC (the one with its yellow LED off) has this error, escalate the problem. (**Status switch-node** will also display the active and standby SNCs.)

b. This error occurs whenever the active SNC determines that there is a problem communicating with an SNI circuit pack in the same carrier via the TPN communication channel. The slot location of the SNI with which the SNC cannot communicate is given in Table 9-599.

1. Check the error log via **display errors**. If more than one SNI in the same carrier have SNI-BD errors with error type 769, replace the SNC.
2. Check the error log via **display errors**. If the SNC has more than one SNC-LINK error with aux data of 2, replace the SNC.
3. Verify that the SNI the SNC is complaining about exists in the slot indicated by the error code. If the SNI does not exist:

   If you do not intend to replace the SNI:

   a. Remove the SNI from circuit pack administration via **change circuit-pack**.
   b. If the error remains, readminister the SNI circuit pack and then remove it from administration again.
   c. If the problem persists, replace the active SNC circuit pack.

   Otherwise:

   a. Insert an SNI circuit pack.

   If this step does not apply, continue with the following steps.

4. Replace the SNI circuit pack that the SNC is complaining about.
5. Retry the command. If this error is still in the error log, continue with the following steps.
6. Replace the SNC circuit pack.
7. If a standby SNC (the one with its yellow LED off) has this error, escalate the problem. (**Status switch-node** will also display the active and standby SNCs.)
8. Retry the command. If this error is still in the error log, escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *configuration audit* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Configuration Audit (#759)	X	X		ND
Failure Audit(#777)	X	X		ND
Processor Route Audit(#760)		X		ND
SNC On-Board Test(#778)	X	X		ND
TPN test(#779)	X	X		ND
Switch Node Clock Reset Test(#780)			X	D

1. D = Destructive, ND = Non-destructive

Refer to maintenance object SNC-BD for descriptions of tests and results.

SNC-REF (Switch Node Clock Reference)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SNC-REF	MAJOR	test board UUCSS s	SNC Reference

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (10 or 12).

The SNC-REF maintenance object reports errors in SNI reference signals detected by the active Switch Node Clock. Descriptions of SNC-REF errors are described on the following pages. For a complete description of SNCs and SNIs, including circuit pack replacement instructions, see maintenance objects SNI-BD and SNC-BD.

Error Log Entries and Test to Clear Value

Table 9-600. SNC Reference Error Log Entries

Error Type	Aux Data	SNI Slot[1]	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[2]	0		Any	Any	Any	test board UUCSS r 1
1(a)	Any	2	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
257(a)	Any	3	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
513(a)	Any	4	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
769(a)	Any	5	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
1025(a)	Any	6	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
1281(a)	Any	7	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
1537(a)	Any	8	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
1793(a)	Any	9	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
2049(a)	Any	13	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
2305(a)	Any	14	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
2561(a)	Any	15	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
2817(a)	Any	16	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
3073(a)	Any	17	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
3329(a)	Any	18	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
3585(a)	Any	19	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1
3841(a)	Any	20	Failure Audit (#777)	MAJOR	OFF	test board UUCSS r 1

1. The slot location of the SNI with which the SNC cannot communicate.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error occurs whenever the active or standby SNC detects problems in its timing reference with an SNI circuit pack in the same carrier. The slot location of the SNI with which the SNC cannot communicate is given in the error table above.

   If duplicated SNCs exist in the carrier:

   1. If the SNCs are duplicated in the carrier, check the error log via **display errors**. If both SNCs have this error, replace the SNI that the SNCs are complaining about.

2. If the error occurred only on the standby SNC and the active SNC in the carrier does not have this error, reset the standby SNC via the **reset board** command. (The active and standby SNCs are displayed via **status switch-node**.) If this error comes back after the standby has been reset, replace the standby SNC.
3. Retry the command. If this error is still in the error log, continue with the following steps.
4. If the active SNC has this error, use the **set switch-node-clock** command to set the standby SNC to active. If the new active SNC had this error, replace the SNI that the SNC is complaining about. Otherwise, replace the SNC that originally had this error.

If only one SNC exists in the carrier:

1. Replace the SNI that the SNC is complaining about.
2. Retry the command. If this error is still in the error log, continue with the following step.
3. Replace the SNC.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *configuration audit* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Configuration Audit (#759)	X	X		ND
Failure Audit(#777)	X	X		ND
Processor Route Audit(#760)		X		ND
SNC On-Board Test(#778)	X	X		ND
TPN test(#779)	X	X		ND
Switch Node Clock Reset Test (#780)			X	D

1. D = Destructive, ND = Non-destructive

Refer to maintenance object SNC-BD for descriptions of tests and results.

SNI-BD (SNI Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
SNI-BD	MAJOR	test board UUCSS s	SNI Circuit Pack
SNI-BD	MINOR	test board UUCSS s	SNI Circuit Pack
SNI-BD	WARNING	test board UUCSS s	SNI Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The TN573 Switch Node Interface (SNI)circuit pack is part of the Center Stage Switch (CSS)configuration. It resides in a switch note carrier that alone or with other switch nodes make up a CSS. SNIs connect to other SNIs or Expansion Interface (EI) circuit packs via fiber links. SNI to EI fiber links are used to connect port networks to a switch node carrier and SNI to SNI fiber links are used as inter-switch node fibers. In critical reliability systems, the fiber link connections are duplicated as part of Port Network Connectivity (PNC) duplication. In standard reliability and high reliability systems, the PNC is not duplicated.

There may be up to 16 SNIs in a switch node carrier. They are located in slots 2 through 9 and slots 13 through 20. Slot 11 in a switch node carrier is not used. One or two TN572 boards (SNCs) must reside in switch node carrier positions 10 and 12. The SNIs connect to other SNIs in the same carrier via the backplane; these connections within the same carrier are referred to as peer-links. Each SNI also connects via an optical fiber or metallic connection to another SNI in another carrier or to an EI in the Processor Port Network (PPN) or in an Expansion Port Network (EPN). These connections are referred to as fiber-links.

The Switch Node Clock (SNC) provides timing for the SNIs in the entire carrier. When two SNCs reside in the same switch node carrier, one is in active mode and one is in standby mode. The yellow LED on the active SNC will be on solid. The yellow LED on the standby SNC will be off. See the SYNC section for an explanation of how SNIs are involved in timing synchronization.

Figure 9-87 shows an unduplicated CSS with one switch node. A single switch node can accommodate up to 16 port networks, including the PPN. A system with two switch nodes can accommodate up to 22 port networks. Figure 9-88 shows a two-switch node CSS with duplicated PNC (four switch node carriers). In this configuration, each PNC (A and B) contains two switch nodes. The cabinet numbers for the switch node carriers are typical cabinet numbers. The EPNs and PPN on the top half of the figure (PNC A) are the same as the EPNs and PPN on the bottom half of the figure (PNC B).

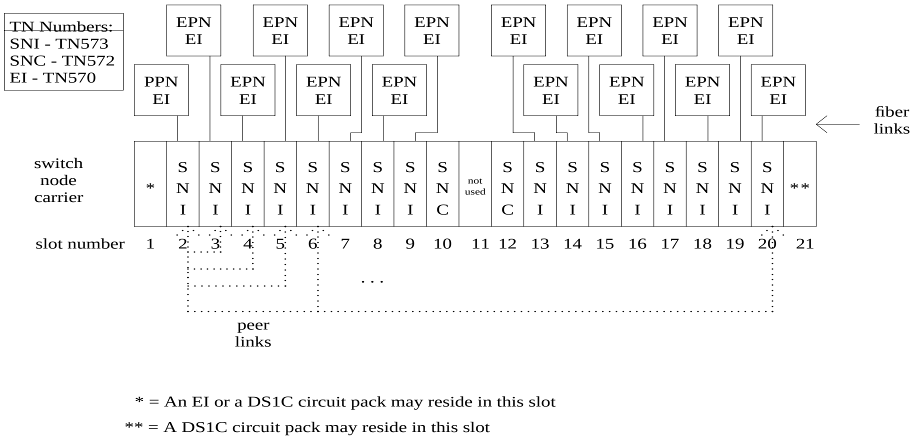

Figure 9-87. CSS Configuration with Simplex PNC and 1 Switch Node Carrier

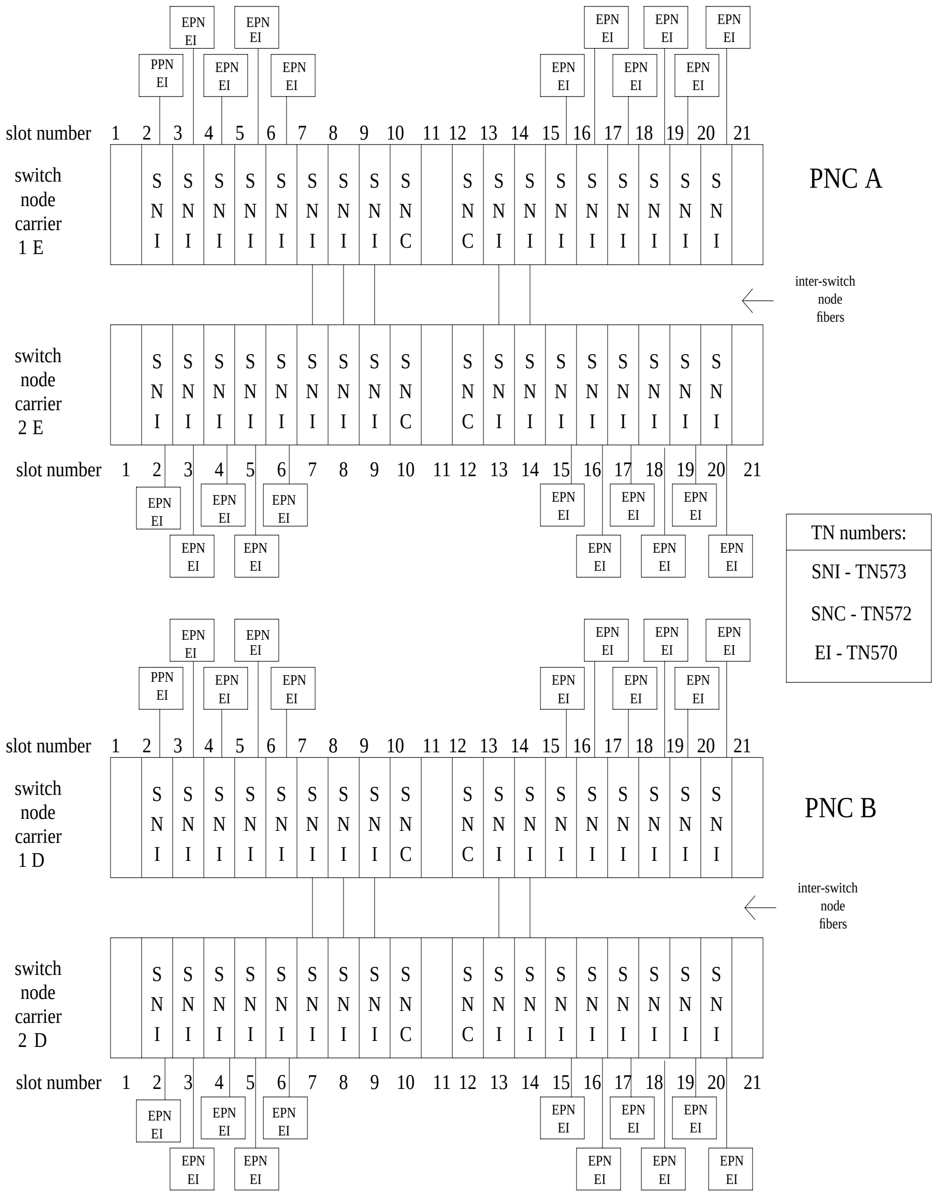

Figure 9-88. CSS Configuration with Duplicated PNC and 4 Switch Node Carriers

Remote EPNs

A DS1 converter complex can used to provide connectivity to a remotely located port network. The DS1 converter complex consists of two TN574 DS1 converter (DS1C) circuit packs connected by 1 to 4 DS1 facilities. The DS1C complex is administered as a fiber link.

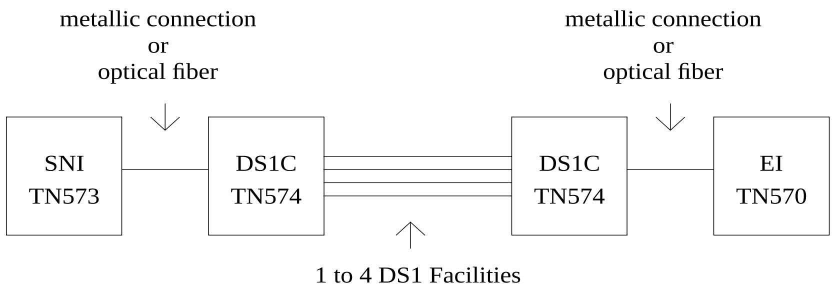

Figure 9-89. Fiber Link over a DS1 Converter Complex

SNI LEDs

The SNI circuit pack has red, green and yellow LEDs. The red and green LEDs have the usual meaning, with red signifying an on-board alarm, and green signifying maintenance testing in progress. The red and green LEDs will come on and then turn off when the circuit pack is reset.

NOTE:
If the red LED is on without any alarms active against the circuit pack, replace the SNI circuit pack. This indicates that SNI firmware has detected a fault and is unable to notify software.

The yellow LED indicates status information as follows:

SNI Yellow LED states

Condition	LED on	LED off
Fiber out of Frame	0.1 second	0.1 second
In frame, No Neighbor [1]	0.5 second	0.5 second
SNI active	solid on	never off
SNI standby	never on	solid off

1. The fiber is in frame but a communication problem exists to the neighbor.

SNI Administration and SNI Board Insertion

The circuit packs in the switch node carrier will not function properly unless administration is performed first. For example, without fiber link administration, phone calls cannot be made through the CSS, CSS circuit packs will not be inserted, and maintenance software cannot test the CSS circuit packs.

For simplex PNC configurations, administration must be done in the following order before SNIs will be inserted:

1. Cabinet Administration: The switch node carriers must be administered into the proper cabinets. When this form is submitted by pressing ENTER, these carriers will be assigned switch node numbers. The **list cabinet** command can then be used to determine the numbers for the carriers of interest.
2. Circuit Pack Administration: All of the boards in the switch node carriers must be administered.
3. Fiber-link Administration: The fibers between the TN570s and the TN573 (or TN573 to TN573) must be administered via the **add fiber-link** command. A DS1C converter complex is added to a fiber link via the **add fiber-link** command also.

For duplicated PNC configurations, administration must be done in the following order before SNIs will be inserted:

1. Activate PNC duplication administration via the **change system-parameters customer-options** command.
2. Cabinet Administration: The switch node carriers and duplicate switch node carriers must be administered into the proper cabinets. When this form is submitted by depressing the "enter" key, these carriers will be assigned switch node numbers. The **list cabinet** command can then be used to determine the numbers for the carriers of interest.
3. Circuit Pack Administration: All of the boards in the switch node carriers must be administered.
4. Fiber-link Administration: The fibers between the TN570s and the TN573 (or TN573 to TN573) must be administered via the **add fiber-link** command. If the system is being changed from a simplex PNC configuration to a duplicate PNC configuration, the **change fiber-link command** can be used to administer the b-pnc fiber link endpoints on the existing fiber links. A DS1C converter complex is added to a fiber link via the **add fiber-link** command also.
5. PNC duplication is enabled via the **change system-parameters duplication** command.

Clear Firmware-Counters Command

SNI firmware generates error reports autonomously. This takes place independently of technician-demanded tests. Therefore, the **test board UUCSS** clear command will not affect the error status reported by firmware. The clear firmware-counters command will clear all firmware-generated errors unconditionally.

The **clear firmware-counters UUCSS** command sends a downlink message to the SNI circuit packs, causing them to clear out their firmware error counters and failure databases. Once the firmware failure database is cleared, the failure audit test (#777) will pass. If problems still exist, the firmware will increment its error counters and the failure audit test will begin failing again.

This command should not be used as a replacement for the repair procedures associated with the hardware error log entries. This command may be useful if a problem has been fixed and off-board alarms associated with the problem are still active.

Replacing an SNI Circuit Pack—Simplex PNC

WARNING:
Do not power down a Switch Node carrier to replace a circuit pack.

WARNING:
Replacing a Switch Node Interface, Switch Node Clock, Expansion Interface or DS1 Converter circuit pack on a simplex system disrupts service. The service effect can range from outage of a single EPN to outage of the entire system.

1.	Enter **busyout board UUCSS**	UUCSS represents the cabinet-carrier-slot address of the circuit pack to be replaced.
2.	Replace the circuit pack	
3.	Wait for the circuit pack to reset	Red and green LEDs will light and then go out.
4.	Enter **release board UUCSS**	**CAUTION:** *Do not busyout any Expansion Interface circuit pack after this point.*
5.	Enter **test alarms long clear** for category **exp-intf**.	
6.	Wait 5 minutes for SNI-BD, FIBER-LK AND DS1C-BD alarms to clear, or enter **clear firmware counters a-pnc**.	

Replacing an SNI Circuit Pack— Duplicated PNC

WARNING:
On a system with duplicated PNC, synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WARNING alarm against TDM-CLK with error type 2305. Repairs to standby PNC in this state may disrupt service. Otherwise, if the active PNC is functional, replacement of a standby component will not disrupt service.

1.	Enter **status pnc**	Verify that the component to be replaced is on the standby PNC.
2.	Enter **busyout pnc**	
3.	Enter **busyout board UUCSS**	UUCSS represents the cabinet-carrier-slot address of the circuit pack to be replaced.

4. Replace the circuit pack

5. Enter **release board UUCSS**

CAUTION:
Do not busyout any Expansion Interface circuit pack after this point.

6. Enter **test alarms long clear** for category **exp-intf**.

7. Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C alarms to clear, or enter **clear firmware counterssp 0 <a-pnc or b-pnc>**.
   Use the letter designation of the pnc which holds the replaced component (the standby pnc).

8. Enter **status pnc**.
   If either PNC state-of-health is not "functional", consult the ''PNC-DUP (PNC Duplication)'' section.

9. Enter **release pnc**.

Switch Node Interface Manual Loop Back Procedure

This procedure is destructive.

This procedure is to be used when an SNI circuit pack cannot be tested by software. This can occur when communication between the switch node carrier and the SPE is down. Before using this procedure, the configuration audit test (#759) should be run on SNI circuit packs where possible via **test board UUCSS s**. Also, the processor route audit test (#760) should be run via the **test board UUCSS long** command for the active SNC in the switch node carrier. If the active SNC is not inserted, test 760 can be run via **test hardware-group pnc P**, where P is **a-pnc** or **b-pnc**.

Before using this procedure, first determine whether more than one SNI is unable to communicate with software. Verify SNI and SNC circuit pack insertion via the **list configuration carrier UUC** command, where UUC is the cabinet and carrier location of a switch node carrier. Check for SNI and SNC insertion for every administered switch node carrier.

If all of the SNIs and SNCs are not inserted ("NO BOARD" is displayed for each board) in the entire PNC (either the a-pnc or the b-pnc), then the link between the PPN EI (on the PNC where SNI and SNC circuit packs did not insert) and the connected SNI is not functioning properly. If this case applies, perform the following steps:

1. Run the **test board UUCSS** command on the PPN EI and fix any problems found.
2. Perform the manual loopback procedure for the PPN EI.

3. Perform the manual loopback procedure for the SNI connected to the PPN EI.
4. Replace the active SNC.

If the system has a two level switch node carrier configuration, i.e. SNI-SNI fiber links exist, and the SNIs and SNCs in the second switch node carrier only (the switch node carrier that has no SNI connected to the PPN EI) are not inserted and at least two SNI-SNI fiber links exist, perform the following steps:

1. Run the **test board UUCSS long** command on the SNIs in the first switch node carrier that are connected to SNIs in the second switch node carrier and fix any problems found.
2. Replace the active SNC.
3. Perform the manual loopback procedure for the SNIs in the second switch node carrier that are connected to SNIs in the first switch node carrier.

If software is unable to communicate with an EPN EI but can communicate with the connected SNI:

1. Run the **test board UUCSS long** command on the connected SNI and fix any problems found.
2. Perform the manual loopback procedure for the EPN EI.

   When the connection to the SNI circuit pack is via fiber, a short length of optical fiber is required for this procedure. If a metallic cable is used in the connection, the metallic connector must be removed from the back of the carrier, and a lightwave transceiver connected in its place. The short length of optical fiber can then be used.

   If this procedure is run on both endpoints on a fiber link (Expansion Interface circuit packs or Switch Node Interface circuit packs), and both check out fine, then the failure is most likely in the connection (fiber or metallic) itself if neither endpoint circuit pack is busied out, but the link remains inactive.

   1. Busyout the circuit pack (Expansion Interface or SNI) using the **busyout board UUCSS** command.
   2. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the circuit pack (Expansion Interface or Switch Node Interface) slot.

      NOTE:
      Note which is the transmit fiber and which is the receive fiber for proper re-connection at the end of this procedure. The fiber connected to the transmit side of the lightwave transceiver on one circuit pack should be connected to the receive side of the lightwave transceiver on the circuit pack on the opposite end of the fiber.

3. Using a spare fiber jumper cable, interconnect the transmit and receive jacks of the lightwave transceiver as shown in Figure 9-90.

   NOTE:
   Make sure that the total length of the fiber jumper cable does not exceed the maximum length recommended for the fiber link connections between cabinets. This is necessary so that the testing of the Expansion Interface or SNI circuit pack is done within connectivity guidelines so that test results are not influenced due to the cable length not meeting requirements.

4. Go to the front of the cabinet and inspect the yellow LED.
   - If the yellow LED flashes on at a rate of once per second, the (Expansion Interface or Switch Node Interface) circuit pack or transceiver should be replaced.
   - If the yellow LED flashes on at a rate of five times per second, the circuit pack (Expansion Interface or Switch Node Interface) or the lightwave transceiver may need replacement. This condition may also be due to a faulty system clock on the network containing the Expansion Interface circuit pack or in the switch node carrier containing the SNI.
   - If the yellow LED was blinking before starting this procedure and the yellow LED is not blinking now, this circuit pack (Expansion Interface or Switch Node Interface) and the lightwave transceiver are functioning properly.
5. Replace faulty component(s) and reconnect the original fiber. Be sure to reconnect the fibers properly as noted in Step 2.
6. Release Expansion Interface circuit pack or Switch Node Interface circuit pack with the **release board UUCSS** command.

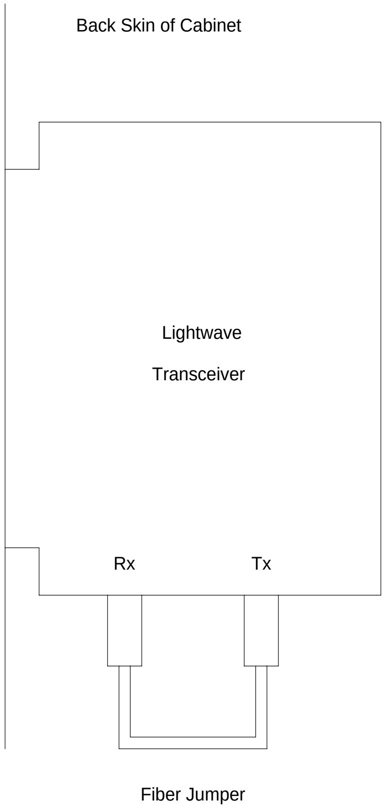

Figure 9-90. Interconnection of Lightwave Transceiver Transmit/Receive Jacks

Error Log Entries and Test to Clear Values

Table 9-601. SNI Board Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS r 1
1(b)	any	failure audit (#777) (a)	MAJ/MIN/WAR	ON	test board UUCSS r 1
18(c)	0	busyout board UUCSS	WARNING	OFF	release board UUCSS
125(d)		None	MINOR	ON	
257(e)	any	failure audit (#777) (a)	MAJ/MIN/WAR	OFF	test board UUCSS r 1
513(f)	any	failure audit (#777) (a)	MAJ/MIN/WAR	OFF	test board UUCSS r 1
769(g)	any	failure audit (#777) (a)	MAJ/MIN/WAR	OFF	test board UUCSS r 1
1025(h)	any	failure audit (#777) (a)	MAJ/MIN/WAR	ON/OFF	test board UUCSS r 1
1281(i)	any	failure audit (#777) (a)	MAJ/MIN/WAR	ON	test board UUCSS r 1
1537(j)	any	failure audit (#777) (a)	MAJ/MIN/WAR	OFF	test board UUCSS r 1
2561(k)	any	failure audit (#777) (a)	MAJ/MIN/WAR	ON	test board UUCSS r 1
2817(l)	any	failure audit (#777) (a)	MAJ/MIN/WAR	ON	test board UUCSS r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The first time you see an SNI-BD error in the error log, run the **test board UUCSS** command. If the failure audit test (#777) fails, enter **display errors** for this SNI circuit pack and continue with the associated repair procedures for SNI-BD errors.

b. This error indicates a problem that the SNI may have trouble communicating with all of the other SNI and SNC circuit packs in the switch node carrier.

   1. Replace the SNI circuit pack.

c. This error indicates that the SNI circuit pack has been busied out via the **busyout board UUCSS** command. To resolve this error, release the SNI circuit pack via the **release board UUCSS** command.

d. The SNI circuit pack is incompatible with the TN1654 DS1 Converter board. A TN573B or later suffix SNI board must be used when connecting to a TN1654 DS1 Converter board. Replace with a newer suffix.

e. This error indicates that the SNI cannot communicate with the active SNC.

   1. Check the error log via **display errors** for other SNI circuit packs with the 257 SNI-BD error. If other SNI circuit packs in the same switch node carrier have error 257, then replace the active SNC.
   2. Replace this SNI.
   3. Replace the active SNC in the same switch node carrier.
   4. Enter **display errors** and if this error is still in the error log, follow normal escalation procedures.

f. This error indicates that the SNI cannot communicate with the DS1C.

   1. Perform the Fiber Fault Isolation Procedure described in Chapter 5.

g. This error indicates a failure communicating synchronization control data with the active SNC.

   Look at all of the SNI-BD errors in the log via **display errors** and **display alarms** to determine whether to follow procedure 1 or procedure 2. See the table below which lists pairs of SNIs that are considered to be adjacent. Use Procedure 2 if either of the following two conditions is present:

   — At least one pair of adjacent SNIs in this carrier has Error 769 with an off-board alarm logged against both SNIs in the pair.

   — The active SNC in this carrier has error 257.

   If neither of the above is true, follow Procedure 1.

Adjacent SNI Slot Numbers
2 & 3
4 & 5
6 & 7
8 & 9
13 & 14
15 & 16
17 & 18
19 & 20

Procedure 1 (suspect TPN link or clock generation out of lock problem):

1. Enter **display alarms** and **display errors** and follow the procedures for any on-board SNI-BD error and alarm entries.
2. If more than one SNI circuit pack in the same switch node carrier has SNI-BD error 769 with an off board alarm, replace the active SNC in the same carrier.
3. Replace this SNI.
4. Replace the active SNC in the same carrier.

Procedure 2 (suspect clock generation out of lock problem):

1. If only one SNC exists in this switch node carrier, replace the SNC. If two SNCs exist in this switch node carrier, perform the following steps:
   a. Set the standby SNC to active by running the **set switch-node-clock UUCSS** command with the standby SNC's location.
   b. If the problem goes away, replace the SNC that was previously active. Then set the SNC that was just replaced to active via the **set switch-node-clock UUCSS** command. If the problem returns, assume that the SNC that was just replaced was not at fault and go to step 2 below.
   c. If the problem persists, switch back to the previously active SNC via the **set switch-node-clock** command and go to step 2 below.
2. Replace the leftmost SNI from the pair of adjacent SNIs.
3. Replace the rightmost SNI from the pair of adjacent SNIs.
4. If none of the above steps cleared this error, this could be a switch node carrier backplane problem.

h. This error indicates a failure communicating synchronization control data over the fiber-link.

If the error is logged as an on-board error:

1. Replace the SNI circuit pack.

If the error is logged as an off-board error:

1. Enter **display errors** and follow the associated repair procedures for FIBER-LK errors.
2. Replace the SNI with this error.

3. Replace the other endpoint of the fiber-link if no DS1C complex is administered on the fiber-link (use **list fiber-link** to determine whether a DS1C complex is administered). If a DS1C complex is administered on the fiber-link, replace the circuit packs in this order:

   i . Replace the DS1C circuit pack connected to this SNI.

   ii.. Replace the other DS1C circuit pack.

   iii.. Replace the other endpoint of the fiber-link.

i. This error indicates a processor complex failure.

   1. Replace the SNI circuit pack.

j. This error indicates that excessive slips have occurred.

   Follow the steps for diagnosing synchronization problems when slips have occurred in the SYNC section.

k. This error indicates that the SNI cannot communicate with its neighbor. The SNI is at fault.

   1. Replace the SNI circuit pack.

l. This error indicates that the SNI cannot communicate with one of its peers. The SNI is at fault.

   1. Replace the SNI circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Configuration Audit* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Configuration Audit (#759)	X	X		ND
Failure Audit(#777)	X	X		ND
Fiber Out of Frame Query(#989)	X	X		ND
Packet Neighbor Test(#767)	X	X		ND
Circuit Path Test(#755)	X	X		ND
Destructive Facility Test(#757)		X		D
Off-board Destructive Facility Test(#756)		X		D
Switch Node Interface Reset Test(#761)			X	D

1. D = Destructive, ND = Non-destructive

NOTE:
Test #982 is not an actual demand maintenance test. This test number is used to report results of executing of the **clear firmware-counters** command. Refer to error codes for Test #777.

SNI Circuit Path Test (#755)

This test is non-destructive. This test performs a non-destructive test of the circuit path.

Table 9-602. TEST #755 SNI Circuit Path Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2302	ABORT	Software received incorrect message data from the SNI circuit pack. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2303	ABORT	The SNI circuit pack responded that software test requested is not valid. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2306	ABORT	The SNI circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that the SNI resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Check **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries. 4. Follow the procedure described above, SNI Manual Loopback to determine whether the circuit pack or the fiber connection is faulty.

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
102	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 2 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 2. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 1. If other SNI circuit packs have SNI-PEER error type 1, then replace the SNI in slot 2. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 1 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 2.
103	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 3 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 3. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 257. If other SNI circuit packs have SNI-PEER error type 257, then replace the SNI in slot 3. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 257 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 3.

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
104	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 4 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 4. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 513. If other SNI circuit packs have SNI-PEER error type 513, then replace the SNI in slot 4. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 513 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 4.
105	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 5 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 5. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 769. If other SNI circuit packs have SNI-PEER error type 769, then replace the SNI in slot 5. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 769 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 5.

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
106	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 6 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 6. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 1025. If other SNI circuit packs have SNI-PEER error type 1025, then replace the SNI in slot 6. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 1025 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 6.
107	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 7 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 7. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 1281. If other SNI circuit packs have SNI-PEER error type 1281, then replace the SNI in slot 7. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 1281 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 1. Replace this SNI. 2. Replace the SNI in slot 7.

Continued on next page

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
108	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 8 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 8. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 1537. If other SNI circuit packs have SNI-PEER error type 1537, then replace the SNI in slot 8. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 1537 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 8.
109	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 9 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 9. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 1793. If other SNI circuit packs have SNI-PEER error type 1793, then replace the SNI in slot 9. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 1793 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 9.

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
117	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 17 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 17. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 3073. If other SNI circuit packs have SNI-PEER error type 3073, then replace the SNI in slot 17. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 3073 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 17.
118	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 18 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 18. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 3329. If other SNI circuit packs have SNI-PEER error type 3329, then replace the SNI in slot 18. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 3329 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 18.

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
119	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 19 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 19. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 3585. If other SNI circuit packs have SNI-PEER error type 3585, then replace the SNI in slot 19. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 3385 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 19.
120	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 20 over the circuit path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 20. Use **display errors** to find any SNI-BD errors and check **display alarms** to see whether the errors have on-board alarms. Then follow the associated repair procedures for SNI-BD. 2. Check the error log via **display errors** for other SNI circuit packs with SNI-PEER error type 3841. If other SNI circuit packs have SNI-PEER error type 3841, then replace the SNI in slot 20. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 3841 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. Proceed as follows: 3. Replace this SNI. 4. Replace the SNI in slot 20.

Continued on next page

Table 9-602. TEST #755 SNI Circuit Path Test — *Continued*

Error Code	Test Result	Description/ Recommendation
122	FAIL	The SNI circuit pack cannot communicate with its neighbor via the circuit path. 1. Fix any on-board errors (SNI-BD, EXP-INTF, and/or DS1C-BD) against the components of this fiber link by using **display errors** and **display alarms** and following the associated repair procedures. (Use the **list fiber-link** command to find the fiber link associated with this SNI. The **display fiber-link** command can then be used to find the endpoints of the fiber link and the DS1C circuit pack locations if this fiber link has a DS1 Converter Complex administered.) 2. Enter **display errors** and follow the associated repair procedures for any FIBER-LK entries for the fiber this SNI is administered on. Check **list fiber-link** to determine the administered fiber. 3. If this fiber link has a DS1 converter complex administered, enter **display errors** and **display alarms** and follow the associated repair procedures for any off-board DS1C-BD or DS1-FAC entries for either of the DS1C boards administered or for the DS1 facilities associated with either of the DS1C boards administered. 4. Replace this SNI.
	PASS	The SNI passed the sni circuit path test.
0	NO BOARD	No board was detected by the test. 1. Check that board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

SNI Off-board Destructive Facility Test (#756)

This test is destructive.

The SNI runs a destructive looparound of the off-board and on-board looparounds. This test returns the result of the off-board looparound, while test 757 returns the result of the on-board looparound.

Table 9-603. TEST #756 SNI Off-Board Destructive Facility Test

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The system will not allow this test to be run because the SNI circuit pack has not been busied out. Busy out the SNI circuit pack with **busyout board**. Repeat the **test board UUCSS long** command.
1415	ABORT	The lightwave transceiver is not present. 1. If a lightwave transceiver is not supposed to be present, do nothing. For example, an SNI connected to a DS1C circuit pack or an SNI with a metallic connection does not have a lightwave transceiver. This test can only be run when a lightwave transceiver exists. 2. Otherwise, check the lightwave transceiver connections. 3. If OK, replace the lightwave transceiver. If a fiber out of frame condition exists and lightwave transceivers are used, check that the lightwave transceivers are of the same type, that is, both are 9823a or both are 9823b. If they are not the same type, replace one of the lightwave transceivers: ■ 9823a is used for distances up to 4900 feet. ■ 9823b is used for distances up to 25,000 feet. 4. If the test continues to abort, replace the SNI circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-603. TEST #756 SNI Off-Board Destructive Facility Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2304	ABORT	SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNI circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that the SNI resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Check **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries. 4. Follow the procedure described above, SNI Manual Loopback to determine whether the circuit pack or the fiber connection is faulty.
127	FAIL	The data is not correctly looped around. 1. Check the lightwave transceiver or metallic physical connections. 2. If connections OK, replace the lightwave transceiver or the metallic interconnect. 3. If the test still fails, replace the SNI circuit pack.

Continued on next page

Table 9-603. TEST #756 SNI Off-Board Destructive Facility Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	No problems associated with this test are detected on the SNI.
0	NO BOARD	No board was detected by the test. 1. Check that board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

SNI Destructive Facility Test (#757)

This test is destructive.

The SNI runs a destructive looparound of the off-board and on-board looparounds. This test returns the result of the on-board looparound, while test 756 returns the result of the off-board looparound.

Table 9-604. TEST #757 SNI Destructive Facility Test

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The system will not allow this test to be run because the SNI circuit pack has not been busied out. Busy out the SNI circuit pack with **busyout board**. Repeat the **test board UUCSS long** command.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Error Code	Test Result	Description/ Recommendation
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNI circuit pack is not responding to software test requests. 1. Run the **test led switch-node** for the switch node that the SNI resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Check **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries. 4. Follow the procedure described above, SNI Manual Loopback to determine whether the circuit pack or the fiber connection is faulty.
127	FAIL	The data is not correctly looped around. 1. Replace the SNI circuit pack.
	PASS	No problems associated with this test are detected on the SNI.

Continued on next page

Table 9-604. TEST #757 SNI Destructive Facility Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	No board was detected by the test. 1. Check that board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Configuration Audit (#759)

This test is non-destructive.

NOTE:
For descriptions of result codes for this test refer to:

- SNC-BD when the circuit pack tested is a Switch Node Clock (circuit pack slots 10 or 12).
- SNI-BD when the circuit pack tested is a Switch Node Interface (circuit pack slots 2-9 or 13-20).

This test is run via the **test board short** or **test board long** command for SNI circuit packs or SNC circuit packs.

For SNI circuit packs, this test queries the SNI for SNCs in the same switch node carrier, SNI peers, DS1Cs, and EI or SNI neighbors that the SNI can communicate with and compares this data to the administered data.

For SNC circuit packs, this test queries the SNC for SNCs and SNIs in the same switch node carrier that the SNC can communicate with and compares this data to the administered data.

Failures of this test cause entries in the error and alarm logs against Switch Node Configuration (SN-CONF) with the board location of the SNI or SNC.

Incorrectly Connected Administered Fibers

Some physically connected fibers that do not match fiber administration can cause port network problems that are not detected and alarmed by PNC tests. The symptoms will usually be many phone calls not working correctly, and port network component alarms because of translation mismatches.

This test is unable to detect the case where an SNI is connected to the same type of board (EI or SNI) as administered but located in a different cabinet but the same carrier and same slot as the administered fiber endpoint. The administered fiber endpoint can be viewed with the **list fiber-link** command. This test can only detect if the fiber endpoint connected to the SNI is in a different carrier, slot location than the administered fiber endpoint.

Incorrectly Connected Administered SNI-EI Fibers

If the SNI is connected to the same type of fiber endpoint as the administered fiber endpoint, but the location is the same as administered except for the cabinet, many phone calls will not work correctly; some phone calls will not go through and some phone calls will ring the wrong phone.

The **test led** command can be used in this case to check connectivity.

1. Run the **test led port-network** command on each administered port network and verify that the LEDs on the correct port network are lit.
2. If they are not lit, check that the fiber connections to the port network are consistent with the administered fibers (**list fiber-link**) that does not light the LEDs as expected.
3. Run **test led switch-node** on each administered switch node carrier and verify that the LEDs on the correct carrier are lit.
4. If they are not, check the connectivity to the switch node carrier that does not light the LEDs as expected.

Incorrectly Connected Administered SNI-SNI Fibers between 3 Switch Nodes

If the system has more than 2 switch nodes, SNI-SNI fibers administered between 2 switch nodes could be incorrectly connected to a third switch node. This is a problem that could occur during installation or when inter-switch node fibers are changed. For multiple fibers to a distant switch node (not the PPN switch node), an incorrect connection would not appear as a problem unless this fiber is used for a system-link to a port network connected to the distant switch node. The **status system-link** command can be used to determine the boards and fiber-links in the path from the PPN to a specific port network. A specific SNI-SNI fiber connection must be in the system-link path to be checked with the port network LED test.

One method to force an SNI-SNI fiber connection to be used as a system-link is to physically remove all SNI-SNI connections except the fiber-link being tested at the distant switch node by physical removing SNI boards in the distant SWItch node.

1. Use the **status system-link** command to verify that this fiber selected for test is in the path to the EPN connected to the distant switch node that will be used for the LED test.
2. Run the **test led** sequence to a port network as described above to verify this fiber connection.
3. Repeat this procedure for each of the other SNI-SNI fibers terminating on this distant switch node.

Another method for testing multiple fiber connections to a distant switch node is described below.

1. Use the **list fiber-link** command to determine the number of SNI-SNI fibers that are administered and terminating on this switch node.
2. Run the **test led port-network** command on a port network connected to this distant switch node and verify that the LEDs on the correct port network are lit.
3. Use the **status system-link** command and select the active EI in the port network connected to the distant switch node being tested. This display will show the path from the PPN and the SNI-SNI fiber being used in this path.
4. If they are not lit, check that the fiber connections to the port network are consistent with the administered fibers (**list fiber-link**) that does not light the LEDs as expected.
5. If the port network LEDs are lit and we have multiple SNI-SNI fibers to this distant switch node, physically remove the SNI that is listed in this path.
6. Use the **status system-link** command to determine the new path from the PPN to the this distant switch.
7. Run the **test led port-network** command on a port network connected to the distant switch node and verify that the LEDs on the correct port network are lit.
8. Continue with steps 5 — 7 above until the last SNI-SNI fiber to this distant switch node has been tested.

Table 9-605. TEST #759 Configuration Audit

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNI circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that this board resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Check **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries. 4. Follow the procedure described above, SNI Manual Loopback to determine whether the circuit pack or the fiber connection is faulty.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.

Retry the command.
115	FAIL	The SNI circuit pack cannot communicate with the equipped SNI in slot 15. 1. Perform the Fiber Fault Isolation Procedure described in Chapter 5. This will resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER error type 2561, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested has SNI-PEER error type 2561, replace the SNI in slot 15. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. Retry the command.
116	FAIL	The SNI circuit pack cannot communicate with the equipped SNI in slot 16. 1. Perform the Fiber Fault Isolation Procedure described in Chapter 5. This will resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER error type 2817, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested has SNI-PEER error type 2817, replace the SNI in slot 16. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. Retry the command.

Table 9-605. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
117	FAIL	The SNI circuit pack cannot communicate with the equipped SNI in slot 17. 1. Perform the Fiber Fault Isolation Procedure described in Chapter 5. This will resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER error type 3073, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested has SNI-PEER error type 3073, replace the SNI in slot 17. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. Retry the command.
118	FAIL	The SNI circuit pack cannot communicate with the equipped SNI in slot 18. 1. Perform the Fiber Fault Isolation Procedure described in Chapter 5. This will resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER error type 3329, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested has SNI-PEER error type 3329, replace the SNI in slot 18. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. Retry the command.
119	FAIL	The SNI circuit pack cannot communicate with the equipped SNI in slot 19. 1. Perform the Fiber Fault Isolation Procedure described in Chapter 5. This will resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER error type 3585, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested has SNI-PEER error type 3585, replace the SNI in slot 19. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. Retry the command.

Table 9-605. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
120	FAIL	The SNI circuit pack cannot communicate with the equipped SNI in slot 20. 1. Perform the Fiber Fault Isolation Procedure described in Chapter 5. This will resolve multiple SNI-PEER errors. 2. If the SNI being tested has SNI-PEER error type 3841, replace the SNI being tested. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. To view SNI-PEER errors, use the **display errors** command with category PNC-PEER. Retry the command. 3. If the SNI being tested has SNI-PEER error type 3841, replace the SNI in slot 20. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. Retry the command.
133	FAIL	No neighbor link is administered, but the SNI has an EI neighbor. 1. Administer the SNI on a fiber link to the EI neighbor it is connected to via the **add fiber-link next** command. Or remove both fiber endpoints (i.e., this SNI and its EI neighbor) and remove the fiber endpoints from circuit pack administration via **change circuit-pack**.
134	FAIL	No neighbor link is administered, but the SNI has an SNI neighbor. 1. Administer the SNI on a fiber link to the SNI neighbor it is connected to via the **add fiber-link next** command. Or remove both fiber endpoints (i.e., this SNI and its SNI neighbor) and remove the fiber endpoints from circuit pack administration via **change circuit-pack**.
135	FAIL	The SNI circuit pack cannot communicate with its neighbor. The SNI has an administered neighbor, but cannot communicate with its neighbor. 1. Check if the administered neighbor is inserted. If not, insert the neighbor circuit pack. 2. Perform the Fiber Fault Isolation Procedure described in Chapter 5.
136	FAIL	The SNI's administered neighbor does not match the physical neighbor connected. The type of neighbor administered is an SNI and the type of neighbor physically connected is an EI. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered.

Continued on next page

Table 9-605. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
137	FAIL	The SNI's administered neighbor does not match the physical neighbor connected. The type of neighbor administered is an EI and the type of neighbor physically connected is an SNI. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered.
138	FAIL	The physical neighbor location does not match administered neighbor location. The carrier and slot of the administered neighbor do not match the carrier and slot of the physical neighbor. Enter **list fiber-link** and verify that the fiber optic cable and metallic cable connections are installed as administered. If the problem does not seem to be caused by a physical connection problem or an administration problem, replace the neighbor circuit pack. It is possible for the neighbor circuit pack to have a hardware problem that causes it to report a wrong angel address (physical carrier/slot address) to software.
139	FAIL	The SNI is administered to be connected to a DS1C but is not physically connected to a DS1C. *If a DS1C is not supposed to be connected to this SNI*, change administration to remove the DS1 converter complex from the fiber link associated with this SNI by: 1. Determine which fiber that this SNI is an endpoint of by checking **list fiber-link**. 2. Remove this fiber with the **remove fiber-link** command. 3. Add the fiber back via **add fiber-link**, and do not administer the DS1 converter complex at this time.
140	FAIL	The SNI is physically connected to a DS1C but is not administered to be connected to a DS1C. **Either** add the DS1 converter complex to the fiber that this SNI is associated with by: 1. Determine which fiber that this SNI is an endpoint of by checking **list fiber-link**. 2. Remove this fiber with the **remove fiber-link** command. 3. Add the fiber back via **add fiber-link**, and at this time also administer the DS1 converter complex. **Or**: 1. Remove the DS1C connection and connect the SNI directly to its administered fiber endpoint. 2. Verify that the fiber optic cable and metallic cable connections are installed as administered by entering **list fiber-link**.

Continued on next page

Table 9-605. TEST #759 Configuration Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The administered data and the circuit packs the SNI can communicate with match.
0	NO BOARD	No board was detected by the test. 1. Check that board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Switch Node Interface Reset Test (#761)

This test is destructive.

This test resets the SNI circuit pack via the **reset board UUCSS** command when an SNI circuit pack location is entered. The SNI is reset via the active SNC circuit pack in the carrier. If the SNI is connected to the PPN EI, the SNI is reset via its PPN EI neighbor. If an SNI with an EPN EI or another SNI as its neighbor cannot be reset via the active SNC, i.e., if no software communication exists between the active SNC and the SPE, an attempt will be made to reset the SNI via its neighbor.

An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software.

If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems.

Table 9-606. TEST #761 Switch Node Interface Reset Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2302	ABORT	Software received incorrect message data from the SNI circuit pack. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2303	ABORT	The SNI circuit pack responded that the software test requested is invalid. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNI circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that the SNI resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Check **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries. 4. Follow the procedure described above, SNI Manual Loopback to determine whether the circuit pack or the fiber connection is faulty.

Continued on next page

Table 9-606. TEST #761 Switch Node Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2316	ABORT	The reset of the SNI circuit pack was attempted via the connected DS1C circuit pack. This ABORT code indicates that the fiber is not administered, but in this particular case it also indicates a software problem. 1. Retry the command at 1-minute intervals a maximum of 1 time.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	The reset message was sent out successfully to the active SNC or to the SNI's neighbor. A PASS does not necessarily mean the SNI circuit pack was successfully reset. The reset can be verified by checking that the red and green LEDs turn on and then turn off. If an SNI circuit pack fails one of the firmware tests run during its reset sequence, the red LED will stay on and the circuit pack should be replaced.
0	NO BOARD	No board was detected by the test. 1. Check that board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Packet Neighbor Link Test (#767)

This test is non-destructive.

This test checks the packet path of the neighbor circuit pack and the peer circuit packs. A packet is sent from the SNI being tested to the peer SNIs and to the neighbor EI or SNI. If the other EI or SNI sends the same data back in the packet, this test passes. Otherwise, this test fails.

Table 9-607. TEST #767 Packet Neighbor Link Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2302	ABORT	Software received incorrect message data from the SNI circuit pack. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2303	ABORT	The SNI circuit pack responded that the software test requested is invalid. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNI firmware is not able to run the test. For this particular test, the SNI circuit pack must be able to communicate with its neighbor. 1. Verify that the SNI can communicate with its neighbor by checking the yellow LED of the SNI to make sure the SNI is in frame or by running the **test board** command for the SNI and checking test 989 for fiber out-of-frame. If the results of Test 989 indicate that the fiber is out-of-frame, follow the recommendation associated with the test failure. If a DS1 converter complex exists on the fiber link, enter **display errors** and follow the associated repair procedures for any DS1C-BD and DS1-FAC entries. 2. Retry the command at 1-minute intervals a maximum of 3 times.

116	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 16 over the packet path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 16. Use the **display errors** command to find any SNI-BD errors and use the display alarms command to determine whether the errors have on-board alarms. Then, follow the associated repair procedures for the SNI-BD as described in the Maintenance manual. 2. Using the **display errors** command, check the error log for other SNI circuit packs with SNI-PEER error type 2817. If other SNI circuit packs have SNI-PEER error type 2817 errors, replace the SNI in slot 16. Replacing an SNI may be service interrupting. Refer to the SNI-BD Maintenance documentation for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 2817 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. 3. Replace the SNI being tested. 4. Replace the SNI in slot 16.

Continued on next page

Table 9-607. TEST #767 Packet Neighbor Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
117	FAIL	The SNI circuit pack cannot communicate with the SNI in slot 17 over the packet path. 1. Fix any on-board SNI-BD errors against this SNI and the SNI in slot 17. Use the **display errors** command to find any SNI-BD errors and use the display alarms command to determine whether the errors have on-board alarms. Then, follow the associated repair procedures for the SNI-BD as described in the Maintenance manual. 2. Using the **display errors** command, check the error log for other SNI circuit packs with SNI-PEER error type 3073. If other SNI circuit packs have SNI-PEER error type 3073 errors, replace the SNI in slot 17. Replacing an SNI may be service interrupting. Refer to the SNI-BD Maintenance documentation for the procedure for replacing an SNI. **NOTE:** If other SNI circuit packs do not have SNI-PEER error type 3073 errors, the problem could be at either of the peer SNI boards. It is arbitrary as to which SNI is replaced first. 3. Replace the SNI being tested. 4. Replace the SNI in slot 17.

</table>

Continued on next page

Table 9-607. TEST #767 Packet Neighbor Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
123	FAIL	The SNI circuit pack cannot communicate with its neighbor via the packet path. 1. Fix any on-board errors (SNI-BD, EXP-INTF, and/or DS1C-BD) against the components of this fiber link by using **display errors** and **display alarms** and following the associated repair procedures. (Use the **list fiber-link** command to find the fiber link associated with this SNI. The **display fiber-link** command can then be used to find the endpoints of the fiber link and the DS1C circuit pack locations if this fiber link has a DS1 Converter Complex administered.) 2. Enter **display errors** and **display alarms** and follow the associated repair procedures for any SNC-BD error entries with corresponding on-board alarm entries. 3. Enter **display errors** and follow the associated repair procedures for any SYNC entries. 4. If this FIBER-LK has circuit, packet, and control path errors, check the lightwave transceiver connections or metallic connections. Use the LED states to verify whether the connections are correct. Also, a test fiber-link s command can be run to determine whether a fiber out of frame condition exists on the fiber link; the SNI Fiber Out-of-Frame Query (#989) reports whether a fiber out of frame condition exists for an SNI endpoint and the Expansion Interface Fiber Out-of-Frame Query test (#238) reports whether a fiber out of frame condition exists for an Expansion Interface endpoint. 5. Replace the lightwave transceivers if present. 6. Replace one of the endpoint boards. 7. Replace the other endpoint board. 8. Replace the DS1 CONV circuit packs if a DS1 CONV converter complex is administered on this fiber.
	PASS	The SNI can communicate with the peer SNIs and the neighbor over the packet path.

Continued on next page

Table 9-607. TEST #767 Packet Neighbor Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	No board was detected by the test. 1. Check that board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Failure Audit (#777)

This test is non-destructive.

This test queries the SNI for any existing failures and any unacknowledged cleared failure messages. Each failure generates an error and alarm entry against SNI-BD, SNI-PEER, or FIBER-LK. An unacknowledged cleared failure message is a message the SNI circuit pack sent to software indicating a previous failure is now gone and the SNI circuit pack did not receive a message from software indicating that the failure message was received by software.

If no failures are detected by the SNI circuit pack, this test will pass.

If this test reports failures, the results screen for the **test board** command will show **FAIL** with no FAIL code. The error log must then be displayed via **display errors** with category PNC to view all SNI-BD and FIBER-LK errors and category PNC-PEER to view all SNI-PEER errors.

Table 9-608. TEST #777 Failure Audit

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2306	ABORT	The SNI circuit pack is not responding to test requests sent by software. 1. Run the **test led switch-node** for the switch node that the SNI resides in to verify whether the LEDs on the board light. 2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 via **test board UUCSS l** for the active SNC in this carrier. Wait 5 minutes and then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNI may be service interrupting. Refer to the SNI-BD section for the procedure for replacing an SNI. 3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the SPE. Check **list fiber-link** to determine the fiber connections to this carrier. Check the LEDs on all SNIs and EIs and fix any fiber problems. Enter **display errors** and follow the associated repair procedures for any EXP-INTF error entries associated with the PPN. Also, follow the associated repair procedures for any SYNC, SNI-BD, SNC-BD, FIBER-LK, or SNI-PEER error entries. 4. Follow the procedure described above, SNI Manual Loopback to determine whether the circuit pack or the fiber connection is faulty.

Continued on next page

Table 9-608. TEST #777 Failure Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The SNI circuit pack reported failures or retransmitted a cleared failure message. 1. If this is the first time this test was run, run the test again. If there were any previous failure messages that software did not acknowledge, this test will FAIL even if the failure messages indicate a FAIL to PASS transition, i.e., a problem has gone away. If this test is run twice and FAILs both times, then at least one problem still exists. 2. Fix any SNI-BD, SNI-PEER, and FIBER-LK errors by following the associated repair procedures. Use the **display errors** and **display alarms** commands with category PNC for SNI-BD and FIBER-LK and category PNC-PEER for SNI-PEER. Fix any problems found by referring to the SNI Board or SNI Peer Error Log Entries tables in this section or Fiber Link Error Log Entries tables in the "FIBER-LK (Fiber Link)" section. 3. If no SNI-BD, SNI-PEER, or FIBER-LK entries exist in the error and alarm logs, retry the command.
	PASS	No problems are detected on the board.
0	NO BOARD	No board was detected by the test. 1. Check that board is properly translated and inserted. 2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNI. It may be necessary to use the **reset board** command if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore the **reset board** command can mask real problems. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Clear Firmware Counters (#982)

This test number is used to report unsuccessful results of the **clear firmware-counters** command. This is not an actual demand maintenance test. If the command aborts, refer to the error codes listed for Test #777.

SNI Fiber Out of Frame Query (#989)

This test is non-destructive.

The SNI circuit pack reports whether a fiber out of frame condition exists, whether a loss of signal condition exists, and whether the lightwave transceiver is present.

Table 9-609. TEST #989 SNI Fiber Out of Frame Query

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
1415	ABORT	The lightwave transceiver is not present. 1. If a lightwave transceiver is not supposed to be present, do nothing. For example, an SNI connected to a DS1C circuit pack or an SNI with a metallic connection does not have a lightwave transceiver. 2. Otherwise, check the lightwave transceiver connections. 3. If OK, replace the lightwave transceiver. If a fiber out of frame condition exists and lightwave transceivers are used, check that the lightwave transceivers are of the same type, that is, both are 9823a or both are 9823b. If they are not the same type, replace one of the lightwave transceivers: ■ 9823a is used for distances up to 4900 feet. ■ 9823b is used for distances up to 25,000 feet. 4. If the test continues to abort, replace the SNI circuit pack.
2300	ABORT	The downlink message necessary to run this test could not be sent. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2301	ABORT	The software timer could not be set before sending the downlink message necessary to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2304	ABORT	SNI circuit pack responded that it is not able to run the test requested by software. 1. Retry the command at 1-minute intervals a maximum of 3 times.

SNI-PEER (SNI Peer Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SNI-PEER	MAJOR	test board UUCSS s	SNI Peer Link
SNI-PEER	MINOR	test board UUCSS s	SNI Peer Link
SNI-PEER	WARNING	test board UUCSS s	SNI Peer Link

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

SNI Peers are Switch Node Interfaces residing on the same Switch Node Carrier. SNI-PEER maintenance involves testing of the links between SNI Peers. SNI-PEER errors are described on the following pages. For a full description of SNIs, including circuit pack replacement, see SNI-BD.

Error Log Entries andTest to Clear Values

Table 9-610. SNI-PEER Hardware Error Log Entries

Error Type	Aux Data	SNI Slot[1]	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[2]	0		Any	Any	Any	test board UUCSS r 1
1	any	2	Failure Audit (#777)	MAJ/MIN/ WAR	OFF	test board UUCSS r 1

Continued on next page

Table 9-610. SNI-PEER Hardware Error Log Entries — *Continued*

Error Type	Aux Data	SNI Slot[1]	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3329	any	18	Failure Audit (#777)	MAJ/MIN/WAR	OFF	test board UUCSS r 1
3585	any	19	Failure Audit (#777)	MAJ/MIN/WAR	OFF	test board UUCSS r 1
3841	any	20	Failure Audit (#777)	MAJ/MIN/WAR	OFF	test board UUCSS r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. The slot location of the SNI at the other end of the peer link indicted by the SNI reporting the error.

Notes:

For **all** errors in Table 9-610, the SNI circuit pack reporting the error is indicating that it has a problem with the control path, circuit path, or packet path to the SNI peer in the slot indicated on the error table.

First, the Failure Audit test (#777) should be run to confirm whether the error still exists.

If the SNI is reporting an SNI-PEER error against a slot that does not contain an SNI, either change circuit pack administration via **change circuit-pack** to unadminister the SNI, or insert an SNI into the indicated slot. **List configuration carrier** can be used to determine whether an SNI circuit pack is inserted. Otherwise, **display errors** and look at *all* of the SNI-PEER errors in the log. If either of the following two conditions are present, follow Procedure 2 below.

- Do many SNIs have SNI-PEER errors pointing to the same 2 adjacent SNIs?
- Do 2 adjacent SNIs have SNI-PEER errors pointing to many other SNIs?

If neither condition is present, follow Procedure 1 below. When using either procedure, refer to SNI-BD or SNC-BD for circuit pack replacement instructions.

Slot Numbers of Adjacent SNIs	Point to This SNI Pair
2, 3	1, 257
4, 5	513, 769
6, 7	1025, 1281
8, 9	1537, 1793
13, 14	2049, 2305
15, 16	2561, 2817
17, 18	3073, 3329
19, 20	3585, 3841

Procedure 1: Proceed through the following steps *until* the problem is resolved:

1. Perform the Fiber Fault Isolation Procedure described in Chapter 5.
2. Replace the SNI pointed to by the SNI-PEER error type (see the SNI Slot column in the preceding table, *SNI-PEER Error Log Entries*).
3. Replace the SNI reporting the SNI-PEER error.
4. Replace the active SNC.

Procedure 2: If either of the two patterns described before are present, then the clock signal between active SNC and 2 Adjacent SNIs is suspect. Proceed through the following steps *until* the problem is resolved:

1. If only one SNC exists in this switch node carrier, replace the SNC. If two SNCs exist in this switch node carrier, perform the following steps:
   a. Set the standby SNC to active by executing **set switch-node-clock** UUCSS with the standby SNC's location.
   b. If the problem persists, switch back to the previously active SNC via the **set switch-node-clock** command and go to step 2 below.
   c. If the problem went away, replace the SNC that was previously active. Then set the newly replaced SNC to active. If the problem returns, assume that the SNC that was just replaced was not at fault and go to step 2 below.
2. Replace the leftmost SNI from the pair of adjacent SNIs.
3. Replace the rightmost SNI from the pair of adjacent SNIs.
4. This could indicate a problem with the switch-node-carrier backplane.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Configuration Audit* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Configuration Audit (#759)	X	X		ND
Failure Audit (#777)	X	X		ND

SPE-SELE (SPE Select Switch)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
SPE-SELE	MAJOR	none	SPE Select Switch
SPE-SELE	WARNING	none	SPE Select Switch

The SPE Select Switch MO monitors the position of the SPE Select switches located on the front of each UN330B Duplication Interface board. Each switch may be in one of three possible positions: Auto, A selected, B selected. Both switches, one on the active Duplication Interface board and one on the standby, should be set to the same designation. The switches control selection of the active SPE and cause alarms as follows:

- If both switches are in the AUTO position, the SPE that is the healthiest, as determined by the state-of-health bits on the boards, is selected as active. No alarm is raised.
- If one SPE Select switch is in the AUTO position and one selecting either A or B carrier as active, or one switch selects A and the other selects B, the boards default to handling the selection of which carrier is active as if both switches were in the AUTO position. A WARNING alarm appears after one hour. The alarm is resolved 5 minutes after the switches are returned to identical positions.
- If both switches select either A carrier or B carrier active, then the Duplication Interface boards will force that carrier active (irrespective of state-of-health) and the red Override LED is lit. A MAJOR alarm is raised by SPE-SELE if the switches remain in these positions for more than 6 hours. The alarm is resolved within 5 minutes of the switches being returned to AUTO.

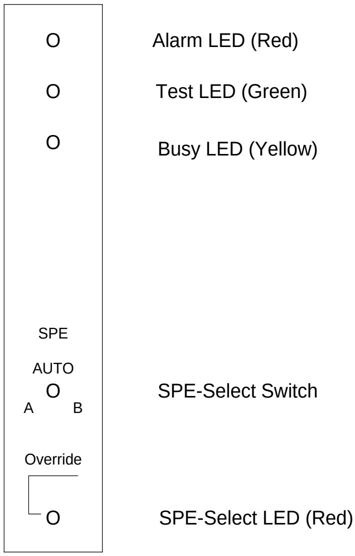

Figure 9-91. Duplication Interface Circuit Pack

Error Log Entries and Test to Clear Values

Table 9-611. SPE Select Switch Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	
1(a)	0	none	WARNING	OFF	
257(b)	0	none	MAJOR	OFF	

1. Check the position of the SPE-Select switches.

Notes:

a. Error 1 appears when one SPE Select Switch is in the AUTO position and the other is in the select A or select B position. Placing both switches in the AUTO position will retire the alarm immediately.

b. Error 257 appears when both SPE Select Switches are in the select A or select B position for more that 6 hours. Placing both switches in the AUTO position will retire the alarm immediately.

SRP-EPN

MO Name in Alarm Log	Alarm Level	Full Name of MO
SRP-EPN	MAJOR	SRP-EPN

The Survivable Remote Expansion Port Network (SREPN) provides EPN service to the customer when the link to the main processor fails or is broken, or when the processor or center stage fails. SREPN is a disaster recovery operation rather than an additional reliability option.

Due to the hardware solution for Survivable Remote Processor (SRP), maintenance tests to make sure the SRP can go into "survive" mode are not possible.

When the `Survivable Remote Processor` field on the **system-parameters customer-options** form is set to y, then the following alarming strategy is used:

1. When the SRP is not in control of the SREPN (which is the normal state), then all alarms associated with the SREPN are downgraded to WARNING alarms. These include the EXP-INTF in the SRP, the EXP-LINK between the SRP and the SREPN, and all maintenance components in the SREPN.
2. When the SRP is in control of the the SREPN (the EXP-LINK is up between the SRP and SREPN), the disaster recovery state is in effect. A MAJOR alarm is raised against the SRP-EPN maintenance object. All other maintenance objects use their normal alarm strategies.

If the G3r PPN loses control (connectivity) to a SREPN, and the SRP associated with the SREPN does not raise a MAJOR alarm against the SRP-EPN maintenance object, then the disaster recovery mechanism is **NOT** working.

There are no tests associated with the SRP-EPN maintenance object. The only way to resolve the SRP-EPN alarm is to fix the connectivity problem(s) between the G3r PPN and the SREPN.

STBY-SPE (Standby SPE Maintenance)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
STBY-SPE	MAJOR	test spe-standby l	Standby SPE Maintenance
STBY-SPE	MINOR	test spe-standby l	Standby SPE Maintenance
STBY-SPE	WARNING	test spe-standby l	Standby SPE Maintenance

The general principles of SPE duplication, including the following topics, are discussed in Chapter 1:

- Standby Maintenance Architecture
- Standby State-of-Health and Availability
- Handshake Communication
- Memory Shadowing and Refresh
- Maintenance Software
- Standby Initialization

Troubleshooting a duplicated SPE, and replacing SPE components, are discussed in Chapter 5. The SPE-Down or SPE-Locked interface is discussed in Chapter 4.

Maintenance of the standby SPE is organized around the STBY-SPE maintenance object. It relies on documentation of the other SPE maintenance objects:

PROCR	SYSAM	MEM-BD
SW-CTL	H-ADAPTR	R-MEDIA
DISK	DUPINT	DUP-CHL

Once a general SPE problem has been isolated to the level of one of these individual packs, the service documentation for that MO should be consulted. It is the responsibility of standby SPE maintenance described here to keep the standby SPE fully available for an interchange.

Standby Availability

Various factors affect the availability of the standby SPE:

- The condition of the individual hardware components of the standby SPE
- Standby memory content
- Standby State-of-Health (SOH)
- Standby SPE-Down
- System Time-of-Day

The health of both the active and standby is tracked as a State-of-Health (SOH) value. State-of-Health is discussed fully in Chapter 1.

The SOH of the standby SPE can be determined with the "status spe" command. A complete description of this command and its output appears in Chapter 8. For the standby to be fully available, the fields (for the SPE with mode *standby*, where applicable) should read as follows:

Duplicated?	yes
SPE Selected?	auto (otherwise, the SPE-Select switches will prevent any interchange)
Standby Busied	no
Standby Refreshed?	yes
Standby Shadowing	on
Standby Handshake?	up
Recent Spontaneous Interchange?	no
State-of-Health	functional

Any divergence from these conditions, except during system recovery or technician-initiated maintenance, requires immediate investigation.

Locking the Active SPE

Duplication Interface hardware supports the ability to lock the active SPE into active mode. On each Duplication Interface circuit pack is an SPE-SELECT switch which can be set in three positions: A, B, Auto. These are normally set with both switches on AUTO, allowing system software to govern which SPE is active. When the SPE-SELECT switches on both SPE's Duplication Interface circuit packs are set to the position A, then the SPE in carrier A is locked active and the B-carrier SPE is locked standby. Setting both to B locks the B carrier active. Any other combination of settings results in AUTO mode. *In locked mode, the system operates as if it is simplex:*

- The standby SPE is inaccessible to the active SPE and active G3-MT login.
- No SPE-interchange is possible.
- Handshake is down and memory shadowing is off.

WARNING:
Transition the system into the lock mode with extreme care. Always move the switches into the position designating the ***active*** *SPE carrier. Switching to a faulted standby can cause a total service outage.*

The locked state is intended for temporary use to prevent interchanges during maintenance sessions. Alarms are raised if the switches are left out of the AUTO position for an extended length of time (SPE-SEL).

To lock the SPEs, first determine which is active:

- The active Duplication Interface's yellow LED will be lit.
- **status spe** reports active/standby status of each SPE.

Making sure you are grounded, move the switches one at a time to the letter designating the active carrier. Wait a few seconds, then verify that the lock took effect:

- The red LED labeled OVERRIDE on both Duplication Interface circuit packs should be lit.
- **status spe** displays `spe-a locked` in the `SPE SELECTED` field if the A SPE is locked active. This verifies that internal software is aware of the lock state. The screen will also indicate that handshake is down, memory shadowing is off and the standby is not refreshed. The standby SPE is technically not in service while locked, and its SOH can vary.

To unlock the active SPE, move both SPE-SELECT switches back to AUTO. System software will automatically try to bring the standby SPE into full service, by establishing handshake, refreshing memory, and raising the standby's SOH if appropriate.

CAUTION:
When exiting the locked state, a spontaneous SPE interchange is possible if active SPE SOH is not functional. Always check first with ***status spe*** *(unless the interchange is desired).*

After exiting the locked state, make sure the standby returns fully to service (SOH functional). When the system is in the locked state, all alarms against the standby SPE (STBY-SPE), (except the WARNING alarm raised in the busyout state), are automatically cleared by the system.

Replacing SPE Circuit Packs

To replace any SPE circuit pack on a duplicated system, always use the "lock-and-power-down" procedure described fully in Chapter 5. This procedure allows replacements without service disruption, and guarantees that the system is returned to full normal operation.

Memory Shadowing

Memory shadowing is used to keep the standby SPE's memory content up-to-date relative to the active SPE's memory. A standby SPE that has just rebooted, exited lock mode or just been released from busyout must undergo this full re-initialization. System software tracks the operation and raises a major alarm when refresh failure occurs. If shadowing stays on, system software automatically tries to refresh again 5 minutes later.

Generally, memory shadowing should always remain on unless:

- The standby SPE is undergoing any restart.
- The active SPE is undergoing a restart level of 2 or greater.
- The active SPE is locked.
- The standby SPE is busied out.

In any other situation, it is an error condition for shadowing to be off. The first two situations are transitory and shadowing should automatically be restored within 10 minutes. If shadowing has been on for several minutes, it is an error condition for the standby not to be refreshed. A standby SPE with no critical component alarms that is either not refreshed or does not have shadowing on should have SOH level *not refreshed.*

Busyout of the Standby SPE

The standby SPE can be placed in the state of maintenance busyout with the command **busyout spe-standby**. This creates the following conditions:

- The SOH of the standby SPE is kept artificially at level *partially-functional* regardless of the actual state of its components.
- Memory shadowing is turned off. Standby memory content is not in agreement with that of the active SPE
- A Warning alarm is raised against STBY-SPE with error type 18. This Warning alarm supersedes all other alarms against STBY-SPE.
- The **status spe** field `Standby Busied?` will display `yes`.

release spe-standby causes the following:

- The standby SPE’s SOH returns to the appropriate level based on its component alarms.
- After verifications, software turns on shadowing and refreshes the standby’s memory.

Busyout is used to discourage the likelihood of interchange and prevent side effects of memory shadowing. For example:

- When it is necessary to run the long demand test sequence for the duplication-interface hardware or to reset the standby SPE’s Packet-interface circuit packs
- To allow destructive testing of components relevant to shadowing (packet-interface, memory, or duplication interface packs).

When the standby SPE is busied out, handshake communication is maintained if possible. The standby SPE can be busied-out at any time the G3-MT interface is available, including when the system is initializing or when the active SPE is locked. Busyout applies to only one instance of the SPEs. If SPE B is busied out and an SPE interchange occurs A-carrier SPE is not busied out.

When releasing a standby SPE from the busyout state, make sure that the standby SPE is brought fully back to service. Wait until the standby is refreshed and its SOH returns to level *functional* to make sure repair actions did not disable the standby SPE.

Initialization: Bringing the Standby SPE Up

When the standby SPE has been out of service or is first coming up, SPE software executes the following steps:

1. Establishes handshake communication
2. Raises the standby SPE's SOH to *not refreshed* if it has no critical component alarms, or *partially functional* if it does have critical component alarms
3. Tests for component mismatch (test number 920)
4. Turns on memory shadowing
5. Refreshes standby memory
6. If there are no critical-component major alarms, raises the standby SPE's SOH to *functional*

This normally takes about 5 minutes. Should a step of this initialization sequence fail, the step is retried until it succeeds. The failed condition is alarmed so that it can be diagnosed and corrected.

Other Mechanisms: Status Command and SPE-Down Interface

There are certain maintenance tools available for dealing with the standby SPE which can be used regardless of the state of handshake communication or memory shadowing.

Always start with and continue to use **status spe** to determine completely the status of the standby SPE.

When handshake communication is down, there is no access from the usual G3-MT connection to test the standby. In this case, locking the active SPE with the switches has no harmful effect on switch service and allows terminal access into the standby SPE via the SPE-Down or SPE-Locked Interface. With this interface, you can run low level tests on individual components and request reboots of the standby SPE. Whenever the SPEs are locked and the SPE-Locked Interface is in use. Instructions on how to bring up and use this interface are described in Chapter 4. When using this tool, do not unlock the SPE until all tests of standby SPE components have passed.

Recent Interchange Mode

The event of a spontaneous SPE interchange is intended to be a rare event and reflects a serious hardware failure on the formerly active SPE. Generally, when such an interchange has occurred, that SPE (now standby) requires diagnosis and repair action. There should be information in the error and alarm logs to indicate the specific problem. System software will attempt to establish handshake communication with the SPE, refresh its memory, bring it into service as a standby SPE, and diagnose its problems.

Regardless of any success in bringing that standby SPE into service, software will not improve the SOH of that SPE until either:

- Technician-demanded testing addresses the problem
- One hour has passed since the interchange

This mode, called Recent Interchange Mode, is reported on the **status spe** screen and serves to prevent further interchanges from occurring too quickly. Additionally, a minor alarm with error 103 is logged against STBY-SPE and the SOH of that SPE is allowed to get no better than *partially functional*. *Troubleshooting a Duplicated SPE* in Chapter 5 describes an approach to diagnosing problems under this condition.

There are two ways in which the standby SPE can exit recent interchange mode.

a. You can run **test spe-standby long clear** and wait until all the tests of STBY-SPE have completed. (this runs tests of *all* components of the standby SPE in addition to those for STBY-SPE). The first test of the sequence (#855) fails, because the standby SOH is at level *partially functional*. The execution of this sequence clears the minor alarm against STBY-SPE and allows normal treatment of the standby SPE. If the standby is refreshed and has no major alarms against critical components, its SOH will be allowed to improve to *functional*.

b. Alternately, when one hour has passed since the last spontaneous interchange, system software automatically transitions the standby SPE out of recent interchange mode. The minor alarm clears and the standby SPE’s SOH level is allowed to go to its appropriate value (typically *functional* if there are no major component alarms and it is refreshed).

Resolving Error Conditions on the Standby SPE

Divergence of the standby SPE from the state of full availability involves one of the following events:

- Handshake communication is down
- Memory shadowing is off
- The standby SPE is not refreshed
- The standby SOH is not *functional*

A hierarchical approach is recommended in the above order. Follow the steps presented in the following diagram.

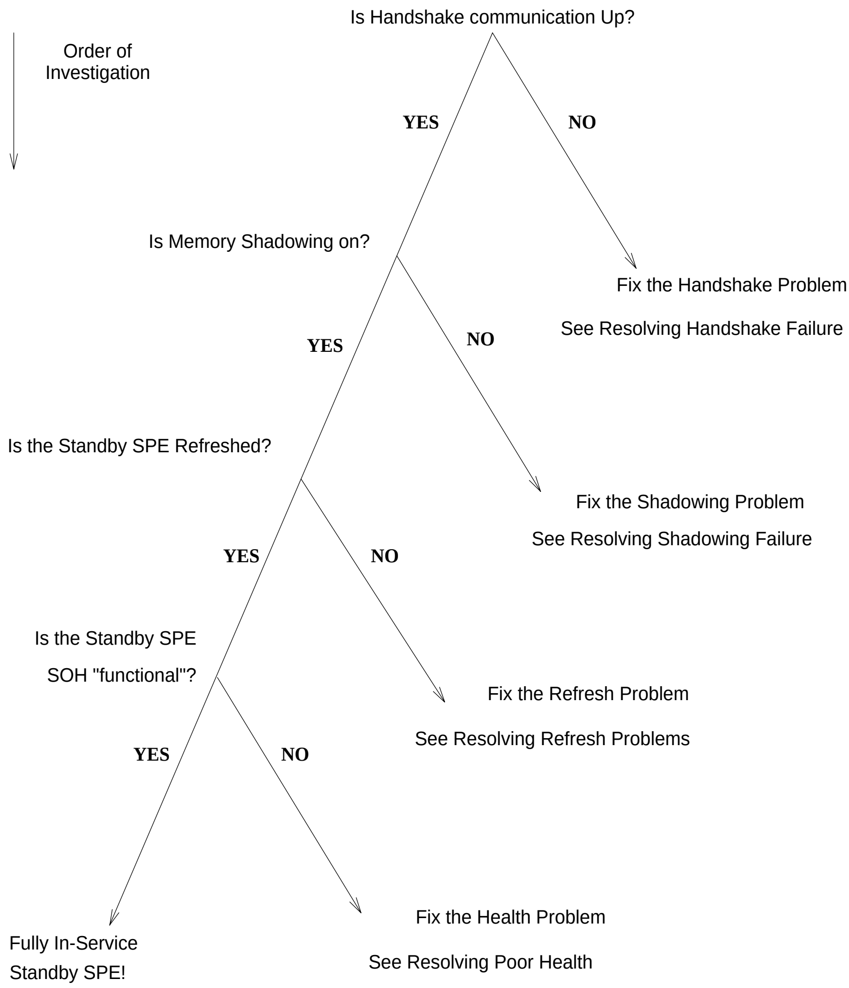

Figure 9-92. Resolving Standby-SPE Errors

Resolving Handshake Failure

When handshake fails, a major alarm with error 1 is repeatedly logged against STBY-SPE reflecting the fact that over a 2-minute period, no successful communication has occurred with the standby SPE. When the system is in lock mode, handshake is taken down with no alarm or error logged. When the standby SPE is busied out, handshake communication is kept up. If handshake should fail during busyout, the major alarm will not appear, but error 1 and the usual busyout warning alarm with error 18 will be logged. You can always determine if handshake is up with **status spe**.

To restore handshake, proceed through the following steps.

1. Make sure that the SPE is not locked, and that it has power. Resolve any CARR-POW alarms on the standby SPE carrier. (If the standby SOH is partially functional or better, you can assume that the standby SPE has power.)
2. Busyout the standby SPE and run **test dup long**. Some DUP-CHL tests may abort due to the absence of handshake. If any tests *fail*, follow procedures in DUPINT and then DUP-CHL to resolve the problem. If you replace any DUPINT hardware, wait to see if the standby SPE can be fully restored to service.
3. If the above tests did not fail, lock the SPEs with the SPE-select switches and use the SPE-down interface to test the standby components as described in Chapter 4. If all tests pass, proceed to the next step. Replace any component that fails testing. (Use the lock-and-power-down technique.) Bring the SPE back up as described in Chapter 4.
4. With the standby still busied out, issue the command **r** to reboot the standby SPE and immediately unplug the STANDBY terminal connector. The standby should still be busied out. Wait for the yellow LED on the standby Processor to begin flashing, unlock the SPEs, and monitor the standby with **status spe**.
5. If handshake is established, release the standby SPE from busyout and monitor its recovery with **status spe**. If the onset of memory shadowing or refresh causes handshake to fail, then suspicion is cast on these standby circuit packs:
   - DUPINT
   - PKT-INT
   - MEMORY
   - MSSNET

   Replace each of these in the standby in the above order, using lock-and-power-down. For each one, bring up the standby SPE and wait to see if handshake and memory refresh succeed.

Resolving Shadowing Failure

This section addresses the situation in which handshake communication is up, but memory shadowing is not on after reasonable initialization time, or is repeatedly turning on and off. If the onset of memory shadowing is causing handshake failure, see the preceding section.

The following conditions prevent memory shadowing:

- Busyout of the standby SPE
- Locking of the SPEs by means of the SPE-select switches
- Alarms against components relevant to shadowing
- A mismatch between the hardware configurations of the active and standby SPEs
- Incomplete initialization of the standby after a restart

When memory shadowing is not on, system software checks every 30 seconds to see if the above conditions are gone, allowing it to restore shadowing. Examine the Hardware Error Log for any of the following indications.

STBY-SPE Error 257

This usually represents inhibiting of memory shadowing by the standby SPE. This can occur if the standby SPE is undergoing any level of restart or if the standby PKT-INT circuit pack is being reset. Typically this condition clears quickly. In the case that the standby SPE has restarted, there should be an STBY-SPE error 514 logged. If the 257 error persists with handshake staying up, look for problems with the standby PKT-INT board (red LED). It may be necessary to reset the standby PKT-INT board (**reset packet-interface**) to clear the inhibiting of shadowing. See “PKT-INT”.

STBY-SPE Error 260

This indicates that the mechanism in the active SPE’s Duplication Interface circuit pack to turn on shadowing has somehow failed. When this occurs, busyout the standby SPE and run **test dup long**. Follow instructions for DUPINT.

STBY-SPE Error 1537

This error indicates a component mismatch between the active and standby SPEs. Use **list config control** to determine what components are in the PPN carriers A and B. Correct any mismatches. Use the lock-and-power-down method described in Chapter 5 to replace circuit packs.

DUPINT or DUP-CHL Alarms

As long as any alarms against either of these MOs persist, memory shadowing will not be turned on.

Standby PKT-INT Major Alarms

These prevent memory shadowing. See “PKT-INT”. It may be necessary to reset the board (**reset packet-interface**).

Standby MEM-BD Major Alarms

These prevent memory shadowing. See “MEM-BD”.

When you observe any of the above problems, first busyout the standby SPE, then fix the given problem (usually with a lock-and-power-down replacement), then release the standby SPE.

If any of the above problems persist, or if none of them appears but shadowing remains off in the presence of good handshake, escalate the problem.

Resolving Refresh Problems

It can happen that handshake communication and memory shadowing can both be maintained to a standby SPE, but for some reason that SPE cannot be completely refreshed. In this case, one must distinguish between delays in refresh completion and outright failure. This section addresses the situation in which shadowing remains on, handshake remains up, but refresh will not complete.

Delays in Refresh

Under extremely heavy occupancy loads, standby refresh can be delayed but it is still expected to complete within 10 minutes of the time when memory shadowing was turned on. You should not see delays greater than this without some STBY-SPE alarm.

Failure of Refresh

The refresh operation occurs in two steps:

- Refresh of Packet Interface dual port RAM (very quick execution)
- Refresh of all memory on all memory boards

A failure can occur in either of these steps. When refresh fails, STBY-SPE error code 1281 is logged. The auxiliary data indicates which aspect of refresh failed. Aux code 1383 indicates that the memory board part has failed. This typically indicates a problem with *active* SPE memory circuit packs. Execute the long test sequence against both active SPE memory circuit packs and see “MEM-BD”. If no problems are revealed in the memory long test sequence, but memory refresh persists in failing with error 1281 error aux 1383, escalate the problem.

Error code 1281 with auxiliary data 1381 indicates that refresh of the packet-interface dual port RAM has failed. If this persists, one should look for problems with either active SPE or standby SPE packet-interface boards. Follow the procedures outlined in PKT-INT to fully test the active SPE’s Packet-interface. Note that, since the standby SPE is not refreshed, one cannot execute the long demand test sequence on the standby Packet Interface. One can however trigger a reset of that circuit pack. If the active PKT-INT passes all tests of the long sequence and if the standby PKT-INT successfully resets, the problem should clear. If error 1281 aux 1381 persists, escalate the problem.

Error code 1281 with auxiliary data 1380 indicates that memory shadowing was turned off during refresh and the refresh has therefore terminated in failure. This situation should be treated as a shadowing failure and approached as described in the section *Resolving Shadowing Failure*. If memory shadowing is restored, but refresh again fails with code 1380, escalate attention to the problem.

One particular way memory or PKT-INT refresh can be led to fail is by inserting one of these circuit packs into its slot without powering down the carrier. If this happens, it may be necessary to cycle power on the given carrier and let the LMM run all tests of components on the carrier to clear the problem. If such an SPE is in standby mode, **reset spe-standby 4** would also cause the appropriate initialization to occur. Always follow the lock-and-power-down approach to replace circuit packs on the standby SPE.

Resolving Poor Health

It can happen that a standby SPE is properly maintaining handshake communication, shadowing is on and the standby is fully refreshed, but for some reason the SOH of that standby SPE remains at a level other than *functional*.

For example, in a heavily loaded system, the standby SOH may temporarily stay at *not refreshed*, but eventually it should clear. Once refresh completes, system software begins an effort to improve the standby SOH from *not refreshed* to *functional*. This effort can be delayed, but within a few minutes one should see the change. If one sees an indefinite persistence of this health level, in an otherwise perfect standby SPE, escalate the problem. This should be an extremely rare event.

If the standby SOH Stays at *partially functional*, either the standby SPE is in *recent interchange mode* or there is a major alarm against some critical standby component (see the table above). For the first case, verify the situation with

status spe and then clear the recent interchange mode by executing **test spe-standby long**. Wait until at least the first four tests of the sequence complete, then cancel out of the command. The standby SOH should eventually be raised to *functional.* In the second case, check the alarm log to see if there is any major alarm against any component of the standby SPE. If you find one, fix that problem, (usually by replacing the circuit pack). Then the SOH problem should eventually clear. If you lock-and-power-down the standby SPE to replace the given pack, you'll need to test it while in locked mode until all tests pass and then unlock and wait for system software to re-initialize the standby SPE. Only then should you expect standby SOH to be improved to level *functional.*

If neither the recent interchange mode nor a standby component alarm exist, but standby SOH persists at level *partially functional*, escalate the problem.

Error Log Entries and Test to Clear Values

Table 9-612. STBY-SPE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test spe-standby l
1(a)		Standby SPE Handshake Test (#919)	MAJOR	OFF	
18(b)		busyout spe-standby	WARNING	OFF	rel spe-standby
103(c)		None	MINOR	OFF	test spe-standby l
257(d)		standby SPE status query (#855)	MAJOR	OFF	
260(e)		standby SPE status query (#855)	MAJOR	OFF	
514(f)		None	MAJOR	OFF	
770(g)		standby SPE TOD Comparison Test (#858)	MINOR	OFF	test spe-standby l
1025(h)		standby SPE status query (#855)	MAJOR	OFF	test spe-standby l
1281(i)	any	standby SPE status query (#855)	MAJOR	OFF	
1537(j)	any	standby SPE configuration Matchup test (#920)	MAJOR	OFF	test spe-standby l

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Indicates that a single handshake attempt has failed. Use "status spe" to see if handshake is down. If "status spe" indicates that handshake is up, ignore this error. If handshake is down, see *Resolving Handshake Failure*.

b. Presence of this error indicates that the standby SPE has is busied out. When busied out, standby SPE's health is kept at the level *partially functional* and memory shadowing is kept off.

c. Error 103 indicates that a spontaneous interchange has taken place. This lowers the now standby SPE's state-of-health to *partially functional*, raises a MINOR alarm against the standby SPE, and invokes recent interchange mode (anti-thrashing). After one hour, or entering **Test spe-standby long** or **busyout spe-standby**, the alarm clears, recent interchange mode is lifted, and the standby's state of health assumes the appropriate value (usually *functional*).

   After a spontaneous SPE interchange has occurred, the Alarm Log retains a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. This record is retained for three hours and may indicate the cause of the interchange when testing is not possible or conclusive. If handshake has not been restored (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, and such an alarm is logged against SW-CTL, replace the standby MSSNET circuit pack. If handshake is up, and such an alarm is logged against one of the other SPE components, execute a **test long clear** of the alarmed standby component and follow repair instructions for that maintenance object.

d. This error represents inhibiting of memory shadowing by the standby SPE. If this error occurs accompanied by error 514, then the standby SPE has reset, so wait 5 minutes for this condition to clear. If the 257 error persists, or did not occur with a 514, then how you proceed depends on whether handshake is up. If handshake is not up, deal with the handshake failure problem (see the section *Resolving Handshake Failure*). If handshake is up, look for errors or red LEDs indicting the standby packet-interface circuit pack or either of the duplication-interface circuit packs. If such problems exist consult the appropriate MO documentation. When no PKTINT errors or alarms are present, the PKTINT may still be the cause of the problem. Try **reset packet-interface [a|b]** to reset the standby PKTINT and wait two minutes, after which shadowing should be turned on. If 257 continues to persist, with handshake up, and no associated packet-interface or duplication-interface problems, escalate the problem.

e. This error indicates that shadowing could not be turned on due to a problem with the duplication-interface hardware. **Busyout spe-standby**, run **test duplication-interface long**, and consult the DUPINT section. Once all tests of duplication-interface have passed, and all alarms against it have cleared, **release spe-standby** and wait 10 minutes for normal initialization to complete. If error 260 recurs, escalate the problem.

f. This error indicates that the standby SPE has been reset. Wait 5 minutes and then use "status spe" to see if the standby SPE is refreshed. If so, ignore the 514 error. If not, or if 514 recurs frequently, then lock the standby SPE and proceed to trouble-shoot it with the SPE-Down Interface. If all SPE-Down Interface tests pass, and error 514 recurs, then there is probably a software problem in the standby SPE: follow normal escalation procedures.

g. Indicates that the two Time-of-Day (TOD) clocks of the active and standby SPEs were detected to be more than 30 seconds apart. Run the short test sequence on each of the two SPEs' SYSAM circuit packs (see service documentation for TN1648). If any of these tests fail, fix the problem with that SYSAM pack (as described in TN1648 service documentation). If no SYSAM tests fail, and if the 770 persists, then replace the standby SYSAM pack (via the lock-and-power-down approach) and wait for the repaired standby SPE to initialize again (after unlocking). If, after all this, the 770 persists, then, once the standby SPE is fully refreshed and of *functional* health, perform a planned SPE interchange ("reset system interchange") and replace the now-standby (other) SYSAM pack (again: use lock-and-power-down). Now let the standby re-initialize. If the 770 error persists, escalate the problem.

h. This indicates that the standby SPE is down (has a power or sanity problem) and is associated with a *non-functional* SOH level (as revealed by "status spe"). Check for any power alarms (CARR-POW) and deal with them. If none, trouble-shoot the standby SPE by locking and using the SMT. Do not unlock the standby SPE until all SMT tests of it have passed.

i. Represents an instance of refresh failure. Look at the auxiliary data associated with the error. There are the following possibilities:

- Aux data 1380

  This indicates that memory shadowing was turned off during refresh. Proceed as you would to solve a shadowing problem (see the section *Resolving Shadowing Failure*). If shadowing returns, wait 10 minutes for the system to automatically retry refresh. Also, problems with the standby PKT-INT might lead standby software to turn off shadowing during refresh. So look for a red LED on the standby PKT-INT. If you find this, follow PKT-INT service documentation to repair. Then wait for the automatic retry of refresh.

- Aux data 1381

  This indicates a failure of PKT-INT refresh. Consult PKT-INT service documentation to test and repair both active and standby PKT-INTs while the standby is not refreshed. Then wait for the automatic retry of refresh.

- Aux data 1383

  This indicates that refresh of one of the memory packs has failed. Typically this indicates a problem with one of the active SPE MEM-BDs. Consult MEM-BD service documentation of execute the long test sequence on these packs. Fix any problems you encounter. Then wait for the automatic retry of refresh.

- any other value

  System software problem; escalate the problem.

If all memory and packet-interface packs pass all test and refresh failure persists, escalate the problem.

j. This error indicates a possible mismatch in hardware configuration between active and standby SPEs for other than disk and removable media components. Auxiliary data indicates the general area of the mismatch:

- Aux data 1374

  Indicates a mismatch of PKT-INT circuit packs

- Aux data 1375

  Indicates a mismatch of MEM-BD circuit packs

- Aux data 1376

  Indicates a mismatch of Processor, SYSAM, DUPINT or MSSNET circuit packs

If handshake is up, use the "list config control" command to compare components of the two SPEs; then verify and correct the discrepancy. If no discrepancies are revealed, escalate the problem. If handshake is down, fix that problem (see *Resolving Handshake Failure*).

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Standby SPE Status Query Test (#855)	X	X	ND
Standby SPE Handshake Test (#919)	X	X	ND
Standby SPE Time-of-Day Comparison Test (#858)	X	X	ND
Standby SPE Configuration Matchup Test (#920)		X	ND

1. D = Destructive, ND = Non-destructive

The **reset spe-standby [1|2|3|4]** command executes a restart of the specified level on the standby SPE. It can be used to attempt to clear certain apparent software problems. Handshake must be up. Any standby restart causes memory shadowing to be turned off, requiring several minutes for refresh to complete.

Standby SPE Status Query Test (#855)

This test *does not require handshake communication.* It reads the active SPE's duplication interface circuit pack hardware register to determine standby SOH, status of the lock switches, and whether shadowing is currently turned on. It updates all internal status data kept about the standby SPE (which can be read via the "status spe" command). This test is considered to pass if standby SOH is *functional*, memory shadowing is turned on and the standby memory is fully refreshed. It returns different failure codes depending of which of these conditions is not met. Abort codes reflect that the status data could not be read.

Table 9-613. TEST #855 Standby SPE Status Query Test

Error Code	Test Result	Description/ Recommendation
1330	ABORT	Test cannot run due to duplication-interface hardware failure. 1. **busyout spe-standby** 2. **test duplication-interface long** 3. Proceed according to the DUPINT and DUP-CHL service documentation in this chapter. 4. If all DUPINT tests pass, rerun command.
1338	ABORT	Test cannot run because a planned SPE interchange is in progress 1. Wait for the planned SPE interchange to complete (this might have been stimulated by a craft request or by scheduled maintenance).
1321	FAIL	Test failed because the SPEs are in locked mode. 1. Check that the SPE-SELECT switches on the two DUPINT packs agree with this. This failure will clear once the SPEs are unlocked.

Continued on next page

Table 9-613. TEST #855 Standby SPE Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1322	FAIL	Test failed because memory shadowing is off (but not inhibited). When not inhibited by the standby SPE, memory shadowing can be off for the following reasons: 1. Shadowing has not been turned on yet (temporary condition). To allow for this, the test again (or **status spe**) after 5 minutes to see if shadowing is then on. 2. There is a failure in the duplication-interface hardware: to allow for this, look for errors or alarms against the duplication-interface hardware (DUPINT and DUP-CHL): address these according to duplication-interface documentation. Then re-run the test. 3. Handshake has not been established between the two SPEs: use "status spe" to see if handshake is up. If it is not, address that problem according to the section *Resolving Handshake Failure*. 4. There is a hardware configuration mismatch between components of the two SPEs. Look for error 1537 in the hardware error log and use "list config control" to identify the hardware discrepancy between SPEs. Fix this. 5. There is a major alarm against the memory (MEM-BD), packet-interface (PKT-INT) or switch-control (SW-CTL) circuit packs of the standby SPE. Look for alarms against these and correct the problem.

Continued on next page

Table 9-613. TEST #855 Standby SPE Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1324	FAIL	Test failed because standby SPE has *partially functional* SOH; 1. Use "display alarms" to see alarms against standby SPE components. 2. If a MINOR alarm is active against the current carrier of STBY-SPE, associated with an error 103, then clear this condition with "test spe-standby long". If a WARNING alarm exists against STBY-SPE, use "status spe" to see if the standby is busied out. If so, "release spe-standby" will clear the health problem. 3. Use "status spe" to see if handshake is up. If it is not, deal with that problem according to the section *Resolving Handshake Failure*. 4. Otherwise look for a MAJOR, ON-BOARD alarm against the processor (PROCR), memory (MEM-BD), switch-control (SW-CTL), packet-interface (PKT-INT), or SYSAM circuit packs of the standby SPE. Using the lock-and-power-down approach, replace the offending circuit pack on the standby SPE. Consult the documentation for that component to clear its alarms. Once the alarm against the offending component clears, the SOH of the standby SPE will automatically improve from the *partially functional* level. If error 1324 persists and either none of the above cases is true or you have fixed all of these particular problems, escalate the problem.
1325	FAIL	Test failed because memory shadowing is off due to its being inhibited from the standby SPE 1. This can be a temporary condition, wait 5 minutes and run the test again. 2. If handshake is not established (use **status spe** to see this), deal with that problem according to the preceding section "Resolving Handshake Failure" 3. Rerun the test; if the same 1325 failure recurs, look for problems with the duplication-interface circuit packs (both SPEs) or with the standby SPE's packet-interface pack (look for red LEDs on these). Fix these problems according to the service documentation for these packs.
1326	FAIL	Test failed because standby memory is not refreshed. 1. Retry the test (or "status spe") after 10 minutes, to see if standby is then refreshed.

Continued on next page

Table 9-613. TEST #855 Standby SPE Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1329	FAIL	Test failed because standby SPE has *non-functional* SOH; this means that the standby SPE is down. 1. Look for power alarms (CARR-POW) against the standby SPE carrier; address these. 2. Otherwise, lock the standby SPE and trouble-shoot it with the SMT (as you'd diagnose any down SPE. If you cannot revive the standby SPE or if, upon getting it out of the SPE-down state, error 1339 persists for this test, follow normal escalation procedures.
	PASS	Standby SPE is fully in service (SOH functional, memory content refreshed).

Standby SPE Time-of-Day Comparison Test (#858)

This test, available only when handshake communication is up, compares the SYSAM board's Time-of-Day clock values in the two SPEs. The test passes if the two clocks differ by less than 20 seconds. Failure of this test means that the two clocks have drifted apart but that each clock appears to be moving forward. Having the two TOD clocks more than 20 seconds apart can make spontaneous SPE interchanges disruptive to the point of dropping calls. Repeated failure of this test indicates that one or both of the two SYSAM packs will have to be replaced.

Table 9-614. TEST #858 Standby SPE Time-of-Day Comparison Test

Error Code	Test Result	Description/ Recommendation
1000 2029	ABORT	Either of these codes indicates that the test cannot run because internal resources cannot be allocated to read active clock. 1. Consult SYSAM service documentation for time-of-day clock tests.
1338	ABORT	Test cannot run because a planned SPE interchange is pending. 1. Wait for the planned interchange to complete, then for handshake to come up, then re-run test on newly standby SPE.
1339	ABORT	Test cannot run because handshake communication is not up. 1. Wait 5 minutes and try test again. If handshake is still not up (you get a 1339), solve the handshake problem as described in *Resolving Handshake Failure*
1346	ABORT	Test could not read standby SPE's TOD clock. 1. Test standby SPE's SYSAM and consult that section in this chapter.
1377	ABORT	A-carrier SPE's clock is not moving forward. 1. Test A-carrier SYSAM's time-of-day clock according to SYSAM service documentation.
1378	ABORT	B-carrier SPE's clock is not moving forward. 1. Test B-carrier SYSAM's time-of-day clock according to SYSAM service documentation.
2000	ABORT	Effort to read the clock timed out. 1. Test each of the two SPE's SYSAMs (test maint {1a|1b}) as described in SYSAM service documentation. Once these all pass, repeat this test.

Continued on next page

Table 9-614. TEST #858 Standby SPE Time-of-Day Comparison Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Standby TOD clock differs from active's by more than 20 seconds. 1. Wait 1-minute; repeat the test. If test passes, there is no problem. 2. If test fails, use the lock-power-down approach to replace the TN1648 SYSAM circuit pack on the standby SPE. After the repaired standby SPE is fully initialized (handshake has been re-established), repeat the test. 3. If the test fails again, run it again it 1-minute later. If it fails again, perform a planned SPE interchange and wait for it to complete, Replace the standby SYSAM pack with another new replacement pack. Note that this repair procedure requires two extra SYSAM circuit packs.
	PASS	The two SPE's TOD clocks are within tolerable limits of one another.

Standby SPE Handshake Test (#919)

This test causes software to send a handshake request message to the standby SPE (this is the same handshake request message sent every 30 seconds automatically by the software). For this test to pass, standby software must respond to this message in less than 3 seconds. Persistent failure of this test indicates that handshake communication is down (as can be discerned from the "status spe" command). This should be dealt with as described in the preceding section “Resolving Handshake Failure.”

Table 9-615. Test #919 Standby SPE Handshake Test

Error Code	Test Result	Description/ Recommendation
1321	ABORT	Test cannot run due to SPEs being locked. 1. Inter-SPE communication is not possible while in locked mode. Verify that SPEs are locked with lock switches. Handshake communication may resume once the SPEs are unlocked.
1330	ABORT	Test cannot run due to problem in DUPINT hardware. 1. Test the duplication-interface hardware according to the service documentation for DUPINT and DUP-CHL.

Continued on next page

Table 9-615. Test #919 Standby SPE Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1338	ABORT	Test cannot run due to planned SPE interchange pending. 1. Wait for the planned SPE interchange to complete, then retry the test.
	FAIL	Standby SPE did not respond to handshake request within 3 seconds. 1. Wait 2 minutes and try the test again. 2. If test fails again, use "status spe" to see if handshake communication is up. If it is not and there is a STBY-SPE MAJOR alarm, then deal with the problem according to the preceding section Resolving Handshake Failure.''
	PASS	Handshake request was responded to within 3 seconds; handshake communication is up.

Standby SPE Configuration Matchup Test (#920)

This test requires that handshake be up. It checks to see if the hardware configuration of the standby SPE is in agreement with that of the active SPE, *ignoring removable media and disk components.* Active SPE software sends a message to the standby requesting a list of the latter's components. This list is compared to the list of known components on the active SPE.

This match is necessary for memory shadowing to operate correctly, and for the standby SPE to be able to take on active SPE status correctly. Failure indicates that, for some SPE component other than disk or removable media, the two SPE configurations disagree. This is a serious problem. Memory shadowing is automatically turned off as long as a configuration mismatch exists. As long as this condition holds, any spontaneous SPE interchange which might occur results in all calls being dropped and a COLD-1 restart on the newly active SPE.

Table 9-616. TEST #920 Standby SPE Configuration Matchup Test

Error Code	Test Result	Description/ Recommendation
1338	ABORT	Test cannot run because a planned SPE interchange is pending. 1. Wait for the planned interchange to complete, then for handshake to come up, then re-run test on newly standby SPE.
1339	ABORT	Test cannot run because handshake communication is not up. 1. Wait 5 minutes and try test again. If handshake is still not up (you get a 1339), solve the handshake problem as described in ‘‘Resolving Handshake Failure’’.
2000	ABORT	Communication with Standby SPE timed out. 1. Retry the test once after 2 minutes.
1374	FAIL	Test failed due to mismatch in packet-interface circuit packs. 1. Use **list config control** to verify discrepancy. 2. Fix the indicated discrepancy in packet-interface packs. 3. Re-run test. This mismatch test is not sensitive to firmware differences between the two packet-interface circuit packs. See the PKT-INT section for dealing with firmware variations.
1375	FAIL	Test failed due to mismatch in memory circuit packs. 1. Use "list config control" to verify discrepancy. 2. Fix the indicated discrepancy in memory packs. 3. Re-run test.
1376	FAIL	Test failed due to mismatch in either PROCR, SYSAM, DUPINT, or MSSNET circuit packs. 1. Use **list config control** to verify this highly unlikely discrepancy. 2. Fix the indicated discrepancy. 3. Re-run test.
	PASS	Active and standby SPEs’ hardware configurations agree in all critical components.

STO-DATA (Stored Data)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
STO-DATA	MINOR	test stored-data [long]*	Stored Data
STO-DATA	WARNING	test stored-data	Stored Data

NOTE:
STO-DATA problems can be caused by faulty MSS hardware or hardware used to provide communication between active and standby SPEs. If hardware errors are present for H-ADAPTER, R-MEDIA, DISK, or DUPINT, investigate those first and then run **test stored-data** to address file inconsistencies.

The Mass Storage System (MSS) consists of the following components which are part of the system's SPE:

- TN1657 Disk circuit pack
- TN1656 Tape circuit pack or TN2211 Optical Disk circuit pack (Removable media drive)
- Host Adapter circuit located on the UN332 MSS/Network Control circuit pack

Each disk and removable media drive stores 2 copies of each of the following:

- The software that the system runs (the "boot image")
- Translation data
- Software update data (also known as program updates or patches)
- Announcement files from the TN750 Announcement circuit pack
- File directory
- Error log
- In special circumstances, a core dump of all system memory (single copy)

The disk is the primary storage device. Files on disk are generally used to reboot the system or to restore files that are lost or corrupted during a malfunction. The removable media is used to backup the disk and as a portable medium for data, such as is used for introduction of a new software load.

In High and Critical Reliability systems (duplicated SPE) the removable media and disk drives are duplicated as part of the PPN control carrier, resulting in a total of 4 devices, each storing 2 copies of the aforementioned files. Ideally, the files on all of the devices are identical, but malfunctions or even normal operations can lead to inconsistencies.

Data Inconsistencies and STO_DATA Tests

The STO-DATA maintenance object is not a hardware component, but a strategy used to test for consistency between corresponding files on the different storage devices. When inconsistencies are found, STO-DATA errors and alarms are generated. The translation, announcement, and software update files are checked by comparing timestamps created when the files were saved from system memory. The boot image files are checked by comparing vintage numbers. The other files are not checked.

On systems with simplex SPE, a STO-DATA test compares the files on removable media to those on the disk. On systems with duplicated SPEs, the following comparisons of corresponding files are made:

1. Disk to removable media (active SPE)
2. Disk to removable media (standby SPE)
3. Disk (active SPE) to disk (standby SPE)
4. Removable Media (active SPE) to removable media (standby SPE)

The data consistency tests are run as part of the short and long demand test sequences and automatically during daily scheduled maintenance. Test results point to which files, if any, are out of date.

In addition to the data consistency tests, checksum tests are run during the long demand test sequence to verify that the checksums of both copies of the boot image on each storage device are the same. This capability is useful when the system has booted using a boot image other than the first copy on disk. (An alarm and unique error code identify this situation). In addition to test results, you can use the **list configuration software** command to retrieve detailed information about the files on each storage device.

Backing Up Data: MSS Commands

Several commands are available for copying files from system memory to the MSS, and for copying files from one MSS device to another. They are summarized in the following table. Refer to Chapter 8, for complete descriptions and additional options for these commands.

Table 9-617. Mass Storage System Commands

Command	Execution Time *	Action/Remarks
save translation [disk][1]	2 minutes	Copy translation from system memory to disk. File is timestamped at time of command.
save announcement	40 minutes	Copy announcement file from TN750 to disk. File is timestamped at time of command. Use after recording announcements.
restore announcement	40 minutes	Copy announcement file from disk back to TN750. Use after a TN750 or announcement administration error.
backup disk [incremental]	20-50 minutes	Copy from disk to removable media all files on disk that are newer. Done to both SPEs if duplicated
backup disk full	50 minutes	Copy all disk files to removable media. Done to both SPEs if duplicated. Use after replacing removable media cartridge.
restore disk [full]	50 minutes	Copy all removable media files to disk. Use after disk is replaced. Done to both SPEs if duplicated.
copy announcement removable-media	2 minutes	Copy announcement file from disk to removable media. Keeps timestamps consistent.
copy update-file removable-media	2 minutes	Copy update file from disk to removable media. Keeps timestamps consistent.

1. Execution times vary; those shown are expected maximums. Entries in brackets ([]) are defaults and need not be entered. Pipes (|) indicate a choice between options.

The following commands are not used in normal backup or maintenance procedures. They are sometimes useful in special situations such as software updates or resolving specific file inconsistencies between devices.

Table 9-618. Special Purpose MSS Commands

Command	Execution Time[1]	Action/Remarks
save translation removable-media	10 minutes	Copy translation from memory to removable media. Use only for special situations. Causes STO-DATA tests to fail since removable media timestamp is newer than disk.
copy announcement spe-a|spe-b disk	2 minutes	Copy announcement data from removable media to disk. Useful for restoring announcement file on disk
copy update-file spe-a|spe-b disk	2 minutes	Copy update (patch) data from removable media to disk. Useful for restoring update data on disk
copy bootimage [spe-a|spe-b|both] removable-media	2 minutes	Copy boot image from disk to removable media. Useful for restoring boot image on removable media.
copy bootimage [spe-a|spe-b|both] disk	2 minutes	Copy boot image from removable media to disk. Useful for restoring boot image on disk

1. Execution times vary; those shown are expected maximums. Entries in brackets ([]) are defaults and need not be entered. Pipes (|) indicate a choice between options.

Automatic Backups

During normal operations, files in system memory, on disk, and on removable media can become inconsistent (for example, when translations are changed, when announcements are saved). During daily scheduled maintenance, several actions are take to keep data files consistent:

1. At the start of scheduled maintenance, translations and error logs are saved. This step must be enabled by the “Save Translation” field on the **change system-parameters maintenance** form.
2. Disk files are backed up to removable media.
3. STO-DATA tests are run along with other daily maintenance tests.

At the end of this sequence, disk and removable media files should all be identical, and translations and error logs files should be current with system memory. Announcement files are not saved automatically, and should be manually saved after recording or altering announcements. The automatic backup will however transfer these from disk to removable media.

File Inconsistencies: Causes

A number of things can cause files to become inconsistent between devices. **Test stored data** and **list configuration software** can be used to identify which files are affected. Described below are some of the causes of inconsistencies.

Save commands

Whenever a **save translation** or **announcements** is executed, the files on disk are newer than the files on removable media until a **backup disk** is performed either by command or by daily scheduled maintenance. If **test stored-data** is run before a backup, Tests #833 and #834 will fail with error code 1 or 8, generating a warning alarm against STO-DATA. Once a disk backup is performed, running the stored data tests will clear the alarm. A copy command can be used instead of backup to save time; take extra care to enter the right options so good files are not lost.

When **save translation removable-media** or **save announcements removable-media** is executed, timestamps on the removable media files will be newer than those on the disk files. (This is the opposite of normal operational sequences.) These commands should not be used as part of standard administration or repair procedures. When the files are in this state, automatic or demand incremental backups from disk will be prevented from overwriting the removable media files, and subsequent STO-DATA tests will fail, generating warning alarms.

Save to removable media commands may be useful when the disk has failed and the removable media is being used temporarily for primary storage. Once the disk is replaced, **restore disk** can be used to recoordinate the files.

Dirty Files

Two copies of each file are stored on each MSS device. This protects against data loss in case a failure occurs while data is being written. If such a failure occurs, or if a removable media cartridge is pulled out of the drive while data is being written to it, the incomplete file is marked as a “dirty” file. The system will then use the other copy for reading data and will generate a minor alarm against R-MEDIA or DISK. As long as one of the copies is clean, STO-DATA tests will test the clean copy and not report any errors.

Removable Media Replacement

If the removable media is a tape, the tape cartridges are periodically replaced (for example, after a R-MEDIA warning alarm with error type 2305, indicating that 90% of its useful life has been exceeded). Until a full disk backup is performed, the new removable media will be inconsistent with the disk.

Inconsistent Files: Solutions

The best way to clear STO-DATA alarms is to perform a **save translation** or **announcements** (if those files are affected), followed by a **backup disk**. Daily scheduled maintenance also performs this sequence. There are unusual situations in which other actions are required. If problems exist on the TN750 Announcement circuit pack, avoid saving announcements until resolving those problems. Otherwise, good copies of the files could be overwritten by bad ones.

The default for the backup command is “incremental,” meaning that files on removable media with newer timestamps than those on disk are not overwritten. This can occur when a save is made to removable media. Save followed by backup will still work, but time can be saved by **restore disk**.

Inconsistency across SPEs

When the SPE is duplicated, disruptions to inter-SPE communication, or MSS writes on one SPE but not on the other, can cause files to be inconsistent between devices on the different SPEs. You can detect this situation by running **list configuration software long** and inspecting the timestamps and software version numbers. Correct procedure depends on which device has the correct boot image.

Disk on Active SPE Has Correct Boot Image:

1. **save translation active** (2 min)
2. **backup disk active** (40 min)
3. Put the removable media cartridge from the active SPE into the removable media drive on the standby SPE. Put the removable media cartridge from the standby SPE into the removable media drive on the active SPE.
4. **backup disk active** (40 min)
5. **restore disk standby** (40 min)
6. **test stored data**

Removable Media on Active SPE Has Correct Boot Image:

1. **save translation removable-media active** (2 min)
2. **restore disk active** (40 min)
3. Put the removable media cartridge from the active SPE into the removable media drive on the standby SPE. Put the removable media cartridge from the standby SPE into the removable media drive on the active SPE.
4. **backup disk active** (40 min)
5. **restore disk standby** (40 min)
6. **test stored data**

Error Log Entries and Test to Clear Values

Table 9-619. STORED-DATA Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1 (a)	1 to 6	Carrier A Removable Media-Disk Consistency Test (#833)	WARNING	OFF	test stored-data
257 (b)	1	Carrier A Removable Media-Disk Consistency Test (#833	WARNING	OFF	test stored-data
513 (a)	1 to 6	Carrier B Removable Media-Disk Consistency Test (#834)	WARNING	OFF	test stored-data
542 (c)	0	Scheduled translation save	-	-	
543 (d)	0	Scheduled disk backup	-	-	
769 (b)	1	Carrier B Removable Media-Disk Consistency Test (#834)	WARNING	OFF	test stored-data
1025 (e)	1 to 6	Removable Media-Removable Media Consistency Test (#835)	MINOR	OFF	test stored-data
1281 (f)	1	Removable Media-Removable Media Consistency Test (#835)	MINOR	OFF	test stored-data
1537 (e)	1 to 6	Disk-Disk Consistency Test (#836)	MINOR	OFF	test stored-data
1793 (f)	1	Disk-Disk Consistency Test (#836)	MINOR	OFF	test stored-data
2049 (g)	1 to 3	Carrier A Boot Image Test (#837) (Runs at system boot time only)	MINOR	OFF	test stored-data long
2305 (g)	1 to 3	Carrier B Boot Image Test (#837) (Runs at system boot time only)	MINOR	OFF	test stored-data long

Continued on next page

Table 9-619. STORED-DATA Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3073 (h)	30004 30014 30201	Carrier B Removable Media Checksum Test (#831)	MINOR	OFF	test stored-data long
3329 (h)	30004 30014 30201	Carrier B Disk Checksum Test (#832)	MINOR	OFF	test stored-data long
3585 (i)	Any		WARNING	OFF	test stored-data
3586 (j)	Any		WARNING	OFF	test stored-data
3587 (k)	Any		WARNING	OFF	test stored-data
3841 (i)	Any		WARNING	OFF	test stored-data
3842 (j)	Any		WARNING	OFF	test stored-data
3843 (k)	Any		WARNING	OFF	test stored-data

Notes:

a. Error types 1 and 513 indicate that one or more of the following conditions has occurred on Carrier A or Carrier B respectively: the timestamps of the translation files on the two storage devices are inconsistent, the timestamps of the announcement files on the two storage devices are inconsistent, or the timestamps of the program update files on the two storage devices are inconsistent.

   The auxiliary data for the error type can be used to determine which files are inconsistent. That information is presented in the table below. More than one data inconsistency may exist, but only the fault with the highest auxiliary data number will appear in the error log. Enter the **test stored-data** command to obtain more information about the failure and follow the associated repair procedures.

Table 9-620. Auxiliary Data for Error Types 1 and 513

Aux Data	Data File Inconsistency
1	Disk translation data is newer than the removable media translation data
2	Removable Media translation data is newer than the disk translation data
3	Disk announcement data is newer than the removable media announcement data
4	Removable Media announcement data is newer than the disk announcement data
5	Disk program update data is newer than the removable media program update data
6	Removable Media program update data is newer than the disk program update data

b. Error types 257 and 769 indicate that the vintages of the boot images on the two storage devices on Carrier A or Carrier B respectively, are inconsistent.

1. Use the **list configuration software-vintage** command to get the vintage numbers and install the correct vintage.
2. Run the data storage tests by entering **test stored-data** to retire the alarm.
3. If the STORED-DATA tests fail, refer to the repair procedures for those tests for further information.

c. Error type 542 indicates that the scheduled daily save-translation operation failed. If a STORED-DATA alarm is active, it is due to a data inconsistency.

1. Refer to the alarm log and clear any failures associated with the HOST ADAPTER, R-MEDIA, or DUPINT circuit and clear those problems first.
2. Then save translation manually by entering **save translation** and backup the disk manually by entering **backup disk**. Note: this operation may take up to an hour.
3. Run the data storage tests by entering **test stored-data** to retire the alarm.
4. If the STORED-DATA tests fail, refer to the repair procedures for those tests for further information.

d. Error type 543 indicates that the scheduled daily disk backup operation failed. If a STORED-DATA alarm is active, it is due to a data inconsistency.

1. Refer to the alarm log and clear any failures associated with the H ADAPTR, DISK, or DUPINT circuit and clear those problems first.
2. Then backup translation manually by entering **backup disk**. Note: this operation may take up to an hour.
3. Run the data storage tests by entering **test stored-data** to retire the alarm.
4. If the STORED-DATA tests fail, refer to the repair procedures for those tests for further information.

e. Error types 1025 and 1537 indicate that one or more of the following conditions has occurred between the removable media cartridges or between the disks respectively, in each carrier: the timestamps of the translation files on the two storage devices are inconsistent, the timestamps of the announcement files on the two storage devices are inconsistent, or the timestamps of the program update files on the two storage devices are inconsistent.

This auxiliary data for the error type can be used to determine which files are inconsistent. That information is presented in the table below. More than one data inconsistency may exist, but only the fault with the highest auxiliary data number will appear in the error log. Enter the **test stored-data** command to obtain more information about the failure and follow the associated repair procedures.

Auxiliary Data for Error Types 1025 and 1537

Aux Data	Data File Inconsistency
1	Translation data on the carrier A device is newer than the translation data on the carrier B device
2	Translation data on the carrier B device is newer than the translation data on the carrier A device
3	Announcement data on the carrier A device is newer than the announcement data on the carrier B device
4	Announcement data on the carrier B device is newer than the announcement data on the carrier A device
5	Program update data on the carrier A device is newer than the program update data on the carrier B device
6	Program update data on the carrier B device is newer than the program update data on the carrier A device

f. Error types 1281 and 1793 indicate that the vintages of the boot images on two the storage devices on Carrier A or Carrier B respectively, are inconsistent. Use the **list configuration software-vintage** command to get the vintage numbers and install the correct vintage.

g. Error types 2049 and 2305 indicate that a copy of the boot image other than the primary copy on the primary device on Carrier A or Carrier B, respectively, was used to boot the system. The check of which copy of the boot image was used is made only at boot time. Use the following procedures based on the Auxiliary Data to clear the problem on Carrier A or Carrier B.

Table 9-621. Auxiliary Data for Error Types 2049 and 2305

Aux Data	Description / Recommendation
1	The secondary boot image on the disk was used to boot the system. 1. Run **test stored-data long** to verify that the primary copy of the boot image is invalid. 2. Restore the bad copy from the removable media by issuing a **restore disk** command. 3. Run **test stored-data long** to retire the alarm.
2	The primary boot image on the removable media was used to boot the system. 1. Run **test disk long** for the disk on the SPE carrier which reports the failure. If any tests fail, refer to DISK repair procedures for further action. 2.) Run **test stored-data long** to verify that the primary and secondary copies of the boot image on the disk are invalid. 3. Restore the copies on the primary device from the copies on the secondary device by issuing a **restore disk** command. 4. Run **test stored-data long** to retire the alarm.
3	The secondary boot image on the removable media was used to boot the system. 1. Run **test stored-data long** to verify that the primary and secondary copies of the boot image on the disk and the primary copy of the boot image on the removable media are all invalid. 2. Insert a backup removable media cartridge of the correct vintage. 3. Run **save translation removable-media** to get the latest translation on the backup removable media. 4. Run **copy announcement removable-media** to get the latest announcements on the backup removable media. 5. Run **restore disk** to copy the good boot images, translations, announcements and software update files to the disk. 6. Run **test stored-data long** to retire the alarm.

h. Error types 2561, 2817, 3073, and 3329 indicate that the checksum test for the two copies of the boot image on the Carrier A removable media, Carrier A disk, Carrier B removable media, or Carrier B disk, respectively, are inconsistent. (Auxiliary data 30004 indicates that the device could not be read, auxiliary data 30014 indicates that the file type is invalid, and auxiliary data 30201 indicates the checksum is bad).

i. Error types 3585 and 3841 indicate that a save translation to disk failed on carrier A or B, respectively.

  1. Refer to the alarm log and clear any H-ADAPTR, DISK, R-MEDIA, or DUPINT alarms first.
  2. Enter **save translation**. This operation may take up to an hour.
  3. Run **test stored-data** to retire the alarm.
  4. If the Stored Data tests fail, refer to the repair procedures for those tests.

j. Error types 3586 and 3842 indicate that an attempt to restore the disk from removable media failed on carrier A or B, respectively.

  1. Refer to the alarm log and clear any H-ADAPTR, DISK, R-MEDIA, or DUPINT alarms first.
  2. Enter **restore disk**. This operation may take up to an hour.
  3. Run **test stored-data** to retire the alarm.
  4. If the Stored Data tests fail, refer to the repair procedures for those tests.

k. Error types 3587 and 3843 indicate that an attempt to backup the disk to the removable media failed on carrier A or B, respectively.

  1. Refer to the alarm log and clear any H-ADAPTR, DISK, R-MEDIA, or DUPINT alarms first.
  2. Enter **backup disk**. This operation may take up to an hour.
  3. Run **test stored-data** to retire the alarm.
  4. If the Stored Data tests fail, refer to the repair procedures for those tests.

System Technician-Demanded Tests

The sequence of tests performed depends on whether the SPE is duplicated.

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *A Carrier R-Media Checksum Test*, for example, you may also clear errors generated from other tests in the testing sequence.

	Short Sequence				Long Sequence			
SPE:	**Simplex**		**Duplex**		**Simplex**		**Duplex**	
MSS (D:disk/r-media, R:r-media only)	**D**	**R**	**D**	**R**	**D**	**R**	**D**	**R**
A Carrier Removable Media Checksum Test (#829)					X	X	X	X
B Carrier Removable Media Checksum Test (#830)							X	X
A Carrier Disk Checksum Test (#831)					X		X	
B Carrier Disk Checksum Test (#832)							X	
A Carrier Removable Media to Disk Consistency Test (#833)	X		X		X		X	
B Carrier Removable Media to Disk Consistency Test (#834)			X		X		X	
A to B Carrier Removable Media Consistency Test (#835)			X	X			X	X
A to B Carrier Disk Consistency Test (#836)			X				X	

The A/B Carrier Boot Image Test (#837) runs only at system boot time.

A Carrier and B Carrier Removable Media Checksum Tests (#829/#830)

A checksum is done on the primary copy of the boot image on the removable media and also on the secondary copy of the boot image on the removable media. A comparison is made to verify that these two checksums are the same. This test is run as part of the **test stored-data long** demand test.

Table 9-622. TESTS #829 and #830 Removable Media Checksum Tests

Error Code	Test Result	Description/ Recommendation
1303	ABORT	Could not run the test—internal MSS error 1. Retry the command
1304	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (Use the **display system-parameters maintenance** command to display the start time for scheduled maintenance and the "y/n" option for saving translation daily).
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby SPE is restored to service (use **status spe** to determine state of standby SPE) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby SPE is restored to service (use **status spe** to determine state of standby SPE) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 retries.

Continued on next page

Table 9-622. TESTS #829 and #830 Removable Media Checksum Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
30004	FAIL	The removable media cartridge could not be read. 1. Verify a removable media cartridge is in the removable media drive. 2. Retry the command at 1-minute intervals for a maximum of 5 retries.
30014	FAIL	An invalid file system was found. 1. Verify the correct removable media cartridge is in the removable media drive. 2. Otherwise, insert the correct removable media cartridge and re-run **test stored-data long**.
30201	FAIL	The checksums of the boot images for the removable media are inconsistent. 1. If a removable media-only system, replace the removable media. Follow the procedures presented in the Section **XXX** of this manual. 2. If a disk/removable media system, run **backup disk full** on the carrier containing the bad removable media (this could take up to an hour to complete). 3. Run **test stored-data long** to resolve the alarms.
	PASS	The checksums are consistent between the two boot images on the removable media. 1. If other mss errors are present, refer to the maintenance information for the H ADAPTR, R-MEDIA, and DISK maintenance objects to clear those errors.

A and B Carrier Disk Checksum Tests (#831/#832)

A checksum is done on the primary copy of the boot image on the disk and also on the secondary copy of the boot image on the disk. A comparison is made to verify that these two checksums are the same. This test is run as part of the **test stored-data long** demand test.

Table 9-623. TESTS #831 and #832 Disk Checksum Tests

Error Code	Test Result	Description/ Recommendation
1303	ABORT	Could not run the test—internal MSS error.
1304	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.

Continued on next page

Table 9-623. TESTS #831 and #832 Disk Checksum Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
30201	FAIL	The checksums of the boot images for the disk were inconsistent. 1. Run **restore disk full** on the carrier containing the bad disk (this could take up to an hour to complete). 2. Run **test stored-data long** to resolve the alarms.
	PASS	The checksums are consistent between the two boot images on the disk. 1. If other mss errors are present, refer to the maintenance information for the H ADAPTR, R-MEDIA, and DISK maintenance objects to clear those errors.

Test #833 (A Carrier) and #834 (B Carrier) Removable Media to Disk Consistency Tests

There are two copies of the boot image, translation data, announcement data, and program update date on each storage device. In each of the checks performed by these tests, the system chooses one copy of each that it deems "best." These tests then perform four checks. First, the vintage of one of the boot images on removable media is compared to the vintage of one of the boot images on disk. The test verifies that the two chosen copies are consistent. Second, the time stamp of one of the copies of the translation file on the removable media is compared to the time stamp of one of the translation files on the disk. If the files are inconsistent, the test reports which one is newer. Next, the time stamp of one of the copies of the announcements file on the removable media is compared to the time stamp of one of the announcements files on the disk. Finally, the time stamp of one of the copies of the program update file on the removable media is compared to the time stamp of one of the program update files on the disk. If the files are inconsistent, the test again reports which one is newer.

This test is run as part of the **test stored-data** demand test and during daily scheduled maintenance. The following table is used in diagnosing fail results.

Table 9-624. TESTS #833 and #834 Failure Numbers

Failure Number	File Inconsistency
1	The translation file on the disk is newer than the translation file on the removable media.
2	The translation file on the removable media is newer than the translation file on the disk.
4	The vintages of the boot images on the removable media and disk are inconsistent.
8	The announcement file on the disk is newer than the announcement file on the removable media.
16	The announcement file on the removable media is newer than the announcement file on the disk.
32	The program update file on the disk is newer than the program update file on the removable media.
64	The program update file on the removable media is newer than the program update file on the disk.

Table 9-625. TESTS #833 (A Carrier) and #834 (B Carrier) Removable Media to Disk Consistency Tests

Error Code	Test Result	Description/ Recommendation
1304	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1333	ABORT	Could not run the test—internal MSS error.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Continued on next page

Table 9-625. TESTS #833 (A Carrier) and #834 (B Carrier) Removable Media to Disk Consistency Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.

Continued on next page

Table 9-625. TESTS #833 (A Carrier) and #834 (B Carrier) Removable Media to Disk Consistency Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	One or more of the 4 files checked was inconsistent with the file on the other device. 1. Enter **list configuration software** to determine the inconsistent file. If a file on removable media is the older file, use **backup disk** to copy the disk file to the removable media. If a file on disk is older file, use **restore disk** to copy the removable media file to the disk. 2. If for some reason the **list configuration software** command does not provide the necessary data: a. Convert the error code to a set of failure numbers. The error code returned by the test is the sum of one or more failure numbers listed in the table at the beginning of this test description, *Tests 833 and 834 Failure Numbers*. Using that table, subtract the largest failure number possible (so as to leave a positive remainder) from the error code and note the associated inconsistency from the table. Continue subtracting failure numbers from the remainder until the remainder is 0. The numbers subtracted represent the inconsistencies found. b. Use the results of the four consistency tests (#833, #834, #835 and #836) to determine the device with the incorrect files. If the files on the removable media are newer than the files on the disk, restore the disk from the removable media (**restore disk**). If the files on the disk are newer than the files on the removable media, backup the removable media from its disk (**backup disk**).
	PASS	The files are consistent between the disk and the removable media. 1. If other MSS errors are present, refer to the H-ADAPTR, R- MEDIA, and DISK sections.

Removable Media to Removable Media and Disk to Disk Consistency Tests (#835/#836)

There are two copies of the boot image, translation data, announcement data and program update data on each storage device. In each of the checks performed by these tests, the system chooses one copy of each that it deems "best." These tests then perform four checks. First, the vintage of one boot image on the Carrier A device is compared to the vintage of one boot image on the Carrier B device. The test verifies that the two chosen copies are consistent. Second, the time stamp of one copy of the translation file on the Carrier A device is compared to the time stamp of one copy of the translation file on the Carrier B device. If the files are inconsistent, the test reports which one is newer. Next, the time stamp of one copy of the announcement file on the Carrier A device is compared to the time stamp of one copy of the announcement file on the Carrier B device. Finally, the time stamp of one copy of the program update file on the Carrier A device is compared to the time stamp of one copy of the program update files on the Carrier B device. If the files are inconsistent, the test again reports which one is newer.

This test is run as part of the **test stored-data** demand test and during daily scheduled maintenance. The following table is used in diagnosing fail results.

Table 9-626. TEST #835 and #836 Failure Numbers

Failure Number	File Inconsistency
1	The translation file on the Carrier A device is newer than the translation file on the Carrier B device.
2	The translation file on the Carrier B device is newer than the translation file on the Carrier A device.
4	The vintages of the boot images on the two devices are inconsistent.
8	The announcement file on the Carrier A device is newer than the announcement file on the Carrier B device.
16	The announcement file on the Carrier B device is newer than the announcement file on the Carrier A device.
32	The program update file on the Carrier A device is newer than the program update file on the Carrier B device.
64	The program update file on the Carrier B device is newer than the program update file on the Carrier A device.

Table 9-627. TESTS #835 and #836 Removable Media to Removable Media and Disk to Disk Consistency Tests

Error Code	Test Result	Description/ Recommendation
1304	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1333	ABORT	Could not run the test—internal MSS error.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.

Table 9-627. TESTS #835 and #836 Removable Media to Removable Media and Disk to Disk Consistency Tests — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	One or more of the 4 files checked was inconsistent with the file on the other device. 1. Enter **list configuration software** to determine the inconsistent file. If a file on removable media is the older file, use **backup disk** to copy the disk file to the removable media. If a file on disk is older file, use **restore disk** to copy the removable media file to the disk. 2. If for some reason the **list configuration software** command does not provide the necessary data: a. Convert the error code to a set of failure numbers. The error code returned by the test is the sum of one or more failure numbers listed in the table at the beginning of this test description, *Tests 835 and 836 Failure Numbers*. Using that table, subtract the largest failure number possible (so as to leave a positive remainder) from the error code and note the associated inconsistency from the table. Continue subtracting failure numbers from the remainder until the remainder is 0. The numbers subtracted represent the inconsistencies found. b. Use the results of the four consistency tests (#833, #834, #835 and #836) to determine the device with the incorrect files. If the files on the removable media are newer than the files on the disk, restore the disk from the removable media (**restore disk**). If the files on the disk are newer than the files on the removable media, backup the removable media from its disk (**backup disk**).
	PASS	The files are consistent between the compared devices. 1. If other MSS errors are present, refer to the H-ADAPTR, R-MEDIA, and DISK sections.

STRAT-3 (Stratum 3 Clock)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
STRAT-3	MAJOR	test synchronization	Stratum 3 Clock
STRAT-3	MINOR	test synchronization	Stratum 3 Clock

The *Digital Synchronization Network Plan (PUB 60110)* specifies a hierarchy of synchronization nodes consisting of strata 1 to 4, where the sole Stratum 1 clock in the network is the most accurate. The Release 5r system supports both Stratum 3 and Stratum 4 operations. Refer to “SYNC (Synchronization)” for details on Stratum 4 operation.

A Stratum 3 clock derives its timing from two DS1 references connected to a Stratum 3 or better source. The Stratum 3 clock provides a holdover of at least 24 hours should both DS1 references fail. (After 24 hours, the Stratum 3 clock still provides service but its accuracy may be degraded). The *Digital Synchronization Network Plan (PUB 60110)* requires that the Stratum 3 clock have duplicated components.

The Stratum 3 clock can be configured with only one DS1 input if one of the Clock Input cards is removed. Also, the Stratum 3 clock can free run (use its internal clock without using DS1 inputs, if both Clock Input cards are removed).

The recognition of the Stratum 3 clock itself as well as its alarm signals, is supported only by the TN780 Tone-Clock circuit pack. The TN780 Tone-Clock circuit pack is also backwards-compatible with the TN768 Tone-Clock circuit pack. The Stratum 3 clock may be connected to the PPN if the TN780 Tone-Clock circuit pack(s) is present in that port network. The Stratum 3 clock should never be connected to an EPN.

The only operation that software can perform is a query of the alarm leads. The only recovery action that can be performed on a catastrophic failure of the Stratum 3 clock is using the local oscillator on the active TN780 Tone-Clock circuit pack. Neither software nor the TN780 Tone-Clock circuit pack can request additional information about the health of the Stratum 3 clock other than the information provided by the alarm leads. Furthermore, neither the software nor the TN780 Tone-Clock circuit pack can request that the external clock switch references, change configuration, disable/enable, initialize, and so forth.

In the system, the Stratum 3 clock has been implemented as an external which follows the specification in PUB 60110 for Stratum 3. The only external Stratum 3 clock that is supported is the Telecom Solutions Digital Clock Distributor™ for Customer Premise Timing (DCD-CPT) Stratum 3 clock. Figure 9-93 shows how the Stratum 3 hardware configuration provides clock and alarm signals to the TN780 Tone-Clock circuit pack(s). The reference DS1 facilities connect directly to the Stratum 3 clock for timing purposes, but the DS1 data may be routed into the switch by using a Y connector (H-600-274 G1 for the 50 pin DS1 end or H-600-274 G2 for the 15 pin DS1 end).

For more information on the installation of the Stratum 3 clock, see the *DEFINITY Enterprise Communications Server Release 5.4 Installation and Test for Multi-Carrier Cabinets*.

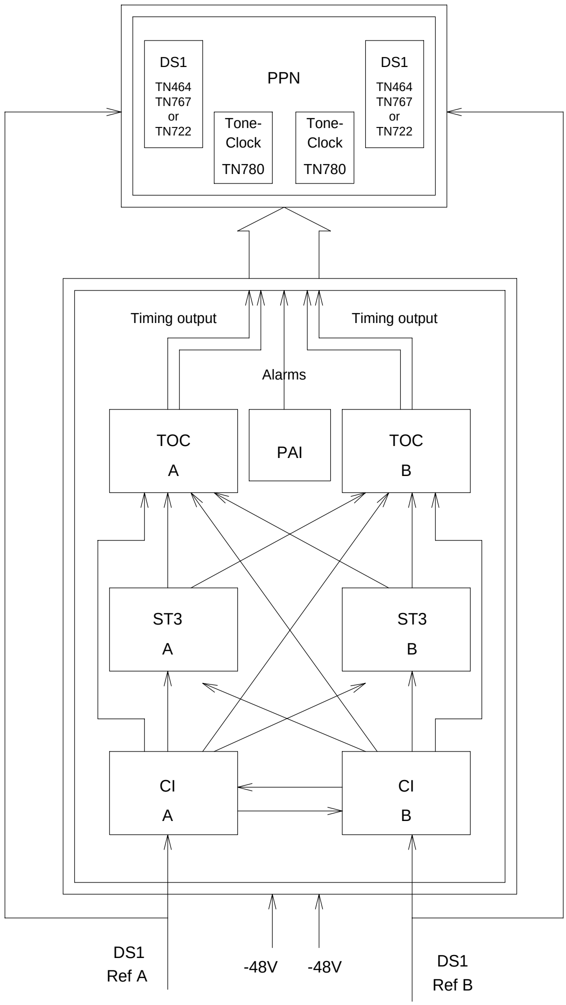

Figure 9-93. Stratum 3 Clock Hardware Configuration

Stratum 3 Clock LED Strategy

NOTE:
When looking in the Stratum 3 cabinet, ‘‘A’’ card is on the left and ‘‘B’’ card is on the right.

NOTE:
The normal LED scheme is not followed for this device. Green LEDs do not indicate maintenance activity. There are no yellow LEDs, and there are more than three LEDs per circuit pack.

NOTE:
Removal of a card in the Stratum 3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum 3 clock to full service.

The Stratum 3 clock has the following components:

- 2 Clock Input cards (CI)

  Provides the logic to select the better DS1 reference or Clock Input card. The red FAIL LED on this card indicates a failure with the card or the DS1 reference connected to it.

- 2 Stratum 3 Cards (ST3)

  Provides 24-hour holdover. The red FAIL LED on this card indicates a failure with the card. Replace the card.

- 2 Timing Output Cards (TOC)

  Provides cable length compensation, multiple output ports, selection of the ST3, and CI outputs. This type of card has two red failure LEDs: one indicates a failure of the card; the other indicates a failure in one or more output ports. In either case, replace the card.

- 1 PBX (Private Branch Exchange) Alarm Interface (PAI)

  Filters power supplied to the clock, provides fuse protection, and provides alarm indications based on inputs supplied by other cards. The six LEDs on this card provide indications for the six alarm or status conditions as follows:

  — Loss of DS1 reference A

  — Loss of DS1 reference B

  — Loss of one clock unit

  — Loss of both clock units

  — Loss of one power supply

  — Loss of both power supplies

The output of the CI and PAI cards go directly to the TN780 Tone-Clock circuit pack via two 25-pair amphenol-terminated cables. All of the cards have red and/or green LEDs for providing status or alarm indications. The abbreviations used in the table are defined above except for SRC (source) and PLL (Phase Locked Loop).

Table 9-628. Stratum 3 Clock LED Indications

Card	Name	Color	Indication
PAI	REF A	Red	Loss of input reference A or CI A failed
	REF B	Red	Loss of input reference B or CI A failed
	ST A	Red	Failed Stratum 3 clock A
	ST B	Red	Failed Stratum 3 clock B
	PWR A	Green	-48VDC A present
	PWR B	Green	-48VDC B present
CI	FAIL	Red	Card failure
	DS1	Green	DS1 source present
	CC	Green	Composite clock source[1] present
	SRC ACTIVE	Green	Card is currently on-line
ST3	FAIL	Red	Card failure
	LOCK	Red	PLL lost sync with reference or holdover mode
	REF A	Red	Timing Reference from CI A
	REF B	Red	Timing Reference from CI B
TOC	FAIL	Red	Card failure
	PORT ALM	Red	Output port alarm (one or more)
	ST	Green	Reference present from ST clock
	INPUT	Green	Reference present from CI
	500’	Green	500 feet phase advance
	1000’	Green	1000 feet phase advance

1. Composite Clock (CC) source refers to the protocol used to electrically transfer timing from the Stratum 3 clock to the switch. The Composite Clock source is not relevant to the system.

Error Log Entries and Test to Clear Values

Table 9-629. Stratum 3 Clock Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test synchronization r 4
1(a)	Any	Stratum 3 Clock Alarm Query (#649	MINOR	OFF	test synchronization r 4
18(b)	0	disable sync	WARNING	OFF	enable sync
257(c)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR	OFF	test synchronization r 4
513(d)	Any	Stratum 3 Clock Alarm Query (#649	MINOR	ON	test synchronization r 4
769(e)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR	ON	test synchronization r 4
1025(f)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR/ MAJOR(h)	ON	test synchronization r 4
1281(g)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR /MAJOR(h)	ON	test synchronization r 4
1537(i)		none	MINOR/ MAJOR(h)	ON	
1793(j)		none	MINOR/ MAJOR(h)	ON	

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error type corresponds to FAIL code 1 of the Stratum 3 Clock Alarm Query (test #649): either reference A failed or the CI card A failed.

b. This error indicates that Synchronization Maintenance has been disabled via the **disable synchronization-switch** command. Execute the **enable synchronization-switch** command to enable Synchronization Maintenance reference switching and to resolve this alarm.

c. This error type corresponds to FAIL code 2 of the Stratum 3 Clock Alarm Query (test #649): one power supply failed.

d. This error type corresponds to FAIL code 4 of the Stratum 3 Clock Alarm Query (test #649): one clock unit failed.

e. This error type corresponds to FAIL code 8 of the Stratum 3 Clock Alarm Query (test #649): either reference B failed or the CI card B failed.

f. This error type corresponds to FAIL code 16 of the Stratum 3 Clock Alarm Query (test #649): all power supplies failed.

g. This error type corresponds to FAIL code 32 of the Stratum 3 Clock Alarm Query (test #649): all clock unit(s) failed.

h. An OFF-BOARD alarm on the Stratum 3 clock, indicates a DS1 facility problem; an ON-BOARD alarm indicates a fault in either the Stratum 3 clock or the connection between the Stratum 3 clock and the switch. If the Stratum 3 clock cannot be referenced and the local oscillator on the TN780 Tone-Clock circuit pack must serve as the reference, a Major alarm is raised. Otherwise, a Minor alarm is raised.

i. This error can be caused by one of the following conditions:

- One or both TOCs (Timing Output Cards) has failed.
- The connection between the Stratum 3 clock and the TN780 Tone-Clock circuit pack is faulty.
- The TN780 Tone-Clock circuit pack is defective.

A Minor alarm results if the Stratum 3 clock can still provide timing to the switch; otherwise, a Major alarm will be raised because the Stratum 3 clock is not providing timing and the switch is referencing the local oscillator on the TN780 Tone-Clock circuit pack. If only the Active TN780 Tone-Clock circuit pack is faulty, the Standby TN780 Tone-Clock circuit pack becomes active and remains synchronized to the Stratum 3 clock. When the system switches to the Standby Tone-Clock circuit pack, the alarm is resolved, and a TDM-CLK alarm is raised to indicate a possible problem on the TN780 Tone-Clock.

If the alarm is minor:

Look for a red LED on either or both TOC cards. If there is a red LED, then replace the card. If there is no red LED, then, using the *Stratum 3 Wiring Guide*, check that the wiring installation is correct. After replacing the card or correctly rewiring the installation, clear the alarm by first issuing the **disable synchronization-switch** command followed by the **enable synchronization-switch** command. The latter procedure will cause synchronization software to switch back to using the Stratum 3 clock again. Wait 2 minutes and then execute the **status synchronization** command. If Maintenance Name on the status screen shows ‘‘STRAT-3,’’ then the problem is resolved.

CAUTION:

*The **disable synchronization-switch** command followed by the **enable synchronization-switch** command may cause slip alarms. The circuit packs that can experience slips and the associated error log entry for slips are as follows.*

Table 9-630. Timing Slip Error Types

Circuit Pack Name	Error Log Name	Error Log Entry for Slips
DS1 Interface	DS1-BD	3073 to 3160
Expansion Interface	EXP-INTF	2305
Switch Node Interface	SNI-BD	1537
Tone-Clock	TDM-CLK	1025
UDS1 Interface	UDS1-BD	3073 to 3160

If the alarm is major:

Check connections between the Stratum 3 clock and the switch. If there are no loose connections, then, using the *Stratum 3 Wiring Guide*, check that the wiring installation is correct. After reconnecting the loose connection or correctly rewiring it, clear the alarm by first issuing the **disable synchronization-switch** command followed by the **enable synchronization-switch** command. Wait 1-minute, and then execute the **status synchronization** command. If Maintenance Name on the status screen shows "STRAT-3," then the problem is resolved.

If the Standby Tone-Clock circuit pack became active:

Check the connection between the Stratum 3 clock and the TN780 Tone-Clock circuit pack from which the system has just switched. If there are no loose connections, then, replace the TN780 Tone-Clock circuit pack. Refer to the "How to Replace the Tone-Clock circuit pack" section in the TDM-CLK (TDM Bus Clock) Maintenance documentation. Before switching back to the new TN780 Tone-Clock circuit pack, use the **test tone-clock UC long** command to check that the Tone-Clock is receiving a signal from the Stratum 3 clock. If all tests pass, switch to the new Tone-Clock circuit pack via the **set tone-clock UC override** command. If Test #651 fails, then the original TN780 Tone-Clock should be reinserted, and the cable between the Stratum 3 clock and the TN780 Tone-Clock circuit pack should be replaced. If Test #651 continues to fail, then escalate the problem.

For all of the above cases if slip alarms exist after following the repair procedures, clear the slip alarms by running the **test board** command with the **clear** option. See the table on the previous page for a list of circuit packs and associated slip error log entries.

This error indicates that the Tone-Clock circuit pack in the master port network is not a TN780. If duplicate Tone-Clock circuit packs exist in the master port network, this error may mean that one or both Tone-Clock circuit packs are not TN780s. Verify that the Tone-Clock(s) in the master port network are TN780s.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Stratum 3 Clock Alarm Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

The **test synchronization** commands also runs the Test Synchronization test (test #417). Test 417 is described in the SYNC section.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Stratum 3 Clock Alarm Query (#649)	X	X	ND

1. D = Destructive, ND = Non-destructive

Stratum 3 Clock Alarm Query (#649)

This test queries the Stratum 3 clock for its alarm status and reports the results of the query. The Stratum 3 clock provides the system with the following six alarm indications via the TN780 Tone-Clock circuit pack:

- Reference A failed or CI card A failed.
- Reference B failed or CI card B failed.
- One power supply failed.
- All power supplies failed.
- One clock unit failed.
- All clock unit(s) failed.

CAUTION:
The removal of a card in the Stratum 3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum 3 clock to full service.

Table 9-631. TEST #161 Looparound Test

Error Code	Test Result	Description/ Recommendation
1001	ABORT	The system could not allocate the necessary resources to run this test. 1. Retry the command at 1-minute intervals up to a maximum of 3 times.
1005	ABORT	This test aborts when it is run on a Stratum 4 system. Do not change synchronization to Stratum 3 without consulting the synchronization plan administrator for this switch.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.
1	FAIL	Either Reference A failed or CI card A failed. This condition usually indicates a failure of the DS1 reference; however, there may also be a failure of the CI card to which the reference is connected. The system technician dispatched to investigate this problem should take a spare CI card in case the CI card caused the failure. If you are NOT ON-SITE, use the following procedure: 1. Look for DS1-BD (DS1 Interface Circuit Pack) errors using the **display error** command. Refer to the DS1-BD Maintenance documentation for recommended strategy to resolve any DS1-BD errors found. 2. If there are no DS1-BD errors OR after resolving all DS1-BD errors, issue the **test synchronization r 4** command to determine if the alarm is still present. If all repetitions of the tests pass, then the alarm no longer exists. Otherwise, the system technician should be dispatched with a spare CI card to use the following instructions on-site. (*continued*)

Continued on next page

Table 9-631. TEST #161 Looparound Test — *Continued*

<table>
<tr><th>Error Code</th><th>Test Result</th><th>Description/ Recommendation</th></tr>
<tr><td>1</td><td>FAIL</td><td>(continued)
If you are ON-SITE, use the following procedure:
1. Look for a red LED on CI card A (i.e., the left CI card). If there is a red LED, then replace the CI card, if a spare is available. If no spare CI is available on-site, proceed to Step 3. If after replacing the CI card, the red LED on the new CI card lights also, then proceed to Step 3.
2. If a spare CI card is available, replace the suspect CI card. Otherwise, issue the test synchronization r 4 command to clear the alarm. If any test repetitions fail, then follow the procedure for those failures.
3. Look for DS1-BD (DS1 Interface Circuit Pack) errors using the display error command. Refer to the DS1-BD Maintenance documentation for recommended strategy to resolve any DS1-BD errors found. If there are no DS1-BD errors, then proceed to Step 5.
4. After all DS1-BD errors have been resolved, then determine if the alarm still exists by issuing the test synchronization r 4 command to clear the alarm. If any test repetitions fail, then follow the procedure for those failures.
5. Check the DS1 reference A connections to the Stratum 3 clock.
6. Determine if the alarm still exists by issuing the test synchronization r 4 command to clear the alarm. If any test repetitions fail, then follow the procedure for those failures.</td></tr>
<tr><td>2</td><td>FAIL</td><td>One power supply failed. This error only occurs when the Stratum 3 clock has two power supplies, and one of them has failed. However, the clock can function with one power supply.
1. Locate the failed power supply by looking for a power supply with a red LED and replace it. The power supply is located under the Stratum 3 clock carrier.
2. Determine if the alarm still exists by issuing the test synchronization r 4 command to clear the alarm. If any test repetitions fail, then follow the procedures for those test failures.</td></tr>
</table>

Continued on next page

Table 9-631. TEST #161 Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL	One clock unit failed. 1. Look at the Stratum 3 cabinet for a red LED on a circuit card marked “ST3.” Replace the card. 2. Determine if the alarm still exists by issuing the **test synchronization r 4** to clear the alarm. If any test repetitions fail, then follow the procedures for those failures.
8	FAIL	Reference B failed or CI card B failed. This condition usually indicates a failure of the DS1 reference; however, there may also be a failure of the CI card to which the reference is connected. The system technician dispatched to investigate this problem should take a spare CI card in case the CI card caused the failure. If you are NOT ON-SITE, use the following procedure: 1. If there were no DS1-BD errors, OR if all DS1-BD errors have been resolved, enter **test synchronization r 4** to determine if the alarm is still present. If all repetitions of the tests pass, the alarm no longer exists. Otherwise, the system technician should be dispatched with a spare CI card to perform the following instructions on-site.
8	FAIL *(cont’d.)*	If you are ON-SITE, use the following procedure: 1. Look for a red LED on a CI card B (the CI card on the right). If there is a red LED, then replace the CI card, if a spare is available. If no spare CI is available on-site, proceed to Step 3. If, after replacing the CI card, the red LED on the new CI card lights, proceed to Step 3. 2. Otherwise, enter **test synchronization r 4** to clear the alarm. If any test repetitions fail, follow the procedure for those failures. 3. Enter **display errors** and look for DS1-BD errors. If there are any, refer to “DS1-BD”. If there are no DS1-BD errors, proceed to Step 5. 4. After all DS1-BD errors have been resolved, determine if the alarm still exists with **test synchronization r 4**. If any test repetitions fail, follow procedures for those failures. 5. Check the DS1 reference A connections to the Stratum 3 clock. 6. Determine if the alarm still exists with **test synchronization r 4** to clear the alarm. If any test repetitions fail, then follow procedures for those failures.

Continued on next page

Table 9-631. TEST #161 Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
16	FAIL	All power supplies failed. 1. Replace the failed power supplies. 2. If battery backup for the Stratum 3 clock is not supplied or if the battery backup holdover time has been exceeded, then the system will be referencing the local oscillator on the Active TN780 Tone-Clock circuit pack until software detects that one or both power supplies has(have) been restored (approximately 40 minutes). To speed up this restoration, issue the **test synchronization r 4** command. All tests should pass. If any repetitions should fail, then follow the procedures for those failures. The battery backup is located under the Stratum 3 clock carrier.
32	FAIL	All clock unit(s) failed. 1. Look at the Stratum 3 cabinet for red LEDs on circuit cards marked “ST3.” Replace the card(s). 2. Determine if the alarm still exists by issuing the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, then follow the procedure for those failures.
2101	FAIL	The TN780 Tone-Clock circuit pack detects loss of signal. Refer to note h of the STRAT-3 Hardware Error Log Entries table in the STRAT-3 (Stratum 3 Clock) Maintenance documentation for replacement procedures.
	PASS	The Stratum 3 clock has reported that it has no alarm conditions. If synchronization problems have been reported, look for SYNC errors and refer to SYNC (Synchronization) Maintenance documentation for recommended strategy for those errors.

SVC-SLOT (Service Slot)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
SVC-SLOT	MINOR	none	Service Slot

The Service Slot maintenance object detects the insertion of an invalid circuit pack a dedicated SERVICE slot. The SERVICE slot is the leftmost slot in the J58890BB Port Carrier, and is identified as slot location "00" in all commands, field entries, and displays on the management terminal.

Since this slot does not provide tip and ring connectivity to the wall field, only the following circuit packs are allowed:

- TN744 Call Classifier
- TN750 Integrated Announcement
- TN771 Maintenance/Test
- TN725 Speech Synthesizer
- TN433 Speech Synthesizer
- TN457 Speech Synthesizer
- TN748 Tone Detector
- TN420 Tone Detector
- TN755 Neon Power Unit

A MINOR alarm is generated against the Service Slot maintenance object when a circuit pack with a type other than that listed above is inserted in a SERVICE slot.

The Service Slot maintenance object name is used instead of the maintenance object name for the illegal circuit pack to prevent any attempt to assign a port to an illegal circuit pack physically inserted in the SERVICE slot.

Error Log Entries and Test to Clear Values

Table 9-632. Service Slot Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
600(a)		None	MINOR	ON	

Note:

a. Error type 600 indicates that a non-permitted circuit pack was inserted in slot 00, the SERVICE slot, of a J58890BB port carrier. See the preceding list of valid circuit packs for this slot.

The code of the invalid circuit pack can be displayed by using the **list configuration board UUCSS** command where UU is the cabinet number, C is the carrier letter, and SS is the slot number (always 00) of the alarmed circuit pack.

To retire the alarm, remove the invalid circuit pack.

SW-CTL (Switch Control)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SW-CTL	MAJOR[2]	test switch-control [a|b] short	Switch Control
SW-CTL	WARNING	test switch-control [a|b] short	Switch Control

1. In a system with simplex SPE, the carrier location, a need not be specified. In a system with duplicated SPEs, carrier a or b must be specified.
2. After a spontaneous SPE interchange has occurred, the Alarm Log retains for three hours a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and such an alarm is logged against SW-CTL, then replace the standby MSSNET circuit pack using the "lock-and-power-down" procedure described in Chapter 5.

The Switch Control resides on the MSSNET (Mass Storage System and Network Control) circuit pack (UN332). The Mass Storage System Host Adapter (HA) also resides on the MSSNET circuit pack. Systems equipped with the Standard Reliability configuration have a single MSSNET circuit pack and systems equipped with the High Reliability or Critical Reliability configuration have two MSSNET circuit packs, one in each Switch Processing Element (SPE) complex. The MSSNET cannot be replaced in a system with one SPE complex without bringing the system down. The MSSNET in the standby SPE of a system equipped with the High Reliability or Critical Reliability option can be replaced without affecting normal system operation.

The Switch Control sends control information between the SPE and port circuit packs on the Processor Port Network (PPN) as shown in Figure 9-94. This control information is sent via the PPN cabinet’s TDM (Time Division Multiplexed) bus. The portion of the TDM bus used to transmit control messages is called the control channel. The control channel can be on either TDM bus A or TDM bus B, but only one of the two buses is used for the control channel at any give time.

The Switch Control is involved in sending control channel messages for the setup and takedown of all calls involving endpoints connected to the PPN, but is not involved in the voice or data transmission that takes place during established calls. The Switch Control is also involved in setting up system links used for control of calls involving endpoints connected to Expansion Port Networks (EPNs). Once those links are set up at system boot time, a failure of the Switch Control will not affect existing calls or new calls involving those EPN endpoints.

One of the functions of the Switch Control is to detect when port circuit packs are plugged into or removed from the PPN cabinet. The Switch Control also monitors the health of the control channel on the PPN cabinet TDM bus and informs the SPE when errors occur.

The Switch Control also contains hardware to monitor critical system timing signals and informs the SPE when these signals fail. For example, if the timing signals from a Tone/Clock circuit pack fail, the Switch Control will inform the SPE and the SPE can then switch to a standby Tone/Clock circuit pack, (if Tone-Clocks are duplicated).

On High and Critical Reliability systems (duplicated SPE), a MAJOR alarm failure of the Switch Control circuit on the active SPE results in an SPE interchange, if the health of the standby SPE permits. (Refer to Chapter 1for more information about duplicated SPEs.) The following sections assume that if the SPEs are duplicated, and if a Switch Control circuit has a MAJOR alarm, the MSSNET circuit pack associated with that Switch Control circuit is located in the standby SPE.

As mentioned above, the MSSNET circuit pack contains both the Switch Control circuit and the MSS Host Adapter circuit. A failure of either circuit will light the red LED on the MSSNET circuit pack.

The **test mssnet** command tests both the Switch Control circuit and the MSS Host Adapter circuit on the MSSNET circuit pack. Whenever the MSSNET circuit pack is replaced, **test mssnet** should be used to verify that both circuits are operating correctly.

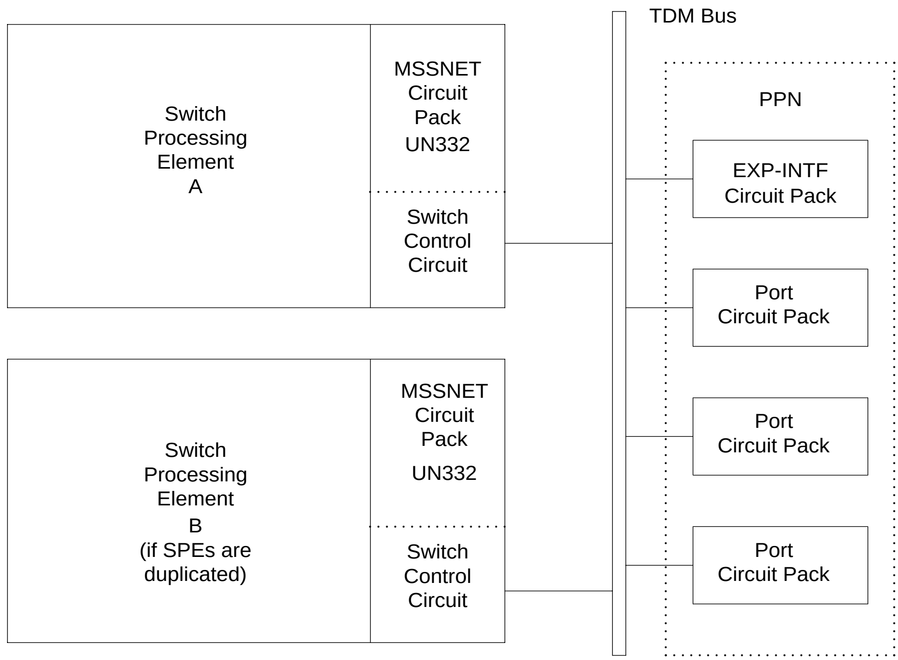

Figure 9-94. Switch Control Connectivity

Error Log Entries and Test to Clear Values

Table 9-633. Switch Control Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test switch-control [a|b] r 3
1(a)		Control Transmission Test (#94)Channel	MAJOR[2]	ON	test switch-control [a|b] r 3
2(b)		Control Channel Transmission Test (#94)	MAJOR[2]	ON	test switch-control [a|b] r 3
150(c)	Any	None	MAJOR[2]	ON	test switch-control [a|b] l c
257(d)	Any	None			
769(e)		None			
1025(f)		Control Channel Interface Test (#92)	MAJOR[2]	ON	test switch-control [a|b] r 2
1281(g)		None			
1537(h)		Switch Control Reset Test (#93)	MAJOR[2]	ON	test switch-control [a|b] l r 2
1793(i)		None			
2561(j)		None	WARNING	OFF	

1. Indicates that an alarm was raised but the associated error could not be entered into the hardware error log due to a momentary overload condition. Run the short test sequence and refer to the appropriate test description for tests that fail.
2. After a spontaneous SPE interchange has occurred, the Alarm Log retains for three hours a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and such an alarm is logged against SW-CTL, then replace the standby MSSNET circuit pack using the "lock-and-power-down" procedure described in Chapter 5.

Notes:

a. A 1 error indicates that there has been 8 or more Processor Port Network circuit pack removals in less than 15 minutes. This action may be forced manually by removing power to a port carrier or pulling out at least 8 port circuit packs within 15 minutes. The generation of this error may indicate that there is a problem with the Switch Control circuit on the MSSNET circuit pack or that there is a problem with the TDM bus. Three successful completions of the Control Channel test (#94) will resolve the MAJOR alarm caused by this error.

b. A 2 error indicates that the Switch Control Channel Transmission test (#94) failed. This error may not cause a Switch Control alarm if Error Type 769 is also present since this error may actually be caused by the loss of clock signals and not by a Switch Control failure. If the system is not equipped with the High Reliability or Critical Reliability option, or if the Switch control circuit is on the active processor, use the **test switch-control** command to test the Switch Control.

   In a system is equipped with duplicated SPEs and the hardware error is reported against the Switch Control on the standby processor, use the following procedures. The Control Channel Transmission test which detected this error cannot run on the Switch Control circuit on the standby SPE since the Switch Control circuit on the standby SPE is not allowed access to the TDM bus. Therefore if the system is equipped with duplicated SPEs and if this error is associated with the Switch Control circuit on the standby SPE, the error was detected while the Switch Control circuit was running on an active SPE.

   To allow the Control Channel test to run on this circuit, it will be necessary to initiate an SPE interchange, using the procedures described below. This action should only be taken during a time that would cause the least service disruption since exiting calls may disconnect if a failure detected on the newly active Switch Control circuit causes a spontaneous switch back to the other SPE. If this possible action is *not* acceptable, first verify that no TDM bus problems are detected when the **test TDM 1** command is entered and then replace the MSSNET circuit pack on the standby SPE. If TDM problems are detected, refer to the TDM-BUS maintenance documentation to clear those problems.

   1. Initiate a test of the Switch Control circuit on the standby SPE using the **test switch-control C long** command (where C represents the carrier location of the standby SPE) to make sure no other failure conditions can be detected. If failures are detected, use the diagnostic information associated with those tests to clear the failure before proceeding.

   2. Initiate an SPE interchange using the **reset system interchange** command. This should be done at a time that would cause the least service disruption since a fault may still exist on the MSSNET circuit pack. If the system reset command fails, refer to *Failure of Planned Interchange* in Chapter 5 for further actions.

   3. Enter the **test switch-control** command for the Switch Control now on the active SPE and verify that the Control Channel Transmission test (#94) passes. If a failure occurs, an automatic SPE interchange may occur. If an interchange back to the original SPE occurs, replace the MSSNET board on the standby SPE and go back to step 1 above. If other failures are detected, use the repair procedures associated with those tests to clear the failure.

c. A 150 error indicates that a SPE interchange occurred and that the Switch Control circuit on the MSSNET circuit pack was the cause of the spontaneous interchange.

   1. If other SW-CTL errors are present, investigate those errors

   2. If no other SW-CTL errors are present, run the **test switch-control a|b long clear** command and investigate those failures.

d. A 257 error is logged when the Switch Control circuit reports that tests of its internal memory (RAM or ROM) have failed. The receipt of this error causes Switch Control maintenance to run specific Switch Control tests. If there is a problem, the Switch Control tests will normally cause other errors to be logged. In the rare case where no other errors are logged but 257 errors are occurring at a high rate (more than 10 in the last hour) the MSSNET circuit pack should be replaced during a time that would cause the least service disruption. If the system is equipped with the High Reliability or Critical Reliability Configuration this can be done immediately since a MSSNET circuit pack on the standby SPE can be replaced without affecting service.

e. A 769 error occurs when the Switch Control reports a loss of timing signals to the SPE. When this error is present, the Switch Control will not normally be alarmed since any Switch Control test failures are really the result of faulty signals from the Tone/Clock circuit pack. See "TDM-CLK" for the procedures needed to diagnose Tone/Clock circuit pack troubles.

f. A 1025 error indicates that there has been a failure of the Control Channel Interface Test (#92). Refer to the diagnostics for that test to clear the problem.

g. A 1281 error is called a Switch Control handshake error. It is an in-line error not produced by any test. The Aux Data for this error is not meaningful. This error can be ignored.

   The receipt of this errors causes Switch Control maintenance to run specific Switch Control tests. If there is a problem, the Switch Control tests would cause other errors to be logged. 1281 errors do not cause alarms so there is no specific action that can be taken when these errors are observed.

h. A 1537 error indicates that the Switch Control Reset test (#92) failed. A MAJOR alarm is raised if this test fails. Refer to the repair procedures for the Switch Control Reset test (#93).

i. A 1793 error is an in-line error that indicates a possible problem with the interface between the Switch Control and the SPE. The Aux Data for this error is not meaningful. The receipt of this error causes Switch Control maintenance to run specific Switch Control tests. If there is a problem, the Switch Control tests will normally cause other errors to be logged. In the rare case where no other errors are logged but 1793 errors are occurring at a high rate (more than 10 in the last hour) the MSSNET circuit pack should be replaced during a time that would cause the least service disruption. If the system is equipped with the High Reliability or Critical Reliability Configuration this can be done immediately since a MSSNET circuit pack on the standby SPE can be replaced without affecting service.

j. A 2561 error indicates that a software message buffer for downlink port board messages has overflowed and those messages were thrown away. The Aux Data for this error is not meaningful. The SPE is sending more downlink port board messages to the Switch Control than the Switch Control is able to process. A WARNING alarm for this condition will automatically be resolved if no errors of this type are detected within a 15 minute period. If no other errors are logged but 2561 errors are occurring at a high rate (more than 10 in the last hour), follow normal escalation procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Switch Control Reset Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Switch Control Reset Test (#93)		X		D
Control Channel Interface Test (#92)	X	X		ND
Control Channel Transmission Test (#94)[2]	X	X		ND

1. D = Destructive, ND = Non-destructive
2. When the SPE is duplicated, this test runs only on the Switch Control circuit on the active SPE. An interchange must be performed to test the other one.

Switch Control Channel Interface Test (#92)

Loop-back messages are sent to the Switch Control via the interface used for control channel messages. The messages are returned to the SPE for verification via the same interface. The TDM bus is not involved in this test since the messages are looped back on the MSSNET circuit pack.

Table 9-634. TEST #92 Control Channel Interface Test

Error Code	Test Result	Description/ Recommendation
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Switch Control on the MSSNET circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the MSSNET circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2012 2500	ABORT	Internal System Error 1. Retry the command.
2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 retries.
2334	ABORT	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-634. TEST #92 Control Channel Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	Messages could not be looped back through the control channel interface. If the system is equipped with the Standard Reliability configuration, you will probably not be able to make or receive calls involving telephones connected to the Processor Port Network. 1. This failure could be due to either a MSSNET circuit pack hardware failure or the loss of system timing signals. If the Switch Control is alarmed, then a MSSNET circuit pack failure should be suspected. If the Switch Control is not alarmed, then investigate the possibility of the loss of system timing signals before attempting to replace the MSSNET circuit pack. See “TDM-CLK”. A TDM Bus Clock problem may cause many port circuit pack red LEDs to light. If only the MSSNET circuit pack LED is lit, suspect the MSSNET circuit pack. If many port circuit pack red LEDs are lit, suspect a TDM Bus Clock problem. Test #92 and Test #94 run as part of the test sequence for the **test switch-control C** command (where C represents the carrier location of the circuit under test). Both tests will fail if the system timing signals are lost. If test #94 passes, then do not suspect the loss of timing signals.
Any *(cont'd.)*	FAIL	2. Run the short test sequence several times to make sure that this failure is occurring consistently. Then run the long test sequence to reset the Switch Control. Sometimes running the long test sequence may clear the problem. If the test is still failing, proceed to step 3 or 4. 3. If the system is still able to process calls, replace the MSSNET circuit pack during a time that would cause the least service disruption. If the system is equipped with the High Reliability or Critical Reliability Configuration this can be done immediately since a MSSNET circuit pack on the standby SPE can be replaced without affecting service. The procedure for replacing the MSSNET circuit pack is described in ''Replacing SPE Circuit Packs'' in Chapter 5. 4. If calls cannot be made, then replace the MSSNET circuit pack immediately. The procedure for replacing the MSSNET circuit pack is described in ''Replacing SPE Circuit Packs'' in Chapter 5.
	PASS	The control channel interface between the SPE and the Switch Control is working correctly

Switch Control Reset Test (#93)

This test is destructive if the Switch Control is on the active SPE.

This test resets the Switch Control and determines if it can successfully go through its initialization sequence. The test is destructive if the Switch Control circuit is on an active SPE since there is the possibility of losing some control messages to or from port circuit packs. This test will not affect established calls but call setup may be affected for several seconds.

Table 9-635. TEST #93 Switch Control Reset Test

Error Code	Test Result	Description/ Recommendation
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby Switch Control on the MSSNET circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The *SPE Selected* field on the **status spe** screen will display *spe a* or *spe b* if the SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the MSSNET circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2012	ABORT	Request for results timed out.
2500	ABORT	Internal System Error 1. Retry the command two times.

Continued on next page

Table 9-635. TEST #93 Switch Control Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 retries.
2334	ABORT	The hardware mailbox in the standby Duplication Interface circuit pack is not ready to receive messages. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The Switch Control could not be successfully reset. If the system is equipped with the Standard Reliability configuration, you will probably not be able to make or receive calls involving telephones connected to the Processor Port Network. 1. This failure could be due to either a MSSNET circuit pack hardware failure or the loss of system timing signals. If the Switch Control is alarmed, then a MSSNET circuit pack failure should be suspected. If the Switch Control is not alarmed, then investigate the possibility of the loss of system timing signals. See "TDM-CLK". A TDM Bus Clock problem may cause many port circuit pack red LEDs to light. If only the MSSNET circuit pack LED is lit, suspect the MSSNET circuit pack. If many port circuit pack red LEDs are lit, suspect a TDM Bus Clock problem. Test #92 and Test #94 run as part of the test sequence for the **test switch-control C** command (where C represents the carrier location of the circuit under test). Both tests will fail if the system timing signals are lost. If test #94 passes, then do not suspect the loss of timing signals. If the MSSNET circuit pack is determined to be at fault, proceed to step 2. 2. If the system is still able to process calls, replace the MSSNET circuit pack during a time that would cause the least service disruption. If the system is equipped with the High Reliability or Critical Reliability Configuration this can be done immediately since a MSSNET circuit pack on the standby SPE can be replaced without affecting service. The procedure for replacing the MSSNET circuit pack is described in ''Replacing SPE Circuit Packs'' in Chapter 5. 3. If calls cannot be made, then replace the MSSNET circuit pack immediately. The procedure for replacing the MSSNET circuit pack is described in ''Replacing SPE Circuit Packs'' in Chapter 5.
	PASS	The Switch Control has initialized correctly. Look at results of the other tests to see if it is operating correctly.

Switch Control-Channel Transmission Test (#94)

Control channel messages are sent from the SPE to selected port circuit packs and the response from the port circuit packs is checked. This tests the ability of the Switch Control to send and receive messages on the control channel of the TDM bus.

For the case when the system is equipped with the High Reliability or Critical Reliability configuration, this test cannot run on the Switch Control in a standby SPE. However, this test may have run and failed while the Switch Control was on the active SPE which will alarm the Switch Control and cause an SPE interchange. In that case, Error Types 2 and 150 will be entered in the error log for the Switch Control on the standby SPE, indicating that a failure of the Switch Control Transmission Test caused a spontaneous SPE interchange. Refer to the Error Log information presented earlier in this repair document for the procedures to clear problems associated with a SW-CTL error log entry of 2.

Table 9-636. TEST #94 Control Channel Transmission Test

Error Code	Test Result	Description/ Recommendation
0	ABORT	The port circuit packs necessary for this test are not available. For this test to pass, it must receive a successful response to a circuit pack query message from at least one of the following circuit pack types in the PPN cabinet: Tone/Clock circuit pack (TN768 or TN780) Tone Detector circuit pack (TN599) 1. Retry the command at 1-minute intervals a maximum of 5 retries. 2. If the test keeps aborting with this abort code, replace the MSSNET circuit pack. 3. If the test keeps aborting with this abort code, verify that the PPN has at least one of the circuit packs listed above.
1335	ABORT	Internal System Error. The MSSNET circuit pack is on the standby SPE and this test is not allowed to execute on a MSSNET circuit pack on the standby SPE. 1. If this abort code is received for a Switch Control on a standby SPE in a system equipped with the High Reliability or Critical Reliability configuration, there must be a software error. Test #94 is not allowed to run on a standby Switch Control. 2. Retry the command at 1-minute intervals, a maximum of 5 times.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-636. TEST #94 Control Channel Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012 2500	ABORT	Internal System Error 1. Retry the command.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 retries.
0	FAIL	The Switch Control cannot communicate on the TDM bus control channel. If the system is equipped with the Standard Reliability configuration, you will probably not be able to make or receive calls involving telephones connected to the Processor Port Network. 1. Run the short test sequence several times to make sure that this failure is occurring consistently. Then run the long test sequence to reset the Switch Control. Sometimes, running the long test sequence may clear the problem. Remember that the long test sequence is *destructive*. Placing and receiving of calls will be affected for several seconds. 2. If there are no TDM Bus alarms against the standby TDM bus, switch the control channel from its current bus to the standby bus using the **set tdm** command. Refer to the TDM-BUS maintenance documentation for information on how to use this command. If this test passes on the new bus, then investigate the possibility of TDM Bus failures. If the test fails even after the control channel is switched to the standby TDM bus, then proceed to Step 3 or 4. 3. If the system is still able to process calls, replace the MSSNET circuit pack during a time that would cause the least service disruption. If the system is equipped with the High Reliability or Critical Reliability Configuration this can be done immediately since a MSSNET circuit pack on the standby SPE can be replaced without affecting service. The procedure for replacing the MSSNET circuit pack is described in "Replacing SPE Circuit Packs" in Chapter 5. 4. If calls cannot be made, then replace the MSSNET circuit pack immediately. The procedure for replacing the MSSNET circuit pack is described in "Replacing SPE Circuit Packs" in Chapter 5.
	PASS	The Switch Control can communicate with selected port circuit packs over the TDM bus.

SYNC (Synchronization)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
SYNC	MINOR	display errors	Synchronization
SYNC	WARNING	test synchronization	Synchronization

This section discusses synchronization problems local to the switch. For further information about synchronization including network synchronization, see the *AT&T Network and Data Connectivity*.

Synchronization Maintenance is composed of both hardware and software components and its purpose is to provide a common reference frequency for reliable digital communication between the G3r system and other PBXs, Central Offices(COs) or Customer-Premises Equipment (CPE). Synchronization is implemented using several system components including:

- TN768 or TN780 Tone-Clock
- TN722, TN767 and TN 464 DS1 Interfaces (all suffixes)
- TN572 Switch Node Clock
- TN573 Switch Node Interface
- TN570 Expansion Interface

Synchronization is achieved between the Processor Port Network (PPN) and the Expansion Port Networks (EPNs) via the port network connectivity (PNC) between the networks. Depending on the network synchronization plan and the status of synchronization sources, the system timing reference may be a Tone-Clock circuit pack, DS1 interface or UDS1 circuit packs, or an external Stratum 3 clock. Stratum 4 synchronization extracts timing information directly from a DS1 reference, UDS1 reference, or a Tone-Clock. Stratum 3 synchronization requires the use of a Stratum 3 clock that provides a timing signal derived from DS1 references to the Tone-Clock circuit pack. The external Stratum 3 clock is a more stable timing source than the Stratum 4 clock and provides 24-hour holdover in case of reference failures and redundant components.

If both a primary and a secondary reference are administered for Stratum 4 synchronization, both references must reside in the same port network.

Stratum 4 Synchronization

The system can be configured with primary and secondary synchronization references (DS1 or UDS1 interface circuit packs) when using Stratum 4 synchronization. If this is the master synchronization source for the network, then its local oscillator is used and no DS1s are used as references. If this system is a slave in the network, a primary reference must be used as the synchronization reference and the secondary reference is optional:

- If the primary synchronization reference is not providing a valid timing signal, the system automatically switches to the secondary synchronization reference.
- If the primary synchronization reference is invalid and secondary reference does not provide a valid timing signal or is not administered as a synchronization reference, a Tone-Clock circuit pack provides the system timing source.
- If the system is using the local oscillator as the timing source (both the primary and secondary references are providing invalid timing signals), should either the primary or secondary reference becomes valid again, the system switches back to the primary or secondary source.
- When both the primary and secondary source become valid, the system switches to the primary source, since the primary source is always preferred over the secondary source when both sources are equally healthy.

If the primary synchronization reference is providing a valid timing signal, then the flow of system synchronization would travel from the DS1 interface circuit pack in the PPN across the active PPN to EPN fiber links to the two EPNs. The PPN DS1 interface circuit pack provides a timing signal for the PPN Tone-Clock circuit pack and the PPN Tone-Clock circuit pack provides timing for all circuit packs in the PPN. Each PPN Expansion Interface circuit pack uses the timing generated by the Tone-Clock circuit pack to clock data from the fiber links to the Expansion Interface circuit packs in the two EPNs. The active EPN Expansion Interface circuit pack uses the received data stream to generate a timing signal. The Tone-Clock circuit packs in the EPNs use this signal to generate timing for all the circuit packs in their respective EPNs. The PPN, in the above mentioned scenario, is designated the *master* port network and the EPNs are called *slave* port networks. The *master* port network is defined as the port network that contains the system synchronization source. If the primary synchronization reference does not provide a valid timing signal, Synchronization Maintenance will switch to the secondary reference. *Both the primary and secondary references must reside in the same port network, which may be any port network. The PPN is the recommended location.*

If TDM-CLK error 2305 is in the error log, then a slave Tone-Clock loss of signal condition exists on the slave Tone-Clock circuit pack that has this error. If only one loss of signal occurred, the slave Tone-Clock circuit pack is receiving the timing signal from the standby EI circuit pack (in this example, the timing is coming from the PPN to the EPN over the standby fiber link). If another loss of signal occurred after the Tone-clock circuit pack switched to receive timing from the standby EI, the Tone-clock circuit pack will run on its local oscillator. The yellow LED on the Tone-clock circuit pack flashes at the 2.7 seconds on and .3 seconds off rate (mostly on) if timing is received from an external source (an EI in this example). Otherwise, if the Tone-clock circuit pack is running on its local oscillator, the yellow LED flashes at the .3 seconds on and 2.7 seconds off rate (mostly off).

The TN722 DS1 Interface circuit pack does not provide a synchronization reference as reliable as the TN767 or TN464C circuit packs. Therefore, it is recommended that the TN767 or TN464C circuit packs are used as primary or secondary sources instead of the TN722 type DS1 circuit packs.

Stratum 3 Synchronization

Figure 9-95 illustrates one possible configuration of Stratum 3 synchronization.

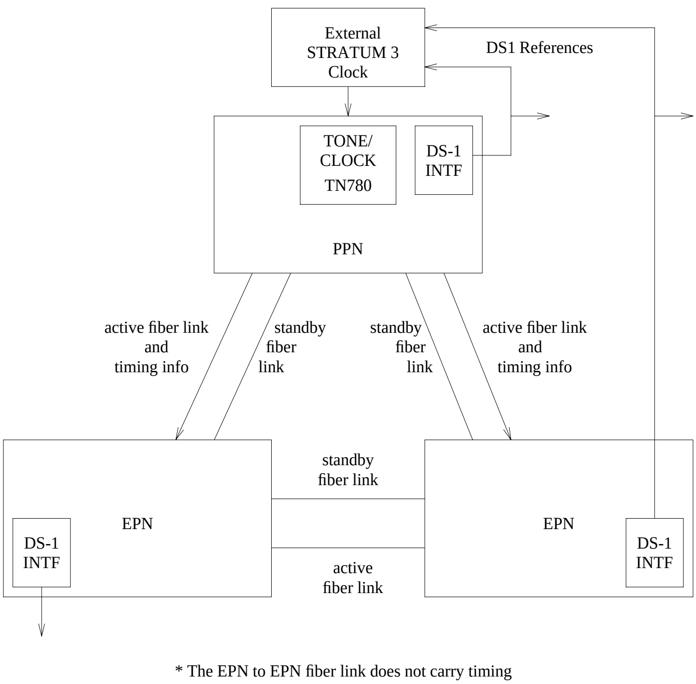

Figure 9-95. Typical Duplicated Direct-Connect Stratum 3 Synchronization Configuration

For Stratum 3 synchronization, an external clock provides a timing signal to a TN780 Tone-Clock circuit pack, and the TN780 provides timing to all circuit packs in the PPN in which the TN780 resides (the external stratum 3 clock is only allowed in the PPN). Each PPN Expansion Interface circuit pack uses the timing generated by the TN780 to clock data from the active PPN to EPN fiber links. The active EPN Expansion Interface circuit packs use the received data stream to generate a timing signal which is used by the Tone-Clock circuit packs in the EPNs to provide timing for all circuit packs in their respective EPNs. (The EPN Tone-Clock circuit packs can be either TN780s or TN768s; only the Tone-Clock circuit pack(s) connected to the external Stratum 3 clock must be TN780s.) The PPN, in the above mentioned scenario, is designated the *master* port network and the EPNs are called *slave* port networks. The *master* port network is defined as the port network that contains the system synchronization source, the Stratum 3 clock in this case. The Stratum 4 equipment (usually a PBX) should never provide timing to a Stratum 3 PBX.

If TDM-CLK error 2305 is in the error log, then a slave Tone-Clock loss of signal condition exists on the slave Tone-Clock circuit pack that has this error. If only one loss of signal occurred, the slave Tone-Clock circuit pack is receiving the timing signal from the standby EI circuit pack (in this example, the timing is coming from the PPN to the EPN over the standby fiber link). If another loss of signal occurred after the Tone-clock circuit pack switched to receive timing from the standby EI, the Tone-clock circuit pack will run on its local oscillator. The yellow LED on the Tone-clock circuit pack flashes at the 2.7 seconds on and .3 seconds off rate (mostly on) if timing is received from an external source (an EI in this example). Otherwise, if the Tone-clock circuit pack is running on its local oscillator, the yellow LED flashes at the .3 seconds on and 2.7 seconds off rate (mostly off).

Synchronization in a Center Stage Switch Configuration

In the following typical duplicated Center Stage Switch (CSS) configuration, the timing signal from the *master* port network, the PPN in this diagram, is sent to all circuit packs in its network. The timing signal is sent from the Expansion Interface (EI) circuit packs in the PPN to the Switch Node Interface (SNI) circuit packs in the switch node carriers. The EIs in the *master* port network also sends out a timing priority number (TPN) of 1. Every *slave* port network EI sends out a TPN of 30. The active Switch Node Clock (SNC) circuit pack in each switch node carrier decides which SNI is providing the timing signal that the switch node carrier should synchronize to by looking at each SNI's incoming TPN. The SNC chooses the SNI with the lowest numbered TPN to synchronize to. The SNC then sends the timing signal to all SNIs and the standby SNC, if a standby SNC is present, in the switch node carrier. The SNC also sends out a TPN equal to 1 plus the lowest incoming TPN. Each SNI in the switch node sends the timing signal received from the SNC and the TPN from the SNC out on its associated fiber.

If TDM-CLK error 2305 is in the error log, then a slave Tone-Clock loss of signal condition exists on the slave Tone-Clock circuit pack that has this error. In this case, the slave Tone-Clock circuit pack is receiving the timing signal from the standby EI circuit pack in the port network that has the TDM-CLK 2305 error or from its local oscillator. The yellow LED on the Tone-clock circuit pack flashes at the 2.7 seconds on and .3 seconds off rate (mostly on) if timing is received from an external source (for example, an EI circuit pack). Otherwise, if the Tone-clock circuit pack is running on its local oscillator, the yellow LED flashes at the .3 seconds on and 2.7 seconds off rate (mostly off).

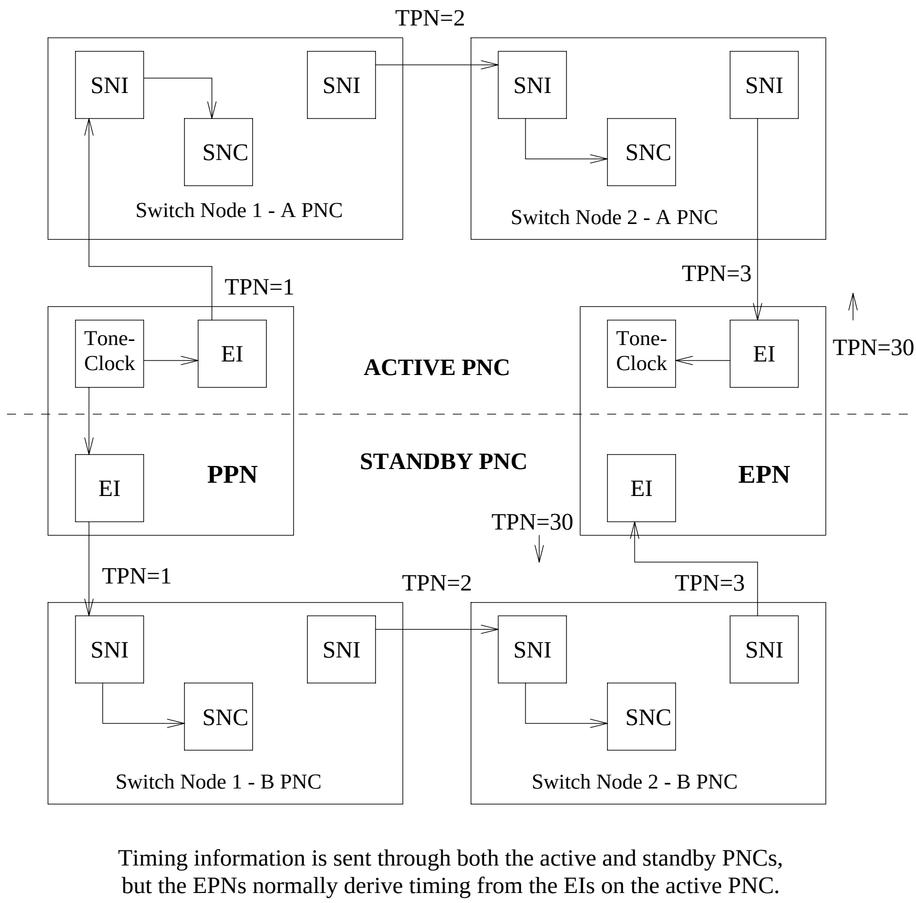

Figure 9-96. Typical Center Stage Switch Synchronization Configuration -Two Switch Nodes, Duplicated PNC

Synchronization Troubleshooting

For both Stratum 3 and 4 operation, major and minor alarms indicate that there is a problem with the system synchronization references. These alarms will be resolved when the alarmed synchronization reference is restored.

The **change synchronization** command is used to administer whether Stratum 3 or Stratum 4 synchronization is being used. The **change synchronization** command allows primary and secondary references to be administered for the Stratum 4 option.

The **status synchronization** command shows the current synchronization reference. The **display synchronization** command shows the synchronization references (e.g. primary, secondary, stratum 3) that are administered.

The **list timing-source** command displays all DS1 and UDS1 locations that are allowed to be administered as primary or secondary references with the **change synchronization** command.

Other commands associated with Synchronization Maintenance are **disable synchronization-switch** and **enable synchronization-switch.** These commands are used to disable the ability of Synchronization Maintenance to switch between synchronization references and to enable this switching ability, respectively. The **set synchronization** command is executed only after synchronization has been disabled and is used to manually switch to a specific synchronization reference. This command is useful to diagnose synchronization problems by forcing a specific reference (DS1, UDS1, or Tone-Clock) to be the system synchronization reference to determine if a specific reference is providing a valid timing signal. To switch synchronization to the Stratum 3 clock, use the **enable synchronization-switch** command after verifying that the Stratum 3 clock is wired correctly.

Approach to Troubleshooting

Slip errors are the primary symptom associated with being unsynchronized.

A correct Synchronization plan for the network keeps the systems within the network transmitting data at approximately the same rate to avoid situations where:

- One system transmits data at a rate faster than another system can receive the data (in which case data is lost).
- One system transmits data at a rate slower than another system expects to receive data (in which case data is repeated).

Either of these situations, data being lost or repeated, is a slip.

When troubleshooting synchronization problems when slips are the primary error log entry indications of a synchronization problem, requires that the problem be isolated to:

- A problem outside of the switch, i.e., the switch is not properly synchronized to the rest of the network.
- A problem internal to the switch.

DS1 and UDS1 circuit packs can be administered with slip detection enabled via the **Slip Detection?** field set to a **y** (see the **add ds1**, **change ds1**, and **display ds1** commands). All DS1 and UDS1 circuit packs administered as slip enabled will be counted in the following algorithm:

When over half of the DS1 and UDS1 circuit packs administered as slip enabled are experiencing slips, and the primary or secondary synchronization reference is the current synchronization reference, synchronization will try the other administered synchronization reference.

In situations where one or many circuit packs in the system are experiencing slips, the problem could be with the synchronization reference, with individual circuit packs, or with phase modulation of the transmitted digital bit streams due to environmental variations of the transmission facilities (such as temperature variations that affect the electrical length of a transmission line). The circuit packs that can experience slips and the associated error log entry for slips are as follows.

Table 9-637. Error Log Entries for Slip Errors

Circuit Pack	Error Log Name	Error Log Entry for Slips
DS1 Interface	DS1-BD	3073 to 3160
Expansion Interface	EXP-INTF	2305
Switch Node Interface	SNI-BD	1537
Tone-Clock	TDM-CLK	1025
UDS1 Interface	UDS1-BD	3073 to 3160

When slips occur on the circuit packs mentioned above, first consult the individual circuit pack section in the manual for each circuit pack that has slips. If slips occur in low numbers, they may be due to environmental conditions as described above. If no service degradation is occurring, no action is necessary. Whenever the system switches synchronization sources, slips can be expected from DS1-BD, UDS1-BD, and EXP-INTF circuit packs. If service degradation occurs, after following the repair steps in the individual section, use the following trouble shooting techniques.

The following table lists circuit packs that can report slips and related circuit packs whose hardware problems that cause those slips.

Table 9-638. Slips and Related Circuit Packs

Circuit Pack Reporting Slips	Associated Circuit Packs That Can Cause Slips
DS1 Interface	Active Tone-Clock in same port network
Expansion Interface	Active Tone-Clock in same port network or circuit pack at opposite end of fiber or metallic connection
Switch Node Interface	Circuit pack at opposite end of fiber or metallic connection, or active Switch Node Clock circuit pack in same switch node carrier
Tone-Clock	Current DS1 reference
UDS1 Interface	Active Tone-Clock in same port network

Troubleshooting Synchronization Problems

The following flow chart presents a logical approach to troubleshooting synchronization problems in conjunction with the background information presented above. Explanatory notes follow the charts.

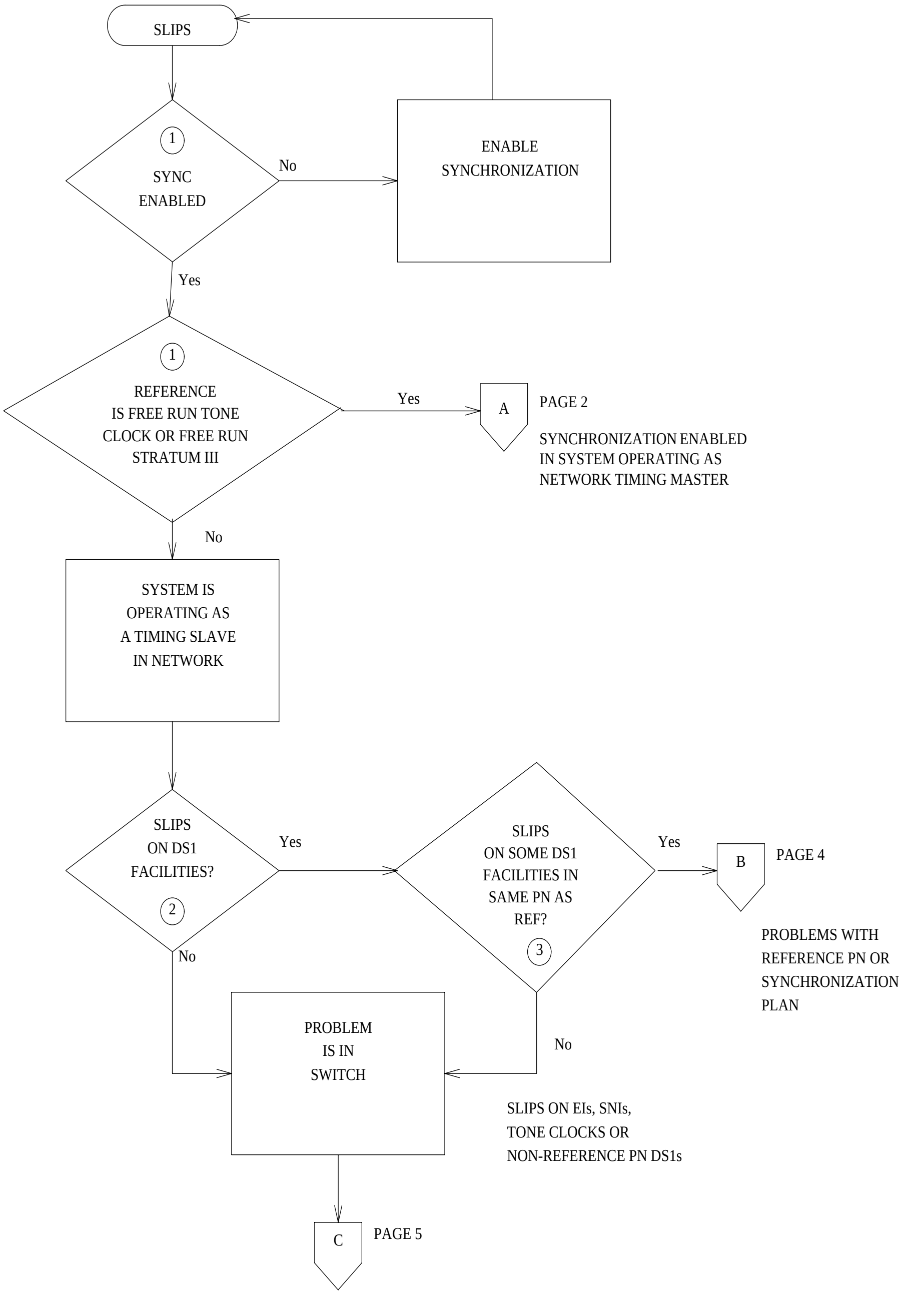

Figure 9-97. Synchronization Troubleshooting, Page 1 of 6

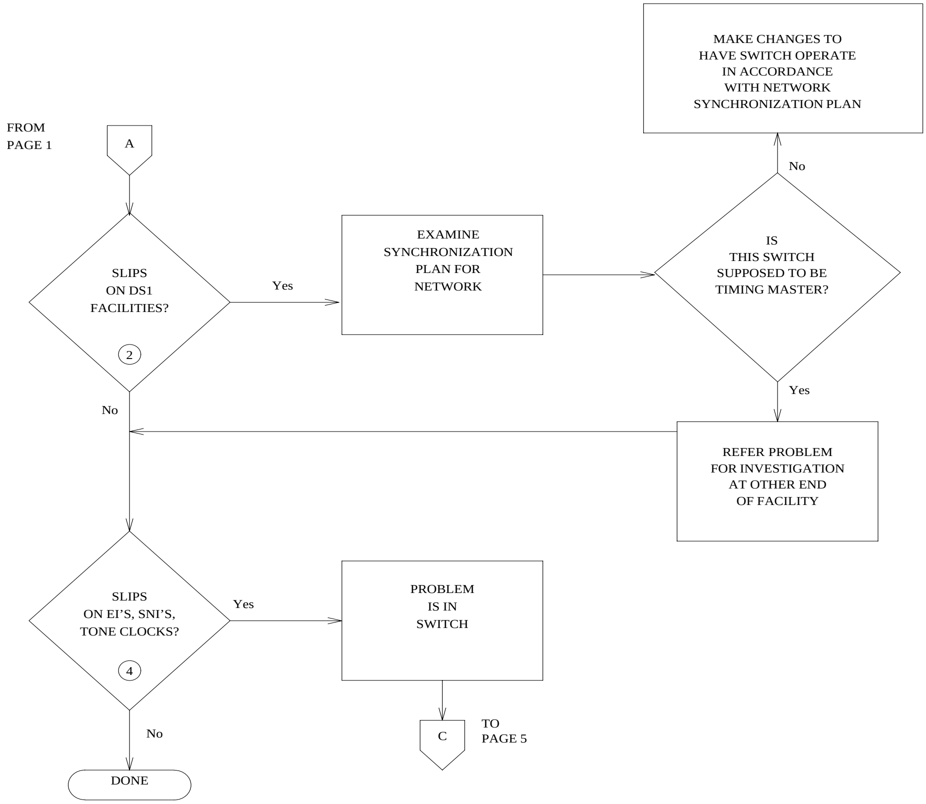

Figure 9-98. Synchronization Troubleshooting, Page 2 of 6

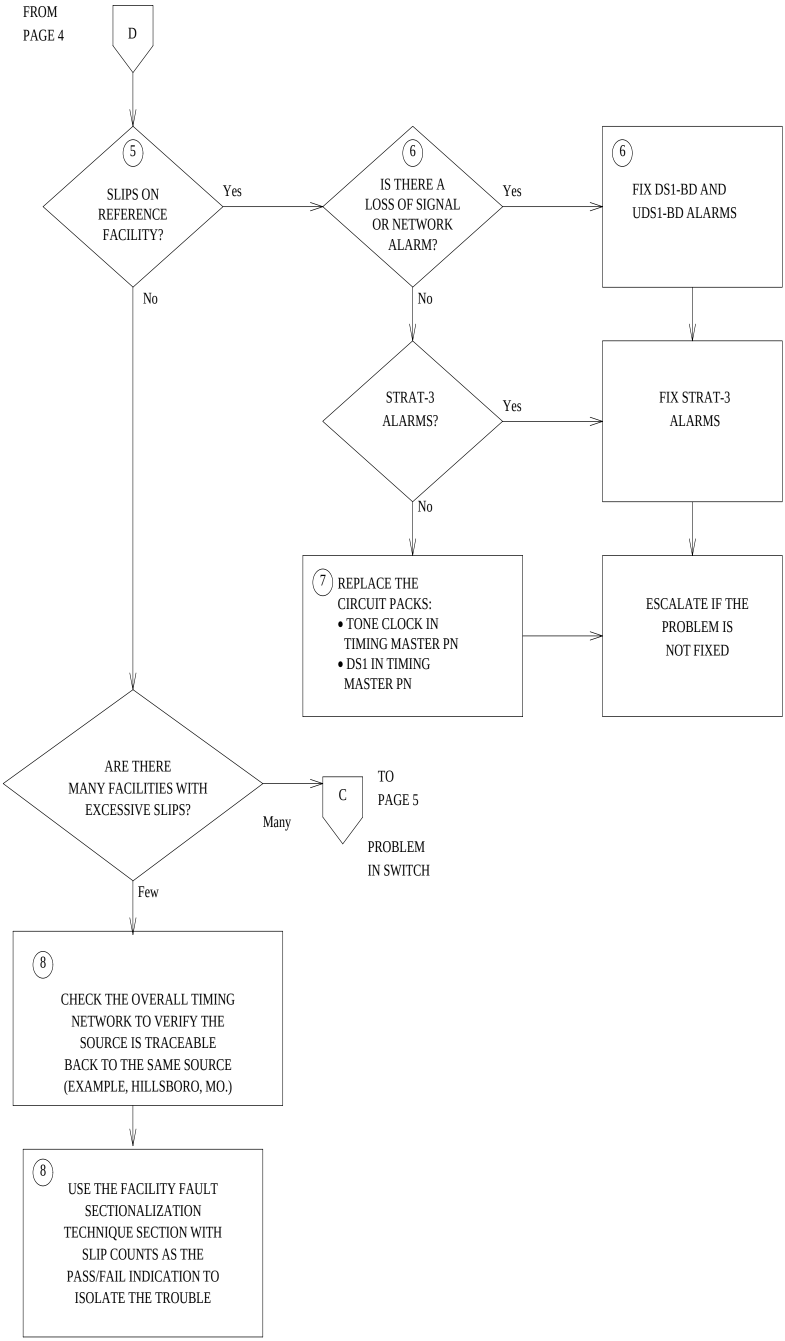

Figure 9-99. Synchronization Troubleshooting, Page 3 of 6

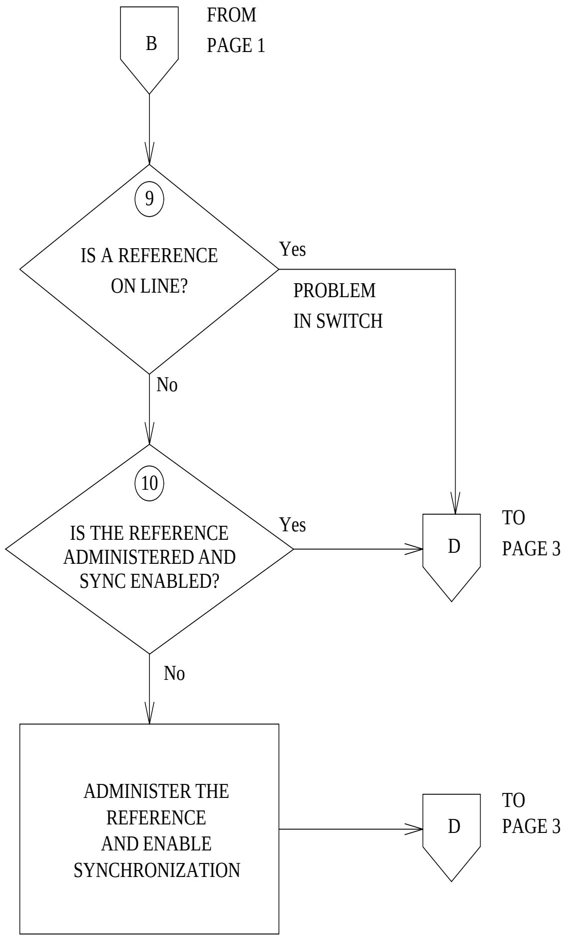

Figure 9-100. Synchronization Troubleshooting, Page 4 of 6

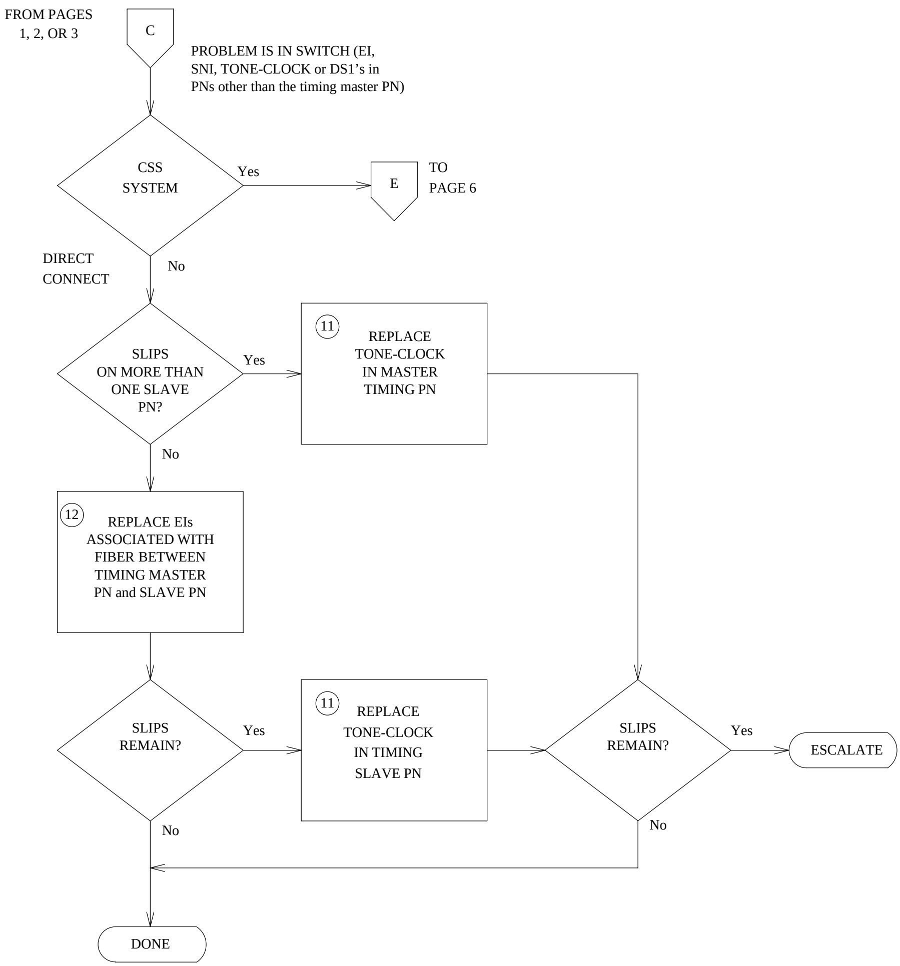

Figure 9-101. Synchronization Troubleshooting, Page 5 of 6

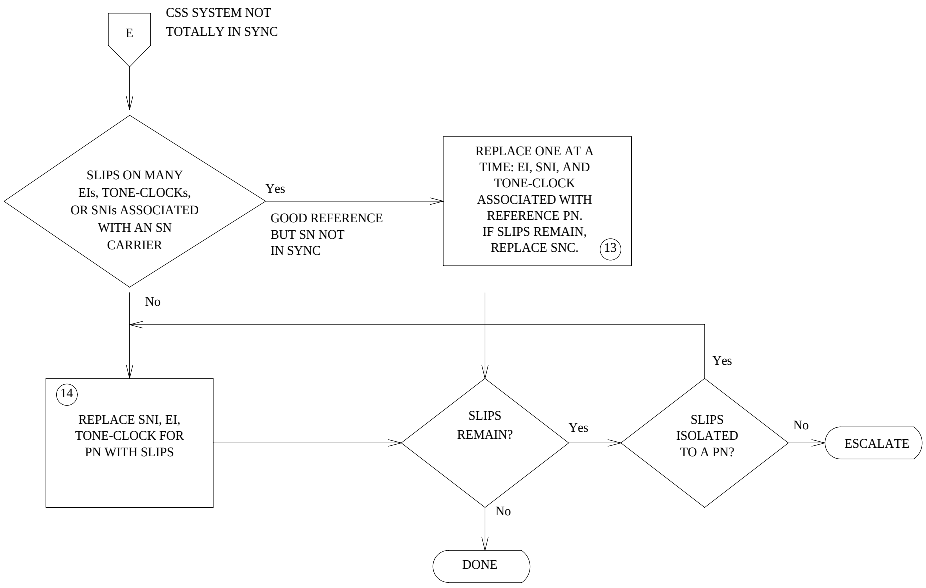

Figure 9-102. Synchronization Troubleshooting, Page 6 of 6

Notes for Sheet 1 through Sheet 6 flowcharts (when checking for slip errors, use the table above, *Error Log Entries for Slip Errors*):

1. Use the **status synchronization** command to determine whether synchronization is enabled and to determine the on-line reference. If the on-line reference is a tone-clock board, the switch is operating in free run mode. If the Stratum 3 is displayed, and no DS1s are connected to the Stratum 3 clock or no DS1 connection existed to the Stratum 3 clock for over 24 hours, then the Stratum 3 clock is in free run mode.
2. Check for slip errors against DS1-BD and UDS1-BD.
3. If Stratum 3 is administered (**display synchronization**) and on-line (**status synchronization**), check for DS1-BD or UDS1-BD slip errors for the DS1(s) or UDS1(s) used as input to the Stratum 3 clock. Check the LED indications on the Stratum 3 clock to determine which DS1 is providing input to the Stratum 3 and examine the cross connect information for that DS1.
4. Check for slips errors against EXP-INTF, SNI-BD, and TDM-CLK.

5. Check **status synchronization** for the current DS1 reference. If a DS1 or UDS1 is on-line, check for slips on that DS1 or UDS1. If Stratum 3 synchronization is administered and the Stratum 3 clock is used as the reference (i.e. the tone-clock local oscillator is not on-line), follow the procedure in step 3 to determine the DS1 reference used as input to the Stratum 3 clock and check for slips on that reference.
6. Check for LOS, Blue, Yellow, and Red Alarms on the on-line reference facility and fix those problems first. See the DS1-BD and/or UDS1-BD for the error log entries associated with the above mentioned alarms. Replace the circuit packs one at a time and wait at least one hour to determine if the problem has gone away. This procedure is disruptive and should be done after hours if possible. An alternative to replacing the tone-clock circuit pack in systems where the tone-clocks are duplicated, is to run the **set tone-clock** command to switch tone-clocks. If the problem goes away, the previously active tone-clock should be replaced.
7. If a few facilities are experiencing slips or are unusable references, the clock source for facilities with slips or that are unusable is not traceable to the same ultimate source as the clock source for the on-line reference facility.

   Examine the overall timing network for the interconnected DS-1 to determine if the clock can be traced back to a single source and if the reference designations for each location in the distribution of timing is supplied in accordance with the *synchronization plan* for the customer. Examine the capability of the external transmission equipment to pass or provide timing.

   Verify the integrity of the on-site hardware by using the *Facility Fault Sectionalization* section, which loops the transmit signal to the receive signal and verifies that the excessive slips or the unusable reference are no longer observed.

   This is a time consuming process that disrupts service. You should perform it after hours if the service being provided by the system is acceptable as determined by checking with the customer.
8. Use **status synchronization** to determine the on-line reference. If a DS1 or Stratum 3 reference is not on-line and the local oscillator of a tone-clock board is on-line, then the answer to this question is "no".
9. Use **display synchronization** to find out what references, if any, are administered. Use **status synchronization** to find out whether synchronization is enabled.
10. If tone-clocks are duplicated, the **set tone-clock** command can be used to switch tone-clocks. If slips go away, then replace the tone-clock that was just switched away from.

11. Use **status pnc** to determine which PNC is active. Then use **list fiber-links** to determine the EIs on the active PNC and the EIs associated with the slave PN. If the switch does not have PNC duplication, the EIs are all on the active PNC, A-PNC. A PNC interchange can be done via **reset pnc interchange** before replacing EIs if the system has PNC duplication. If the slips go away after the PNC interchange, replace the EIs that were previously active.

12. Replace the circuit packs one at a time and wait at least one hour to determine if the problem has gone away. This procedure is disruptive and should be done after hours if possible.

    An alternative to replacing the EI and SNI in systems where the PNC is duplicated, is to perform a PNC interchange via **reset pnc interchange**. If the problem goes away, either the EI or the SNI on the previously active PNC should be replaced. Replace one at a time and make that PNC active again to determine whether the problem is fixed.

    An alternative to replacing the tone-clock circuit pack in systems where the tone-clocks are duplicated, is to run the **set tone-clock** command to switch tone-clocks. If the problem goes away, the previously active tone-clock should be replaced.

    Also, before replacing an SNC circuit pack, the **set switch-node-clock** command can be used if SNCs are duplicated in the carrier. If the problem goes away, the previously active SNC should be replaced.

13. Replace the circuit packs one at a time and wait at least one hour to determine if the problem has gone away. This procedure is disruptive and should be done after hours if possible.

    An alternative to replacing the EI and SNI in systems where the PNC is duplicated, is to perform a PNC interchange via **reset pnc interchange**. If the problem goes away, either the EI or the SNI on the previously active PNC should be replaced. Replace one at a time and make that PNC active again to determine whether the problem is fixed.

    An alternative to replacing the tone-clock circuit pack in systems where the tone-clocks are duplicated, is to run the **set tone-clock** command to switch tone-clocks. If the problem goes away, the previously active tone-clock should be replaced.

    Also, before replacing an SNC circuit pack, the **set switch-node-clock** command can be used if SNCs are duplicated in the carrier. If the problem goes away, the previously active SNC should be replaced.

Facility Fault Sectionalization

DS-1 facility fault sectionalization involves looping around the DS-1 signal at on-site access points to localize the source of the problem to equipment and wiring on either the near side or far side of the loop-around point.

WARNING:
The facility fault sectionalization technique disrupts service. When you perform the looparound on a facility, make sure it is not the on-line synchronization reference or a system outage will occur.

When you use this technique to investigate problems on facilities with multiplex or DACS equipment, the technique becomes cumbersome because all of the 64 Kbps (B-channels) or subrate channels corresponding to the DS-1 facility need to be looped around.

Figure 9-103 shows a sequence of units (1 though n) that may be connected as the on-site equipment. A typical example is the case where the only on-site equipment is channel-terminating equipment designated Unit #1. A more complex, less typical example might have a DACS as Unit #1, a protection switch as Unit #2, and a DS-1-level microwave radio system as Unit #3.

The flowchart in Figure 9-104 gives an overview of the facility fault sectionalization technique. It is important that you know the configuration and wiring of the equipment for the problem facility in order to support this technique.

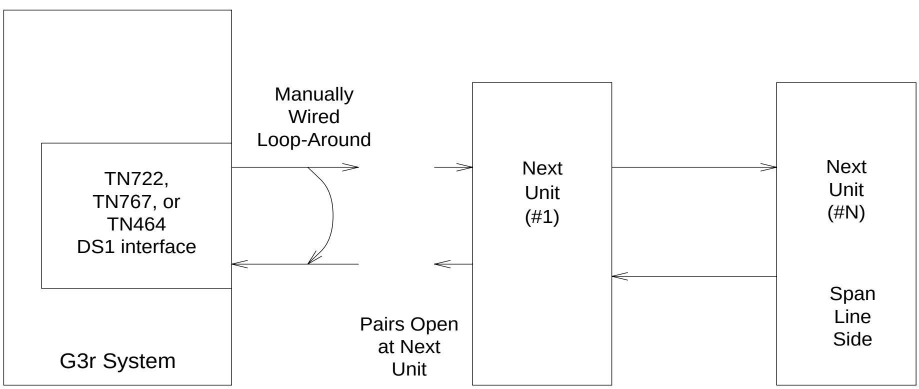

Figure 9-103. Manual Looparound for Facility Fault Sectionalization

Since the technique is time consuming, fix any DS1-BD, UDS1-BD, STRAT-3, or SYNC errors first that are not slip errors.

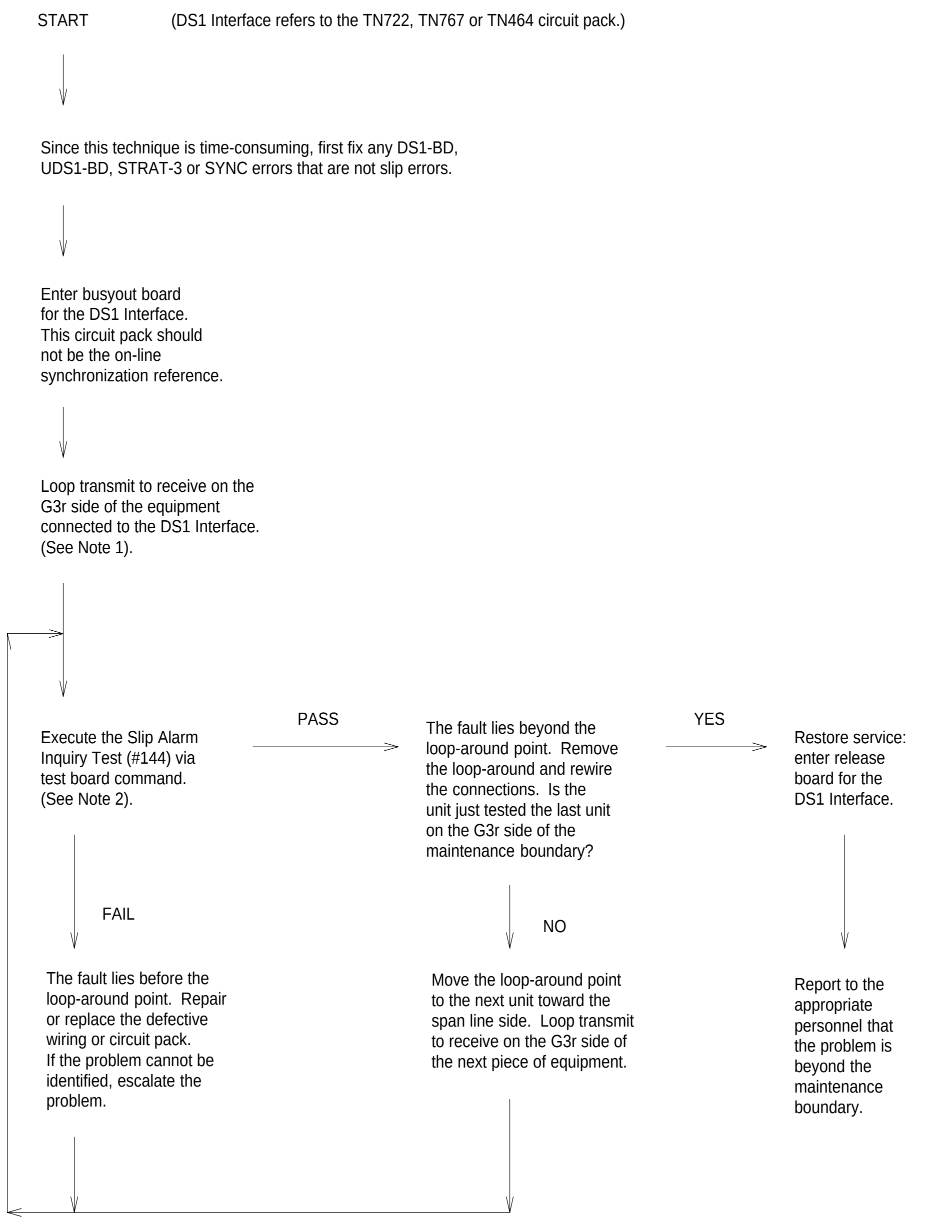

Figure 9-104. Facility Fault Sectionalization

Notes to Facility Fault Sectionalization Flowchart

1. Loop transmit to receive on the system side.

   Remove the transmit signal from the TN722, TN767, or TN464 circuit pack inputs and outputs and loop it around to the receive signal going toward the TN722, TN767, or TN464 circuit pack at the first unit wired to the TN722, TN767, or TN464 circuit pack. (See Figure 9-103).

   The looparound signal may take different forms depending on the installation.

   - In some cases, the unit connected to the system may provide a switch or a terminal interface to control the desired looparound. Make sure that the signal is looped toward the system and that the timing signal is looped.
   - In most cases, it may be necessary to temporarily rewire connections at the cross-connect fields to loop the signal back toward the switch.

   The point at which the signal is looped should be one at which physical access is easy and where the signal level is within the line compensation (i.e. equalization) range of the hardware connected. A few cases exist where access to the looparound cannot be easily provided at locations where the signal level is within the line compensation range of the hardware. The line compensation can be changed via the **change ds1 UUCSS** command.

2. Execute the **test board UUCSS** command for the TN722, TN767 or TN464. Look at results of Test #144, the Slip Alarm Inquiry Test. When this test fails, the error code gives the number of slips detected since the last Slip Inquiry Test was run. If the test fails, run it at least one more time to ensure that slips have occurred since the looparound was installed.

Timing Loops

A timing loop exists whenever a system receives timing from another system whose timing reference is directly or indirectly derived from itself. The system synchronization planner *must avoid creating a timing loop* when administering the synchronization references in a system. Timing loops can lead to loss of digital data between systems that are exchanging data with any system within the loop. An invalid timing signal will also be generated by any system within the loop, thus propagating the invalid timing signal to any system(s) using a system within the loop as a synchronization reference.

A correctly designed network has no loops and each piece of equipment in the network is supplied by a clock of equal or lower stratum (i.e.,: the inputs to a Stratum 3 clock should NEVER be from a Stratum 4 device). *Synchronization administration changes should never be done without consulting the overall synchronization plan for the network. If you suspect that synchronization administration changes are needed, follow normal escalation procedures.*

Synchronization Switches Away from the Current Timing Reference

Synchronization will switch away from a DS1 reference (primary or secondary) if the current DS1 reference is not providing a valid timing signal. The other DS1 reference will be used if one is administered and providing a valid timing signal. Otherwise, the local oscillator of the Tone-Clock circuit pack in the same port network as the DS1 reference will be used. The following conditions will cause a synchronization switch:

- The current DS1 reference is not inserted (i.e. **list configuration board UUCSS** shows "no board").
- The current DS1 reference has a loss of signal error (DS1-BD and UDS1-BD error type 1281), a blue alarm error (DS1-BD and UDS1-BD error type 1793), a red alarm error (DS1-BD and UDS1-BD error type 2049), or a hyperactive angel error (DS1-BD and UDS1-BD error type 1538). A corresponding alarm log entry is not required.
- DS1 and UDS1 circuit packs can be administered with slips detection enabled via the **Slip Detection?** field set to a **y** (see the **add ds1**, **change ds1**, and **display ds1** commands). When over half of the DS1 and UDS1 circuit packs administered as slip enabled are experiencing slips, and the primary or secondary synchronization reference is the current synchronization reference, synchronization will try the other administered synchronization reference if the other administered reference does not have the above two conditions. The **list measurements ds1-log** command can be used to get an historical perspective of DS1 facility operation.

The following conditions will cause a switch to the other DS1 reference if one exists and the other DS1 reference is more healthy:

- The current DS1 reference has a misframe error (DS1-BD error type 3329 to 3345 or UDS1-BD error type 3585-3601). A corresponding alarm log entry is not required.
- The current DS1 reference has a slip alarm (DS1-BD and UDS1-BD error type 3073 to 3160). A corresponding alarm log entry is required.

If the above conditions are repaired and no longer apply, synchronization will switch back to the primary reference.

Tone-Clock Circuit Pack LEDs

The yellow and green LEDs of the TN768 and TN780 Tone-Clock circuit packs flash in a specific pattern to indicate the status of the circuit pack. For example, these flashing LED patterns are used to indicate if a Tone-Clock circuit pack is deriving timing from an external source or whether the Tone-Clock circuit pack is providing the timing signal for the port network.

The yellow and green LED patterns for the TN768 and TN780 Tone-Clock circuit pack are as follows:

Table 9-639. Tone-Clock Yellow/Green LED Flashing Codes

Circuit Pack Condition	Tone-Clock State	Explanation
[1]flashing yellow 2.7 seconds on .3 seconds off	active	This light pattern indicates that an external timing source is being used as a synchronization reference.
flashing yellow .3 seconds on 2.7 seconds off	active	This light pattern indicates that the circuit pack is being used as a synchronization reference.
steady yellow on	active	This light pattern indicates that the light has been reset but has not been told which synchronization reference source to use.
steady yellow off	standby	This light pattern indicates that the circuit pack is in standby mode (neither generating tones nor supplying clocks).
"jingle bells" green and yellow .1 seconds on, .2 seconds off, .1 seconds on, .4 seconds off, .4 seconds on, .4 seconds off,	standby	The system is running maintenance tests on the standby circuit pack. (the standby Tone-Clock circuit pack is providing tones.)
other green and yellow	active	The system is running maintenance tests on the active circuit pack

1. The external synchronization reference being used is a primary reference, a secondary reference, or the external stratum 3 clock when the Tone-Clock is in the master port network. The external synchronization reference used in a slave port network is the Expansion Interface circuit pack.

Error Log Entries and Test to Clear Values

Table 9-640. Synchronization Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test synchronization
1(a)*		None	WARNING/MINOR(h)	OFF	None
18(b)	0	disable sync	WARNING	OFF	enable sync
257(c)*		None	WARNING/MINOR(h)	OFF	None
513(d)*		None	WARNING/MAJOR(h)	OFF	None
769(e)		None	MAJOR	OFF	None
1793(f)[2]	0-50	None	MAJOR	OFF	None
2049(g)[2]	0	None	WARNING	OFF	None

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. It may take up to 1 hour for these alarms to clear via the ‘‘leaky bucket’’ strategy.

Notes:

a. This error indicates a problem with the primary DS1 reference. It will be cleared when the primary reference is restored. The following steps should give an indication of the source of the problem:

1. Check if the primary DS1 interface circuit pack is inserted in the carrier via the **list configuration board UUCSS** command.
2. Verify that the administered primary reference matches the DS1 reference from the network synchronization plan.
3. Test the primary DS1 interface circuit pack via the **test board UUCSS long** command. Check the Error Log for DS1-BD or UDS1-BD errors and refer to the DS1-BD or UDS1-BD (DS1 Interface Circuit Pack or UDS1 Interface Circuit Pack) Maintenance documentation to resolve any errors associated with the primary DS1 (DS1 or UDS1) interface circuit pack. If the only errors against DS1-BD or UDS1-BD are slip errors, then follow the procedures described in the troubleshooting section above. If no errors are listed in the Error Log for the primary DS1 interface circuit pack, continue with the following steps.

4. Test the active Tone-Clock circuit pack in the master port network via the **test tone-clock UUC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 (TDM Bus Clock Circuit Status Inquiry test) passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to the TDM-CLK (TDM Bus Clock) Maintenance documentation to resolve the problem. If not, continue with the following steps.
5. Execute the **disable synchronization-switch** and then the **enable synchronization-switch** commands. These two commands (when executed together) will switch the system synchronization reference to the primary DS1 interface circuit pack. Check the Error Log and execute the **status synchronization** command to verify that the primary DS1 interface circuit pack is still the system synchronization reference. If the primary DS1 interface circuit pack is not the system synchronization reference, and the master port network does not have duplicate Tone-Clock circuit packs, escalate the problem. If not, continue with the following step.
6. *Duplicated Tone-Clock circuit packs in the master port network:* Switch Tone-Clock circuit packs on the master port network via the **set tone-clock UUC** command, and repeat the disable/enable commands described in the previous step.

   Switch Tone-Clock circuit packs on the master port network via the **set tone-clock UUC** command, and repeat the disable/enable commands described in the previous step.

b. This error indicates that Synchronization Maintenance has been disabled via the **disable synchronization-switch** command. Execute the **enable synchronization-switch** command to enable Synchronization Maintenance reference switching and to resolve this alarm.

c. This error indicates a problem with the secondary DS1 reference. It will be cleared when the secondary reference is restored. Refer to note (a) to resolve this error substituting **secondary** for **primary** in the preceding resolution steps.

d. This error indicates that the Tone-Clock circuit pack is providing the timing source for the system. The primary and secondary (if administered) are not providing a valid timing signal. Investigate errors 1 and 257 to resolve this error.

e. This error indicates that the external Stratum 3 Clock fails to provide the system timing reference. Refer to Stratum 3 Clock Maintenance document to resolve the defective synchronization reference.

f. This error indicates excessive switching of system synchronization references has occurred. When this error occurs, synchronization is disabled and the Tone-Clock circuit pack (in the master port network) becomes the synchronization reference for the system. Execute the following steps to resolve this error:

   1. Check for timing loops and resolve any loops that exist.
   2. Test the active Tone-Clock circuit pack in the master port network via the **test tone-clock UUC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 (TDM Bus Clock Circuit Status Inquiry test) passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to "TDM-CLK" to resolve the problem. If not, continue with the following steps.
   3. *Duplicated Tone-Clock circuit packs in the master port network:* Switch Tone-Clock circuit packs on the master port network via the **set tone-clock UUC** command.

      Switch Tone-Clock circuit packs on the master port network via the **set tone-clock UUC** command.

      For simplex Tone-Clock circuit packs in the master port network: If this is not a Stratum 3 system, replace the primary and secondary (if administered) DS1 Interface circuit packs.
   4. Investigate any other SYNC or STRAT-3 errors.

g. This error indicates that the Expansion Interface circuit packs are experiencing timing slips. This error will increase the bit error rates for data transmission between port networks. The Expansion Interface circuit packs with timing slips have EXP-INTF error 2305.

   1. Check the LEDs on the active Tone-Clock circuit packs in the system and verify that the system is properly synchronized.
   2. Verify that all the TDM/LAN Bus cables on the backplane are marked WP-91716. Also for a Multi-Carrier Cabinet (MCC), check that the bus terminator type is a ZAHF4 TDM/LAN.

      For a Single Carrier Cabinet verify that the bus terminator type is a AHF110 TDM/LAN.
   3. Check for timing loops, and resolve any loops that exist.
   4. Check the Error Log for any active as well as resolved Expansion Interface circuit pack errors and refer to EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation to resolve any errors found.

5. *Duplicated Tone-Clock circuit packs in the slave port networks:*

- Switch Tone-Clock circuit packs in the slave port networks where EXP-INTF error 2305 also occurs via the **set tone-clock UUC** system technician command. The error count for this particular error should start decrementing once the problem is solved—if the count does not decrease in 15 minutes the problem still persists.
- If the problem still persists, switch the Tone-Clock in the slave port network back to the previous configuration. Then, perform a PNC interchange via the **reset pnc interchange** command.
- If the problem still persists, switch the PNC back to the previous configuration via the **reset pnc interchange** command. Then, switch the Tone-Clock circuit packs in the master port network via **set tone-clock UUC**.
- If the problem still persists, switch the Tone-Clock circuit packs in the master port network back to the previous configuration via **set tone-clock UUC**.
- Replace the active Expansion Interface circuit pack in the master port network.
- In a CSS configuration, replace the Switch Node Interface circuit pack connected to the active Expansion Interface circuit pack in the master port network. The **list fiber-link** command can be used to determine the Switch Node Interface circuit pack that is connected to the active Expansion Interface circuit pack in the master port network.
- If the system synchronization reference is a Tone-Clock circuit pack or the Stratum 3 Clock, follow normal escalation procedures. If the system synchronization reference is a DS1 interface circuit pack, administer a different DS1 interface circuit pack as the primary synchronization reference. If the problem still is not resolved and any slip errors remain, follow the procedures described in the troubleshooting section above.

6. *Simplex Tone-Clock circuit packs in the slave port networks:*

   - Switch the Tone-Clock circuit packs in the master port network via **set tone-clock UUC**.
   - If the problem still persists, switch the Tone-Clock circuit packs in the master port network back to the previous configuration via **set tone-clock UUC**. Test the Tone-Clock circuit packs in the master and slave port networks via the **test tone-clock UUC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 (TDM Bus Clock Circuit Status Inquiry test) passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to “TDM-CLK” to resolve the problem. If not, continue with the following steps.
   - If the master and slave Tone-Clock circuit packs *do not* fail TDM Bus Clock Test #150 (TDM Bus Clock PPM Inquiry test), replace the Expansion Interface circuit packs that have EXP-INTF error 2305.
   - If the system synchronization reference is a Tone-Clock circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, follow the steps listed in “TDM-CLK” to replace the master Tone-Clock circuit pack.
   - If the system synchronization reference is a DS1 interface circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, the primary or secondary (if administered) synchronization references are not providing valid timing signals for the system. Check the system synchronization references administered, and follow the steps outlined in note (a) if the primary synchronization reference is providing timing for the system or note (c) if the secondary synchronization reference is providing timing for the system.
   - If the slave Tone-Clock circuit pack fails TDM Bus Clock Test #150 but the master Tone-Clock *does not* fail this test, the master Tone-Clock circuit pack must be replaced. Follow the Tone-Clock replacement steps listed in “TDM-CLK”.
   - Replace the active Expansion Interface circuit pack in the master port network.

- In a CSS configuration, replace the Switch Node Interface circuit pack connected to the active Expansion Interface circuit pack in the master port network. The **list fiber-link** command can be used to determine the Switch Node Interface circuit pack that is connected to the active Expansion Interface circuit pack in the master port network.
- If the problem still is not resolved and any slip errors remain, follow the procedures described in the troubleshooting section above.

This error is cleared by a leaky bucket strategy and takes one hour to clear (leak away) the error counter once it is alarmed. Therefore, it may take up to one hour to clear the alarm after the problem is cleared.

h. Noise on the DS1 line can cause transient alarms on synchronization. Therefore, when a sync problem occurs on error types 1, 257, or 513, a WARNING alarm is first raised for 15 to 20 minutes before the alarm is upgraded to a MINOR or MAJOR alarm.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system.

If Stratum 3 is administered via **change synchronization**, the Stratum 3 Clock Alarm Query test (test #649) will also execute when the **test synchronization** command is run. Test 649 is described in the STRAT-3 section.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Test Synchronization Test (#417)	X	X	ND

1. D = Destructive, ND = Non-destructive

Test Synchronization Test (#417)

This test updates all the Synchronization Maintenance component circuit packs with the correct information regarding their role in providing synchronization for the system. All the Tone-Clock, Expansion Interface, DS1 Interface and UDS1 Interface circuit packs in the system are updated via this test. This test will either pass or abort.

Table 9-641. TEST #417 Test Synchronization Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.
1115	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	The Synchronization Maintenance component circuit pack parameters have been successfully updated. The system should be synchronized after successful execution of this test. If synchronization problems still exist, refer to the Error Log to obtain information regarding the source of the problem.

SYS-LINK (System Links)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
SYS-LINK	MINOR	test sys-link UUCSSpp	SYSTEM LINKS
SYS-LINK	WARNING	test sys-link UUCSSpp	SYSTEM LINKS

System Links are packet links that originate at the Packet Interface board and traverse various hardware components to specific endpoints. The hardware components involved on the forward and reverse routes can be different, depending upon the configuration and switch administration. Various types of links are defined by their endpoints:

EAL	Expansion Archangel Link terminating at an Expansion Interface board. This link carries CCMS messages.
INL	Indirect Neighbor Link terminating at a Switch Node Interface board
PACL	PNC ATM Control Link terminating at a PNC ATM EI board. This link carries ATM signaling commands from CaPro to the remote TN2238 (ATM-EI) boards.
PGC	Packet Gateway Call-Control Link terminating at a Packet Gateway board
PRI	ISDN PRI D-Channel Link terminating at a Universal DS1 board
RSCL	Remote Socket Control Link terminating at a C-LAN board
RSL	Remote Socket Link teminating at a C-LAN board
SAP	System (Access) Port Link terminating at a Packet Data port
X.25	BX.25 Link terminating at a Packet Gateway port

Recording System Link Events

The system links maintenance object records all errors encountered on the links. Most of these events are not extraordinary unless they occur with an alarming frequency. The events are logged as they occur, leaving a “trail” to help analyze abnormal behavior exhibited by the endpoints attached to the links or the links themselves.

When a link goes down, an alarm is raised immediately. For EAL, INL, and PACL link types a MINOR alarm is raised; for all other link types a WARNING alarm is raised. Other alarming conditions that do not cause the link to go down get a WARNING alarm, regardless of the link type.

Identifying a System Link

In order to trace problems associated with a system link, it is necessary to find its location. The following methods can be used to find the location of the system link:

Display Errors/Alarms

The output of the **display errors** or **display alarm** commands shows the location of the system link for entries with a Maintenance Name of SYS-LINK. You can restrict the scope of the output of these commands by specifying **sys-link** in the `Category` field on the input form. The link type and channel number, if any, are listed under the `Alt Name` field of the report.

List sys-link

The **list sys-link** command lists all system links (location, link type, and channel number) present in the system.

NOTE:
In case of the X.25 link type, a single endpoint carries multiple links. A combination of the endpoint and channel number is used to uniquely identify the link. All other links can be uniquely identified by their endpoints.

Common Procedure for Repairing Link Problems

The state of a system link is dependent on the state of the various hardware components that it travels over. To resolve any problems associated with a system link, use the following procedure.

The switch maintains a list of hardware components over which the link travels, called the hardware path. There are two hardware paths: the current hardware path and the faulted hardware path for each of the system links. The current hardware path is present only for those links that are currently up. When a link is down, the current hardware path is empty. The faulted hardware path is always present once the link has gone down and is *not cleared when the link subsequently recovers.* The faulted path preserves the path that the link traversed when it last went down. The time at which the faulted path was last recorded is preserved and is accessible through the **status sys-link** ***location*** and **list sys-link** commands. Therefore, the focus of attention for problems which do not involve a link that is down is the current hardware path. If the link is down, faulted hardware path is the focus of attention.

The **status sys-link *location*** command shows the state of both the hardware paths (current and faulted) along with the state of each of the components in the hardware path. When analyzing any system link problem

1. Look for alarms on the components listed under desired hardware path.
2. If any alarms are present, then follow the maintenance procedures for the alarmed components to clear those alarms first.

   NOTE:
   For systems using ATM-EI (TN2305/6 circuit packs) and where link alarms are present, refer to ''ATM-BCH (ATM B-Channel Trunk)'' and the ''ATM Tips'' section in Chapter 5.

3. When all the components are alarm free, wait for 3 minutes to allow the links to recover.
4. Test the system link (**test sys-link PCSSpp long clear**) and notice any tests that fail.
5. If there are any failures, fix the problems indicated by the tests and repeat the procedure.

Error Log Entries and Test to Clear Values

Table 9-642. Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
13 (a)		System Link Status (985)	MINOR/ WARNING	OFF	
257 (b)			WARNING	OFF	test sys-link UUCSSpp l cl
513 (c)			WARNING	OFF	test sys-link UUCSSpp l cl
772 (d)			WARNING	OFF	test sys-link UUCSSpp l cl
1025 (e)			WARNING	OFF	test sys-link UUCSSpp l cl
1281 (f)			WARNING	OFF	test sys-link UUCSSpp l cl
1537 (g)			WARNING	OFF	test sys-link UUCSSpp l cl
1793 (h)			WARNING	OFF	test sys-link UUCSSpp l cl

Notes:

a. This error indicates that the link went down. The link may have gone down or never come up. Enter command **status sys-link location** and check the value of the `Faulted Path` field. If the value is `default`, then the link never came up. If the value is `present`, then the link came up and then went down.

   1. Follow the information in the "Common Procedure for Repairing Link Problems" section above.
   2. Wait for 3-5 min. before checking the link state.
   3. Repeat the procedure until there are no problems with the components.

b. This error indicates that the link has experienced uplink flow control. Manifest effect of this error is that the end-point may be hyperactive. The system link is alarmed if 4 or more errors of this type are detected within 10 min.

   1. Follow the information in the "Common Procedure for Repairing Link Problems" section above.
   2. Clear errors and wait for 10 min.

c. This error indicates that the link has experienced downlink flow control, meaning that some information packets from the packet interface board have been lost. The link is reset on first occurrence, hence, Error 1025 is also logged. The system link is alarmed if 2 or more errors of this type are detected within 10 min.

   1. Follow the information in the "Common Procedure for Repairing Link Problems" section above.
   2. Clear errors and wait for 10 min.

d. This error indicates that the link experienced a temporary disconnect due to excessive resets or state transitions, meaning that the link is taken down and then brought up again. The system link is alarmed if 2 or more errors of this type are detected within 10 min.

   1. Follow the information in the "Common Procedure for Repairing Link Problems" section above.
   2. Clear errors and wait for 10 min.

e. This error indicates that the link has been reset, meaning that information packets queued at the time of reset are lost. The system link is alarmed if 20 or more errors of this type are detected within 10 min.

   1. Follow the information in the "Common Procedure for Repairing Link Problems" section above.
   2. Clear errors and wait for 10 min.

f. This error indicates that the link has experienced slow transmit rate because the remote endpoint is busy. The effect of this error is that the endpoint location may experience slower throughput rate and/or noisy transmission. The system link is alarmed if 4 or more errors of this type are detected within 10 min.

   1. Ensure that the remote endpoint is functioning properly.
   2. If the problem persists, follow the information in the "Common Procedure for Repairing Link Problems" section above.
   3. Clear errors and wait for 10 min.

g. This error indicates that the link has experienced slow transmit rate due to excessive retransmission. Possible causes for this error may be that the switch is overrunning the endpoint or that the endpoint is sick. The effect of this error is that the endpoint location may experience slower throughput rate. The system link is alarmed if 4 or more errors of this type are detected within 10 min.

   1. Follow the information in the "Common Procedure for Repairing Link Problems" section above.
   2. Clear errors and wait for 10 min.

h. This error indicates that the link has experienced slow transmit rate due to unknown causes, meaning that the endpoint location may experience slower throughput rate and the Packet Interface may experience backup or congestion. The system link is alarmed if 4 or more errors of this type are detected within 10 min.

1. Follow the information in the ''Common Procedure for Repairing Link Problems'' section above.
2. Clear errors and wait for 10 min.

System Technician-Demanded Tests: Descriptions and Error Codes

Testing for system links is different from the standard test procedures for Maintenance Objects. In addition to testing the system link maintenance object, the user is allowed to test all the components in the path of the system link. There are two paths preserved for the link. The current path, if present, represents the path traversed by the link currently. This path is not present when the link is down. The other path, the faulted path, is present if the link has ever gone down or never come up. If the link came up and went down, then the faulted path is marked `present`. If the link never came up, the faulted path is marked `Default`. In either case, it represents the path on which the link was attempted or established unsuccessfully.

Test command for the system links, **test sys-link UUCSSpp** can be specified with current or faulted as an optional argument if the user wishes to test all the components in the specified path. The tests executed will be the same if the user were to test each component manually. In the event that the user does not specify any path, then only the tests specified for the system links are executed.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
System Link Status (#985)	X	X	N

1. D = Destructive, ND = Non-destructive

System Link Status (#985)

This test is non-destructive. This test queries the switch for the status of the system link and verifies that all switch components have the same view of the link state.

Table 9-643. TEST #985 System Link Status

Error Code	Test Result	Description/ Recommendation
1007	ABORT	Could not locate the system link associated with this location 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
6	FAIL	The system link is down. 1. Follow the procedure for Error Type 13.
	PASS	The system link is up.

SYS-PRNT (System Printer)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
SYS-PRNT	MINOR	test sp-link l	System Printer
SYS-PRNT	WARNING	release sp-link	System Printer

The Report Scheduler feature provides the capability to schedule printing of output form selected administration commands on an asynchronous System Printer (SYS-PRNT) or a Personal Computer (PC). The System Printer device connects to the system via a data module (PDM, MPDM, DTDM) connected to a port on a TN754 Digital Line circuit pack which is administered as a data extension. A System Printer device can also be connected through an ADU to a port on TN726B Data Line circuit pack. The System Printer link to the processor is via a system port. A system port is comprised of a port on the TN726B Data Line circuit pack and a port on the TN553 Packet Data circuit pack connected to each other in a null-modem fashion. Refer to the PDATA-PT section for information on the system port connectivity.

System Printer Link Maintenance provides a strategy for maintaining the link between the system and an external SYS-PRNT output device. The strategy includes a set of tests for detection of errors during normal operation, troubleshooting actions, and alarms for serious problems. System Printer Link Maintenance uses a try-and-wait mechanism for maintaining the SYS-PRNT link. A minor alarm is raised when the link set-up fails. A warning alarm is raised when the SPE has been busied out. A maximum of two link retry attempts is made. After the second attempt, set-up attempts are only made by the application software. (The 15-minute timer fires and jobs are printed unless an immediate job was entered.) After two unsuccessful attempts to establish the link, a MINOR alarm is raised. If the System Printer Link is torn down due to an error, System Printer Link Maintenance will raise a MINOR alarm but will not attempt to bring up the System Printer Link.

System Printer Link Maintenance does not cover the elements comprising the SYS-PRNT physical link: the external SYS-PRNT output device, the Data Module (PDM/MPDM/DTDM) and TN754 Digital Line, or the ADU and TN726B Data Line. If System Printer Link Maintenance cannot restore the System Printer Link, the maintenance tests of these individual components of the System Printer Link must be executed to diagnose faults.

Procedures for Restoring the System Printer Link

1. Determine the status of the System Printer Link via the **status sp-link** command. Verify that the System Printer Link is not busied out for maintenance. This is indicated by a no in the `Maintenance Busy?` field. If the System Printer Link has been busied out, issue the **release sp-link** command. If the link is down, proceed to Step 2.
2. Issue the **display system feature** command to determine the location of the System Printer Link.

   Enter the **status data-module <extension>** command and verify that the data extension is in-service/idle. If the data extension is *not* available, refer to the `Port` field. Look for errors and/or alarms on the circuit pack with which this extension is associated. Follow repair instructions for the appropriate MO. Continue with Step 3.
3. Verify the availability of the external SYS-PRNT output device. Make sure that the output device is *on-line* and ready-for-service. Check the physical connectivity between the Data Module and the SYS-PRNT output device.
4. Verify that there is at least one system port available. The System Printer Link can not be established unless there is a system port available. Refer to "PDATA-PT" for more information on system ports.
5. If the problem is not found in the above steps, check the system port for any problems. Refer to "PDATA-PT" for description about system port and its connectivity.

It should be noted that when restoring the System Printer link it is necessary to execute tests on different maintenance objects that comprise the System Printer link. It is recommended that you busy out the System Printer link before trying to restore the link. When the System Printer Link is busied out, all System Printer Link maintenance actions are deactivated, and interference with tests of other MOs is prevented.

Error Log Entries and Test to Clear Values

Table 9-644. SYS-PRNT Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	test sp-link
18 (a)	0	busyout sp-link	WARNING	OFF	release sp-link
257(b)	1, 3 4, 5, 6	Link Retry Test (#215)	MINOR/[1] WARNING	OFF	test sp-link l
513 (c)	0	None	MINOR	OFF	test sp-link

1. Minor alarms may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. The System Printer Link has been busied out.

b. A failure was encountered while attempting to set up the System Printer Link. This attempt could have been initiated by either Report Scheduler software or by link maintenance during automatic link retry or as a result of a Link Retry Test (#215) request. The Aux Data field indicates the following:

1	No system port available. Refer to PDATA-PT for explanation.
3, 4	Time-out during setup attempt. Most likely due to problem with physical link or printer status.
5	Internal system error. Most likely temporary/sporadic failure.
2, 6	The data module the printer is trying to use is busy with another call. Use the **Status data module** command to determine when the port is available for testing.

Refer to the preceding section “Procedures for Restoring the System Printer Link for recommended maintenance strategy.

c. The SYS-PRNT was interrupted for one of the following reasons:

- The cable to the SYS-PRNT output device is disconnected
- The SYS-PRNT output device is powered off
- The data extension to which the SYS-PRNT output device connects has been busied out
- Internal software error

Check the connectivity of the wires and cables among the wall jacket, data module, and SYS-PRNT output device. Follow the instructions provided in *Procedures for Restoring the System Printer Link* above.

System-Technician-Demanded Tests: Descriptions And Error Codes

When inspecting errors in the system and deciding which ones to address, always investigate errors in the order they are presented in the table below. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND

1. D = Destructive, ND = Non-destructive

Link Tear Down Test (#213)

This test is destructive.

The Link Tear Down Test disconnects the existing link between DEFINITY Generic 3 and the external SYS-PRNT output device. If the link has been disconnected already, this test just returns PASS. All resources allocated for a System Printer Link are released after this test.

Table 9-645. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40, 50	ABORT	Internal System Error. 1. Retry the command at 1 -minute intervals a maximum of two times.
1010	ABORT	The System Printer Link has been busied out. 1. Enter the **release sp-link** command to release the System Printer Link from the busyout state. 2. Reissue the **test sp-link long** command to execute the test.
2012	ABORT	Internal System Error. 1. Retry the command at 1-minute intervals a maximum of five times.
	FAIL	Internal System Error. 1. Retry the command at 1-minute intervals a maximum of two times.
	PASS	The System Printer Link is torn down or a Short Test Sequence was executed and the link was not torn down.

Link Retry Test (#215)

This test sends a message to the System Printer management software process instructing it to make a data call to the extension connected to the printer. If the System Printer link is already up, this test passes without making any data call.

Table 9-646. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10, 20	ABORT	Internal System Error. 1. Retry the command at 1-minute intervals a maximum of two times.
30	ABORT	Internal System Error. 1. Refer to the ''Procedures for Restoring the System Printer Link'' section for recommended maintenance strategy.
1010	ABORT	The System Printer Link has been busied out. 1. Enter the **release sp-link** command to release the System Printer Link from the busyout state. 2. Reissue the **test sp-link long** command to execute the test.
2012	ABORT	Internal System Error. 1. Retry the command at 1-minute intervals a maximum of five times.
	FAIL	The System Printer Link CANNOT be established. 1. Refer to the ''Procedures for Restoring the System Printer Link'' section for recommended maintenance strategy.
	PASS	The System Printer Link is up.

SYSAM (Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SYSAM	MAJOR[2]	test maintenance UUC l	System Access and Maintenance circuit pack
SYSAM	MINOR	test maintenance UUC s	System Access and Maintenance circuit pack
SYSAM	WARNING	test maintenance UUC s	System Access and Maintenance circuit pack

1. UU is the cabinet number (always 1, not required). C is the carrier designation (a or b). With simplex SPE the carrier location is not required. With duplicated SPEs, carrier a or b must be specified.
2. After a spontaneous SPE interchange has occurred, the Alarm Log retains for three hours a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.

The System Access and Maintenance (SYSAM) circuit pack, TN1648:

- Is a required component of the SPE Complex
- Monitors the sanity of the RISC Processor circuit pack and environmental conditions
- Provides the serial interface for the G3-MT terminal and the communication interface to INADS or other service locations for alarm reporting and remote maintenance capability
- Provides the Time-Of-Day Clock for the system.

In addition to the usual red, green, and yellow LEDs, the SYSAM circuit pack has alarm, acknowledgment and emergency transfer LEDs whose meanings are explained in the ''SYSAM and Maintenance Circuit Pack LEDs'' in Chapter 7.

NOTE:
Pay attention to the extra LEDs on the *active* SYSAM only. Indications given by these extra LEDs on a *standby* SYSAM (duplicated SPE) are not meaningful.

Error Log Entries and Test to Clear Values

Table 9-647. SYSAM Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test processor UUC s r 1
1		SYSAM Reset Test	MAJOR[2]	ON	test maintenance UUC l r 1
150 (a)	Any	None	MAJOR[2]	ON	test maintenance UUC l c
257		Analog Looparound Test (#917)	MINOR	ON	test maintenance UUC l r 3
513 (b)		G3-MT Looparound Test (#915)	MINOR	ON	test maintenance UUC s r 3
769(c)	Any	Sanity Handshake Test	WARNING	OFF	test maintenance UUC s r 3
1025		Out-Pulse Relay Test (#916)	MINOR	OFF	test maintenance UUC l r 5
1281		Time of Day Clock Test	MAJOR[2]	ON	test maintenance UUC s r 3
1537		Sanity Handshake Test	MINOR	ON	test maintenance UUC s r 3
1793(d)	None		WARNING	ON	
2049		SYSAM Dual Port Ram Test	MAJOR[2]	ON	test maintenance UUC l r 1
2561 (e)		G3-MT Looparound Test(#915)	MINOR	ON	test maintenance UUC s r 3
2817 (f)	Any	External Modem Present Test (#912)	MINOR	OFF	test maintenance UUC s r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. After a spontaneous SPE interchange has occurred, the Alarm Log retains for three hours a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. If a spontaneous interchange has occurred (as indicated by STBY-SPE error type 103 or the **display initcauses** screen), and handshake is down, (check with **status spe**), replace the alarmed circuit pack on the standby SPE. If handshake is up, execute a **test long clear** of the alarmed circuit pack and follow recommended procedures.

Notes:

a. Error 150 indicates that a SPE interchange has occurred and that the SYSAM circuit pack was the cause of the spontaneous interchange.

   1. If other SYSAM errors are present, investigate these errors.
   2. If no other SYSAM errors are present, run the **test maintenance a|b long clear** command and investigate any test failures.

b. Error 513 indicates that the circuitry associated with active port on the SYSAM circuit pack is not functioning properly. This circuitry can only be tested when the SYSAM is in the active SPE.

c. Error 769 indicates that one of the following in-line errors has occurred:

    1. The "No Case" error indicates that the SYSAM firmware received a message that does not match any known message format.

    2. The "Background Fault" error indicates that one of the following SYSAM firmware background test failed: CPU Test, EPROM Checksum Test, RAM Test, or NVRAM Checksum Test.

    3. The "Logical Inconsistency" error indicates that the SYSAM firmware has determined that the SYSAM circuit pack is in a logically inconsistent state.

   These errors indicate that the SYSAM's sanity may be questionable. SYSAM software will run the Sanity Handshake Test in response to these errors. If these errors are reported repeatedly, SYSAM software will reset the SYSAM circuit pack via the SYSAM Reset Test.

d. Error 1793 indicates that the Sanity Timer Test initialization test failed on the last time the system rebooted. (Refer to "Routine Maintenance Procedures"). Replace the SYSAM circuit pack and verify that the Sanity Timer Test passes after replacing the circuit pack. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5.

e. Error 2561 indicates that the standby G3-MT port on the standby SYSAM circuit pack is not functioning properly. Standby port circuitry on the active SYSAM is not tested.

f. Error 2817 with aux 2060 indicates that external modem is administered on a switch with an active TN1648 suffix A. The external modem capability requires a TN1648 suffix B or later. Set the `Modem Connection:` field on the System-parameters Maintenance screen to **internal**.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *SYSAM Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
SYSAM Reset Test (#909)(a)		X	X	D
SYSAM Dual Port Ram Test (#910)(a)		X	X	D
Sanity Handshake Test (#911)	X	X		ND
Time of Day Clock Test (#913)	X	X		ND
G3-MT Looparound Test (#915)	X	X		ND
Outpulse Relay Test (#916) (b)	X	X		ND
Analog Looparound Test (#917) (b)	X	X		ND
External Modem Present Test (#912) (b)(c)	X	X		ND

1. D = Destructive, ND = Non-destructive

Notes:

a. If you are invoking the long test sequence from the PPN G3-MT, the SYSAM Reset Test and SYSAM DPR Test will cause the PPN G3-MT to logoff and tear down any SYSAM Remote Access connection. After the test sequence runs, the Error Log should be examined for SYSAM errors of type 1 and 2049 to determine if either SYSAM Reset Test or SYSAM DPR Test have failed. If you are invoking the long demand test sequence from an EPN G3-MT, all tests listed above will run and the results will display on the EPN G3-MT. The PPN G3-MT will still be logged off and any SYSAM Remote Access connection will be torn down.

b. These tests can be run only on the active SYSAM circuit pack. If you are invoking the long test sequence on the standby SYSAM circuit pack, these tests (Outpulse Relay Test, Analog Looparound Test, and External Modem Present Test) do not run.

c. This test aborts if an external modem is not administered.

SYSAM Reset Test (#909)

This test is destructive.

This test resets the SYSAM circuit pack. The destructive nature of this test causes the PPN G3-MT to logoff and any SYSAM Remote Access connection (for example, INADS connection) to be torn down.

The reset test causes terminals connected to the SYSAM either directly or through the remote access port to logoff prior to the test results being displayed. To determine a test result from one of these locations, log back in and examine the Error Log for SYSAM error type 1 with no Aux Data. This error entry indicates that the SYSAM Reset Test failed and that the SYSAM circuit pack should be replaced.

If the test is being run from somewhere other than the SYSAM ports, (for example, a G3-MT connected to an EPN Maintenance circuit pack), test results are displayed on the screen without a logoff taking place.

Table 9-648. Test #909 SYSAM Reset Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1318 1335 2029 2033 2500	ABORT	Internal System Error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-648. Test #909 SYSAM Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs set as the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE Selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is a High or Critical Reliability configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The circuit pack was reset, but responded with a NOT PASS status indicating it did not pass initialization correctly. The SYSAM is not functioning correctly. The system should continue to operate but will not have the ability to perform alarm origination, if needed. Environmental monitoring, the PPN G3-MT, and the System Sanity Timer are lost. 1. Retry the command. 2. If test continues to fail, replace the SYSAM circuit pack. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5.
	PASS	The circuit pack was reset, it did pass initialization correctly. The other SYSAM tests should be examined to verify that the SYSAM is functioning normally. 1. Execute **test maintenance a|b short** and verify that the SYSAM is operating correctly.

SYSAM Dual Port RAM Test (#910)

This test is destructive.

This test terminates any PPN G3-MT or SYSAM Remote Access session. This is a coordinated test of the Processor circuit pack's and SYSAM circuit pack's on-board microprocessor ability to access the SYSAM's Dual Port RAM (DPR). Control messages and data are passed through the DPR. The test forces both the Processor and the on-board microprocessor to read and write the DPR simultaneously in alternate locations.

The DPR test causes the PPN G3-MT and SYSAM Remote Access sessions to logoff prior to the test result being displayed. To determine the test result, log back in and examine the Error Log for an error against SYSAM, Error Code 2049, no Aux Data. This error entry indicates that the SYSAM DPR Test failed and that the SYSAM circuit pack should be replaced.

If the test is being run from somewhere other than the PPN G3-MT or SYSAM Remote Access connection (for example, EPN G3-MT), the test results will be displayed on the screen.

Table 9-649. Test #910 SYSAM Dual Port RAM Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1318 1335 2029 2033 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-649. Test #910 SYSAM Dual Port RAM Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is a High or Critical Reliability configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The DPR is not functioning correctly. Communication between the Processor and SYSAM is lost. The system is not able to report environmental alarms, use the PPN G3-MT, or use the SYSAM Remote Access connection if the need should arise. 1. Retry the command. 2. If the test continues to fail, replace the SYSAM circuit pack. 3. Retry the command. 4. If the test continues to fail, replace the Processor circuit pack. 5. Retry the command. 6. Replace the SPE circuit packs. See "Replacing SPE Circuit Packs" in Chapter 5.
	PASS	Dual Port RAM is functioning. Communication does exist between the Processor and SYSAM circuit packs.

Sanity Handshake Test (#911)

This test checks the SYSAM circuit pack's ability to respond to queries. A message is sent to the SYSAM circuit pack, which then returns a message. The SYSAM must reply for this test to pass. If this test fails, the SYSAM circuit pack should be considered insane, the circuit pack should be reset with the **reset maintenance a | b** command.

Table 9-650. Test #911 Sanity Handshake Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1318 1335 2029 2033 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.

Continued on next page

Table 9-650. Test #911 Sanity Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2318	ABORT	The standby SYSAM was not responding within the allowable time period. 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	The SYSAM did not respond to the sanity handshake query. 1. Run the **test maintenance 1a|b long** command. The terminal login drops, and you must login again. 2. If test continues to fail, replace the SYSAM circuit pack at the earliest convenience. 3. Retry the command. 4. Replace the SYSAM circuit pack. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5.
	PASS	The SYSAM did respond to the sanity handshake query. 1. Examine other SYSAM tests for errors.

SYSAM Refresh Test (#912)

This test checks the current state of the Alarm Panel LEDs on the SYSAM circuit pack and attempts to resynchronize them to reflect the current alarm levels in the system. Any discrepancies are resolved by changing the Alarm Panel LEDs to what maintenance believes the alarm levels should be. The SYSAM Refresh Test runs only in G3r V1 software loads preceding Release 6.0. Newer software has replaced the SYSAM Refresh Test with the External Modem Present Test (*both* use the Test #912 number).

Table 9-651. Test #912 SYSAM Refresh Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1318 1335 2029 2033 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.

Continued on next page

Table 9-651. Test #912 SYSAM Refresh Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is a High or Critical Reliability configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2005	FAIL	Could not handshake with the SYSAM circuit pack. The SYSAM circuit pack did not respond to a query message sent to it. Run the **test maintenance a|b short**, and refer to the repair procedures outlined for the Sanity Handshake Test.
2318	ABORT	The standby SYSAM was not responding within the allowable time period. 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
	FAIL	Internal System Error 1. Retry the command
	PASS	The SYSAM circuit pack has been sent the correct state for the system LEDs. If the LEDs do not reflect the system alarms shown in the alarm log, the SYSAM circuit pack may have problems. 1. Verify the LEDs on the SYSAM circuit pack can be changed by issuing the **test led port-network 1** command. All the SYSAM circuit pack LEDs should go on and then off, and then be refreshed. 2. After the **test led port-network 1** command finishes, if the SYSAM circuit pack LEDs do not reflect the alarm log, follow normal escalation procedures.

Time-Of-Day Clock Test (#913)

The short term accuracy of the time-of-day clock is tested. The test reads the clock once, waits 10 seconds, and then reads the clock again. The second reading of the clock must be within certain limits (10 seconds) relative to the first reading for the test to pass. The **display time** command can be used to display the current setting of the time-of-day clock.

If the time-of-day clock is not functioning correctly, the software time-of-day clock is used (this clock is not as accurate as the hardware clock).

Table 9-652. Test #913 Time-Of-Day Clock Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1318 1335 2029 2033 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.

Continued on next page

Table 9-652. Test #913 Time-Of-Day Clock Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is a High or Critical Reliability configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2318	ABORT	The standby SYSAM was not responding within the allowable time period. 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
any	FAIL	The short term accuracy of the time-of-day clock is not within limits (10 seconds >= difference <= 20 seconds). **NOTE:** Error Code *any* indicates the difference between the two reads. A zero (0) indicates that the time-of-day clock is not running. 1. Run the short test sequence several times to make sure the error is occurring consistently. 2. If test continues to fail consistently, replace the SYSAM circuit pack at the earliest convenience. 3. After replacing the SYSAM, you must set the time-of-day clock via the **set time** command. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5.
	PASS	The short term accuracy of the time-of-day clock on the SYSAM circuit pack is within limits.

SYSAM G3-MT Looparound Test (#915)

This test places the G3-MT port on the SYSAM circuit pack into loop-around mode and verifies the data integrity of the channel. The test is non-destructive but may cause a momentary loss of keyboard input from the G3-MT while the test is running (about 1 second).

On High and Critical Reliability systems, there are two G3-MT ports on each of the two SYSAM circuit packs: one is labeled ACTIVE and the other STANDBY. On the current active SYSAM circuit pack, only the ACTIVE port is tested. On the current standby SYSAM circuit pack, only the STANDBY port is tested.

Table 9-653. TEST #915 SYSAM G3-MT Looparound Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1318 1335 2029 2033 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run with a planned SPE interchange in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable, and related repair actions. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.

Continued on next page

Table 9-653. TEST #915 SYSAM G3-MT Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is equipped with the High Reliability or Critical Reliability Configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2334	ABORT	The hardware mailbox on the standby Duplication Interface board is not ready to receive messages. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
2318	FAIL	The STANDBY port on the SYSAM circuit pack on the standby SPE did not respond to the test in time. If this test fails at least 3 times in a row, the STANDBY port is probably unusable for diagnostics through the SPE-Down or SPE-Standby Interfaces. Other than this unavailability, this failure should cause no service effects. 1. Try the test again at 1-minute intervals up to a maximum of 3 times. 2. If the test fails all 3 attempts, replace the standby SYSAM circuit pack at the earliest convenience. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5.
	FAIL	The SYSAM G3-MT channel failed the loop around test. The G3-MT will probably be unusable for administration or maintenance. The EPN G3-MT, if available, or remote access can still be used. 1. Retry the command. 2. If test continues to fail, replace the SYSAM circuit pack at the earliest convenience. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5.
	PASS	The G3-MT channel passed the loop around test. 1. If the PPN G3-MT is not usable, check the G3-MT and associated cabling.

SYSAM Outpulse Relay Test (#916)

This test validates the operation of the SYSAM Remote Access CO trunk used for Alarm Origination and remote access. The SYSAM goes off-hook and then on-hook on this trunk. If loop current is detected then the test passes. If the external modem is administered, the SYSAM sends an AT command sequence that causes the external modem to go off-hook and wait for dial-tone. If the modem detects dial-tone, the test passes.

This test is not allowed if the remote access line is in use or if the SYSAM is on the Standby SPE in SPE Duplication Option systems. Also, this test must be administered for testing through the **change system-parameters maintenance** form.

NOTE:
When using an active TN1648 (prior to suffix B), and even though the modem is administered as “external,” this only tests the internal modem.

Table 9-654. TEST #916 SYSAM Outpulse Relay Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1018	ABORT	The test has been disabled via administration. 1. To enable test, set the `Test Remote Access Port` field to **y** on the system-parameters maintenance screen. 2. Retry the command.
1318 1335 2029 2033 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-654. TEST #916 SYSAM Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.
1364	ABORT	The component on which the test was to be run is on the Standby SPE. This test may only be run on this component when it resides on the Active SPE. 1. To verify the remote access line is working (connected), run this on the Active SYSAM.
1379	ABORT	System could not determine if testing of remote access port is administered. 1. Check system-parameters maintenance screen for a **y** in the `Test Remote Access Port` field. 2. Retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is s High or Critical Reliability configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2034	ABORT	The remote access port is busy. A remote user is probably dialed into the switch. 1. If a remote user is dialed in, remote access line is working. No need to run test. Use the **status logins** command to verify that the SYSAM-RMT port is in use.

Continued on next page

Table 9-654. TEST #916 SYSAM Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	SYSAM reported test failure. No loop current detected. 1. Retry the command. 2. For an external modem, if the test continues to fail: a. If the External Modem Present Test (#912) failed, use the external modem recommendations listed in Test #912. b. If the External Modem Present Test (#912) passes, the SYSAM most likely received a `NO DIALTONE` response to the ATD command sent from the SYSAM. This problem is between the modem and the INADS trunk. 3. If test continues to fail, examine SYSAM remote access line for connectivity, manually check line for loop current. 4. If SYSAM remote access line checks out fine, but test still fails, check backplane connector cabling. Also, check the cabling from the wall field to the backplane. 5. If backplane cabling checks out fine, replace SYSAM circuit pack at earliest convenience. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5.
	PASS	SYSAM detected loop current on remote access port. 1. If system cannot call remote maintenance facility or remote maintenance facility cannot contact system, check with local Central Office for problems with SYSAM remote access line.

SYSAM Analog Looparound Test (#917)

This test checks the on-board modem circuitry of the SYSAM circuit pack associated with the SYSAM remote access port. Test data is looped through the on-board modem and verified for integrity. If the external modem is administered, the test loops data in the MTP DUART ahead of the connection to the external modem. This test also causes the MTP DUART to verify that Clear-To-Send (CTS) is being supplied by the modem.

This test is not allowed if the remote access port is in use or if the SYSAM is on the Standby SPE in SPE Duplication Option systems. Also, this test must be administered for testing through the **change system-parameters maintenance** screen.

NOTE:
This test does not send any data onto the SYSAM remote access line, but the test does require the line to be present to pass reliably.

NOTE:
When using an active TN1648 (prior to suffix B), and even though the modem is administered as “external,” this only tests the internal modem.

Table 9-655. TEST #917 SYSAM Analog Looparound Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1018	ABORT	The test has been disabled by administration. 1. To enable test, set the `Test Remote Access Port` field to **y** on the system-parameters maintenance screen. 2. Retry the command.
1318 1335 2029 2033 2500	ABORT	Internal System Error 1. Retry the command.

Continued on next page

Table 9-655. TEST #917 SYSAM Analog Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the STBY-SPE maintenance documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.
1364	ABORT	The component on which the test was to be run is on the Standby SPE. This test may only be run on this component when it resides on the Active SPE. 1. To verify the remote access line is working (connected), run this on the Active SYSAM.
1379	ABORT	System could not determine if testing of remote access port is administered. 1. Check system-parameters maintenance screen for a **y** in the `Test Remote Access Port` field. 2. Retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is a High or Critical Reliability configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code then changes to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2034	ABORT	The remote access port is busy. A remote user is probably dialed into the switch. 1. Wait until the remote user session is terminated, retry the command.

Continued on next page

Table 9-655. TEST #917 SYSAM Analog Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2317	ABORT	Test #916 SYSAM Outpulse Relay Test failed. 1. Follow instructions for FAIL result for SYSAM Outpulse Relay Test (#916).
	FAIL	SYSAM reported test failure. The system is not able to reliably contact any remote maintenance facility with alarm data or dialed into through the SYSAM remote access port. The system continues to provide reliable service. 1. For an internal modem: a. If SYSAM Outpulse Relay test (#916) is also failing, check for presence of SYSAM remote access line and resolve SYSAM remote access line problems. b. If test #916 passes, the fault is on the SYSAM circuit pack, replace at the earliest convenience. To replace the SYSAM circuit pack, refer to "Replacing SPE Circuit Packs" in Chapter 5. 2. For an external modem: a. Check the power to the modem. b. Check the RS-232 connection from the external modem connector to the modem. Transmit, Receive, RTS, and CTS signals must be communicating between the MTP DUART hardware and the modem hardware. c. The SYSAM DUART or related circuitry on the processor circuit pack may have failed. The circuit pack should be changed at your convenience.
	PASS	SYSAM detected correct data through loop around connection. 1. If system cannot call remote maintenance facility or remote maintenance facility cannot contact system, check with local Central Office for problems with SYSAM remote access line.

SYSAM External Modem Present Test (#912)

This test is a nondestructive test on the remote access line, and will run only if the channel is idle. The test validates the presence of an external modem with a firmware invoked AT command. The test passes if the modem responds with "OK" to the AT command. This test also validates external modem administration. This test will fail if an external modem is administered on a switch with an active TN1648 suffix A.

This test is not allowed if the remote access line is in use or if the SYSAM is on the Standby SPE in SPE Duplication Option systems. Also, this test must be administered for testing through the **change system-parameters maintenance** screen.

Table 9-656. TEST #912 SYSAM External Modem Present Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command.
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals, a maximum of 5 times.
1018	ABORT	The test has been disabled by administration. 1. To enable test, set the `Test Remote Access Port` field to **y** on the system-parameters maintenance screen. 2. Retry the command.
1049	ABORT	External modem is not administered. When using an active TN1648 (prior to suffix B), this abort code is normal, because only this test only applies to external modems.
1318 1335 2029 2033 2500	ABORT	Internal system error 1. Retry the command.
1338	ABORT	The test is not allowed to run since a planned SPE interchange is in progress. This may be caused by a planned interchange initiated automatically during 24 hour scheduled testing. 1. Wait 3 minutes and retry the command.

Continued on next page

Table 9-656. TEST #912 SYSAM External Modem Present Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	The test could not run on the standby SYSAM circuit pack in the standby SPE carrier because the standby SPE is unavailable. 1. Refer to the "STBY-SPE (Standby SPE Maintenance)" documentation for information on why a standby SPE may be unavailable and what repair actions should be taken. The screen for the **status spe** command should indicate that handshake is down. This may be caused by a variety of reasons such as the SPE-SELECT switches on the DUPINT circuit packs being set to the position of the active SPE, a failure of the DUPINT circuit pack, or loss of power on the standby SPE. The `SPE selected` field on the **status spe** screen displays `spe a` or `spe b` if both SPE-SELECT switches are in the a or b positions, respectively.
1364	ABORT	The component on which the test was to be run is on the Standby SPE. This test may only be run on this component when it resides on the Active SPE. 1. To verify the remote access line is working (connected), run this on the Active SYSAM.
1379	ABORT	System could not determine if testing of remote access port is administered. 1. Check system-parameters maintenance screen for a **y** in the `Test Remote Access Port` field. 2. Retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. If the system is a High or Critical Reliability configuration and if the SYSAM circuit pack is on the standby SPE, this abort code may indicate that the standby SPE is not responding to the handshake message. If this is the case, the standby SPE maintenance software may take up to two minutes to indicate that handshake communication with the standby SPE is down. The ABORT code will then change to 1339 (standby SPE unavailable). 1. Retry the command at 1-minute intervals, a maximum of 3 times.
2034	ABORT	The remote access port is busy. A remote user has probably dialed into the switch. 1. If a remote user is dialed in, remote access line is working. No need to run test. Use the **status logins** command to verify that the SYSAM-RMT port is in use.

Continued on next page

Table 9-656. TEST #912 SYSAM External Modem Present Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2080	FAIL	An external modem is administered on a switch with an active TN1648 (prior to suffix B.) 1. Set the `Modem Connection:` field on the system-parameters maintenance screen to **internal**. (The external modem capability requires a TN1648 suffix B or later.) 2. Retry the command.
	FAIL	SYSAM reported test failure. The SYSAM did not receive an "OK" response after sending the "AT" command to the modem. 1. If the Analog Looparound Test (#917) failed, follow the external modem recommendations for that failure. 2. If the Analog Looparound Test (#917) passes: a. Check the RS-232 connection from the external modem connector to the modem. RTS and CTS signal are being communicated between the SYSAM DUART hardware and the modem hardware. Transmit and receive signals may not be communicated correctly. b. Check the modem administration using the change system-parameters maintenance command, especially changes from default parameters. c. Check the modem settings, especially changes from factory defaults. **NOTE:** The fault may be on the SYSAM circuit pack. The circuit pack may need to be replaced.
	PASS	Modem administration matches SYSAM capability and SYSAM detected loop current on remote access port. 1. If system cannot call remote maintenance facility or remote maintenance facility cannot contact system, check with local Central Office for problems with SYSAM remote access line.

SYSTEM (System)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
SYSTEM	None	None	System

1. SYSTEM has no associated alarms and thus appears only in the Error Log. There are no tests that run on SYSTEM.

The SYSTEM maintenance object is used to log information about system resets, including interchanges. When software encounters a problem with hardware, or with its own processes, and requests a restart to clear the problem, an error is logged under SYSTEM. For example, if there is a loss of clock in the Processor Port Network (PPN) in a system with duplicated SPEs, the system switches to the other clock and then executes a level 2 system reset to recover from hardware problems caused by the loss of clock. Errors logged under SYSTEM can help to determine the cause of a reset. The **display initcauses** screen should also contain information about the reset. See "Troubleshooting a Duplicated SPE" in Chapter 5 for more information about interchanges.

Error Log Entries and Test to Clear Values

Table 9-657. System Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
8 (a)	0	None			
9 (b)	Any	None			
10 (c)	Any	None			
601 (d)	Any	None			
602 (e)	Any	None			
605 (f)	(p)	None			
606 (g)	Any	None			
607 (h)	Any	None			
6001 (i)	Any	None			
6002 (j)	(o)	None			
6003 (k)	(o)	None			
6101 (l)	Any	None			
6102 (m)	(o)	None			
6103 (n)	(o)	None			

Notes:

a. Software requested a System Restart Level 3.

b. Software requested a System Restart Level 2.

c. Software requested a System Restart Level 1.

d. An error occurred during initialization.

e. Translation data was corrupted, so the system requested a Restart Level 3 to reload translation data from the Mass Storage System (MSS).

f. A **reset system interchange** or a scheduled SPE interchange failed. The AUX Data indicates the cause of the failure. Consult the table in note p. Use **status spe** to determine the current SPE status and follow the Standby SPE Maintenance procedures to resolve the problems that are preventing the SPE interchange.

g. A **reset system interchange health-override** command has failed. The standby SPE state-of-health (SOH) would not allow a spontaneous SPE interchange. Use **status spe** to determine the current SPE status and follow the Standby SPE Maintenance procedures to resolve the problems that are preventing the SPE interchange.

h. A requested SPE interchange has failed because the SPEs are locked by means of the SPE-Select switches on the duplication interface circuit packs. with the SYSAM lock switches.

i. Error 6001 indicates that an operating system error occurred on the active SPE. The aux data gives the source of the error:

Aux-Data Value	Operating System Error Type
5	Software Abort
6	SPE Bus Error

j. Error 6002 indicates that an application error occurred on the active SPE. See note (o) to diagnose the error using the aux data.

k. Error 6003 indicates that an application alarm occurred on the active SPE. See note (o) to diagnose the error using the aux data.

l. Error 6100 indicates that an operating system error occurred on the standby SPE. See error 6001 (i) to interpret the aux data.

m. Error 6102 indicates that an application error occurred on the standby SPE. See note (o) to diagnose the error using the aux data.

n. Error 6103 indicates that an application alarm occurred on the standby SPE. See note (o) to diagnose the error using the aux data.

o. For error types 6002, 6003, 6102, and 6103, the aux-data value points to the MO that the error or alarm is logged against. The following table lists possible aux-data values and their associated MOs. Locate the Error Log entry for the indicated MO and follow the instructions for that error.

AUX Data	Implicated Maintenance Object
4137	PKT-INT
16384	PROCR
16385	MEM-BD
16386	SYSAM
16389	DUPINT
16391	SW-CTL
16392	H-ADAPTR
16397	R-MEDIA
16398	DISK

p. The following table and notes give causes and recommendations for each AUX data value for error 605.

Table 9-658. SYSTEM Error 605 AUX Data, Failure of Planned Interchange

Aux Data	See Note	Explanation
1352	1	Standby SOH "non-functional"
1353	1	Standby SOH not "functional"
1355	1	Handshake Communication with Standby SPE is down
1356	1	Memory Shadowing not enabled
1357	1	Standby memory not refreshed
1358	2	Mass Storage System was in use
1359	3	PKT-INT link migration failed
1360	1	Interchange failed *
1361	4	SW-CTL failure
1369	7	Could not suspend G3-MT connectivity *
1370	4	Could not freeze active SW-CTL *
1371	5	Internal Error associated with processor interrupts *
1372	6	Minor alarm on standby SYSAM or PKT-INT
1395		SPE Duplication not administered
1396	3	PKT-INT Link Migration failure in Begin Step *
1397	3	PKT-INT Link Migration denied, (peer test in progress)
1398	3	PKT-INT Link Migration failure in Completion Step *
1399	3	PKT-INT Link Migration failure in Finish Step *
1400	4	Could Not Idle SW-CTL dual port RAM *
1401	4	Could Not Refresh SW-CTL dual port RAM *
1402	5	Internal Error (could not get duplication status)
1403	5	Unable to inhibit Standby Maintenance Monitor
1404	5	Failure to determine Standby SPE alarm status
1406	3	Active SPE's PKT-INT in held-reset state
1418	8	Active Duplication Interface circuit pack is in a bad state and needs to be reset.
2500	5	Internal Software failure (* sometimes)

Notes for SYSTEM Error 605 AUX Data:

1. Follow repair instructions in “STBY-SPE” for the particular standby SPE problem. After fixing that problem, try the interchange again.
2. Mass Storage System is in use. Check Disk and Removable Media LEDs for activity. Wait until all MSS activity completes, then retry the interchange again. If the problem persists, check for alarms and errors against MSS components and follow the repair procedures for the “MSS” maintenance object.
3. Test the PKT-INT on both carriers with the long test sequence. Follow procedures for “PKT-INT”. Once *all* tests of both PKT-INTs pass, try the interchange again.
4. Consult SW-CTL service documentation. Test SW-CTL on both carriers with the long test sequence. Follow repair instructions for any failures. Once *all* tests of both SW-CTLs pass, try the interchange again.
5. Make sure the standby SPE is refreshed, then try the interchange again.
6. Examine alarm log to determine which of the PKT-INT or SYSAM circuit packs has a minor alarm against it. Consult the section in this chapter for that circuit pack.
7. Check for errors or alarms against active SPE’s SYSAM. If you find any, consult SYSAM service documentation. If you find none, and if all tests of the SYSAM long sequence pass, try the interchange again.
8. Run **test duplication-interface long** and follow instructions for any test that does not pass.

TAPE

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TAPE	WARNING	test tape a|b long	MSS Tape circuit pack
TAPE	MINOR	test tape a|b long	MSS Tape circuit pack
TAPE	MAJOR[2]	test tape a|b long	MSS Tape circuit pack

1. In a system with a simplex SPE, the carrier need not be specified. In a system with duplicated SPEs, carrier a or b must be specified.
2. This alarm occurs when the system undergoes a reset of level 3, 4, or 5, and the switch cannot load translation from tape; it also occurs when a program update cannot be applied. See the Error Log Table, error type 3585.

Description

The TN1656 Tape circuit pack is part of the Mass Storage System (MSS). The MSS provides non-volatile storage for system software, translation data, announcement data and program update data. As shown in Figure 9-105, the MSS consists of a Host Adapter circuit on the UN332 MSS-Network Control circuit pack (MSSNET), a Small Computer System Interface (SCSI) bus, a TN1656 Tape circuit pack and the TN1657 Disk Drive circuit pack. The Disk Drive acts as the primary storage device. The Tape Drive serves as a backup device and as a removable medium for system data.

The system is usually booted from the bootimage stored on disk. The **save translation** and **save announcements** commands save to disk the memory-resident translation data and TN750-resident announcement data, respectively. The **backup disk** command copies data from the disk to the tape for backup storage. The **restore disk** command copies data from the tape back to disk. All MSS components reside in the SPE, or PPN control carrier (carrier A for a simplex SPE, carriers A and B for a duplicated SPE).

The Tape circuit pack contains SCSI bus terminators, a -48V to +12V power converter, an industry standard SCSI based Tape Drive, and interface circuitry to the private bus to control the LEDs, detect the presence of the circuit pack, and identify the vintage of the hardware.

A -48V to +12V converter circuit on the Tape circuit pack provides power for both the Tape Drive and the Disk Drive. The presence of +12V on these circuit packs is monitored separately by maintenance software so that a failure of the +12V converter on the Tape circuit pack can be identified or ruled out as the source of the problem when the Disk Drive loses +12V power.

The Host Adapter Circuit, Tape circuit pack, and Disk circuit pack are treated as separate, but related, maintenance objects (H-ADAPTER,TAPE, and DISK). Since the Disk circuit pack is controlled by SCSI commands which are generated by the Host Adapter, problems with the Host Adapter can prevent communications with the Disk. Whenever the Host Adapter is taken out of service by the **busy-out host-adapter** command, or due to failure of a critical Host Adapter test, the Tape and Disk maintenance objects are also placed in a maintenance busyout state.

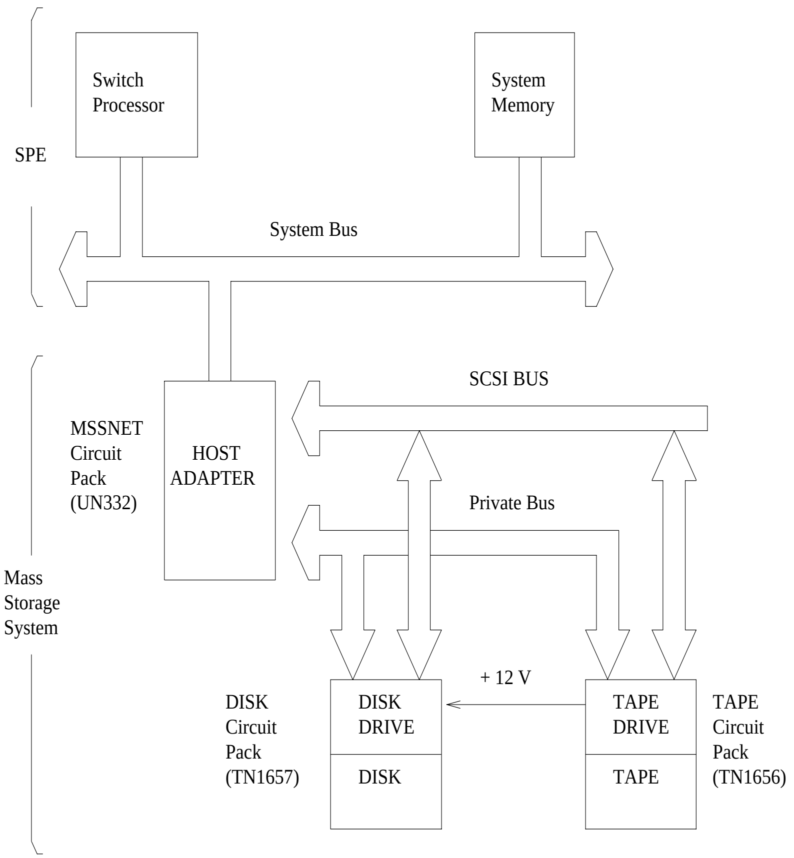

Figure 9-105. Mass Storage System Interactions

General Repair Procedures for TAPE

The following guidelines should be followed when troubleshooting and resolving tape problems.

1. Cleaning the tape drive head is very important. Dirty tape drive heads may cause problems that appear to be hardware related.

   A tape drive head with abrasive particles can permanently damage a new tape. A worn tape may leave abrasive particles in the tape drive head. Follow the tape head cleaning instructions that appear at the end of the test descriptions for TAPE.

2. *Avoid saving translations or announcements* on the backup tape cartridge if all other Tape Drive and Host Adapter problems have not been resolved.

   If there is something wrong with the Mass Storage System, an attempt to save translations or announcements could destroy a good copy of the files on the tape cartridge.

3. In a system configured with duplicated SPEs, the tests run on the standby Tape circuit pack are identical to those run on the active Tape circuit pack. Communications between the active and standby SPEs is provided by the DUPINT circuit pack for both the control channel and memory shadowing. Therefore, problems with the DUPINT circuit pack may affect maintenance tests of the standby Tape circuit pack.

4. Check the error log for power related problems and refer to the maintenance documentation on power.

5. The *data on the tape cartridge will likely be destroyed* if:

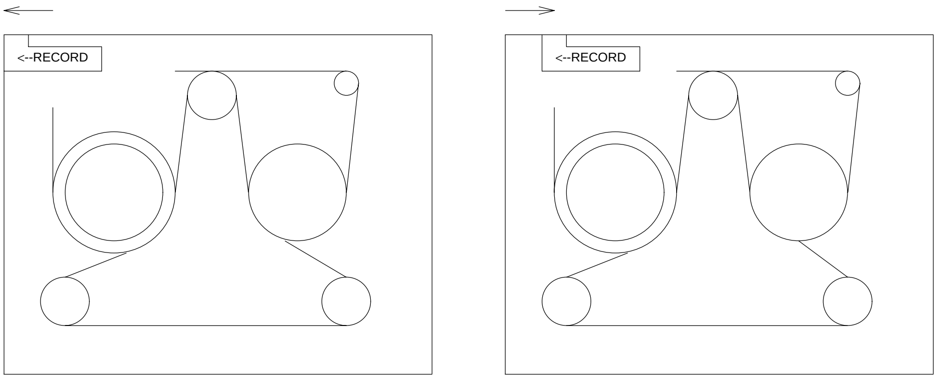
   - The tape cartridge is removed when the amber LED on the Tape circuit pack is on.
   - The Tape circuit pack is removed while the amber LED on the Tape Circuit is on.
   - Power is removed from the Tape Drive while the amber LED on the Tape circuit pack is on.

6. The *data on the disk will likely be destroyed* if the Tape circuit pack is removed while the amber LED on the Disk Drive is on.

7. Dirty Tape Drive heads may cause problems that appear to be hardware related. To clean the tape heads in the Tape Drive, follow the tape head cleaning procedure at the end of this section.

8. Since maintenance software cannot always distinguish between errors caused by the tape cartridge and those caused by the Tape Drive or Host Adapter, check for tape cartridge errors first.

   - Make sure there is a tape cartridge in the Tape Drive.
   - Make sure that the write protect lock is not active. To deactivate write protect, slide the *RECORD* switch on the tape cartridge in the direction of the arrow on the switch.



Tape cartridge in record position

Tape cartridge in write-protect position

Figure 9-106. Mass Storage System Interactions

Replacing a TAPE Cartridge

If the tape cartridge needs to be replaced, follow the procedure given below:

1. Resolve all other Tape circuit pack alarms/problems.
2. Install a new tape cartridge which has the same release number or, if that is not practical, install a tape cartridge with the same file layout as the original tape cartridge. Generally the file layouts are the same for tapes formatted for same product (G3r V1 or G3r V2). However, for G3r V1, a new file was added to the tape starting with the 6.1 release to support the **restore disk install** command. Therefore depending on the release number of the existing tape, a tape earlier than 6.1 or later than 6.0 should be used for G3r V1.

   When a tape cartridge is first inserted, there should be a spinning noise indicating that the Tape Drive is performing a retension pass (moving the tape forward and then back to the tape mark several times). This may take several minutes.
3. Verify that the tape cartridge has an acceptable release number by checking the Software Version via the **list configuration software-vintage** command.
4. If a new tape cartridge is not available, but all other tape alarms/problems have been resolved, then replace the damaged tape cartridge with the backup tape cartridge. Wait for the retension pass to complete.
5. Verify that the tape cartridge has the latest translations by issuing the **list configuration software-vintage** command. If the tape cartridge does not have the latest translation or announcement files, then perform a **backup disk**.

Replacing the TAPE Circuit Pack

For a Simplex SPE:

a. Enter **busyout host-adapter**. The Host Adapter should be "busied out" to prevent other applications from trying to access the tape or the disk. The Tape circuit pack supplies +12V to the Disk circuit pack so when it is removed, the Disk circuit pack will also go out of service.

b. Replace the Tape circuit pack and insert the tape cartridge into the new Tape circuit pack.

c. Issue the **reset host-adapter** command. This may take up to 3 minutes to complete since it waits for the tape to retension.

d. Issue the **release host-adapter** command.

e. Issue the **status spe** command and check that the status screen indicates that the tape and disk are now in service.

For a Duplicated SPE:

a. See "Replacing SPE Circuit Packs" in Chapter 5.

b. After the standby SPE is powered up and fully refreshed, test the standby tape using the **test tape long** command.

Error Log Entries and Test to Clear Values

Table 9-659. TAPE Error Log Entries

Error Type	Aux Data[1]	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1 (a)	any	Tape Reset (#894)	MINOR	OFF	reset tape a|b[2]

3585 (u)	409		MAJOR/ MINOR	OFF	
3841 (v)	[3]	Miscellaneous	MINOR	OFF	test tape a|b* long rep 1

1. The number of times the tape has been accessed. This number is at least 90% of the manufacturer's recommended limit.
2. In a system with a simplex SPE, the carrier does not have to be specified. In a system with duplicated SPE, the carrier (a or b) must be specified.
3. If error type 1 with aux data of 123 is present, this field will have the out of service cause data. See the *MSS Error Actions* table at the end of the section on TAPE.

The "service state" field in the Alarm Log refers to the accessibility of the device. IN (in service) means that users can access the device and all maintenance tests will run. MTC (maintenance busy) means that the device is "busied out" and users cannot access it although all demand maintenance tests will run. OUT (out of service) means that users cannot access the device but background and demand testing can run.

Notes:

a. Error type 1 means that the device is out of service as a result of maintenance tests detecting a critical failure of the tape drive.

b. Error type 18 means that the Tape was busied out on demand from the System Access Terminal.

c. Error type 250 means that the Reset Test (#809 or #894) failed.

d. Error type 257 means that the device could not be accessed.

e. Error type 513 means that on-board tape drive diagnostics tests requested by the Tape Diagnostic Test (#813) failed.

f. Error type 526 means that the Host Adapter was busied out. This also causes the Tape to be busied out.

g. Error type 529 means that there was a failure to put the tape in service or to take it out of service.

h. Error type 769 means that the tape Loop-around Test (#814) failed.

i. Error type 1025 means that a tape medium error was detected when the tape was read or written. The tape cartridge should be replaced if this error continues to be reported.

j. Error type 1281 indicates that a hardware failure condition was detected by the Firmware Error Counters Read and Clear Test (#812). See the *MSS Error Actions* table at the end of the section on TAPE.

k. Error type 1537 indicates that the tape cartridge is write protected. Check the RECORD switch on the tape cartridge. It should be pushed forward in the direction shown by the arrow on the switch.

l. Error type 1793 is an in-line error from the tape control software that indicates there was a problem with the SCSI Bus Access Failure or Memory Access Failure between the Host Adapter circuit pack and the Tape circuit pack. See the *MSS Error Actions* table at the end of the section on TAPE.

m. Error type 2049 indicates that a bad command was sent to the tape drive. This may be caused by a software error or a hardware failure. Execute the **test tape long** command and fix any failures associated with those tests.

n. Error type 2305 means that the tape has exceeded 90% of the manufacturer’s recommended limit of accesses. The tape should be replaced as soon as practical. This alarm can be retired by issuing the **reset tape** command but it will reappear each time the Tape Firmware Counter Test (#812) is run.

o. Error type 2306 means that a block has been reassigned on the tape or an attempt to reassign a block has failed. The tape should be replaced as soon as practical.

p. Error type 2561 indicates that the Data Write-Read Test (#810) failed.

q. Error 2817 indicates that the Tape Status Test (#815) detected a fault. See the *MSS Error Actions* table at the end of the section on TAPE.

r. Error type 3073 indicates in-line errors reported by the tape control software. See the *MSS Error Actions* table at the end of the section on TAPE.

s. Error type 3329 indicates that the Tape Audit Test (#811) detected a corrupted directory file. Execute the **test tape long** command and fix any failures associated with those tests. The Auxiliary Code for this Error Log entry and the failure code for the Tape Audit test indicate the directory file that is corrupted. If Test 811 does not fail, follow normal escalation procedures.

t. Error type 3585 with auxiliary data 408 indicates that there was an error in reading translation data from the tape and/or disk.

   This error only occurs on a system reset 3,4, or 5 (Cold 1, system reboot, or extended system reboot). If a disk is present, the system first tries to read translation from the first and second copies of translation on the disk and, if that fails, it tries to read translation from the first and second copies of translation on the tape.

   If an error was detected with reading translation from the disk and then the tape, a 408 error will be logged. This error will invoke *Emergency Transfer* on a system with simplex SPE. It will cause an SPE interchange if the system is equipped with duplicated SPEs. To clear this alarm, correct all other tape errors.

   If the SPE is not duplicated, it may be necessary to use a backup tape to first restore translation data to the disk. A new backup tape should be obtained as soon as possible.

   If the system is equipped with duplicated SPEs and if the alarm is associated with the tape on the standby SPE the active SPE should be running with the most current translation. Therefore after correcting any hardware failures associated with the tape and disk on the standby SPE, a **save translation** command should be used to save translations to the disk and tape on the standby SPE.

u. Error type 3585 with auxiliary data 409 means that there was an error in reading the program update file from both the disk and tape or there was an error in applying the program update file once it was successfully read from the disk or tape.

   This error only occurs during a system reset 4 or 5 (system reboot or extended system reboot). If a disk is present, the system will try to read the program update file from the disk first and, if that fails, it will try to read the program update file from the tape. After it succeeds in reading a copy of the program update file, it will check to see if the program update information is appropriate for the software version in memory before it applies it to the software boot image.

If an error is detected with any part of the process of reading the program update file from the disk or tape and applying the program update to memory, a hardware error 409 will be generated. This error will invoke a MAJOR alarm and *Emergency Transfer* on a system with simplex SPE. It will initiate an SPE interchange followed by a MINOR alarm on a system with duplicated SPEs. When this error occurs, the copies of the program update files on the disk and tape are invalidated so that those files no longer appear when a **list configuration software** command is entered from the System Access terminal.

To clear this alarm, first correct any other tape and disk alarms. Then restore the two copies of the program update files on the disk and tapes and apply those upgrades using "Software updates" in Chapter 6.

v. Error type 3841 is used to record miscellaneous data when an out-of-service condition occurs. See the *MSS Error Actions* table at the end of the section on TAPE.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Tape Reset Test (#809)	X	X		ND
Tape Diagnostic Test (#813)	X	X		ND
Tape Looparound Test (#814)	X	X		ND
Tape Status Test (#815)	X	X		ND
Tape Firmware Error				
Counters Read and Clear Test (#812)	X	X		ND
Tape Write-Read Test (#810)		X		ND
Tape Audit Test (#811)		X		ND
Tape Reset (#894)			X	ND

1. D = Destructive; ND = Nondestructive

Tape Reset Test (#809 and #894)

The Tape Reset Test consists of the following steps controlled by firmware on the Host Adapter Circuit (located on the MSSNET CIRCUIT PACK):

- Tape Drive reset

  An SCSI ''BUS DEVICE RESET'' message is transmitted to the Tape Drive to reset it.

- Presence test

  An SCSI ''INQUIRY'' command is sent to the Tape Drive to attempt to query with it. If the Tape Drive is present, it will return information about the device type, whether or not its medium is removable, compatibility with established standards, vendor and product IDs, and other miscellaneous information.

- Capacity test

  An SCSI ''READ CAPACITY'' command is sent to the Tape Drive. It returns with the logical block address and the block length of the last logic block on the medium.

  An SCSI ''READ DATA BUFFERS'' command is sent to the Tape Drive. This returns the size of the controller memory data buffers.

  An SCSI ''READ DEFECT DATA'' command is sent to the Tape Drive. This returns the addresses of bad blocks on the tape that must be mapped around.

- Device Diagnostic Tests

  An SCSI ''SEND DIAGNOSTICS'' command is sent to the Tape Drive to initiate a set of device-dependent self-tests that are run as a unit. Failures can be for multiple reasons and the return code which indicates the cause of failure is vendor unique. A failure condition will be reported as single failure type since the only repair action is to replace the Tape circuit pack.

Table 9-660. TEST #809/#894 Tape Reset Test

Error Code	Test Result	Description/ Recommendation
526	ABORT	The Host Adapter has been busied out. 1. Issue the **release host-adapter** command.
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run test on Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.

Continued on next page

Table 9-660. TEST #809/#894 Tape Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The tape has been placed in the "uninstalled" state. 1. Verify that a tape cartridge is installed and not write-protected and that the tape drive is fully inserted and powered up. 2. Attempt a demand reset of the tape.
201	FAIL	The Tape Drive is not responding or it may not be present. 1. Verify that the Tape circuit pack is present and powered. 2. Replace the Tape circuit pack. 3. If the reset continues to fail with this error code, replace the Host Adapter circuit pack.
5124	FAIL	It has been detected that no tape cartridge is installed. 1. Verify that a tape cartridge is installed and not write-protected. 2. If the reset continues to fail with this error code, continue with the steps below for the general reset failure case.
[1]	FAIL	The Tape could not be reset successfully. 1. Verify that a tape cartridge is installed and not write-protected. 2. If the test continues to fail, replace the Tape cartridge. Wait for the retension pass to complete. If the test succeeds, issue the **backup disk** command. 3. If the test continues to fail, replace the Tape circuit pack. 4. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Tape was reset correctly. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on TAPE.

Tape Write-Read Test (#810)

The Tape Write-Read Test verifies that data can be written to a specific file on the tape and read back successfully. It does not test the integrity of other files on the tape. This test consists of the following steps:

1. Maintenance software in the SPE issues a request to the Host Adapter for a transfer of data between SPE memory and a specified block on the tape.

   The Host Adapter firmware issues an SCSI **WRITE** command to the Tape Drive which results in a transfer of data between the SPE memory and the tape.

2. Maintenance software in the SPE issues a request to the Host Adapter to run a checksum on the data previously written to the tape.

   The Host Adapter reads the data off the tape and computes a checksum which is returned to the SPE maintenance software.

3. Maintenance software compares the value of the checksum from the Host Adapter with the checksum it previously calculated on the data it stored on the tape.

Multiple failure conditions can occur during this test since it uses both the software and hardware functions used during normal operations.

Table 9-661. TEST #810 Tape Write-Read Test

Error Code	Test Result	Description/ Recommendation
1301 1302	ABORT	Could not run the test—internal MSS error 1. Retry the command
1304	ABORT	Could not allocate the Mass Storage System to run this test. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (Use the **display system-parameters maintenance** command to display the start time for scheduled maintenance and the "y/n" option for saving translation daily).
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).

Continued on next page

Table 9-661. TEST #810 Tape Write-Read Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe**), retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When standby is restored to service (use **status spe**), retry command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The tape has been placed in the "uninstalled" state. 1. Verify that a tape cartridge is installed and not write-protected and that the tape drive is fully inserted and powered up. 2. Attempt a demand reset of the tape.

Continued on next page

Table 9-661. TEST #810 Tape Write-Read Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The tape could not be accessed, the checksum on the data written did not match the checksum in memory or the data read did not match the data written. 1. Verify that a tape cartridge is installed and not write-protected. 2. If a non-write-protected tape was inserted, remove it and clean the Tape Heads. 3. If the test continues to fail, replace the Tape Cartridge. Wait for the retension pass to complete. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the Tape circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Tape write-read test succeeded. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on TAPE.

Tape Audit Test (#811)

The Tape Audit Test verifies the following Tape Medium conditions.

- The directory can be read.
- There are no "dirty" files. A file is said to be "dirty" if the data in the file is not complete or if the directory entry for that file was not updated after the data was written to the device.
- The tape has not exceeded the number of passes recommended by the manufacturer. If the tape has exceeded 90% of the manufacturer’s recommended limit of accesses, the tape should be replaced. An alarm indicating this will appear nightly after scheduled maintenance is executed. This alarm can be retired by issuing the **reset tape** command.

Table 9-662. TEST #811 Tape Audit Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals for a maximum of 5 retries. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).

Continued on next page

Table 9-662. TEST #811 Tape Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The tape has been placed in the "uninstalled" state. 1. Verify that a tape cartridge is installed and not write-protected and that the tape drive is fully inserted and powered up. 2. Attempt a demand reset of the tape.
1	FAIL	The audit of the tape directory failed. 1. Verify that a tape cartridge is installed. 2. Perform a **backup disk**. This may take up to an hour to complete. 3. If the test continues to fail, replace the Tape Cartridge. Wait for the retension pass to complete and rerun the test. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the Tape circuit pack. 5. If the test continues to fail, determine if other Tape, Disk, or Host Adapter tests fail, and if they do, follow the repair procedures for those failures.
	PASS	The tape directory audit succeeded. Check other results to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on TAPE.

Tape Firmware Error Counters Read and Clear Test (#812)

The Host Adapter firmware is constantly running background tests on each of its devices. When an error is detected by one of these background tests, the appropriate counter in the host adapter dual port RAM is incremented. The Tape Firmware Error Counters Read and Clear Test requests that the firmware return these errors to the software and clear the area in dual port RAM. If any counter is non-zero, the software then increments the appropriate software counter. The 16 errors reported by the firmware are:

- Unexpected interrupt from the SCSI Bus Interface Controller Chip (SBICC)
- SBICC timed out during SCSI command
- Error interrupt from the Direct Memory Access Controller (DMAC)
- DMAC timeout without issuing interrupt
- Tape self-test failed

- Tape external looparound test failed
- Command failed with bad sense key
- Tape could not be accessed
- Flaw detected in tape medium
- Unrecoverable hardware error on tape
- Invalid parameter in SCSI command
- Media removed or device reset
- Tape is write protected
- Tape reached end of medium
- Block reassigned on tape
- Block reassignment on tape failed

Also this test checks for two other conditions: the presence of grown defects on the tape medium, and whether the tape has been accessed in excess of 90% of the manufacturer's suggested maximum.

Table 9-663. TEST #812 Tape Firmware Error Counters Read and Clear Test

Error Code	Test Result	Description/ Recommendation
1305	ABORT	Could not read firmware error counters. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1306	ABORT	Could not read configuration area for defect information. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.

Continued on next page

Table 9-663. TEST #812 Tape Firmware Error Counters Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When standby is restored to service (use **status spe** to determine state of standby) retry command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When standby is restored to service (use **status spe** to determine state of standby) retry command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When standby is restored to service (use **status spe** to determine state of standby) retry command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The tape has been placed in the "uninstalled" state. 1. Verify that a tape cartridge is installed and not write-protected and that the tape drive is fully inserted and powered up. 2. Attempt a demand reset of the tape.

Continued on next page

Table 9-663. TEST #812 Tape Firmware Error Counters Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	Background tests run by the Host Adapter detected that the tape could not be accessed at some time previous to executing the read-and-clear test. This error may have been caused by removing and reinserting the tape cartridge. The read-and-clear test or reset test must be run at least once before this error is cleared. 1. Try **test tape** again to see if the error has cleared. 2. Verify that the Tape Cartridge is present. 3. If the test continues to fail, replace the Tape circuit pack.
11	FAIL	Background tests run by the Host Adapter detected that the Tape drive was reset at some time previous to executing the read-and-clear test. This error may have been caused by removing and reinserting the tape cartridge. The read-and-clear test or reset test must be run at least once before this error is cleared. 1. Try **test tape** again to see if the error has cleared. 2. If the test continues to fail, replace the Tape circuit pack.
5504	FAIL	A tape block has been reassigned to a different location on the tape as a result of a medium error. This is referred to as a "grown defect." Tape performance will be affected since the tape drive must search ahead to read or write this block and then return to where it left off. Continued testing will not correct the problem. The tape should be replaced as soon as practicable. 1. Run the STO-DATA tests to verify that the boot images, translations, announcements, etc., are valid. 2. If errors are detected, run **backup disk full** to restore good copies to the tape. 3. If the STO-DATA tests continue to fail, replace the tape.
5512	FAIL	Ninety per cent of the manufacturer’s recommended limit for tape accesses has been exceeded. Continued testing will not correct the problem and the tape will need to be replaced as soon as practicable.

Continued on next page

Table 9-663. TEST #812 Tape Firmware Error Counters Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	At least one of the firmware error counters was non-zero. 1. Run the **test tape** command again to verify that this failure was not from a failure condition which has been cleared as a result of this test clearing the firmware counters. 2. Verify that a tape cartridge is installed and not write-protected. 3. If a non-write-protected tape was inserted, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to fail, remove the tape cartridge and clean the Tape Heads. 5. If the test continues to fail, replace the Tape Cartridge. Wait for the retension pass to complete. If the test succeeds, issue the **backup disk full** command. 6. If the test continues to fail, replace the Tape circuit pack. 7. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The firmware error counters were zero. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on TAPE.

Tape Diagnostic Test (#813)

The Tape Diagnostic test causes the Host Adapter to send an SCSI **SEND DIAGNOSTICS** command to the TAPE circuit pack. This initiates a set of device-dependent self-tests that are run as a unit. Failures can be for multiple reasons. The return code which indicates the cause of failure is vendor unique. A failure condition will be reported as single failure type since the only repair action is to replace the Tape circuit pack.

Table 9-664. TEST #813 Tape Diagnostic Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-664. TEST #813 Tape Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The tape has been placed in the "uninstalled" state. 1. Verify that a tape cartridge is installed and not write-protected and that the tape drive is fully inserted and powered up. 2. Attempt a demand reset of the tape.
[1]	FAIL	A Tape diagnostic test failed. 1. Verify that a tape cartridge is installed and not write-protected. 2. If a tape was inserted, remove it and clean the Tape Heads. 3. If the test continues to fail, replace the Tape Cartridge. Wait for the retension pass to complete. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the Tape circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Tape passed all diagnostic tests. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on TAPE.

Tape Loop-around Tests (#814)

This test extends the Host Adapter Loop-Around test to send data from the Host Adapter to buffers on the Tape circuit pack and back to the Host Adapter. It may detect errors related to the Host Adapter, SCSI bus, and the Tape circuit pack. It is intended to functionally test the Tape Drive circuit pack to the extent possible without actually writing data to the tape.

This test consists of two sets of tests:

- Tape Internal Loop-around

  Data is generated in the RAM of the Host Adapter and transferred to its SCSI Data Memory. An SCSI **WRITE DATA BUFFERS** command is sent to the Tape circuit pack which causes the Tape Drive circuit pack to copy the data to its buffers. An SCSI **READ DATA BUFFERS** command is then sent by the Host Adapter to the Tape Drive circuit pack which causes the Tape circuit pack to transfer the data from its buffers back to the Host Adapter's SCSI Data Memory. The Host Adapter then copies the data back to its private RAM where it compares it with the original test data.

- Tape External Loop-around

  This test is similar to the Internal Loop-around test except that the data originates in the Host Adapter's Dual Port RAM and it is transferred to and from the SCSI Data Memory using SPE system bus accesses. Only a small amount of data is sent to the Tape Drive circuit pack in order to keep system bus access to a minimum.

Table 9-665. TEST #814 Tape Loop-around Test

Error Code	Test Result	Description/ Recommendation
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the 'y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.

Continued on next page

Table 9-665. TEST #814 Tape Loop-around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the 'y/n" option for saving translation daily).
	NO BOARD	The tape has been placed in the "uninstalled" state. 1. Verify that a tape cartridge is installed and not write-protected and that the tape drive is fully inserted and powered up. 2. Attempt a demand reset of the tape.
1	FAIL	The Tape loop-around test failed. 1. Verify that a tape cartridge is installed and not write-protected. 2. If a tape was inserted, remove it and clean the Tape Heads. 3. If the test continues to fail, replace the Tape Cartridge. Wait for the retension pass to complete. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the Tape circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Tape loop-around test passed. Look at the results of other tests to see if it is operating correctly.

Continued on next page

1. See the MSS Error Actions table at the end of the section on TAPE.

Tape Status Test (#815)

The Tape Status Test verifies the following:

- The Host Adapter knows about the existence of the Tape Drive circuit pack.
- The LEDs on the faceplate can be turned on and off correctly.

  Note that this only verifies that the control and status logic for the LEDs is operating correctly. The operation of the LEDs may also be tested visually by using the **test led** command.
- +12V from on-board DC-to-DC converters are present.

Table 9-666. TEST #815 Tape Status Test

Error Code	Test Result	Description/ Recommendation
1306 1307 1308	ABORT	Internal software error between maintenance software and MSS driver. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1316	ABORT	Could not get access to the Mass Storage System. Other application software may be using it or background maintenance tests may be running. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
1335	ABORT	Could not run the test on the Standby SPE—Duplication not administered. 1. Refer to the documentation for STBY-SPE maintenance. 2. Administer standby present.
1338	ABORT	Could not run the test on the Standby SPE—Interchange pending. 1. Refer to the documentation for STBY-SPE maintenance. 2. After interchange occurs, run test on new active SPE.
1339	ABORT	Could not run the test on the Standby SPE—Handshake down. 1. Refer to the documentation for STBY-SPE maintenance. 2. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.

Continued on next page

Table 9-666. TEST #815 Tape Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1347	ABORT	Could not run the test on the Standby SPE—Refresh not complete. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
1350	ABORT	Could not run the test on the Standby SPE—Shadowing not enabled. 1. When the standby is restored to service (use **status spe** to determine state of standby) retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Could not run the test on the Standby SPE—Internal software error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
5102	ABORT	Could not allocate the Mass Storage System to run this test 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, verify that the daily translation-save operation is not in progress (issue the **display system-parameters maintenance** command to display the time for scheduled maintenance and the "y/n" option for saving translation daily).
	NO BOARD	The tape has been placed in the "uninstalled" state. 1. Verify that a tape cartridge is installed and not write-protected and that the tape drive is fully inserted and powered up. 2. Attempt a demand reset of the tape.
[1]	FAIL	The tape configuration information shows the tape circuit pack is missing or the tape LED test failed. 1. Verify that a tape cartridge is installed and not write-protected. 2. If a tape was inserted, remove it and clean the tape heads. 3. If the test continues to fail, replace the Tape Cartridge. Wait for the retension pass to complete. If the test succeeds, issue the **backup disk** command. 4. If the test continues to fail, replace the Tape circuit pack. 5. If the test continues to fail, replace the MSSNET circuit pack.
	PASS	The Tape status test passed successfully. Check other test results to see if it is operating correctly.

1. See the MSS Error Actions table at the end of the section on TAPE.

Tape Reset Test (#894)

The Tape Reset Test is run on as part of the **reset tape** command. The test results for Test 894 are the same as those for Test 809, which is run as part of the **test tape** sequence. All tape alarms are cleared when Test 894 passes, while only some tape alarms may clear when Test 809 passes. Refer to results for Test 809 for repair procedures.

Tape Drive Head Cleaning Procedure

The following procedures should be used to clean the PBX Tape Drive(s). **A Tape Drive should be cleaned once every three months** to reduce the risk of losing information and to prevent unexpected service calls. An entry should be made in the Lucent Preventive Maintenance Log when this is done (see Chapter 6).

A DC2000 Series Data Cartridge Tape Drive Cleaning Kit from 3M is used to clean the tape head and the tape capstan. This kit consists of a Cleaning Positioning Cartridge and 20 cleaning wands (Comcode 406622464 or 3M Reorder number DC051111-12947). A refill kit of 20 cleaning wands is also available (Comcode 406622472 or 3M Reorder Number DC051111-12948).

NOTE:
The cleaning wands are flammable. Dispose of properly.

1. Busy out the Tape circuit pack using the **busyout tape c** command where *c* is the carrier number (a or b). This prevents background maintenance tests and other application software from trying to access the tape.
2. Eject the Tape Cartridge from the Tape circuit pack (TN1656). Insert the Cleaning Position Cartridge into the Tape Drive with the **label side to the left** (see Picture 1).
3. Prepare the cleaning wand for use as follows: Hold the bristle end down, crush the wand at the "x" area and squeeze to release fluid and saturate the bristles.
4. Insert the wand into **R/W Head Slot** (top of cartridge, see Picture 2) with gentle twisting motion. Stop when solid resistance is felt. Rotate the wand 6 turns while raising and lowering end of wand.
5. Remove the used wand and discard.
6. Prepare a second wand as described in step 3 above.
7. Eject the Cleaning Position Cartridge out of the Tape circuit pack and reinsert it. This will condition the tape drive to move the capstan when the cleaning wand is inserted in the next step.

8. Insert the wand into the **Capstan Slot** (middle of cartridge, see Picture 2) within 10 seconds after the Cleaning Position Cartridge was reinserted.
9. Apply a gentle forward pressure to the wand for about 15 seconds. You should be able to feel the capstan moving.
10. Remove the used wand and discard.
11. Eject the Cleaning Positioning Cartridge and insert the PBX Tape Cartridge back into the Tape Drive.

    NOTE:
    After the Tape Cartridge is inserted back into the Tape Drive, it will run through a retension pass which will take up to two minutes to complete. During that time, the **reset tape** command entered in the next step causes a "please wait" message to flash on the terminal screen while the tape is retensioning, but the command will complete after the retension pass completes.

12. Reset the Tape circuit pack using the **reset tape c** command where *c* is the carrier number (a or b). This will clear out a tape error that indicates the tape cartridge had been removed and reinserted.
13. Release the Tape from its maintenance busy-out state using the **release tape c** command where *c* is the carrier number (a or b).

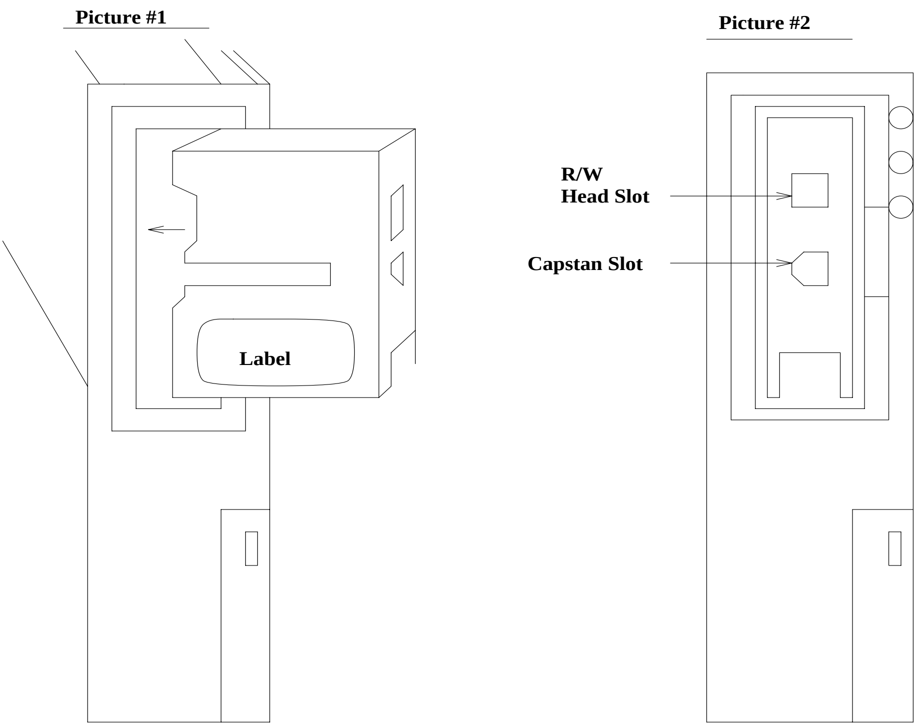

Figure 9-107. Mass Storage System Interactions

Table 9-667. MSS Error Actions

Code	Description
0	Unexpected interrupt from SBICC.
1	SBICC timed out during SCSI command.
2	DMAC generated error interrupt.
3	DMAC timed out without interrupt.
4	Tape self-test failed.
5	Tape external looparound test failed.
6	Command failed with bad SENSE key.
7	Tape could not be accessed.
8	Flaw detected in tape medium.
9	Unrecoverable hardware failure on tape.
10	Invalid parameter in SCSI command.
11	Media removed or tape reset.
12	Tape is write protected.
13	Tape reached end of medium.
14	Block reassigned on tape.
15	Block reassignment failed on tape.
16	Inconsistent capacity data
17	Device busy
18	Device reservation conflict
19	Request sense failed
101	Unrecognized *opcode*.
102	Unrecognized *modifier*.
103	*xlist_length* too long.
104	Invalid transfer address.
105	Intra-device copy ranges overlap.
121	Device invalid for *opcode* requested.
122	Device non-existent.
123	Device is out of service.
124	*to_byte* or *from_byte* is out of range.
125	*to_byte* + *numbytes* is invalid or *from_byte* + *numbytes* is invalid.

Continued on next page

Table 9-667. MSS Error Actions — *Continued*

Code	Description
126	Type of device is invalid for *opcode* requested.
201	An unexpected interrupt code was returned from the SBICC. This represents a protocol error that could be the result of the HA or the target device. The device may not be present.
251	SBICC timed out. This could be the fault of the HA or target device. The HA will attempt to reset the SBICC.
301	DMAC error. This could be the fault of the HA or the SCSI target device.
351	DMAC timed out. This could be the fault of the HA or the SCSI target device. The HA will attempt to reset the SBICC.
401	Could not save announcements or program update file.
408	Could not read translation from the Disk and Tape as part of system initialization.
409	Could not apply program update file.
422	Could not save translations.
501	A non-critical diagnostic test failed on the Host Adapter. This includes the USART chip test and the LED tests.
511	A diagnostic test requiring bus mastership failed. This happens only as the result of an MSS_DIAG command. This could be the fault of the HA or the system. Therefore the board does not put itself in held reset state. Rather, the error is reported and counters are incremented.
521	The HA looparound test requiring bus mastership failed. This happens only as the result of an MSS_LOOPAROUND command. This could be the fault of the HA or the system. Therefore the board does not put itself in held reset state. Rather, the error is reported and counters are incremented.
531	Target device **SEND DIAGNOSTICS** self-test indicated a hardware error. This indicates that there are problems with the controller or the device, and it should be taken out of service. This error will not occur if other errors (e.g. SBICC) prevent the **SEND DIAGNOSTICS** command from running.
551	The target device internal looparound failed due to data corruption. Other errors (SBICC, SCSI check condition) would cause a different error code to be reported. This failure demonstrates that the target may potentially corrupt data and it should be taken out of service.
552	The target device external looparound failed due to data corruption. Other errors (SBICC, SCSI check condition) cause a different error code to be reported. This failure demonstrates that the target may potentially corrupt data. However, the HA does not take the device out of service as a result of this error. This test is only run following the target device internal looparound which detects actual problems with the target device. This failure implicates the HA bus interface or a system problem.
561	When the MSS_RESET command was issued for a device, it was found not to be present.
562	When the MSS_RESET command was issued for a device, the NQUIRY command failed.

Continued on next page

Table 9-667. MSS Error Actions — *Continued*

Code	Description
563	When the MSS_RESET command was issued for a device, the TEST UNIT READY command failed
564	When the MSS_RESET command was issued for a device, the READ CAPACITY command failed
565	The device reset failed.
566	Device type not supported.
567	Capacity data is inconsistent.
568	Block size doesn't divide into 8K.
601	**REQUEST SENSE** failed.
700	Indicates that there is no specific sense key information for a SCSI target on which a **REQUEST SENSE** was issued. This should never happen because firmware only asks for sense information if errors occurred.
701	SCSI sense information reported a recovered error on a SCSI target where it didn't make sense. Normally recovered errors are filtered by the HA firmware for reads and writes. However, for other commands, this is reported to software.
702	SCSI sense information indicates that the target device cannot be accessed. This will occur if the tape cartridge is not present.
703	SCSI sense information indicates that a SCSI command terminated with a nonrecovered error condition probably caused by a flaw in the medium or an error in the recorded data.
704	SCSI sense information indicates a nonrecoverable hardware failure occurred. The tape may be broken.
705	SCSI sense information indicates that there was an illegal parameter in the command descriptor block or in additional parameters supplied. This could be caused by a HA firmware failure or a problem with the target device.
706	SCSI sense information indicates that the target device's removable medium may have been changed or the target controller has been reset.
707	SCSI sense information indicates that reads or writes were attempted for a medium that was protected from this operation.
708	SCSI sense information indicates that a write-once read-multiple device or a sequential-access device encountered a blank block while reading or a write-once read-multiple device encountered a nonblank block while writing. This should never happen; the HA only supports direct access devices.
709	SCSI sense information indicates a vendor-unique sense key.
710	SCSI sense information indicates a **COPY**, **COMPARE**, or **COPY AND VERIFY** command was aborted due to an error condition on the source device, the destination device, or both. This shouldn't happen since these commands aren't issued by the HA.
711	SCSI sense information indicates that the target controller aborted the command.

Continued on next page

Table 9-667. MSS Error Actions — *Continued*

Code	Description
712	SCSI sense information indicates that a **SEARCH DATA** command has satisfied an equal comparison. This should not happen since this command is not issued by the HA.
713	This indicates that a buffered peripheral device has reached the end-of-medium and data remains in the buffer that has not been written to the medium.
714	This indicates that the source data did not match the data read from the medium. This should not happen since the HA does not issue any commands involving comparisons.
715	SCSI sense information returned a reserved sense key. This should not happen.
758	Device returned busy.
764	Device returned reservation conflict status.
801	HA firmware was attempting to process a command requiring system bus access and the NOGOINT interrupt occurred. This probably indicates that system software failed to enable bus access before issuing an MSS command requiring it. It also could indicate a system problem or a HA problem.
802	HA firmware was accessing the system bus and it timed out. This could be a result of MSS command argument errors, system problems, or a HA problem.
803	HA firmware was accessing the system bus and received a data-parity interrupt. This could indicate a system or HA problem.
804	HA firmware was accessing the system bus and received a error detection and correction interrupt. This could indicate a system or HA problem.
805	System bus error test failed.
1001	Firmware error
1002	Cheetah/Pecos error
1003	Both the 68020 and the DMAC tried to access the same location in the SDM concurrently.
1004	HA firmware couldn't put a response in the response queue because it was full. This could be the fault of the HA, or system software. However, there is no way to recover, therefore the HA places itself in held reset.
2001	A critical diagnostic test on the Host Adapter failed making it dangerous to continue service.
2002	The Host Adapter internal looparound test failed because of data corruption.
3001	An exception occurred indicating a serious hardware or firmware problem. Additional information will be placed in HA DPRAM about which exception occurred and the address at which it occurred.
3002	An interrupt occurred when it should not have. This includes interrupts that are a normal part of command processing but that occurred unexpectedly.
4001	The checksum of the firmware image in memory prior to FLASH PROM programming failed.
4002	Flash PROM programming failed.

Continued on next page

Table 9-667. MSS Error Actions — *Continued*

Code	Description
5000	The tape cartridge has been changed or the tape drive has been reset by firmware.
5001	Alternate copy of file used—primary could not be accessed.
5113	Device out of service
5124	No tape cartridge in tape drive.
5126	Handshake not up
5127	Memory refresh not complete
5200	Kernel call received a notification.
5201	Spurious interrupt from MSSNET.
5202	Message received on an unexpected class.
5203	File system on the device is corrupt.
5204	Driver failed to get parity error interrupt.
5205	Driver failed to get EDC error interrupt.
5206	Driver failed to get timeout interrupt.
5207	Alternate file could not be accessed.
5208	Bad path index on software call.
5209	Driver failed to get bus error interrupt.
5210	MSS client died.
5212	File 0 (directory) corrupt.
5213	File 1 (alternate directory) corrupt.
5214	File 2 (small boot image) corrupt.
5215	File 3 (alternate small boot image) corrupt.
5216	File 4 (program update file) corrupt.
5217	File 5 (alternate program update file) corrupt.

Code	Description
5225	File 13 (alternate announcement file) corrupt.
5226	File 14 (maintenance scratch file) corrupt.
5227	File 15 (small config core dump) corrupt.
5228	File 16 (large boot image) corrupt.
5229	File 17 (alternate boot image) corrupt.
5230	File 18 (large core dump on disk) corrupt.
5231	File 19 (large core dump on tape) corrupt.
5300	Command timed out.
5301	Driver ran out of resources.
5302	Device or host adapter is not ready.
5303	State information is invalid.
5304	Firmware returned unexpected tag.
5305	MSSNET board is not inserted.
5400	Initialization error.
5401	Kernel call failed.
5402	Timer call failed.
5403	DUPINT call failed.
5404	DRIP call failed.
5405	Critical path destroyed.
5406	Internal error.
5504	Block reassigned on tape as a result of a medium error
5505	While running status test, configuration test failed.
5506	While running status test, LED test failed.
5507	Status test found host adapter in "held reset" state.
5508	Unable to obtain path to PAM.
5509	Translations were not locked.
5510	+5V not present
5511	+12V not present
5512	Exceeded 90% of manufacturer’s recommended tape access limit.
5513	Disk capacity not sufficient for memory size.

Continued on next page

Table 9-667. MSS Error Actions — *Continued*

Code	Description
5514	Disk not configured for larger memory size.
30003	Cannot write to tape, cartridge or device error.
30004	Cannot read from tape, cartridge or device error.
30017	Checksum error in block.
30203	Write-read mismatch error.

TBRI-BD (TN2185 ISDN Trunk-Side BRI)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TBRI-BD	MINOR	test board UUCSS l r#	TBRI-BD

1. Where UU is the universal cabinet number (1 for PPN, 2 -44 for EPN), C is the carrier designation (A, B, C, D, or E), SS is the carrier slot address where the circuit pack is located (1, 2, and so forth), and pp is the two-digit port number (1, 2, 3, and so forth).

The TN2185 circuit pack contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64 Kb/s channels (B1 and B2) and over a 16Kb/s signaling (D) channel. The B1 and B2 channels can be simultaneously circuit switched or individually packet switched. Only one channel per trunk can be packet switched due to Packet Processing Element (PPE) limitations. The D channel is either circuit switched or packet switched. Packet switching uses the PPE to combine all D channels into a single physical channel, which is then routed via the concentration highway to the Network Control Element (NCE) and then to the TDM bus. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64Kb/s clear data channels. The packet-switched channels support the LAPD protocol and conform with the CCITT Q.920 Recommendations for D-channel signaling.

LEDs

The three LEDs on the circuit pack's faceplate indicate board status. When illuminated, the red LED indicates a board failure or a major or minor on-board alarm, the green LED indicates that testing is in progress, and the amber LED indicates that the board is in use.

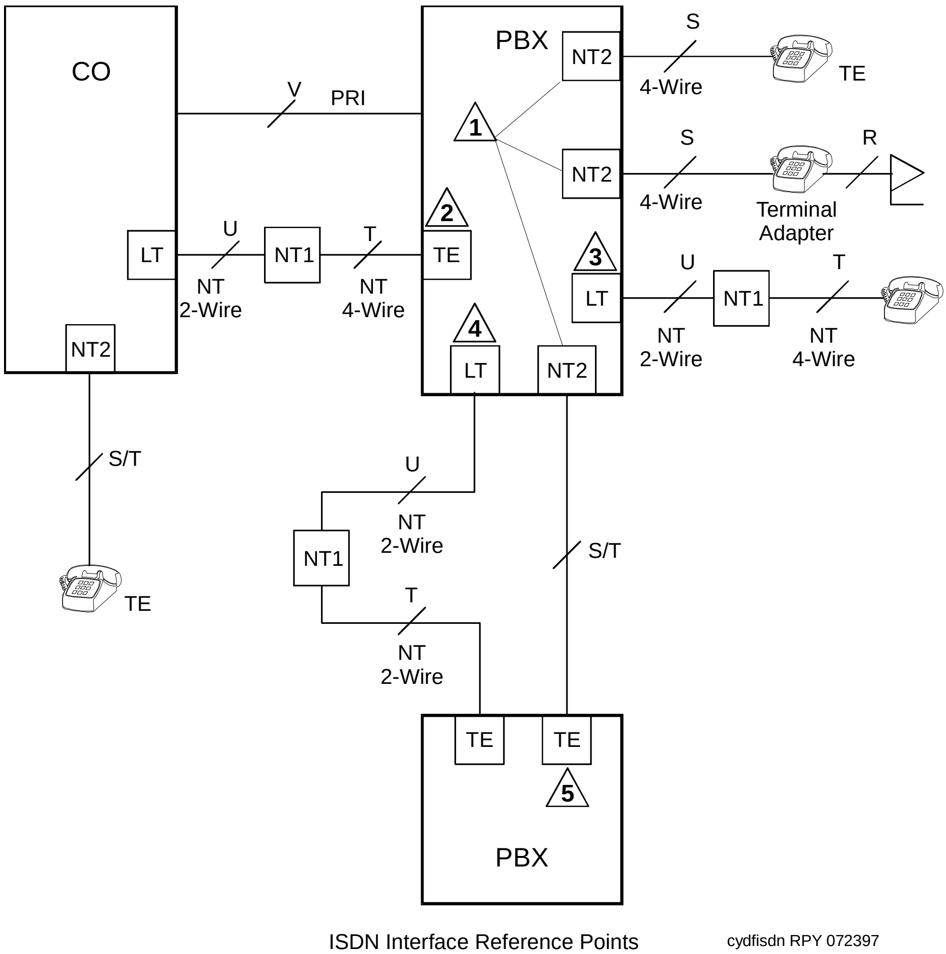

Figure 9-108. Integrated Trunk-Side BRI, ISDN Interface Reference Points

ISDN Interface Reference Point definitions:

LT	Logical Terminal
V	Primary Rate user/network (asymmetrical) trunk interface. The ECS is capable of acting as the user or as the network side of this 1.544 - or 2.048-Mbps interface.
R	Interface between Terminal Equipment and Network Termination
S	Basic Rate network-side 4-wire line interface
S/T	4-wire Basic Rate connection to a Network Termination[1].
T	4-wire Basic Rate interface to a Network Termination.[2]

TE	Terminal Equipment
U	Basic Rate network-side 2-wire line interface.
1	TN556B ISDN-BRI 4-Wire S/T-NT Line (A-law)
2	TN 2185 ISDN-BRI 4-Wire S Interface (Trunk Side)
3	TN2198 ISDN-BRI 2-Wire U Interface
4	TN2198 ISDN-BRI 2-Wire U Interface
5	TN 2185 ISDN-BRI 4-Wire S Interface (Trunk Side)

1. Network Termination 2 (NT2), that terminates Layer 1 and higher layers. PBXs, LANs, and terminal controllers typically provide NT2 functionality including protocol handling and multiplexing for Layers 2 and 3.
2. Network Termination 1 (NT1), that terminates Layer 1 and monitors maintenance, performance, timing, power transfer, multiplexing, and multi-drop termination with contention resolution.

Hardware Error Log Entries and Test to Clear Values

1537 (h)	46082		MINOR	ON	
1793 (i)	46080		MINOR	ON	
1794 (i)	46094		MINOR	ON	

Continued on next page

Table 9-668. TBRI-BD Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1795 (i)	46085		MINOR	ON	
2305 (j)	46104		None	ON	
2306 (i)	46081		None	ON	
3330 (j)	46083		MINOR	OFF	
3586 (k)			MINOR	OFF	
3840(l)	4096 to 4101				
3842 (m)	46095				
3843 (n)	46097				

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The circuit pack stopped functioning or is physically removed from the system.

NOTE:
This alarm logs approximately 11 minutes after removing the circuit pack and/or the SAKI Sanity Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack in the same slot as the error indicates. See note (g).

b. Transient communication problems between the switch and this circuit pack. Execute the **test board UUCSS** command and refer to the repair procedures for the Control Channel Loop Around Test (#52).

c. On-board hardware failure. Aux data values correspond to the following detected errors:

4352	External RAM error
4353	Internal RAM error
4355	ROM Checksum error
4357	Instruction set error

Reset the circuit pack with the **busyout board UUCSS** and **reset board UUCSS** commands. When reset, the circuit pack executes a set of tests to detect the presence of any of the faults listed above. Detection of one of these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedure in Note (a).

d. The circuit pack detects a program logic error. While no action is required, this error can lead to other errors against this circuit pack.

e. The circuit pack cannot update and read back NPE/NCE memory. This error can be ignored, but may lead to other errors against this circuit pack.

f. The TN2185 board notifies maintenance software that it has detected a parity error while accessing its dynamic RAM (that stores the board's translation information and downloadable application firmware). Maintenance software resets the circuit pack.

g. Unable to write LAN Translation RAM Error (internal memory access error). Translation RAM locations for the call connection attempt are not available, and one or more RAM locations are bad due to a translation RAM read-back error. Reset the circuit pack with the **busyout board UUCSS** and **reset board UUCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm with the **test board UUCSS long clear** command. If the Circuit Pack Restart Test (#594) fails, replace the circuit pack.

h. Frame overrun at Packet Bus interface. Due to an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack is alarmed, refer to the repair procedures for those maintenance objects. If this error persists, maintenance software removes the board from service; replace the circuit pack.

i. The circuit pack is has problems transmitting/receiving data to/from the Packet Bus.

1793	Parity errors are detected when transmitting data to the Packet Bus.
1794	Packet Bus transmit buffers overflow.
1795	Circuit pack cannot find end of frame when transmitting to Packet Bus. Clear the alarm with: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long clear**, **release board UUCSS**. If the error recurs within 10 minutes, replace the circuit pack.
2306	Error in a received frame from the Packet Bus, most likely caused by a packet bus problem, but may be due to a circuit pack fault. An invalid Link Access Procedure Data (LAPD) frame error occurs if the frame contains a bad Cyclical Redundancy Check (CRC). If bus parity errors occur, run the LAN Receive Parity Error Counter Test (#595) to determine if the condition has cleared. Refer to the maintenance documentation to determine if the problem is isolated to this circuit pack or is caused by Packet Bus faults.

j. Error Type (2305, 3330): A critical failure in the Circuit Pack's Packet Bus interface. Possible causes include either a Packet Bus fault or an on-board fault, for example, the board received a bad CRC or invalid DLCI. If the Packet Bus is alarmed, refer to the "*Maintenance Manual*" section for Packet Bus fault location and recommended repair procedures. The number of ISDN circuit packs displaying this error increases the probability of errors due to Packet Bus problems.

   If there are no Packet Bus alarms, reset the circuit pack with the **busyout board UUCSS** and **reset board UUCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm with the **test board UUCSS long clear** command. If the Circuit Pack Restart Test (#594) fails, replace the circuit pack.

k. The SPE software detects an excessive number of up-link messages from the TN2185 board within a certain time period. To prevent the faulty board from flooding the switch with data, the switch software takes the board out of service and alarms it. The switch software also tells the Archangel to ignore up-link messages from the board.

   When the board is alarmed due to this error, the switch software periodically puts the board back in service and tells the Archangel to process up-link messages from the board. If the problem still exists, the software takes the circuit pack out of service again. If the circuit pack does not exhibit the problem for a certain time period, then maintenance software resolves the alarm and the circuit pack is left in service.

l. The circuit pack received an inconsistent down-link message (a bad header, port number, data, subqualifier, or logical link) over the Control Channel.

m. The board is receiving data from the bus faster than it can distribute the data to its endpoints, causing the FIFO RAM buffer to overflow. This error can occur occasionally due to the statistical sizing of the buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch. LAPD should recover from this problem, but it may degrade the performance of the LAN bus.

   When this error is reported, maintenance reads and clears the board counter and logs the problem in the maintenance error log.

n. Bad translation RAM detected, but the call continues by using another translation location. The circuit pack reports this error when it cannot update NPE/NCE memory and read it back. This error is not service-affecting and can be ignored, but can lead to other types of errors against this circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

When inspecting errors in the system, always investigate tests in the order listed below. By clearing error codes associated with the *Control Channel Loop Around Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop-Around Test (#52)	X	X	ND
NPE/NCE Audit Test (#50)		X	ND
LAN Receive Parity Error Counter Test (#595)		X	ND

1. D = Destructive; ND = Nondestructive

Control Channel Loop Around Test (#52)

Refer to the repair procedure described in the "XXX-BD (Common Port Circuit Pack)" section.

NPE /NCE Audit Test (#50)

Refer to the repair procedure described in the "XXX-BD (Common Port Circuit Pack)" section.

SAKI Sanity Test (#53)

This is a destructive test.

Refer to the repair procedure described in the "XXX-BD (Common Port Circuit Pack)" section. This test is only run as a part of a reset board procedure.

LAN Receive Parity Error Counter Test (#595)

This test is nondestructive. The test reads and clears the circuit pack's LAN Receive Parity Error Counter. This counter increments when it detects a parity error from the Packet Bus. These errors may indicate problems with a circuit pack, Packet Bus, or with another circuit pack on the bus. Use this test to verify the repair.

Table 9-669. TEST #595 LAN Receive Parity Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack via the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2012	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1-10	FAIL	The circuit pack is still detecting errors of this type. The error code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, verify the validity of the Packet Bus. Run the Packet Bus maintenance test with the **test pkt P long** command. If any Packet Bus tests fail, refer to the "PKT-BUS (Packet Bus)" section for recommended repair procedures. 3. If the Packet Bus test passes, check the validity of the circuit pack. Execute a test that involves data transmission onto the Packet Bus. For example, the **test port UUCSSpp** command may use the connectivity tests of the BRI-PORT maintenance object. If the test fails, refer to the repair procedures; otherwise, proceed to the next step. 4. Other circuit packs on the Packet Bus may be causing of the parity error. Use the **display errors** command to check the Error Log for alarmed other circuit packs. Resolve any alarms for other circuit packs as well. Rerun the LAN Receive Parity Error Counter Test (#595).
	PASS	No errors detected.

TBRI-PT (ISDN Trunk-Side BRI Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TBRI-PT	MAJOR	test port UUCSS l r#	TBRI-PT
TBRI-PT	MINOR	test port UUCSS l r#	TBRI-PT
TBRI-PT	WARNING	test port UUCSS s r#	TBRI-PT

1. Where UU is the universal cabinet number (1 for PPN, 2 -44 for EPN), C is the carrier designation (A, B, C, D, or E), SS is the carrier slot address where the circuit pack is located (1, 2, and so forth), and pp is the two-digit port number (1, 2, 3, and so forth).

This document describes the port maintenance features of the DEFINITY® ISDN Trunk-side BRI board (TN2185). The circuit pack provides 8 S/T ISDN 2B+D ports that interface to either the central office or another PBX.

The TN2185 circuit pack contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64 Kb/s channels (B1 and B2) and over a 16Kb/s signaling (D) channel. The B1 and B2 channels can be simultaneously circuit switched, or individually packet switched. Only one channel per trunk can be packet switched due to Packet Processing Element (PPE) limitations. The D channel is either circuit switched or packet switched. Packet switching uses the PPE to combine all D channels into a single physical channel, which is then routed via the concentration highway to the Network Control Element (NCE) and then to the TDM bus. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64Kb/s clear data channels. The packet-switched channels support the LAPD protocol and conform with the CCITT Q.920 Recommendations for D-channel signaling.

LEDs

The three LEDs on the circuit pack's faceplate indicate board status. When illuminated, the red LED indicates a board failure or a major or minor on-board alarm, the green LED indicates that testing is in progress, and the amber LED indicates that the board is in use.

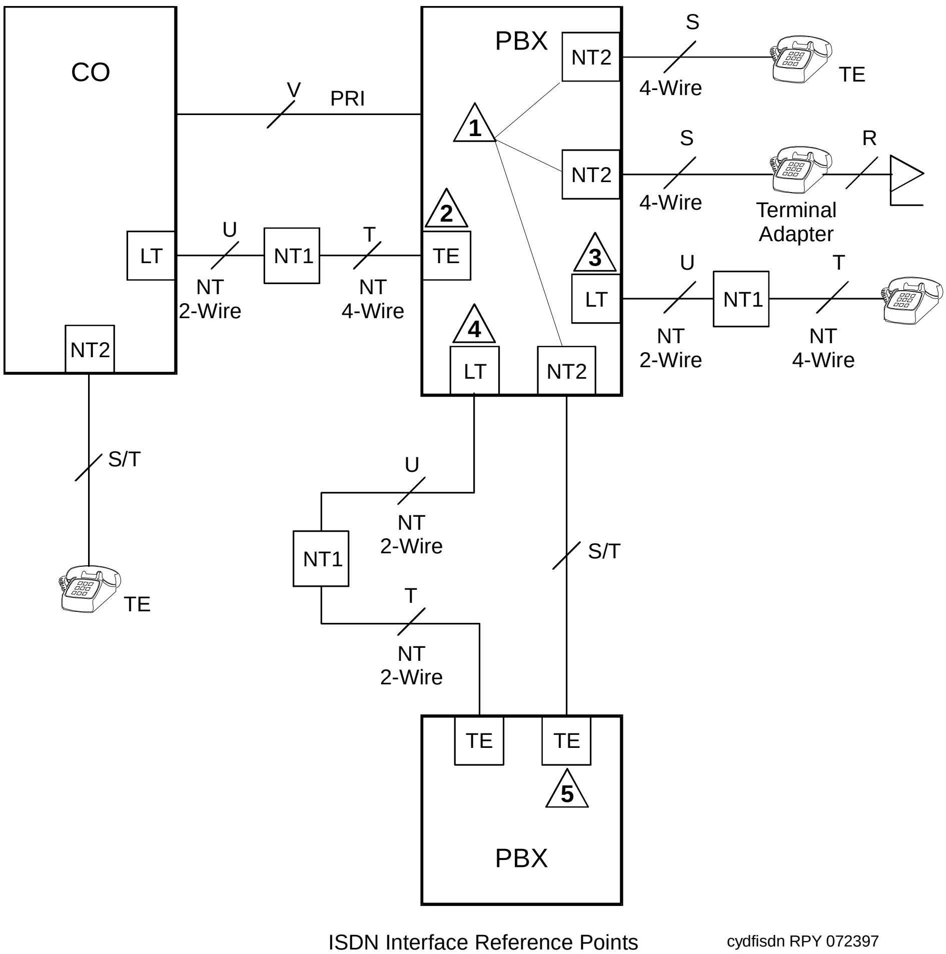

Figure 9-109. Integrated Trunk-Side BRI, ISDN Interface Reference points

ISDN Interface Reference Point definitions:

LT	Logical Terminal
V	Primary Rate user/network (asymmetrical) trunk interface. The ECS is capable of acting as the user or as the network side of this 1.544 - or 2.048-Mbps interface.
R	Interface between Terminal Equipment and Network Termination
S	Basic Rate network-side 4-wire line interface

1538 (i)		CRC error (TDM D-Channel)	MINOR	OFF	

Continued on next page

Table 9-670. TBRI-PT Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1793 (j)		BRI Port Local TDM Looparound Test (#619)	MINOR	ON	
2049 (k)			MINOR	OFF	
2305 (l)		Layer 3 Query (#1243)	MINOR	OFF	
3073 (m)		Slip Query Test (#1244)	MINOR	OFF	
3585 (n)		Receive FIFO Overflow (TDM D-Channel)	Log Only	ON	
3586 (o)					
3587 (p)					
3588 (q)	46223				
3589 (r)					
3590 (s)	46211				
3591 (t)					
3592 (u)					
3841 to 3942 (v)					

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. The far-end switch changed the ISDN service state. This may be a temporary condition.

Notes:

a. Loss of continuity of Layer 1 to the far-end. It is assumed that Layer 1 remains active, even when both B-Channels are idle.

   This test determines whether Layer 1 is active or not. If Layer 1 is not active, the test attempts to activate it. If Layer 1 cannot be activated, the port is taken out of service, and the test fails.

b. The D-Channel failed at Layer 2. Expiration of this timer indicates that attempts to bring the failed link back into service have not succeeded and some recovery actions should be taken on the associated B-Channels. Upon expiration, associated in-service B-channels are put in the out-of-service/far end state.

c. Error Type (513): On-board hardware failure. The FIFO RAM buffers have overflowed, indicating a hardware problem.

d. Error Type (514): Transmit FIFO Overflow - This error indicates that the circuit pack is having problems transmitting data to the TDM D-Channel. This error only occurs only a system that switches the packet implementation of the D-channel over the TDM Bus. This error indicates an on board problem related to the packet implementation of the D-Channel (R6.2 and higher).

e. Error Type (769): The port is generating too many uplinks. The link is being suspended.

f. Error Type (1025): An expired timer has created an unexpected event. The timer could be any of the following:

Timer	Event
T3031	ISDN T3031 timeout
T3032	ISDN T3032 timeout
T305	ISDN T305 timeout
T3081	ISDN T3081 timeout
T3082	ISDN T3082 timeout
TL3	Status Inquiry
T304	Setup ACK
T310	Call Proceeding Receive
T313	Connect SEND

g. Error Type (1281): This error occurs when the NPE Crosstalk Test (#617) has failed. The test will be repeated every 15 minutes until it passes. Follow normal trouble shooting procedures for NPE Crosstalk Test (#617). If this does not fix the problem, follow normal escalation procedures.

h. Error Type (1537): The board received a bad Cyclical Redundancy Check (CRC) over the D-Channel. This error is reported on a per-port basis. When the CRC errors exceed 5 within 15 minutes, the port is taken out of service for 5 seconds. If 5 more CRC errors are received within 15 minutes of the first set of 5 errors, the port is taken out of service for 1 minute. If 5 more CRC errors are received within 15 minutes of the previous 5, the port is taken out of service for 15 minutes.

   This error is most likely due to a problem with backplane wiring, a noise source, or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.

   1. Check the backplane wiring.
   2. If the problem persists escalate the problem.

i. Error Type (1538): This error occurs when a frame with a bad CRC is received by the BRI trunk board. This error only occurs on a system that switches the packet implementation of the D-channel over the TDM bus. This error indicates an off board problem related to the packet implementation of the TDM D-Channel (R6.2 and later).

j. Error Type (1793): The BRI Port Local TDM Loop Around Test (#619) failed. Run the Long Test Sequence paying particular attention to the results of the BRI TDM Port Loop Test (#619).

k. Error Type (2049): The Layer 2 Link Query failed. The test is repeated every 15 minutes until it passes.

l. Error Type (2305): The Remote Layer 3 Query failed. The test is repeated every 15 minutes until it passes.

m. Error Type (3073): A frame of information had to be repeated or deleted. Slips usually occur when the received bit rate is not synchronized with the TDM Bus clock.

n. Error Type (3585): The circuit pack detected an overflow of its receive buffers. This error occurs only a system that switches the packet implementation of the D-Channel over the TDM bus. This error indicates an on board problem related to the packet implementation of the TDM D-Channel (R6.2 and higher).

o. Error Type (3586): Each port can support up to three Terminal Endpoint Identifiers (TEIs). Each channel on the port can request a TEI assignment from the switch if it supports ISDN-BRI TEI assignment procedures. If switch services gets a request for a fourth TEI on a port, it reports this event to maintenance software and initiates TEI check procedures on the port. Check to see if the correct number of channels are administered for this port.

   The user side supports automatic TEI assignment by the network. Both fixed and automatic TEI assignment are supported on the network side.

p. Error Type (3587)Service Profiler IDentifier (SPID) value is invalid or is a duplicate of another SPID that is already initialized at Layer 3 on the port. SPIDs are not used on the TN2185 circuit pack. However there will be related events.

q. Error Type (3588): The board receives D-Channel data from the bus faster than it can process the data. The FIFO RAM buffers overflowed. This error occurs occasionally due to the statistical sizing of the buffers; however, frequent occurrences may indicate a LAPD parameter mismatch between the two endpoints of a packet-switched connection. Run the Long Test Sequence paying particular attention to the results of the Receive FIFO Overflow Test (#625).

r. Error Type (3589): The BRI Port Local LAN Loop Around Test (#618) failed. Run the Long Test Sequence and pay particular attention to the results of Test #618.

s. Error Type (3590): An activated BRI port receives a frame containing a DLCI over a D-Channel for which it does not have a translation. This error normally indicates an off-board problem related to a state mismatch between the far-end and the switch. This error is logged only.

t. Error Type (3591): The port is generating too many uplinks and is taken out of service.

u. Error Types (3841-3942): Table 9-671 contains the received ISDN cause values for Errors 3841-3942 that are recorded in the hardware error logs. Unless otherwise stated, the cause values are D-Channel events. The aux data field shows which port caused the error.

Table 9-671. Cause Values for Error 3841-3942

Value	Type of Problem	Meaning
2	admin	No route to specific transit network
3	admin	No route to destination (or Germany bcap not imp)
6	admin	Channel unacceptable
18	switch problems	No user responding
38	switch problems	Network failure
50	subscription	Requested facility not subscribed
52	admin	Outgoing calls barred
54	admin	Incoming calls barred
62	subscription	Service not authorized
63	admin/sub	Service/option not available
65	admin/sub	Bearer capability not implemented
66	admin/sub	Channel type not implemented
69	admin/sub	Requested facility not implemented
70	admin/sub	Only restricted digital BC available
79	admin	Service/option not implemented
88	admin	Incompatible destination
102	switch problems	Recovery on timer expired

System Technician-Demanded Tests: Descriptions and Error Codes

When inspecting errors in the system, always investigate tests in the order listed below. By clearing error codes associated with the *Control Channel Loop Around Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
BRI Local LAN Port Loop Around Test (#618)		X	D
BRI TDM Port Loop Around Test (#619)		X	D
L1 State Query Test (#1242)	X	X	D
CRC Error Counter Test (#623)		X	ND
Receive FIFO Overflow Test (#625)		X	ND
Layer 3 Query Test (#1243)		X	ND
Slip Query Test (#1244)	X	X	ND
Clear Error Counters Test (#270)	X	X	ND
NPE Crosstalk Test (#617)		X	D

1. D = Destructive; ND = Nondestructive

Clear Error Counters Test (#270)

This test is nondestructive.

This test clears the various error counters associated with each TBRI-PT. This test passes if maintenance software is able to successfully send the downlink messages; the test aborts otherwise.

Table 9-672. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
Any	ABORT	Maintenance could not send the downlink message.
	PASS	The message to clear the error counters of the TBRI-PT maintenance object has been sent.

NPE Crosstalk Test (#617)

This test is conditionally destructive.

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes approximately 20 to 30 seconds to complete. Crosstalk testing is performed on both B-channels (B1 and B2) associated with a BRI port. If this test fails on either channel, any channel connected to the port is taken out-of-service. This test aborts if the port and its associated channels are not in the idle state.

Table 9-673. TEST #617 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension or trunk group/member number of the port. Use the **status bri-port UUCSSpp** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. Wait until the port is idle before retesting. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status bri-port** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	This test is not valid for this type of translation. Ports administered as "ASAI" or "ADJK" can not run this test, because the B channels associated with the port are not used by ASAI or Lucent Adjunct Links. This is a normal condition.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-673. TEST #617 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1, 2	FAIL	The NPE of the tested port was found to be transmitting in error, causing noisy and unreliable connections. Error code 1 indicates that the NPE Crosstalk Test failed on Channel B1. Error code 2 indicates that the NPE Crosstalk Test failed on Channel B2. 1. Replace circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test a maximum of 10 times to ensure it continues to pass. 2. If complaints still exist, examine the connections and wiring.

BRI Port Local LAN Looparound Test (#618)

This test is destructive.

This test checks the connectivity of the BRI port across the LAN bus. Because this test is destructive, run this test only if the port is out-of-service.

Failures of this test indicate either on-board faults associated with the TBRI-PT hardware on the circuit pack or problems with the LAN Bus, which is used to form connectivity between the switch and the TBRI-PT.

If the port is in a state other than out-of-service, the BRI Port Local LAN Looparound Test will abort. If the port is out-of-service, then the port is put into a local looparound mode and the following test is executed.

A looparound test is performed across the Packet Bus for the D-Channel. The switch sends data over a packet connection, which is looped back by the BRI port (D-Channel) and received back by the switch. The test passes if the packet connection can be established and the transmitted data is received unaltered. The test aborts if the Packet Bus is alarmed in the Processor Port Network (or the port network in which that circuit pack resides) or if the Packet Interface board is out-of-service. The test fails due to either on-board faults associated with the BRI port hardware on the circuit pack or problems with the LAN bus.

Table 9-674. TEST #618 BRI Port Local LAN Looparound

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The port is not out-of-service. 1. Use the **status bri-port UUCSSpp** command to determine the status of the port. 2. If it is in use, wait until it is idle, and then use the **busyout port UUCSSpp** command to place it in the out-of-service state and repeat this test. **CAUTION:** *Since the busyout command is destructive, execution of this command prior to the port being idle causes all calls associated with the BRI port to be torn down.*
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. Run the **test port long UUCSSpp** command and verify the repair by viewing the results of the BRI Port Local LAN Looparound Test (#618).
1141	ABORT	The PKT-CTRL is out-of-service. 1. Follow the repair procedures for the PKT-CTRL. 2. Run the **test port long UUCSSpp** command and verify the repair by viewing the results of the BRI Port Local LAN Looparound Test (#618).
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. Run the **test port long UUCSSpp** command and verify the repair by viewing the results of the BRI Port Local LAN Looparound Test (#618).
2012 2100	ABORT	Internal system error Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Looparound Test has failed. 1. If the test fails repeatedly, attempt to reset the circuit pack with the **busyout board UUCSS** and the **reset board UUCSS** commands if the other ports on the board are not in use. 2. If the test fails again, execute **test pkt P**. If this fails, follow failure procedures in the PKT-BUS section. 3. If the tests in Step 2 pass, the problem is local to the BRI board. Replace the trunk circuit pack.
	PASS	The BRI Port Local LAN Looparound Test passed.

BRI Port Local TDM Looparound Test (#619)

This test is conditionally destructive.

This test verifies the connectivity of a BRI port across the TDM Bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack.

This Looparound Test runs the following individual tests on the two B-channels (B1 and B2) associated with the port:

- A Looparound Test across the TDM Bus for B1.
- A Conference Circuit Test for B1.
- A Looparound Test across the TDM Bus for B2.
- A Conference Circuit Test for B2.

The tests are run in the above order. If one fails, the remaining tests in the sequence are not executed, and maintenance software returns an error code.

Table 9-675. TEST #619 BRI Port Local TDM Loop Around

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The system resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status bri-port UUCSSpp** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. Wait until the port is idle before retesting. 2. If the port is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-675. TEST #619 BRI Port Local TDM Loop Around — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command for the trunks associated with this port and determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	This test is not valid for this type of translation. Ports administered as **ASAI** or **ADJK** cannot run this test because the B channels associated with the port are not used by ASAI or Lucent Adjunct Links. This is a normal condition.
2000	ABORT	Response to the test was not received from the BRI-LINE circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack with the **busyout board UUCSS** and the **reset board UUCSS** commands if the other ports on the board are not in use. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1, 2	FAIL	The TDM Looparound failed on one of the channels. ■ Error Code 1 — TDM Loop Around Test failed on B1. ■ Error Code 2 — TDM Loop Around Test failed on B2.
7, 8	FAIL	The Conference Circuit Tests failed on a B-channel. ■ Error Code 7 — test failed on B1 ■ Error Code 8 — test failed on B2. 1. If the test fails repeatedly, attempt to reset the circuit pack with the **busyout board UUCSS**, the **reset board UUCSS**, and then the **release board UUCSS** commands (if the other ports on the board are not in use). 2. If the test fails again, replace the circuit pack.
	PASS	The BRI Port Local TDM Loop Around Test passed.

CRC Error Counter Test (#623)

This test is nondestructive.

This test reads the BRI port's CRC error counters that are maintained on the BRI circuit pack. The Cyclic Redundancy Check (CRC) is a means of error detection used to determine the integrity of data frame contents. The CRC error counter is incremented by the circuit pack when it detects a CRC error. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is non-zero, the test fails, and the value of the counter is displayed in the `Error Code` field.

Table 9-676. TEST #623 CRC Error Counter Test

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	This error occurs when a frame with a bad CRC is received over the D-Channel by the BRI board. This error is reported on a per-port basis when the counter goes over the threshold. This error is most likely due to a problem with the wiring or interference on the wiring caused by a noise source or no termination. It usually does not indicate a problem with the circuit pack.
	PASS	The CRC error counter was read correctly and has a value of 0.

Receive FIFO Overflow Error Counter Test (#625)

This test is nondestructive.

This test reads and clears the BRI port's Receive FIFO Overflow error counter maintained on the TBRI-BD circuit pack. This counter is incremented by the circuit pack when it detects an overflow of its receive buffers. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is non-zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error can occur if signaling frames are being received from the Packet Bus at a rate sufficient to overflow the receive buffers on the circuit pack for a port OR if a hardware fault is causing the receive buffers not to be emptied properly by the circuit pack. This test is useful for verifying the repair of the problem.

Table 9-677. TEST #625 Receive FIFO Overflow Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack with the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
value	FAIL	The TBRI-BD circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, run the Long Test Sequence and pay particular attention to the Looparound Tests (#618 and #619). See the repair procedures for the executed test if it fails. Otherwise, go to the next step. 3. Replace the circuit pack.
	PASS	The Receive FIFO Overflow error counter was read correctly and has a value of 0.

Level 1 Status Inquiry Test (#1242)

This test is nondestructive.

This test determines the state of the transmission facility of a BRI port at the Level 1 (L1) physical layer: Activated, Pending Activation, or Deactivated.

The Activated state is the correct state for an ISDN-BRI port. In this state the L1 interface can send and receive synchronized signals. This test passes if the state of L1 is Activated. This test also passes if software has taken this port out of service. See the description of the L1 “Deactivated State” below for more details.

The Pending Activation state indicates a problem with the channels, the wiring, or the TBRI-BD circuit pack. When in this state, the Level 1 interface is either not receiving any L1 framing from the channel, or it is communicating with the channel but cannot transition to the Activated state.

The Deactivated state indicates a problem with the TBRI-BD circuit pack. When in this state, the Level 1 interface is not active, and an idle signal is transmitted to the channels or that Layer 1 was deactivated by the switch. When an TBRI-PT port is placed in the out-of-service state, Level 1 is also put into the Deactivated state. This could be due either to the system detecting a fault with the port or to a **busyout port UUCSSpp** request.

Table 9-678. TEST #1242 Level 1 Status Inquiry

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The board or port may be busied out. 1. Look in the Error Log for Error Type 18 (port busied out) for this port and TBRI-BD (board busied out). If this error type is present for TBRI-PT only, then release the port with the **release port pp** command and run the test again. If the error is present for both TBRI-BD and TBRI-PT, then release the board with the **release board UUCSS** command and run the test again. **NOTE:** When you release a board, you release all ports associated with it. If certain ports still need to be busied out, use the **busyout port UUCSSpp** command to busy them out. 2. Make sure the endpoint is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack with the **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-678. TEST #1242 Level 1 Status Inquiry — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Received a status of Level 1 Pending Activation. U interface down indicating a problem with a connection between the switch and the NT1, a 2- to 4-wire converter that is used to connect 4-wire terminals to a 2-wire TN2198 or TN2185 circuit pack. 1. Verify that the connections between the switch and the NT1 are good. Verify that the NT1 has power. 2. Execute the **test port UUCSSpp** command and review the results of the Level 1 Status Inquiry Test to verify the repair. If this test still fails, proceed to Step 3. 3. Follow the manufacturers repair procedures for the NT1. Then execute the **test port UUCSSpp** command and review the results of the Level 1 Status Inquiry Test to verify repair.
2	FAIL	Received a status of Level 1 Pending Activation. U interface up, S/T interface down, which indicates a problem with the NT1 or the wiring between the NT1 and the BRI endpoint (S/T interface). 1. Execute the **test port UUCSSpp** command and review the results of the Level 1 Status Inquiry test to verify the repair. If this test still fails, proceed to Step 2. 2. Follow the manufacturer-recommended repair procedures for the NT1. Then execute the **test port UUCSSpp** command and review the results of the Level 1 Status Inquiry test to verify repair.
3	FAIL	Received a status of Level 1 Deactivated; the port is out-of-service. 1. Issue the **status bri-port UUCSSpp** command to verify that the service state of the port is out-of-service. If the service state of the port is not out-of-service, escalate the problem to the next tier. Otherwise, proceed to Step 2. 2. If the port has been placed out-of-service with the **busyout port UUCSSpp** command, try releasing the port by executing the **release port UUCSSpp** command. Then issue the **test port long UUCSSpp** command and review the results of Level 1 Status Inquiry test. If this test still fails, proceed to Step 3. 3. After executing the **test port long UUCSSpp** command, review the results of all the tests. Follow the repair procedures for any tests that fail. Verify repair of the problem by executing the **test port UUCSSpp** command and by determining that the Level 1 Status test passes. If the test continues to fail for this reason, escalate the problem to the next tier.

Continued on next page

Table 9-678. TEST #1242 Level 1 Status Inquiry — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL	Received a status of Level 1 Pending Activation, the NT1 has a loss of power indicating a problem with the NT1. 1. Follow the manufacturer-recommended repair procedures for the NT1. 2. Execute the **test port UUCSSpp** command and review the results of the Level 1 Status Inquiry test to verify the repair.
	PASS	This test indicates that Level 1 is activated or that software has taken the port out of service.

Layer 3 Query Test (#1243)

This test is nondestructive.

This test is used to check the application layer communications across the in-service ISDN D-Channel. The test passes if a status enquiry message is successfully sent, fails if the signaling link is down, and aborts if a query is already running or there is an internal error.

Table 9-679. TEST #1243 Layer 3 Query

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The test aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, a modem pool member or Music on Hold). This error can be ignored.
1019	ABORT	Test is already running.
1113	ABORT	The signaling link is down. 1. Use the **test port UUCSSpp long** command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of Test #626, which is executed with the command. If this test aborts or fails, follow the repair procedure for the Signaling Link Status Test. 3. Escalate problem if BRI Layer 3 Query Test continues to abort.

Continued on next page

Table 9-679. TEST #1243 Layer 3 Query — *Continued*

Error Code	Test Result	Description/ Recommendation
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long UUCSSpp** command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Consult the repair procedure for PKT-CTRL. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the **test port long UUCSSpp** command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1187	ABORT	The circuit pack or port may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for TBRI-BD or TBRI-PT. a. If this error type is present for TBRI-PT, then release the port with the **release port UUCSSpp** command and run the test again. b. If the error is present for both TBRI-BD and TBRI-PT, then release the circuit pack with the **release board PUUCSS** command and run the test again. **NOTE:** When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the **busyout port UUCSSpp** command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The switch has successfully sent a Status Enquiry message.

Slip Query Test (#1244)

This test is nondestructive.

Slips occur when the transmitter and receiver are not running at precisely the same clock rate. The Slip Alarm Inquiry Test polls the total number of slips that have occurred on a link.

When the TN2185 circuit pack detects a slip condition, maintenance software initiates the Slip Alarm Inquiry Test to query the slip counters on the TN2185 circuit pack and total the slip counts in the maintenance software.

If the slip count is over the threshold, a Minor alarm is raised against the TN2185 circuit pack, leaving all ports of the TN2185 circuit pack in the in-service state. If the TN2185 circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See TDM-BUS and SYNC for additional information.

Table 9-680. TEST #1244 Slip Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this error type.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1 to 88	FAIL	The circuit pack and the remote endpoint are not synchronized to the same clock rate, which has generated the Slip alarm. The error code equals the number of slips detected by the TN2185 circuit pack since the last Slip Alarm Inquiry Test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the circuit pack is a TN2185, enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the physical connections of DS1 Interface circuit packs and cable. 5. Replace the local DS1 Interface circuit pack and repeat the test. 6. Contact T1 Network Service to diagnose the remote DS1 endpoint.

Continued on next page

Table 9-680. TEST #1244 Slip Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	No Slip alarm is detected on the DS1 Interface circuit pack.
0	NO BOARD	The DS1 Interface circuit pack is not administered. 1. Administer the DS1 Interface circuit pack by issuing the **add ds1 UUCSS** command. 2. Run the test again. 3. If the test continues to return NO BOARD, escalate the problem.

TBRI-TRK (ISDN Trunk-Side BRI)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TBRI-TRK[2]	MAJOR[3]	test trunk UUCSSpp l	MO_TBRI_TRK
TBRI-TRK	MINOR	test trunk UUCSSpp l	MO_TBRI_TRK
TBRI-TRK	WARNING	test trunk UUCSSpp sh	MO_TBRI_TRK

1. Where UU is the universal cabinet number (1 for PPN, 2 -44 for EPN), C is the carrier designation (A, B, C, D, or E), SS is the carrier slot address where the circuit pack is located (1, 2, and so forth), and pp is the two-digit port number (1, 2, 3, and so forth).
2. For additional repair information, also see TBRI-BD and TBRI-PT Maintenance documentation.
3. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

The TN2185 circuit pack contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64 Kb/s channels (B1 and B2) and over a 16Kb/s signaling (D) channel. The B1 and B2 channels can be simultaneously circuit switched, or individually packet switched. Only one channel per trunk can be packet switched due to Packet Processing Element (PPE) limitations. The D channel is either circuit switched or packet switched. Packet switching uses the PPE to combine all D channels into a single physical channel, which is then routed via the concentration highway to the Network Control Element (NCE) and then to the TDM bus. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64Kb/s clear data channels. The packet-switched channels support the LAPD protocol and conform with the CCITT Q.920 Recommendations for D-channel signaling.

LEDs

The three LEDs on the circuit pack's faceplate indicate board status. When illuminated, the red LED indicates a board failure or a major or minor on-board alarm, the green LED indicates that testing is in progress, and the amber LED indicates that the board is in use.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Services State Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Signaling Link State Check Test (#1251)	X	X	ND
Service State Audit Test (#256)	X	X	ND
Call State Audit Test (#257)	X	X	ND
ISDN Test Call Test (#258)		X	ND

1. Destructive; ND = Nondestructive

Signaling Link State (#1251)

This test is non-destructive.

This test checks the current state of the signaling link. The test looks at the board-level translations, checks that the board is physically inserted, gets the state of the D-Channel and service state of the port.

The test passes if the signaling link (D-Channel) is connected and operating normally. The test fails if the board is not installed, the signaling link is disconnected, or if the port is out of service. The test aborts otherwise.

Table 9-681. TEST #1251 Signaling Link State Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	The test is disabled. 1. Enable the test by entering **enable test #1251**.
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
8	FAIL	The signaling link is down. 1. Consult the procedures for the TBRI-PT maintenance object.
9	FAIL	The port is out of service. 1. Return the port to an in-service state.
	PASS	The signaling link is connected and operating normally.

Service State Audit (#256)

This test is nondestructive.

This test performs a service state audit on an ISDN B-Channel. The test passes if Call Processing informs Maintenance that the Restart message was transmitted successfully, or if the B-Channel was busy and could not send the message.

The test fails if the board is not inserted or translated properly, or if a reply is not received within a certain amount of time.

The test aborts if the signaling link is disconnected, if a message is already outstanding, or if the necessary resources could not be allocated.

To investigate the service state of the TN2185 ISDN Trunk-Side BRI Channel, issue the **status trunk trunk-group/trunk-member** command.

Table 9-682. TEST #256 Service State Audit Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be on a valid call. Use **status trunk** to determine when trunk is available for testing. 1. Check the results of Test #1251 (Signaling Link State Check).
1005	ABORT	The test aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, a modem pool member or Music on Hold). This error can be ignored.
1018	ABORT	The test is disabled. 1. Enable maintenance by entering **y** in the `Maintenance Tests?` field on page 2 of the **change trunk-group** form.
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #1251 (Signaling Link State Test).
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1116	ABORT	The trunk is not in a service state which is appropriate for running the test. This test is only performed in the OOS/FE state.
1117	ABORT	A service state audit message is outstanding. 1. Wait two minutes and then try again.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Wait 4 minutes and then check the Error Log for any new errors of type 3073. If there are none, then both sides of the ISDN connection agree on the service state; the negotiation succeeded. If there is a new 3073 error, then the negotiation failed (the far-end switch twice failed to respond within 2 minutes). The switch automatically retries every 15 minutes. If the trunk was initially in-service, it is now placed in the maintenance/far-end state. Incoming calls are accepted, but no outgoing calls can be originated. If an incoming call is presented, another Service State Audit is immediately performed in an attempt to put the TN2185 ISDN Trunk-Side BRI Channel in the proper state.

Call State Audit Test (#257)

This test is nondestructive.

This test performs a call state audit on an ISDN B-Channel, and upon successful completion, guarantees that both sides of the interface are in a consistent call state for connections using the B-Channel. The test can be helpful when trying to clear a hung call. If the internal call state data to the near-end switch is different from that of the far-end switch, the call will be torn down.

The test passes if the audit is successful.

The test fails if the board is not inserted, if there is an internal system error, or if a reply was not received within the prescribed amount of time.

The test aborts if the signaling link is disconnected, the request is already active, or if the B-Channel is in an Out-Of-Service state.

Table 9-683. TEST #257 Call State Audit Test

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test is disabled. 1. Enable the test by entering **y** in the `Maintenance Tests?` field on page 2 of the **change trunk-group** form.
1019	ABORT	An audit is already in progress. 1. Wait two minutes and try again.
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #1251 (Signaling Link State Check).
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1116	ABORT	The trunk is in an out-of-service ISDN service state. 1. A call cannot be present if the trunk is in an ISDN out-of-service state, so a call state audit would be inappropriate. No action necessary. (Use the **status trunk** command.)
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The audit passed successfully.

ISDN Test Call Test (#258)

This test performs a far-end loop around to a far-end switch over an ISDN trunk. The trunk's service state must be in-service, maint-NE, or out-of-service/NE, and no call can be active on the trunk.

A test call connection is established to a far-end switch over the ISDN trunk to be tested. The digital port on a TN711D Maintenance/Test circuit pack generates a test-pattern bit stream that is sent to the far-end switch and echoed back. The received pattern is then compared to the sent pattern and checked for errors that indicate a loss of integrity on the communications path.

If a test call is running when scheduled maintenance starts, the green LED is turned off. To determine if a test call is still running, use the **list isdn-testcall** and **status isdn-testcall** commands. A lit yellow LED on the Maintenance/Test circuit pack also indicates that a test call is running.

There are two methods available to place an outgoing ISDN Trunk-side BRI trunk test call:

1. The test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN Trunk-side BRI trunk to a data channel. This method is selected when no Maintenance/Test circuit pack resides in the system.
2. The test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN Trunk-side BRI trunk to a digital trunk testing port on the Maintenance/Test circuit pack. The Maintenance/Test Digital Port generates a pseudo bit stream.

A test is run periodically to check if the call is hung. If so, it gracefully tears down the call to release the resources.

Synchronous Commands

You can demand a synchronous outgoing test call by using the following maintenance commands:

- **test trunk trunk-group-no/member-no long [repeat number]**
- **test board UUCsspp long [repeat number]**
- **test port port-location long [repeat number]**

Whenever a circuit translates to an ISDN Trunk-side BRI trunk during a Long Test Sequence, an outgoing test call is invoked, and the duration of the test call is 8.6 seconds. Once the test call completes, the bit error rate is retrieved from the Maintenance/Test Digital Port. A bit error rate greater than zero is reported as a failure to the Manager I terminal (MGRI). A failure indicates the need to run further diagnostics.

If no Maintenance/Test circuit pack exists, the outgoing ISDN Trunk-side BRI trunk test call is established over a high-speed data channel on the Network Control (NETCON) circuit pack (DATA-BD).

Asynchronous Commands

NOTE:
Only one trunk can be tested in a given port network, until the test call is canceled or completes.

Table 9-684. TEST #258 ISDN TEST Call

Error Code	Test Result	Description/ Recommendation
4	ABORT	There is a problem with the Processor Interface Link. 1. Refer to the PI-LINK (Processor Interface Link) Maintenance documentation.
1004	ABORT	B channel in use. 1. Determine if a call is active on this ISDN Trunk-side BRI trunk via the **status trunk** command. 2. When the service state indicates in-service/idle, retry the test.
1005	ABORT	Bad Configuration (that is, no Maintenance/Test circuit pack) Issue the **test trunk <trunk Group/trunk member>** command and make sure there is a DATA-CHL (NETCON channel) administered.
1018	ABORT	Test call is disabled. 1. Enable Maintenance on the Trunk Group form.
1024	ABORT	(M/T-DIG) Maintenance/Test Digital Port in use. 1. Wait until yellow and green LEDs are turned off on the M/T-BD (Maintenance/Test circuit pack). 2. Retry the test. If problem persists, refer to M/T-DIG (Maintenance/Test Digital Port) documentation.
1113	ABORT	The signaling link has failed; the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #1251 (Signaling Link State Check Test).
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 9-684. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
1116	ABORT	The switch could not appropriately change the ISDN service state. 1. Determine if a call is active on this ISDN Trunk-side BRI trunk (use the **status trunk** command). 2. If not, check the Error and Alarm Logs for problems with this TBRI-TRK MO.
1117	ABORT	ISDN B-channel maintenance message is already outstanding. 1. Wait two minutes, then try again.
1118	ABORT	Far-end of ISDN trunk is not administered. 1. Check the administration of the far-end ISDN trunk. 2. Issue the **status trunk** command and try the test again.
1119	ABORT	The test call was aborted due to a normal call attempt on this trunk. The test call is performed only if the trunk is idle. 1. Either wait for the normal call to terminate normally, or force it to be dropped by using the **busyout trunk** command**.**
1120	ABORT	The ISDN Trunk-side BRI trunk is in the ISDN out-of-service/far-end state. 1. Try to change the service state via Test #256 (Service State Audit Test). Then retry this test. **However, the trunk may be in the out-of-service/far-end state due to problems at the far-end switch. If that is the case, no remedial action can be taken at this end.**
1122	ABORT	There is no test line number for the far-end switch. 1. Check the Trunk Group Administration form.
1123	ABORT	There is no Feature Access Code administration for this Facility Test. 1. Check the Dial Plan and Feature Administration forms.
2012 None 2000	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2035	ABORT	The call has timed out, perhaps because of a lack of system resources. 1. Wait 1 minute and try again.
2036 2037	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-684. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2038 2039	ABORT	A problem occurred while trying to read the test data. 1. Wait one minute and then try again. 2. If the test aborts again in the same manner, there is a serious internal problem. If so, escalate the problem.
2040	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2041	ABORT	The call has timed out, perhaps because of a lack of system resources. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2066	ABORT	Could not establish test call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2067	ABORT	The call has timed out, perhaps because of a lack of system resources. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2074	ABORT	Bit and Block Error query failed. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, there may be a serious internal problem with M/T-DIG (Maintenance/Test Digital Port). If this is the case, refer to the M/T-DIG (Maintenance/Test Digital Port) Maintenance documentation.
2075	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2104	ABORT	Call dropped or could not be originated. 1. Make sure service is provisioned by the network. 2. Check the administration of the far-end test line extension on the trunk group administration form. 3. Check the administration of the test call BCC (Bearer Capability Class) on the trunk group administration form. 4. Try the test again.

Table 9-684. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2201 2202 2203 2204 2205	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2206	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2208	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2209 2210	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2211	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2212	ABORT	Call terminated by unexpected disconnect. 1. Wait one minute and then try again.
2213	ABORT	The call has timed-out, perhaps because of a lack of system resources. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2214	ABORT	Call terminated by unexpected disconnect. 1. Wait one minute and then try again.
2215 2216 2217 2218 2219	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2220	ABORT	Call terminated prematurely. 1. Wait one minute and try again.

Continued on next page

Table 9-684. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2221 2222 2223 2224 2225 2226	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2227	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2042	FAIL	**This is the main purpose of the test.** The comparison of the data sent with the data received indicates a loss of integrity on the communications path. 1. The trunk should be taken out-of-service and the quality of the ISDN Trunk-side BRI line should be investigated. The investigation should include an in-depth analysis of the facility including the transmission facility and any external equipment such as DACs, CSUs, etc.
	PASS	The call worked. A test pattern was sent and received properly; the communications path is OK if the synchronous test call command was issued. An in-depth analysis of the ISDN Trunk-side BRI trunk facility including the transmission facility and any external equipment such as DACs, CSUs, and others should take place if the bit and block error rates are not acceptable.

TDM-BUS (TDM Bus)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TDM-BUS	MAJOR	test tdm P	TDM Bus
TDM-BUS	MINOR	test tdm P	TDM Bus
TDM-BUS	WARNING	test tdm P	TDM Bus

1. P is the Port Network number. Use **list cabinet** to find the port network(s) contained in a given cabinet.

Each port network has a pair of TDM busses, designated TDM Bus A and TDM Bus B, each with 256 time slots. This division allows for duplication of control channels and dedicated tone time slots. The first five time slots on each bus are reserved for the control channel, which is active on only one bus at a time in each Port Network. The next 17 time slots are reserved for system tones such as dial tone, busy tone and so on. As with the control channel, these time slots are active on only one bus, A or B, at a time. The rest of the time slots on each bus are for general system use such as carrying call-associated voice data. The 17 dedicated tone time slots that are inactive can also be used for call processing when all other available time slots are in use.

When the system initializes, the control channel is on TDM Bus A and the dedicated tones on TDM Bus B in each Port Network. If a failure occurs on one of the two busses, the system will switch any control, tone and traffic channels to the other bus. Service will still be provided, though at a reduced capacity.

The **set tdm** PC command has the effect of putting both the control channel and tone time slots on a specified bus, A or B. P specifies the port network number, and C specifies the TDM bus, A or B. Throughout this discussion, PC refers to a specific TDM Bus. References to *port circuit packs* include all circuit packs that terminate on the TDM bus, including the Expansion Interface TN570, and the following service circuit port boards: Call Classifier (TN744), Integrated Announcement (TN750), Maintenance/Test (TN771), Speech Synthesizer (TN725B), Tone Detector (TN748 or TN420). Other terms used are:

- Control Channel Bus: the TDM Bus carrying the active control channel.
- Non-Control Channel Bus: the tdm bus with the inactive control channel.
- Tone Bus: the TDM bus carrying the active tone time slots
- Non-Tone Bus: the TDM Bus with the inactive tone time slots

TDM Bus Fault Detection and Isolation

TDM Bus are usually caused by one of the following:

- A defective circuit pack connected to the backplane
- Bent pins on the backplane
- Defective bus cables or terminators

It is possible that a circuit pack can cause a TDM Bus fault and still exhibit trouble-free operation. For example, insertions of any circuit pack into a slot with TDM Bus terminations may bend the backplane pins and short two leads together. Since the TDM Bus is a shared resource, identification of the cause of a TDM Bus fault can be difficult. If a TDM Bus problem is suspected, run the **test tdm P** command. If any of the resulting tests fail, you must perform a manual TDM Bus isolation procedure to identify the cause of the problem.

WARNING:
Since the TDM Bus fault isolation procedure involves removing circuit packs and possibly disconnecting entire carriers, the procedure is extremely destructive to the port network that contains the TDM Bus being tested. If possible, arrange to perform this procedure at a time when traffic is minimal.

As circuit packs are removed or entire carriers are disconnected, any active calls terminating on those circuit packs or carriers will be dropped. If you have any hints about a particular circuit pack that may be causing the TDM Bus problem investigate those before performing this procedure (for example, look at any circuit packs that were inserted into the PN just before the TDM bus problem appeared.

When straightening or replacing backplane pins in a carrier that contains a CFY1B Current Limiter, power to the *cabinet* must be removed. When straightening or replacing backplane pins in a carrier that does NOT contain a CFY1B Current Limiter, power to that *carrier* must be shut off. Failure to follow this procedure may result in damage to circuit packs and power supplies, and can be hazardous to the technician.

NOTE:
Maintenance software requires TN748 or TN420 Tone Detector circuit pack to test the TDM Bus. Before starting these procedures, make sure that one of these is installed in the port network being investigated.

Procedure 1

This procedure is an attempt to isolate the TDM Bus fault to circuit packs that are essential to the system operation. For each of the following circuit packs in the port network where the TDM Bus fault appears, perform Procedure 1.

Circuit Pack	Error Log Names
Tone-Clock	TONE-BD, TONE-PT, and TDM-CLK
MSS/Network Control*	SW-CTL and H-ADAPTER
Tone Detector	DETR-BD, GPTD-PT, and DTMR-PT
Expansion Interface	EXP-INTF
Packet Interface*	PKT-INT

1. Display the Alarm Log for the circuit pack via the **display alarms** command.
2. If there are alarms for the circuit pack, refer to that section and try to resolve the alarms.
3. Whether or not all the alarms can be cleared, test the TDM Bus again via the **test tdm P** command.
4. If some TDM Bus tests fail, implement Procedure 1 for the next circuit pack.
5. If all the TDM Bus tests pass, the problem has been fixed.
6. If all circuit packs in the list have been investigated, go to Procedure 2.

Procedure 2

Procedure 2 removes and reinserts port circuit packs (those in the purple slots) one or more at a time. Use this procedure for each port circuit pack in the port network until the problem is resolved or until all circuit packs in the port network have been tried. To execute diagnostic procedures on the Expansion Interface and Tone/Clock circuit packs, refer to Procedure 3. Although these circuit packs reside in purple slots, procedure 2 does not apply. This procedure *does* apply to the Tone Detector circuit pack.

If the TDM Bus problem is present when the circuit pack is inserted, but is resolved when the circuit pack is removed, either the circuit pack or the backplane pins in that slot are causing the problem. If the backplane pins are intact, replace the circuit pack. If some of the tests fail regardless of whether the circuit pack is inserted or removed, and the backplane pins are intact, the circuit pack is not the cause of the problem. In a multiple failure situation, the circuit pack could be one cause of the TDM Bus problem. However, other simultaneous failures might also be responsible for TDM Bus faults. In Procedure 2, an option of working either with one circuit pack at a time or with multiple circuit packs simultaneously is available. In view of this capability, determine the level of service interruption that will be acceptable during the procedure. If causing a disruption to all users in the port network is deemed permissible, large groups of circuit packs should be worked with in order to get the job done quickly. However, *if large service disruptions are to be avoided*, work with one circuit pack at a time. This option is slower, but it disrupts only the users of a single circuit pack.

1. Remove one or several circuit packs as appropriate. Any circuit packs that reside on the TDM Bus that have been recently inserted should be checked first.

   If you decide to remove multiple circuit packs, consider working with an entire carrier at a time to more quickly and reliably determine which circuit packs are *not* the source of trouble.

2. Run *test tdm P* to determine if the TDM Bus fault is still present.

3. If any of the TDM Bus tests fail:

   - Determine if the backplane pins in the removed circuit pack's slot appear to be bent.
   - If the backplane pins are not bent, reinsert the circuit pack(s), and perform Procedure 2 for the next set of circuit packs.
   - If the backplane pins are bent, remove power to this carrier in the manner described previously.
   - Straighten or replace the pins and reinsert the circuit pack.
   - Restore power and repeat Procedure 2, beginning with Step 2, for the same circuit pack(s).

4. If none of the TDM Bus tests fail:

   - Reinsert the circuit pack(s) *one at a time,* and repeat the following substeps until all of the circuit packs have been reinserted.
   - Run **test tdm P** to determine if the TDM Bus fault has returned.
   - If any of the TDM Bus tests fail, the reinserted circuit pack is defective. Replace this circuit pack and repeat this procedure for the next circuit pack.
   - If none of the TDM Bus tests fail when all of the circuit packs have been reinserted, the problem has been fixed and the procedure is completed.

Continue with Procedure 3 if all the port circuit packs have been checked, but the TDM Bus fault is still not resolved.

Procedure 3

This procedure removes and reinserts SPE and EPN control circuit packs, as listed in the table at the beginning of this section. In the PPN processor carrier (SPE), the TDM Bus terminates on slots 11-15. When running diagnostics in the PPN, the following circuit packs should be tested:

- TN1655 Packet Interface (three slots available per carrier)
- TN768/TN780 Tone/Clock
- UN332 MSSNET
- TN570 Expansion Interface

Although the Packet Interface circuit pack does not communicate over the TDM bus, the bus does terminate at those slots. TDM Bus failures could be caused by bent backplane pins.

When running TDM Bus diagnostics in an EPN, the following circuit packs should be tested with this procedure:

- TN570 Expansion Interface
- TN768/TN780 Tone/Clock

When using this procedure on an EPN, the Tone/Clock circuit pack should be the next-to-last one checked. The Expansion Interface circuit pack (TN570) should be the last one checked, since removing this circuit pack disconnects its EPN. In a system with duplicated PNC, disruption of traffic can be minimized by following the procedure for the standby TN570 Expansion Interface circuit pack, then entering a **reset pnc interchange**. The formerly active Expansion Interface will now be standby and can be checked without affecting service to the EPN.

At steps in the procedure that require the removal and/or replacement of circuit packs, refer to the Maintenance Object documentation for the given circuit pack for instructions. SPE and/or PNC interchanges may be required to complete these steps with the least amount of service disruption.

Procedure for PPN with Simplex SPE or EPN with Simplex PNC

1. Remove the suspect circuit pack.
2. As in Procedure 2, determine if the backplane pins in the removed circuit pack's slot are bent.
3. If the backplane pins are bent, do the following:
   a. Power down the control carrier as described in the previous warning statement.
   b. Straighten or replace the pins.
   c. Insert the same circuit pack.

   d. Turn the power back on to reboot the system or to restart the EPN.
   e. Run **test tdm P** to determine if the TDM Bus fault still exists.
   f. If none of the TDM Bus test fail, the procedure is complete.
   g. If some of the TDM Bus tests fail, replace the suspect circuit pack and go to step 6.

4. If the backplane pins are not bent, replace the circuit pack.
5. Turn the power back on to reboot the system.
6. Run **test tdm P** to determine if the TDM Bus fault is still present. If none of the TDM Bus tests fail, the procedure is completed.
7. If the TDM Bus fault is still present, the suspect circuit pack was not the cause of the TDM Bus failure. Do the following:
   a. Remove the replacement circuit pack that was just inserted and replace it with the previously suspected circuit pack.
   b. Repeat Procedure 3 for the next circuit pack on the list for this procedure.

If Procedure 3 fails to identify the cause of the problem, go to Procedure 4.

Procedure for PPN with Duplicated SPE or EPN with Duplicated PNC

In this type of configuration, the test procedure is made up of several independent parts. In a duplicated system it is desirable to investigate whether or not circuit packs are causing problems on the TDM Bus when they are in active mode or when they are in standby mode or both. The procedure utilizes SPE interchange in the PPN, or a PNC interchange in the EPN. If the TDM Bus fault disappears after the interchange takes place, the newly standby MSSNET (PPN), or Expansion Interface (EPN), is suspect and should be replaced. If the problem still exists, the Tone/Clocks are then interchanged. If the TDM Bus failure then disappears, the newly standby Tone/Clock is suspect and should be replaced. If the TDM Bus problem still exists, then the procedure begins diagnostics on individual circuit packs and backplane pins.

Part 1 (PPN Procedure)

1. If performing this procedure for a PPN carrier, execute **status port-network** to determine which SPE is currently active. Run **reset system interchange** to make the currently active SPE standby.
2. Run **test tdm P** to determine if the TDM Bus fault is still present.
3. If the TDM Bus fault is gone, replace the formerly active MSSNET circuit pack.
4. Run **reset system interchange** again to get the new MSSNET circuit pack on the active SPE.

5. Run **test tdm P** to determine if the TDM Bus fault is still present.
6. If the TDM Bus fault is still present, replace the new MSSNET circuit pack with the original suspect circuit pack, and continue on to Part 3.
7. If the TDM Bus fault has disappeared, the procedure is complete.

Part 2 (EPN Procedure)

1. If doing this procedure for an EPN carrier, execute the **status pnc** command to determine which PNC is currently active. Run **reset pnc interchange** to make the currently active PNC standby.
2. Run **test tdm P** to determine if the TDM Bus fault is still present.
3. If the TDM Bus fault is gone, replace the formerly active Expansion Interface circuit pack.
4. Run **reset pnc interchange** again to make get the new Expansion Interface circuit pack on the active SPE.
5. Run **test tdm P** to determine if the TDM Bus fault is still present.
6. If the TDM Bus fault is still present, replace the new Expansion Interface circuit pack with the original suspect circuit pack, and continue on to Part 3.
7. If the TDM Bus fault has disappeared, the procedure is complete.

Part 3

1. Run **set tone-clock** to make the currently active Tone/Clock standby.
2. Run **test tdm P** to determine if the TDM Bus fault is still present.
3. If the TDM Bus fault is gone, replace the formerly active Tone/Clock circuit pack.
4. Run **set tone-clock** again to make the new Tone/Clock circuit pack active.
5. Run **test tdm P** to determine if the TDM Bus fault is still present.
6. If the TDM Bus fault is still present, replace the new Tone/Clock circuit pack with the original suspect circuit pack, and continue on to Part 4.

Part 4

Part 4 should be used for each individual circuit pack as listed in the previous table. Run this procedure on all circuit packs on the standby SPE or standby PNC. If the TDM Bus failure still exists once the standby circuit packs have all been tested, execute either **reset system interchange** (PPN) or **reset pnc interchange** (EPN), followed by **set tone-clock** to get the currently active circuit packs into standby mode so that this procedure can be run on each of them.

1. Remove the inactive suspect circuit pack.
2. As in Procedure 2, determine if the backplane pins in the removed circuit pack's slot are bent.
3. If the pins are bent, do the following:
   a. Remove power as described in the previous warning statement.
   b. Straighten or replace the pins.
   c. Restore power.
   d. Run **test tdm P** to determine if the TDM Bus fault is still present.
   e. If the TDM Bus failure is still present, the problem is with another circuit pack. Reinsert the original suspect circuit pack and continue with Part 4 for the next circuit pack.
   f. If the TDM Bus failure has disappeared, reinsert the circuit pack and run the **test tdm P** command to see if the TDM Bus failure is still present.

      If any of the TDM Bus tests fail, replace the suspect circuit pack. The procedure is complete.

      If none of the TDM Bus test fail, the procedure is complete.
4. If the backplane pins are not bent, run the **test tdm P** command to determine if the TDM Bus fault is still present.

   command to determine if the TDM Bus fault is still present.
   a. If any of the TDM Bus tests fail, the problem is with another circuit pack. Reinsert the original suspect circuit pack and continue with Part 4 for the next circuit pack.
   b. If none of the TDM Bus tests fail, replace the suspect circuit pack. The procedure is complete.
5. If all standby circuit packs have been tested, and the TDM Bus failure still exists, execute the **reset system interchange** (PPN) or the **reset pnc interchange** commands (EPN), and the **set tone-clock** command to get the currently active circuit packs into standby mode. Continue with Part 4 of this procedure for each of the newly active circuit packs.

Procedure 4

Procedure 4 attempts to isolate the TDM Bus failure to a particular set of carriers. Only the circuit packs in selected carriers are checked. Procedure 4 is used if the preceding procedures fail, because it can help locate multiple circuit pack failures and failures of the carrier hardware itself.

In this procedure, the TDM/LAN Cable Assemblies and TDM/LAN Bus terminators are replaced. If this action does not resolve the TDM Bus fault, the carriers are reconfigured so that certain carriers are disconnected from the TDM Bus. This is done by moving the TDM/LAN Bus terminators (ZAHF4) on the carrier backplane. To terminate a TDM Bus at the end of a particular carrier, the TDM Bus cable that connects the carrier to the next carrier should be unplugged and replaced with the TDM/LAN Bus terminator (see tFigure 9-110). When the length of the TDM Bus is modified the circuit packs that are essential to the system operation and TDM Bus maintenance (for example, MSSNET and Tone/Clock), must still be connected to the new *shortened* TDM Bus.

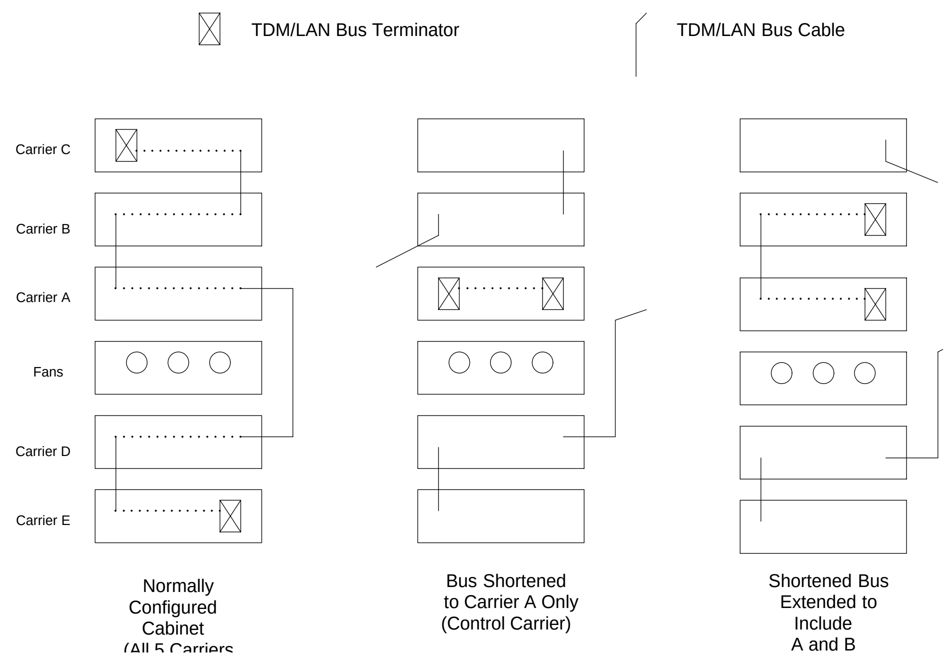

Figure 9-110. Carrier Rewiring Example—Rear View of Five-Carrier Cabinet

After cabling changes are made and verified, power must be restored to the port network. Circuit packs in carriers that are not part of the shortened bus are not inserted. As a result, these circuit packs are alarmed. Ignore these alarms for now. All alarms should be resolved when the cabinet is restored to its original configuration.

Procedure 4 is organized into two parts. Part 1 attempts to clear the TDM Bus fault by replacing all the bus cabling and terminators within a port-network. Part 2 attempts to isolate the fault to a particular carrier by extending the TDM Bus from the control carrier to additional carriers one at a time.

WARNING:

Power must be removed from the entire port network before any cables or terminators are removed. Failure to follow this procedure can cause damage to circuit packs and power supplies, and can be hazardous to the technician.

Part 1

1. If spare TDM/LAN Cable assemblies and TDM/LAN Bus Terminators are not available, go to Part 2 of this procedure.
2. Power down the port network.
3. Replace all of the TDM/LAN Cable Assemblies and both TDM/LAN Bus Terminators.
4. Restore power to the port network.
5. Run the **test tdm P** command to determine if the TDM Bus fault is still present.

   command to determine if the TDM Bus fault is still present.
6. If the TDM Bus fault is resolved, the procedure is completed. Otherwise, go to Part 2.

Processor Port Network:

1. Terminate the TDM Bus so that it extends only across the Active SPE control carrier.
2. Determine if the TDM Bus fault is still present by running the **test tdm P** command. While the TDM bus is extended only across SPE control carriers the non-control channel test (#297) will not run on the non-control channel because of the absence of a Tone Detector on the shortened bus. After the TDM Bus tests are run once, run the **set tdm PC** command to move the control channel to the non-active bus (the **status port-network P** command will show which bus is currently active). After the bus switch has occurred, run the

   command will show which bus is currently active). After the bus switch has occurred, run the **test tdm P** command again to determine if the newly active bus is faulted.

3. If none of the TDM Bus tests fail, extend the TDM Bus to another carrier. If that carrier is an SPE control carrier, repeat this procedure beginning at step 2. If the carrier is not an SPE control carrier, the **test tdm P** command only needs to be executed once since there is now a Tone Detector present on the bus and both the control and non-control channels will be tested in one test sequence.
4. If some of the TDM Bus tests fail, and since Procedures 2 and 3 have not resolved the problem, the added carrier(s) are defective and must be replaced.

Expansion Port Networks:

1. Terminate the TDM Bus so that it extends only across the carrier that contains the Active Expansion Interface.
2. Determine if the TDM Bus fault is still present by running the **test tdm P** command.

   If the *shortened* TDM Bus does not extend to a carrier that contains the Tone Detector circuit pack, the non-control channel test (#297) will not be able to run and the bus that the non-control channel was on will not be tested. If this is the case, run the **set TDM PC** command to move the control channel to the non-active Bus. The **status port-network P** command will show which Bus is currently active. After the Bus switch has occurred, run the **test tdm P** command again to determine if the newly active Bus is faulted.

   Another option in an EPN is to move a Tone Detector circuit pack to an empty slot (if one is available) in the carrier where the TDM bus is terminated. This would allow both the control channel and non-control channel tests to run and would not require that the **set tdm P** command be run.
3. If none of the TDM Bus tests fail, extend the TDM Bus to another carrier, and repeat the procedure in the previous step. When a carrier that causes the fault to recur is added, perform Procedure 2 for only the circuit packs in that carrier.
4. If any of the TDM Bus test fail, and Procedures 2 and 3 have not resolved the problem, the added carrier(s) are defective and must be replaced.

Restarting Non-functioning Port Circuit Packs

A defective TDM Bus Control Channel or system timing reference on one of the networks can result in port circuit packs (those not on a control carrier) on this port network entering the reset state. When this situation occurs, the circuit pack will stop functioning and its red LED will light. The system will not detect the presence of a circuit pack when the circuit pack is in the reset state. Hence, executing the **list config board** command will indicate that the circuit pack is not present.

If a circuit pack enters the reset state it will remain out of service until it receives a restart message form the control channel on the same TDM Bus, A or B, that was active when it reset, or until it is powered up again.

To force the system to send a restart message to all circuit packs on a network, try one of the following methods, depending on the circumstances. A circuit pack that is functioning normally (is not in the reset state) will ignore the restart message.

Procedure 1 (Non-destructive)

Execute the Idle Time Slot Test (#294) by issuing the command **test tdm P** when the control channel is on the same TDM Bus as it was when the circuit pack entered the reset state.

Procedure 2 (Non-Destructive)

If you are at the site, reseat the circuit pack. This action will cause the circuit pack that was in the reset state to begin functioning on the *current* Control Channel bus.

Procedure 3 (Destructive)

Reset the port network that contains the circuit pack that is in the reset state. When a network is reset, two restart messages, one on the control channel of each TDM Bus, are sent to each circuit pack on the network. *To reset an EPN only*, execute the **reset port-network** *P* **level 2** command. *Resetting the EPN will disrupt all calls going to and originating from the EPN.*

Procedure 4 (Destructive)

Execute the **recycle carrier** *PC* command. *This command will remove and return power to the designated port carrier. Thus, any other circuit packs on this carrier will also be temporarily taken out-of-service.*

Error Log Entries and Test to Clear Values

Table 9-685. TDM Bus Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	test tdm P
1	0	Control Channel Test (#296)	MINOR	ON	test tdm P r 3
18(a)	0	busyout tdm PC	WARNING	ON	release tdm PC
35(b)	0-1	TDM Bus Corruption	MINOR	ON	set tdm PC
257(c)	0	None	MAJOR	ON	
513(d)	Any	Idle Time Slot Test (#294)	MINOR	ON	test tdm P r 3
769(e)	Any	Idle Time Slot Test (#294)	WARNING	ON	test tdm P r 3
769(f)	Any	Idle Time Slot Test (#294)			(see Notes)
1025(g)	Any	None			
3872(h)	Any	None			
3873(h)	Any	None			
3874(h)	Any	None			
3877(h)	Any	None			

Notes:

a. The TDM Bus has been busied out by the technician. The error will retire when the technician releases the TDM Bus.

b. This error indicates the TDM Bus is corrupted. If the corruption was on the Control Channel bus, TDM Bus maintenance will automatically switch the control channel and/or tones to the other bus. The same strategy applies if the corruption was on the bus carrying the tones.

   An aux data value of 0 indicates the last reported TDM Bus corruption was on the Control channel bus.

   An aux data value of 1 indicates the last reported TDM Bus corruption was on the Non-Control channel bus.

If this error is logged on both TDM Buses (A and B) on the PPN within two or three minutes, the red LED of several circuit packs may or may not be lit and there could be Switch Control (SW-CTL) errors. Under these circumstances do the following:

- Display the Hardware Error Log via the **display errors** command and look for SW-CTL (Switch Control) errors.
- If there are any errors logged against the Switch Control, try to resolve them.
- Test the TDM Bus via the **test tdm P** command.
- If all the TDM Bus tests pass, the problem has been fixed.

c. This error indicates the TDM Bus was switched to the other bus due to TDM Bus corruption. The aux data value is not meaningful and no action is required. Look for other TDM-BUS errors to determine the cause of this error.

d. This error indicates that some time slots are corrupted in the specified TDM Bus. The Minor alarm is raised when there are more than 50 bad time slots in the bus. The aux data indicates the number of bad time slots found by the test.

e. This error indicates that some time slots are corrupted in the specified TDM Bus. The Warning alarm is raised when there are more than 10 bad time slots but less than or up to 50 bad ones in the bus. The aux data value indicates the number of bad time slots found by the test.

f. This error indicates the idle time slot test found less than 10 bad time slots in the TDM Bus. The aux data value indicates the number of bad time slots found by the test. There is no alarm associated with this error.

g. This error indicates that the daily TDM Bus switch was not successful. The Switch Control (PPN) or Active Expansion Interface (EPN) cannot talk on the bus that software was trying to switch into. There is no alarm associated with this error.

h. These errors indicate communication problems which may be causing message loss. TDM Bus maintenance may switch the Control Channel bus and/or Tone bus to the other bus. Test the TDM Bus via the **test tdm P** command and follow the procedures according to the error codes reported from the test. The aux data value shows the Angel id number for which a downlink message was lost.

Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Control Channel Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Test on the Control			
Channel Bus (#296)	X	X	ND
Digit Detection Test on the Non-Control Channel Bus (#297)	X	X	ND
Idle Time Slot Test (#294)	X	X	ND

1. D = Destructive; ND = Nondestructive

Idle Time Slot Test on TDM Bus A or B (#294)

The Idle Time Slot Test detects noisy time slots on the bus and takes them out-of-service. The Tone Detector circuit pack is told to listen to idle time slots and if it detects any noise on a time slot, it returns a failure. At the end of the test, any out-of-service time slots are retested to see if they are still noisy and restored to service if they are idle. After all the time slots have been tested, maintenance counts the number of bad time slots and reports the number to the technician in the error code field. No more than 220 time slots will be taken out-of-service on one bus and no more than 300 will be taken out-of-service on both buses at one time.

Table 9-686. TEST #294 Idle Time Slot Test on TDM Bus A or TDM Bus B

Error Code	Test Result	Description/ Recommendation
None	ABORT	Could not allocate the necessary system resources to run this test. For example, maintenance could be running on the Tone Detector circuit pack and it is using the CPTRs.
1115	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 3 times.
Any	FAIL	The error code indicates the number of bad time slots that were detected. The cause of this failure is most likely due to a bad port circuit pack and not the TDM Bus itself. 1. Execute the command again. 2. If the error persists, check the Error and Alarm Logs for alarms, on the port network where the faulted TDM Bus resides, on port circuit packs from the NPE Crosstalk Test. Also check for EXP-INTF alarms associated with error type 1537. 3. Refer to the appropriate circuit pack's documentation to clear the circuit pack's problem. 4. Test the TDM Bus again. If the error continues, refer to the "TDM Bus Fault Detection and Isolation Procedure" described earlier.
	PASS	The success of this test indicates all the idle time slots that are supposed to be idle are indeed idle. There is no noise on any of the idle time slots.

Control Channel Test (#296)

This tests the integrity of the Control Channel bus by ensuring that communication through the TDM Bus is operational. The test attempts to query a circuit pack whose presence is required in each port network for proper operation (Tone/Clock or Tone Detector). If a reply from the queried circuit pack is received, the TDM Bus is considered operational and the test passes. If no reply is received, the Bus is not operational and the test fails.

Table 9-687. TEST #296 Control Channel Test

Error Code	Test Result	Description/ Recommendation
Any other than 1005	ABORT	Internal system error. 1. Retry the command at one-minute intervals for a maximum of three times.
1005	ABORT	Since this test is valid only on the control channel bus, it aborts execution when run on the non-control channel bus. This is a valid response. Use the **status port-network** command to verify which bus is the control channel bus.
None	FAIL	Communication through the Control Channel is not working. The problem is not necessarily the TDM Bus itself. 1. Display the hardware error and alarm log for the Tone-Clock circuit pack and for the Tone Detector circuit pack in the port network where the faulted TDM Bus resides. Refer to Maintenance documentation for TONE-BD (Tone-Clock Circuit Pack), TONE-PT (Tone Generator), GPTD-PT (General Purpose Tone Detector Port), and DTMR-PT (Dual Tone Multi-Frequency Port). 2. Resolve the errors and alarms for the Tone-Clock and Tone Detector circuit packs. 3. If the faulted TDM Bus is in the PPN, display the hardware error and alarm log and look for SW-CTL errors and alarms. 4. If the faulted TDM Bus is on the EPN, display the hardware error and alarm log and look for errors and alarms for the active Expansion Interface circuit pack. Refer to EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation and resolve its errors. 5. Execute the **test tdm P** command again. 6. If the test still fails, refer to the “TDM Bus Fault Detection and Isolation Procedure” described earlier.
	PASS	Communication through the control channel bus is operational.

Digit Detection Test (#297)

This test is executed on the Non-Control Channel bus. The Tone-Clock circuit pack is told to put a tone on the Non-Control Channel bus and the Tone Detector circuit pack is told to listen to it. The test passes if the tone is successfully transmitted on the Non-Control Channel bus.

Table 9-688. TEST #297 Digit Detection Test

Error Code	Test Result	Description/ Recommendation
None 1001 2100	ABORT	Could not allocate the necessary system resources to run this test.
1005	ABORT	Since this test is valid only on the non-control channel bus, it aborts execution when run on the control channel bus. This is a valid response. Use the **status port-network** command to verify which bus is the control channel bus.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of three times.
None	FAIL	This failure indicates that communication on the Non-Control Channel is not reliable. 1. Execute the command again. 2. If the problem persists, test the active Tone-Clock circuit pack and Tone Detector circuit pack in the port network where the faulted TDM Bus resides, to make sure they are healthy. Refer to TONE-BD (Tone-Clock Circuit Pack), TONE-PT (Tone Generator), GPTD-PT (General Purpose Tone Detector Port), and DTMR-PT (Dual Tone Multi-Frequency Port). 3. Execute the command again. 4. If the problems persists, refer to the "TDM Bus Fault Detection and Isolation Procedure" described earlier.
	PASS	The non-control channel bus is operational.

TDM-CLK (TDM Bus Clock)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TDM-CLK	MAJOR	test tone-clock UUC short	TDM Bus Clock
TDM-CLK	MINOR	test tone-clock UUC short	TDM Bus Clock
TDM-CLK	WARNING	release tone-clock UUC	TDM Bus Clock

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E).

NOTE:
Replacing the tone/clock circuit pack requires a special procedure described in the documentation for TONE-BD. That section also describes the LED displays for this board.

The Time Division Multiplex (TDM) Bus Clock resides on the Tone-Clock circuit pack, providing clocking signals both for the TDM Bus and the LAN Bus. The Tone-Clock circuit pack is a critical component in the system and is necessary to ensure the operation of all port circuit packs in the system. The TDM buses of the PPN and any EPNs are synchronized together. The system timing reference can be derived internally from the Tone-Clock circuit pack in any PN, or from an external (off-board) timing reference. Currently, the TDM Bus Clock supports synchronizing the TDM Bus with interface rates from Digital Signal 1 (DS1) facilities as primary or primary and secondary references, and from Stratum 3 Clock (STRAT-3) facilities. Only the TN780 tone-clock supports a Stratum 3 clock.

Moreover, the Tone-Clock circuit pack aids in monitoring and selecting synchronization references. The Tone-Clock circuit pack, after detecting that the external source of timing is not valid, will automatically begin its escalation procedure, according to the facilities administered. In the following table, successive losses of signal cause escalation from left to right.

NOTE:
Switching back to a DS1 source is handled by synchronization maintenance, once any problems with it have been corrected and tested. However, once synchronization has been switched to the internal timing source of the master Tone-Clock circuit pack, *switching back to a Stratum 3 Clock must be initiated by a technician* after the external reference has been repaired.

Tone-Clock Role	Synchronization Facilities	Initial External Synchronization Source	Backup External Synchronization Source	Internal Source
MASTER	Stratum 3 Clock	Source "A"	Source "B"	Local oscillator
	DS1 Primary and Secondary	DS1 Primary	DS1 Secondary	
	DS1 Primary Only	DS1 Primary	None	
	No External Source	None	None	
SLAVE	PNC Duplication	Active EI	Standby EI	
	No PNC Duplication	Active EI	None	

See “Synchronization” for more details of the escalation plan. *There exists a strong interdependency among the DS1 Interface circuit pack Maintenance, Synchronization Maintenance, and TDM Bus Clock Maintenance MOs*.

See the section on “TONE-BD” for a discussion of the relationship of Tone-Clock circuit packs with the various Reliability Options.

Error Log Entries and Test to Clear Values

Table 9-689. TDM Bus Clock Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board[1]	Test to Clear Value
0[2]	0	Any	Any	Any	test tone-clock UUC sh r 1
1(a)	0	None	MINOR	OFF	
18(b)	0	busyout tone-clock UUC	WARNING	OFF	release tone-clock UUC
130(c)		None			
257(d)		None	WARNING	OFF	
513(e)	Any	Clock Circuit Status Inquiry (#148)	MINOR[3]	OFF	test tone-clock UUC
769(f)	Any	Clock Circuit Status Inquiry (#148)	MAJOR‡	ON	test tone-clock UUC sh r 10
1025(g)	Any	Clock Slip Inquiry(#149)			test tone-clock UUC sh
1281(h) 1282(h)	Any	None	MINOR	OFF	
1537	Any	Clock PPM Inquiry(#150)			test tone-clock UUC sh
2049(i)	Any	Standby Reference Health Check Test(#651)	MAJOR[3]	ON	test tone-clock UUC
2305(j)	0	None	WARNING	OFF	

1. As a general rule, any *on board* errors against the TDM Bus Clock should be resolved before pursuing any other errors against SPE or PNC components. *Off board* clock errors may be caused by other board errors, and should usually be addressed once any on board errors have been resolved.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
3. Major or Minor alarms on this MO may have been downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. The Tone-Clock circuit pack may have a clock at the edge of its specified frequency. This can cause Expansion Interface circuit packs and SNI circuit packs to go out-of-frame or report no-neighbor conditions. This can is turn cause EPNs, Expansion Archangel Links (EALs), Remote Neighbor Links (RNLs), and/or Local Neighbor Links LNLs) to go down. When this error is alarmed, Clock Health Inquiry Test (#46) will fail with an error code of 1.

   1. Replace the Tone-Clock circuit pack identified in the error log. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

b. The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock UUC** command. It only applies to systems which have the High or Critical Reliability Option administered, because only a standby Tone-Clock circuit pack may be made busy by that command. To resolve this error, execute the **release tone-clock UUC** command for the alarmed circuit pack.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

d. The Tone-Clock circuit pack in the PPN is not a TN780 while a Stratum 3 synchronization is administered. Replace the Tone-Clock in the PPN with a TN780, or change synchronization administration to Stratum 4 if a Stratum 3 clock is not being used.

e. The tone-clock has reported an out-of-lock condition. A aux value of 1 indicates this error is an out-of-lock with the primary reference. A aux value of 2 indicates this error is an out-of-lock with the secondary reference. It could not lock onto the frequency of that synchronization reference. This will lead to a change in the synchronization reference if the condition continues.

f. The Tone-Clock circuit pack may be defective, however it may be a software failure that can be corrected by testing.

1. Check to see if the board is duplicated (**list cabinet** and **status port-network**) on the affected port network.
2. If the board is not duplicated, use test tone UUCSS long to resolve the errors. The long test resets the board and is required to reload on-board RAM associated with the TN2182's DSPs. The effect is that tone detectors are taken out of service momentarily and tones are removed from the TDM bus for about 10 seconds, meaning that no dial tone or touch tones are available during this interval. This will probably not affect calls in progress, but could cause a call origination to abort or a user not to get dial tone when going off hook.
3. If all tests pass and the alarm does not resolve, retest with **test tone UUCSS long clear**.
4. If the test passes, terminate the repair process. If the test fails, replace the circuit pack at the customer's convenience.
5. If this error was logged against the standby Tone-Clock, and if the Aux Data value was 18369, SYNC (Synchronization) maintenance acts on this error. No corrective action is required. For any other Aux Data, go to the next step.
6. If the board is duplicated, switch to the standby side (**set tone**).
7. Test the alarmed board (test tone UUCSS long). This resets the board and is required to reload on-board RAM associated with the TN2182's DSPs.

8. If all tests pass and the alarm does not resolve, retest (**test tone UUCSS long clear**).
9. If the test passes, terminate the repair process. If the test fails, replace the circuit pack at the customer's convenience.

g. Tone-Clock circuit pack on-board maintenance has detected one or more *clock slips*, timing differences between its internal reference source and the synchronization signal provided by the master Tone-Clock. Although no clock slip errors are expected during normal operation, both manual and automatic interchanges of Tone-Clock circuit packs, synchronization references, and PNCs, may result in clock slip counts.

If error 1281 also is logged for the same Tone-Clock circuit pack, it is related to this problem, and should be corrected first. Otherwise, continue with the procedure below.

1. Use **test tone-clock UUC**, and examine the results of test #149 to see if slip errors are still occurring. If no new slip errors are reported, and if these errors are not causing a TDM-CLK alarm, they may be ignored. Use **test tone-clock UUC long clear** to clear the errors.
2. Otherwise, enter the **display errors** command, and follow corrective procedures for any other TDM-CLK, TONE-BD, SYNC, DS1C-BD, EXP-INTF, SNC-BD, and SNI-BD errors logged, except for those in Table 9-690.

Table 9-690. Error Log Entries for Slip Errors

Circuit Pack Name	Error Log Name	Error Log Entry for Slips
DS1 Interface	DS1-BD	3073 to 3160
Expansion Interface	EXP-INTF	2305
Switch Node Interface	SNI-BD	1537
Tone-Clock	TDM-CLK	1025
UDS1 Interface	UDS1-BD	3073 to 3160
DS1C Circuit Pack	DS1C-BD	3329

3. If 1025 errors persist, refer to SYNC Maintenance in this manual and follow the procedures in the "Approach to Troubleshooting" section.

h. Error Type 1281—This error is an indication that the Tone-Clock circuit pack has detected a loss of timing signal from the system synchronization reference. The Tone-Clock circuit pack has switched synchronization references.

1. Resolve any errors logged against the SYNC or STRAT-13 maintenance objects.

2. Refer to SYNC maintenance, in the “Approach to Troubleshooting” section, if the error is not resolved by step 1

Error Type 1282—Indicates that the TN2182 tone-clock was synchronized to a DS1 facility and that the reference frequency provided by the DS1 drifted beyond a range that could be tracked by the TN2182. Therefore the TN2182 is no longer synchronized to that DS1 reference. If a second DS1 is available, the tone-clock may be synchronized to that reference. If no secondary DS1 reference is available, the tone-clock will run off of its internal clock. This may result in slips being reported by the tone-clock and all DS1 facilities.

i. The tone-clock circuit pack in the master port network was unable to detect the incoming synchronization signal, but the other tone-clock was able to detect the references. If the aux data is 0, the problem is with the signal on the primary. If the aux data is 1, the problem is with the signal on the secondary. The system should switch clocks in this situation.

   1. If this error is against a PPN clock board and the system is using a Stratum 3 clock, check the cabling that brings the stratum 3 signal to this clock board.
   2. Replace the current standby Tone-Clock circuit pack. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

j. The indicated active Tone-Clock circuit pack, which is on a port network that does not contain the system synchronization reference (a **slave** Tone-Clock), has detected a loss of timing signal from its EXP-INTF synchronization source.

   1. Enter **display errors** and **display alarms**, and follow the associated repair procedures for EXP-INTF, TDM-CLK, and TONE-BD error log entries that have on-board alarms.
   2. If the 2305 errors persist, follow the repair procedures for EXP-INTF error log entries 257, 769, or 770, or any errors logged against SNI-BD, SNC-BD, or FIBER-LK.
   3. If the 2305 errors persist:

      a. *For Port Networks with more than one Tone-Clock circuit pack*, execute the command test synchronization r 10, and check to see if new 2305 errors against TDM-CLK were reported. If not, execute reset PNC interchange and then test synchronization r 10 again, and recheck for new 2305 errors against TDM-CLK

      b. *For Port Networks with a single Tone-Clock circuit pack*, execute the command test synchronization r 10, and check to see if new 2305 errors were reported.

   If no new instances of the 2305 errors were logged for either test, then enter **test tone-clock UUC long clear** to clear the TDM-CLK errors and the procedure is complete.

4. For Port Networks with more than one Tone-Clock circuit pack, interchange Tone-Clocks with the **set tone-clock UUC**, then run **test synchronization r 10**, and check to see if new 2305 errors are reported against the new active Tone-Clock circuit pack. If not, replace the standby Tone-Clock circuit pack. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section. If this clears the error, the problem has been resolved.
5. Replace the EI circuit pack for the active PNC. In the direct-connect case, use the **list fibers** command to identify which active EI connects with the PPN.
6. If the problem is still not cleared, and the Tone-Clock circuit pack reported in the error log has not been replaced up to now, replace it. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *SAKI Reset Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
SAKI Reset Test (#53) (a)		X		D
Clock Health Test (#46) (b)	X	X		ND
Control Channel Looparound Test (#52) (a)	X	X		ND
Tone Generator Crosstalk Test (#90) (c)		X		ND
Tone Generator Transmission Test (#40) (c)	X	X		ND
Tone Generator Audit/Update Test (#41) (c)	X	X		ND
TDM Bus Clock Circuit Status Inquiry Test (#148)	X	X		ND
TDM Bus Clock Slip Inquiry Test (#149)(e)	X	X		ND
TDM Bus Clock PPM Inquiry Test (#150)	X	X		ND
TDM Bus Clock Parameter Update Test (#151)	X	X		ND
Board Type Check Test (#574)	X	X		ND
Standby Reference Health Check Test (#651) (d)		X		ND

1. D = Destructive; ND = Nondestructive

Notes:

a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.

b. Refer to TONE-BD (Tone-Clock Circuit Pack) documentation for a description of this test.

c. Refer to TONE-PT (Tone Generator) documentation for descriptions of these tests.

d. This test only runs on the Standby Tone-Clock circuit pack in a Port Network with more than one Tone-Clock circuit pack (High or Critical Reliability Option). The circuit pack must be a TN780 code with firmware revision 2 or above, or be a TN2182.

e. Test #149 is not run on the TN2182.

TDM Bus Clock Circuit Status Inquiry Test (#148)

The TDM Bus Clock circuitry is checked for sanity. Any problems that are found are reported via error codes

Table 9-691. TEST #148 TDM Bus Clock Circuit Status Inquiry Test

Error Code	Test Result	Description/ Recommendation
None 1001	ABORT	The system could not allocate the necessary resources for the test. 1. Wait 1-minute, and retry the test.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	This error means the Tone-Clock circuit pack framing verification firmware reports an error in the clock synchronization signal coming into this Port Network. 1. If the Tone-Clock circuit pack reporting the problem is a master clock, then the system synchronization reference is providing a bad timing source. Refer to SYNC (Synchronization) or STRAT-3 (Stratum 3 Clock) Maintenance documentation to change the system synchronization reference. 2. If the Tone-Clock circuit pack is a slave clock, then the EI to which it is listening is providing a bad timing source. Follow the diagnostic procedures specified for TDM-CLK Error Code 2305. 3. If no problem can be found with the incoming synchronization signal, replace the Tone-Clock circuit pack. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.
2	FAIL	This error indicates that Tone-Clock circuit pack has inaccurately detected loss of signal on the incoming synchronization timing source.
4 or 8	FAIL	The local oscillator on the Tone-Clock circuit pack has failed.
16 or 32	FAIL	The circuitry on the Tone-Clock circuit pack used to detect synchronization timing errors has failed. 1. Errors 2, 4, 8, 16, and 32 indicate that there is poor synchronization between port networks and external facilities. It may be noticeable to the customer in the form of errors in data communications. The Tone-Clock circuit pack is defective. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

Continued on next page

Table 9-691. TEST #148 TDM Bus Clock Circuit Status Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
64	FAIL	This message is only sent when an uplink message has reported the loss of valid synchronization timing information coming into this Port Network. It has been reported in TDM-CLK Error Log entries; one or more of 1025, 1281, 1537, 2049 and 2305. 1. Resolve the errors indicated. No separate corrective action is required.
65	FAIL	The tone-clock is currently not able to lock on to the current synchronization reference. If this tone-clock is in the master port networK: 1. Examine the error log for any DS1-BD, SYNC or other TDM-CLK errors and resolve as applicable. 2. Run this test again via the test tone-clock UUC command. 3. Examine the DS1 measurements to determine if the facility is healthy. 4. Administer a new synchronization reference. 5. Replace the DS1 board currently supplying the reference. If this tone-clock is in the slave port networK: 1. Examine the error log for any SYNC, EXP-INTF or other TDM-CLK errors. 2. Run this test again via the test tone-clock UUC command.
66	FAIL	There is an on-board failure of TDM clock hardware. 1. Use **test tone UUCSS long** to resolve the problem. The long test resets the board and is required to reload on-board RAM associated with the TN2182"s DSPs. The effect is that tone detectors are taken out of service momentarily and tones are removed from the TDM bus for about 10 seconds. This means that no dial tone or touch tones are available during this interval. It probably will not affect calls in progress, but could cause a call origination to abort or a user will not get dial tone when going off hook. 2. If the test passes and the alarm does not resolve, retest (**test tone UUCSS long clear**). 3. If the test passes, terminate the repair process. If it fails, replace the circuit pack at the customer's convenience.
	PASS	TDM Bus Clock Circuit Status is sane. There are no clock-detection circuit problems on the Tone-Clock circuit pack.

TDM Bus Clock Slip Inquiry Test (#149)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack.

NOTE:
This test does not apply to the TN2182

Table 9-692. TEST #149 TDM Bus Clock Slip Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system could not allocate the necessary resources for the test.
1001	ABORT	The system could not allocate the necessary resources for the test. 1. Wait 1-minute, and retry the test.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The error code represents the number of timing slips detected on the incoming synchronization source since the last slip inquiry was sent to the Tone-Clock circuit pack. The incoming synchronization signal can be from one of four sources: 1. A Stratum 3 Clock, if that option is administered and the circuit pack tested was the active Tone-Clock in the PPN. 2. A DS1 Interface circuit pack, if DS1 Synchronization is administered, and associated with the circuit pack tested. 3. The local oscillator on the master Tone-Clock circuit pack, if it is providing the system clocking signals. 4. An EXP-INTF circuit pack, if the port network on which the test was executed does not contain the current system synchronization reference. The error code is a variable amount ranging from 1 to 255. 1. Small numbers of slips should not result in service degradation. If the error code is small (1 or 2), rerun the test. If the error only occurs infrequently, it may be ignored. 2. Otherwise, refer to the “Approach to Troubleshooting” section in the Synchronization (SYNC) Maintenance section of this manual.
	PASS	The Tone-Clock circuit pack does not detect any timing slips. This indicates that the incoming synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. The **status synchronization** command should be used to verify that the desired synchronization reference is providing timing for the system.

TDM Bus Clock PPM Inquiry Test (#150)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack.

Table 9-693. TEST #150 TDM Bus Clock PPM Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system could not allocate the necessary resources for the test.
1001	ABORT	The system could not allocate the necessary resources for the test. 1. Wait 1-minute, and retry the test.
255	ABORT	The test was not executed because the Tone-Clock circuit pack was using its local oscillator rather than synchronizing to an external source. 1. Verify that this Tone-Clock circuit pack is expected to be the synchronization source. If not, correct the synchronization information and re-execute the test.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The error code represents the rate (in Parts Per Million, or PPM) at which clock slip errors have been detected on the incoming synchronization source since the last PPM inquiry was sent to the Tone-Clock circuit pack. A failure of this test indicates that we are outside of Stratum 4 or Stratum 3 timing specifications on the incoming timing source. The error code is a variable amount ranging from 1 to 254. 1. If error 1537 is entered in the hardware error log against TDM-CLK, then the board has switched timing sources. Follow the procedures associated with hardware log error code 1537. 2. Otherwise, refer to "Approach to Troubleshooting" in the Synchronization (SYNC) Maintenance section of this manual.
	PASS	The Tone-Clock circuit pack does not detect timing any PPM errors. This indicates that the external synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. Use the **status synchronization** command to verify that the desired synchronization reference is providing timing for the system.

TDM Bus Clock Parameter Update Test (#151)

This test updates the following internal parameters on the Tone-Clock circuit pack:

- Disable in-line duplication status messages.
- Disable in-line subrate frame maintenance messages (TN768, TN780 only).
- Set the PPM threshold at 60 PPM for TN768 and TN780. Set the PPM threshold at 85 PPM for TN2182.
- Enable PPM threshold switching
- Set the number of slips to trigger *loss of signal* - currently 30 per 5 millisecond period
- Enable the on-board synchronization switching algorithm (see above)
- Enable holdover operation (TN2182 only).

This is not a test and will always pass without identifying or reporting any Tone-Clock circuit pack errors

Table 9-694. TEST #151 TDM Bus Clock Parameter Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The Tone-Clock circuit pack parameters have been successfully updated.

Board Type Check Test (#574)

This test verifies that a Tone-Clock circuit pack administered with a Stratum 3 Clock source has code TN780.

Table 9-695. TEST #574 Board Type Check Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
ANY	FAIL	Stratum 3 Clock Synchronization is administered for the carrier in which this Tone-Clock circuit pack resides, but the Tone-Clock does not have code TN780. 1. If the Stratum 3 Clock option is incorrectly administered, remove it. 2. Otherwise, replace the circuit pack. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.
	PASS	The proper (TN780) Tone-Clock circuit pack code is present for Stratum 3 Clock synchronization.

Standby Reference Health Check Test (#651)

This test evaluates the quality of the external synchronization timing source for a standby Tone-Clock circuit pack. All administered synchronization timing sources must be valid for this test to pass. If the tone-clock circuit pack and the synchronization timing sources are in different port networks, the EI circuit packs transport the timing sources to the tone-clock.

Table 9-696. TEST #651 Standby Reference Health Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	This test may already be running due to a tone-clock installation, scheduled maintenance, alarm activity, or a technician-demand test from another terminal. This abort can also occur due to an internal system error. 1. Try the command again at 1-minute intervals up to five times.
1184	ABORT	This test requires an external synchronization source to be administered (DS1 primary, DS1 primary and secondary, or Stratum 3 Clock). 1. Administer the external synchronization source and retry the test.
2500	ABORT	Internal system error 1. Try the command again at 1-minute intervals up to 5 times.
0	FAIL	The external synchronization timing source for side A of the Stratum 3 clock, or for the primary DS1 reference is either absent or invalid. The external synchronization timing source for side B of the Stratum 3 clock, or for the secondary DS1 reference is not yet tested.
1	FAIL	The external synchronization timing source for side B of the Stratum 3 clock, or for the secondary DS1 reference is either absent or invalid. 1. Correct the synchronization source problem. Refer to the Synchronization (SYNC) maintenance section of this manual. 2. If the error still exists, replace the Tone-Clock circuit pack reported in the error log. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.
	PASS	The external synchronization timing source is valid.

TDMODULE (Trunk Data Module)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TDMODULE	MIN	test port UUCSSpp |	Trunk Data Module
TDMODULE	WRN	test port UUCSSpp |	Trunk Data Module

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, and so forth).

The TDMODULE (Trunk Data Module) is covered in the PDMODULE (Data Module).

TIE-BD (Tie Trunk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run[1]	Full Name of MO
TIE-BD	MIN	test board UUCSS sh	Tie Trunk Circuit Pack
TIE-BD	WRN	test board UUCSS sh	Tie Trunk Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also TIE-TRK (Tie Trunk) Maintenance documentation for related trunk information.

TIE-DS1 (DS1 Tie Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
TIE-DS1[1]	MAJOR[2]	test trunk *grp/mbr* l[3]	DS1 Tie Trunk
TIE-DS1	MINOR	test trunk *grp/mbr* l[3]	DS1 Tie Trunk
TIE-DS1	WARNING	test trunk *grp/mbr*	DS1 Tie Trunk

1. For additional repair information, see DS1-BD documentation if the tie trunk is on a TN722 or TN767 DS1 circuit pack. See UDS1-BD documentation if the tie trunk is on a TN464C/D UDS1 circuit pack.
2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75% of the trunks in this trunk group are alarmed. For more information on the **set options** command, see Chapter 8, ''Maintenance Commands''
3. For TN767B vintage 8 or 9 circuit packs, a failure of Test #136 causes a subsequent failure of Test #7. Test #136 is part of the short sequence and generates off-board alarms Test #7 is part of the long sequence and generates on-board alarms. Before entering **busyout**, **release**, **reset** or **test board long** commands, check the vintage number of the circuit pack with **list configuration board** UUCSS. If it is TN767B vintage 8 or 9, do not use the above commands until first making sure that Test #136 passes via **test board short**. Otherwise, extraneous on-board alarms may be generated.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*, for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

The DS1 tie trunk provides both voice and data communications between two PBX switches. There are two types of DS1 interfaces:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link

  32-channel mode is supported only on TN464 circuit packs and on G3r V2 systems.

DS1 Tie Trunks are used widely in the Distributed Communications System (DCS) and Central Attendant Service (CAS) system features.

A DS1 tie trunk can also be used as an access endpoint which is a non-signaling channel with bandwidth for voice-grade data, 56 Kbps data or 64 Kbps data.

DS1 tie trunk maintenance provides a strategy to maintain a DS1 tie trunk via a port on either the TN722 or TN767 DS1 Interface circuit pack or the TN464C/D UDS1 Interface circuit pack. Throughout this TIE-DS1 section, the term DS1 Interface applies to DS1 and UDS1 circuit packs.

The DS1 tie trunk maintenance strategy covers logging DS1 tie trunk hardware errors, running tests for trunk initialization, periodic and scheduled maintenance, system technician-demanded tests, and alarm escalation and resolution. Three different trunk service states are specified in DS1 tie trunk maintenance:

Out-of-service	The trunk is deactivated and cannot be used for incoming or outgoing calls.
In-service	The trunk is activated and can be used for both incoming and outgoing calls.
Disconnect (ready-for-service)	The trunk is in an activated state but can only be used for an incoming call.

If the DS1 Interface circuit pack is out of service, then all trunks on the DS1 Interface circuit pack are also placed into the out-of-service state and a Warning alarm is raised.

Hardware Error Log Entries and Test to Clear Values

Table 9-697. DS1 Tie Trunk Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test trunk *grp*/*mbr*
1(a)	57476 57477 57485 57487				
15(b)	Any	Port Audit and Update Test (#36)			
18(c)	0	busyout trunk *grp*/*mbr*	WARNING	OFF	release trunk *grp*/*mbr*[2]
130(d)		None	WARNING	ON	test trunk *grp*/*mbr*
257(e)	57473 57474				
513(f)	57392	DS1 Tie Trunk Seizure Test (#136)	MIN/MAJ[3]		
769(g)	57393	DS1 Tie Trunk Seizure Test (#136)	MIN/MAJ[3]		

Continued on next page

Table 9-697. DS1 Tie Trunk Maintenance Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1025		DS1 Tie Trunk Seizure (Test #136)	MIN/ WRN[4]	OFF	test trunk *grp*/*mbr* r 2
1281		Conference Circuit (Test #7)	MIN/ WRN[4]	ON	test trunk *grp*/*mbr* l r 4 [2]
1537		NPE Crosstalk Test (#6)	MIN/ WRN[4]	ON	test trunk *grp*/*mbr* l r 3 [2]
1793(h)					test board UUCSS long [2]
2305(i)	50944	DS1 Tie Trunk Seizure Test (#136)	MIN/MAJ[3]	OFF	
2562(j)	16665				
2817(k)	52992				
3840(l)	Any	Port Audit and Update (Test #36)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. For TN767B vintage 8 or 9 circuit packs, a failure of Test #136 causes a subsequent failure of Test #7. Test #136 is part of the short sequence and generates off-board alarms. Test #7 is part of the long sequence and generates on-board alarms. Before entering **busyout**, **release**, **reset** or **test board long** commands, check the vintage number of the circuit pack with **list configuration board** UUCSS. If it is TN767B vintage 8 or 9, do not use the above commands until first making sure that Test #136 passes via **test board short**. Otherwise, extraneous on-board alarms may be generated.
3. This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
4. Major or Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. Error Type 1—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. This error can be caused by incompatible translations. Make sure the parameters administered on the DS1 circuit pack form match those administered on the far-end switch. See *DEFINITY Communications System Generic 3 V2 Implementation*, 555-230-653, and *DEFINITY Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT/ISDN-PRI Reference*, 555-025-107, for details.

The Aux Data field indicates the following hardware error types:

57476	On-hook before wink
57477	On-hook before ready to receive digits
57485	Wink too short for valid signal
57487	The timer expired while waiting for an off-hook signal from the far end as a response at end of digits dialing. Check the far-end switch for related problems.

If all administration errors between the switch and the far-end match, and these errors continue to recur, follow normal escalation procedures.

b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

c. Error Type 18—The DS1 tie trunk has been busied out by a **busyout trunk** grp/mbr command. No calls can be made on this trunk except for the Facility Access Test Call. Facility Access Test Calls are described in Chapter 6 and in *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*.

d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

e. Error Type 257—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. The trunk cannot communicate with the far end because it is unable to interpret digits sent from the far-end switch. The Aux Data field indicates the following:

57473	The rotary dial rate is below 8 pulses per second.
57474	The rotary dial rate is above 12 pulses per second.

Check with the far-end switch or operating company for proper trunk connection.

f. Error Type 513—DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. The trunk is in-service/active and waiting for an ‘‘on-hook’’ from the far-end switch. No calls can be routed over the trunk while it is in this state. Aux Data 57392 indicates no external release on PBX disconnect. Check with the far-end switch or operating company for proper trunk connection.

g. Error Type 769—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. This error usually occurs after an occurrence of error type 513. The trunk has received the belated ‘‘on-hook’’ that it has been waiting for from the far-end switch. The trunk is restored to in-service/idle and can be used for calls. Aux Data 57393 indicates delayed external release on PBX disconnect. This error can be ignored.

h. Error Type 1793—The DS1 Interface circuit pack is out-of-service. See the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Interface Circuit Pack) Maintenance documentation for details.

i. Error Type 2305—Reorder message. The trunk could not be seized. This error causes the Trunk Seizure Test (#136) to run and is only a problem if the Seizure Test fails (in which case Error Type 1025 also appears). In this case, the trunk may be put in ''Ready-for-Service'' state (shown as ''disconnected'' by the status command), which allows only incoming calls. Run the Trunk Seizure Test (#136) and follow its procedures.

j. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

k. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the DS1 Tie Trunk Seizure Test (#136) and follow its outlined procedures.

l. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter **status trunk** command and verify the status of the trunk. If the trunk is out-of-service, then enter **release trunk** command to put it back to in-service. Retry the test command.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 Tie Trunk Seizure Test (#136)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

For TN767B vintage 8 or 9 circuit packs, a failure of Test #136 causes a subsequent failure of Test #7. Test #136 is part of the short sequence and generates off-board alarms Test #7 is part of the long sequence and generates on-board alarms. Before entering **busyout**, **release**, **reset** or **test board long** commands, check the vintage number of the circuit pack with **list configuration board** UUCSS. If it is TN767B vintage 8 or 9, do not use the above commands until first making sure that Test #136 passes via **test board short**. Otherwise, extraneous on-board alarms may be generated.

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes on the order of 20 to 30 seconds to complete.

Table 9-698. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-698. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a user for a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1020	ABORT	The test did not run because of a previously existing error on the specific port or a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: ■ 1281—Loss of signal ■ 1793—Blue Alarm ■ 2049—Red Alarm ■ 2305—Yellow Alarm ■ 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 9-698. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	This can be due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Resolve any EXP-PN and/or EXP-INTF errors. 2. Resolve any TDM-BUS errors. 3. Resolve any TONE-BD and/or TONE-PT errors. 4. Retest when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C/D UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 9-699. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. The **status health** command can be used to determine if the system is experiencing heavy traffic. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-699. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a user for a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1018	ABORT	Test disabled via administration. This only applies to analog stations. 1. To enable test, set the Test field on the station administration screen for the particular analog station being tested to "y." Use the **change station** *extension* command.
1020	ABORT	The test did not run due to a previously existing error on the specific port or because of a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or circuit pack, and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal,1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, or 1537—Hyperactivity. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 9-699. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The NPE of the tested port did not conference the tones correctly. This can cause noisy and unreliable connections. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later. The error log may have error type 1281 entries. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the far-end PBX. Make sure that the near-end and far-end switches and any NTCE equipment (the CSUs) have the correct administration. 6. Replace the circuit pack. **NOTE:** If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 9-699. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to ensure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk kept by the DS1 Interface circuit pack and the switch software.

Table 9-700. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1006	ABORT	The test was aborted because the trunk is out of service. 1. Use the **status trunk** command to verify that the trunk is out of service. 2. If the trunk is out of service, determine why. 3. If it is OK to put the trunk back in service, issue the **release trunk** command to put the trunk back in service, and then retry the test.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-700. TEST #36 Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run but will return PASS. To verify that the trunk is in-service: 1. Enter the **status trunk** command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to step 2. 2. Enter the **release trunk** command to put the trunk back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

DS1 Tie Trunk Seizure Test (#136)

The DS1 Tie Trunk Seizure Test is run to verify the trunk's signaling capability. The test is composed of two parts. The first part queries the circuit pack for the following errors: Loss of Signal, Red Alarm, Blue Alarm, Yellow Alarm, and Hyperactivity Alarm. The second part of the test is performed by sending a seizure message to the DS1 Interface circuit pack and expecting an active reply by the DS1 Interface circuit pack. If maintenance software does not receive any reply and the timer expires, the test fails. Once the active message is received, a dial pause message is sent to the DS1 Interface circuit pack. If the DS1 Interface circuit pack replies with a dial pulse tone message when the far end responds to the seizure, then the DS1 tie trunk Seizure Test passes. If the far end does not respond to the seizure and the timer expires, and the DS1 Interface circuit pack sends a reorder message back to the maintenance software, then the test fails.

This second part of this test *cannot* be run on a trunk if one of the following cases is true:

1. The trunk direction is administered as an incoming only trunk.
2. The trunk is the 24th port on a DS1 Interface circuit pack which is administered using 24th Common Channel Signaling.
3. The trunk has been seized by a normal trunk call.
4. The trunk is administered with maintenance test disabled.
5. The outgoing signal type of the trunk is either automatic or immediate-start.
6. This test always passes if the associated board is the TN802 IP trunk circuit pack.

Table 9-701. TEST #136 DS1 Tie Trunk Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	Far end is seizing the trunk while the test is ongoing. A glare situation is detected. Current test is designed to be aborted. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Verify the following fields on the trunk group administration screen: a. Is trunk direction incoming only? b. Is trunk outgoing type either automatic or immediate-start? c. Is trunk the 24th port of the DS1 Interface circuit pack while common control channel signaling is specified? 2. If the trunk has been administered using the above information, then this test should abort.
1018	ABORT	The test was disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Administration' screen is set to 'n.' To enable the test, change the trunk administration and enter 'y' into the 'Maintenance Test' field. 2. Repeat the test.

Continued on next page

Table 9-701. TEST #136 DS1 Tie Trunk Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to an already existing error on the specific port or due to a more general circuit pack error. 1. Examine the error log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error. 2. Retry the test.
1040	ABORT	The test is invalid for this trunk port because it is administered as an access endpoint. 1. Use **display port** to verify that this port is administered as an access endpoint. In this case the test should abort.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2053	ABORT/ FAIL[1]	At least one of the following errors is found on the DS1 circuit pack: 1281: Loss of Signal 1793: Blue Alarm 2049: Red Alarm 2305: Yellow Alarm 1537: Hyperactivity 1. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD/UDS1-BD Maintenance documentation for the listed error types.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The far-end trunk did not respond to the seizure of the near-end trunk within the allowable time period. This test could have associated in-line errors in the error log. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, a failure of test 136 causes a subsequent failure of test 7 due to a firmware bug. Eventually, the board and all of its ports will be taken out of service and extraneous on-board alarms will be generated. Replace the circuit pack with a TN767C V3 or later. 2. Verify that the ’Trunk Type’ field on the ’Trunk Administration’ screen matches the trunk type administered on far-end switch. 3. Look for DS1-BD or UDS1-BD errors in the hardware error log. If present, refer to the DS1-BD (DS1 trunk circuit pack) Maintenance documentation or to the UDS1-BD (UDS1 trunk circuit pack) Maintenance documentation. 4. Retry the test at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-701. TEST #136 DS1 Tie Trunk Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	FAIL	Response to the seizure message was not received within the allowable time period. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, a failure of test 136 causes a subsequent failure of test 7 due to a firmware bug. Eventually, the board and all of its ports will be taken out of service and extraneous on-board alarms will be generated. Replace the circuit pack with a TN767C V3 or later. 2. Verify that the 'Trunk Type' field on the 'Trunk Administration' screen matches the trunk type administered on far-end switch. 3. Look for DS1-BD or UDS1-BD errors in the hardware error log. If present, refer to the DS1-BD (DS1 trunk circuit pack) Maintenance documentation or to the UDS1-BD (UDS1 trunk circuit pack) Maintenance documentation. 4. Retry the test at 1-minute intervals for a maximum of 5 times.
	PASS	The trunk can be seized for an outgoing call.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

1. Earlier G1 Software Versions reported Error Code 2053 as a FAIL

TIE-TRK (Analog Tie Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1,2]	Full Name of MO
TIE-TRK	MAJOR[3]	test port UUCSSpp l	Tie Trunk
TIE-TRK	MINOR	test port UUCSSpp l	Tie Trunk
TIE-TRK	WARNING	test port UUCSSpp sh	Tie Trunk

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).
2. If ATMS testing is enabled, check the error log for ATMS errors 3840 and 3841. If the error log indicates that measurements exceeded acceptable thresholds, and no other trouble is found with **test trunk**, run the ATMS test call with **test analog-testcall port UUCSSpp full**.
3. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

   This alarm does not apply to TN497.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY Communications System Generic 3 V2 Implementation*, 555-230-653, for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

The following circuit packs, including all suffixes such as TN760D, support analog tie trunks:

Table 9-702. Analog Tie Trunk Circuit Packs

Code	Trunk Type	Signaling Leads
TN760	4-wire	E&M
TN437	4-wire	E&M
TN439	2-wire	A&B (two-way circuits only)
TN458	4-wire	E&M
TN497	2-wire	A&B
TN2140	4-wire	E&M

Each tie trunk circuit pack occupies a port circuit pack slot and contains 4 port circuits. Each port circuit supports 1 analog tie trunk used to connect the switch to another PBX across one-way or two-way dedicated circuits (see preceding list).

A tie trunk port can also be administered as an access endpoint which is a non-signaling channel with a voice-grade data bandwidth. Tie trunk maintenance employs up to 6 tests, depending on the hardware involved, to monitor the operating condition of the trunk and its connections. These are described in the following sections on each test. The port must be idle for these tests to run. If an incoming call seizes the port while a test is in progress, the test aborts and the call proceeds (except for TN497).

Additional in-line testing is performed whenever a call is in progress, logging errors that occur during operation. You can reproduce these types of errors by making a call over the trunk and then checking the Hardware Error Log.

By making translation and cross-connect changes, circuit packs (except for TN497) can be configured for back-to-back testing, also known as connectivity testing. Port operation is tested by connecting two tie trunk ports together in either E&M or simplex modes. See the section *Analog Tie Trunk Back-to-Back Testing*.

3840(r)	8000	Transmission Tests (ATMS)(#844-848)		OFF	test analog-testcall
3841(r)		Transmission Tests (ATMS)(#844-848)	MINOR	OFF	test analog-testcall UUCSSpp r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the MINOR alarm is not downgraded by the **set options** values, then the MINOR alarm will be upgraded to a MAJOR alarm if 75% of the trunks in this trunk group are alarmed. These errors, if applicable, always log a MINOR alarm for TN439 and TN497.

Notes:

a. Digit time-out. This occurs when the far-end PBX began transmitting digits too late (10 seconds) after receiving the signal indicating ready to receive digits (if any). This can occur on an incoming immediate, wink, or delay dial line. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.

b. Rotary dial before wink. This occurs when the far-end PBX starts dialing before the PBX sends the wink on a wink-start or delay-dial trunk. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.

c. Rotary dial too early. This occurs when the far-end PBX starts dialing too soon (about 50ms) after seizure on a wink start or delay dial line. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.

d. On hook before wink. This occurs when the far end goes on hook before a wink. Check the far-end PBX to ensure a translation match at both ends. This error applies only to TN439.

e. On an outgoing wink-start or delay-dial trunk, the wink time was too short (less than 80ms) for a valid signal. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.

f. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

g. This indicates that the trunk in question has been busied-out by maintenance personnel.

h. The circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack. TN439 does not alarm this error. This error does not apply to TN497.

i. The rotary dial rate was too slow — less than 8 pulses per second. Check the far-end PBX to ensure a translation match at both ends.

j. The rotary dial rate was too fast — above 12 pulses per second. Check the far-end PBX to ensure a translation match at both ends.

k. The time between digits was too short (less than 300ms). Check the far-end PBX to ensure a translation match at both ends.

l. These errors do not apply to TN439 and TN497.

m. This indicates that the trunk is still seized with an incoming call. The far-end PBX is not releasing the trunk after the call was dropped. Check the far-end PBX for problems.

   Once the trunk is released from the call, the severity of this problem is decreased. If Error Type 1025 does not appear again, this means that the problem has been corrected. Verify that Error Type 1025 does not reappear in the Error Log.

n. Reorder message. The trunk could not be seized. This error causes the Tie Trunk Seizure Test (#73) to run and is considered a problem only if that test fails, logging error 1793. In this case, the trunk may be placed in the ready-for-service state, allowing only incoming calls. This service state shows up as `disconnected` on the trunk status screen. Run the Tie Trunk Seizure Test and follow recommended procedures.

   TN439 logs aux data 57424 or 50944. Other circuit packs log 50944. This error is associated with Test #747 for TN439, Test #73 for TN497, and no test for the others.

o. These errors apply only to TN497.

p. Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

q. Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the Tie Trunk Seizure Test (#73) and follow its outlined procedures.

r. Error 3841 indicates that test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements in the unacceptable range. Error 3840 indicates measurements were in the marginal range. Use **list testcall detail** to examine the specific transmission parameters which are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, then the AMTS thresholds administered on page 4 of the trunk group form should be changed.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in Table 9-704 when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-704. System Technician-Demanded Tests: TIE-TRK

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Looparound and Conference Circuit Test (#33)		X	ND
Tie Trunk Seizure Test (#73)	X	X	ND
Dial Test #747	X	X	ND
Tie Trunk EPF Test (#74)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND
Transmission Test - ATMS (#844-848)	[2]	†	ND

1. D = Destructive, ND = Non-destructive
2. ATMS tests are not part of either sequence. They are run either on demand with **test analog-testcall**, or by the ATMS schedule.

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that a port's NPE channel talks on the time slot assigned to it and does not cross over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. The test takes 20 to 30 seconds to complete.

Table 9-705. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The trunk may be busy with a valid call. Use the **display trunk xx** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active, but the port is not in use (no connected ports), then check the Error Log for Error Type 1025 (see Error Log table for description of this error and required actions). The port may be locked up. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-705. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Resolve any EXP-PN and/or EXP-INTF errors. i 2. Resolve any TDM-BUS errors. 3. Resolve any TONE-BD and/or TONE-PT errors. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Looparound and Conference Circuit Test (#33)

This test verifies signal transmission and conferencing capabilities of a port using 404-Hz, 1004-Hz, and 2804-Hz tones. This is an on-board test only: each tone is transmitted to and looped around within the port and then returned.

This test can fail due to noise induced by adjacent electric power lines. If this is the case, the customer must resolve it with their local power company. To temporarily alleviate an alarm caused by failure of this test, you can disable it via the `Test` field on the trunk administration form.

Table 9-706. TEST #33 Looparound and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
7	ABORT	The conference circuit test was aborted. 1. Retry the command at 1-minute intervals a maximum of 5 times.
129	ABORT	The 404-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
131		The 1004-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
133		The 2804-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The trunk may be busy with a valid call. Use the **display trunk xx** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active, but the port is not in use (no calls), then check the Error Log for Error Type 1025 (see Error Log table for description of this error and required actions). The port may be locked up. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-706. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized force. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting.
1018	ABORT	The test has been disabled via administration. Verify that the 'Maintenance Test' field on the 'Trunk Group' form is set to 'n.' To enable the test, issue the 'change trunk-group x' command (x equals the number of the trunk group to be tested). Then, change the entry in the 'Maintenance Test' field on the form to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
7, 129, 131, or	FAIL	The conference capabilities of the port failed (Error Code 7). The reflective 404-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 129). The reflective 1004-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 131).

Continued on next page

Table 9-706. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
133		The reflective 2804-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 133). FAULT ISOLATION: Proceed as follows unless power or tone problems are suspected (see notes on the next page). 1. To make sure the problem is on-board, disconnect the port from the CO and retry the test. Coordinate this with the CO, or do it after busy hours; otherwise, the CO may put the connection out of service. 2. If the retry fails, replace the circuit pack. 3. If the retry passes and no troubles have been reported, disable the test. If the retry passes and troubles have been reported, refer the problem to the CO. *More information continues on the next page.*
7, 129, 131, or 133 *(cont'd .)*	FAIL *(cont'd.)*	**NOTE:** If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see FAULT ISOLATION above.
	PASS	Tie trunk Looparound and Conference Test is successful. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port.

Continued on next page

Table 9-706. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Audit Update Test (#36)

This test sends to the circuit pack updates of translations for all administered ports on the circuit pack. It is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response is expected from the circuit pack. Port translation data includes:

- Start type: immediate, automatic, wink-start, or delay dial
- Rotary or DTMF senderization in or out
- Disconnect timing: 10 to 2550ms in 10ms increments
- DMTF time slot
- Continuous-seize-ack? (TN2140

Table 9-707. TEST #36 Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-707. TEST #36 Audit Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. If the trunk is busied out, the test will not run, but will return PASS (except on TN439 and TN497). 1. If signaling troubles are reported, verify translation information for this port. 2. To verify that the trunk is in-service, enter **status trunk** command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 3. Enter **release trunk** command to put trunk back into in-service. 4. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Tie Trunk Seizure Test (#73) and Tie Trunk Dial Test (#747)

For wink-start, delay-dial and TN2140 (cont-seize-ack or discont-seize-ack) trunks, this test activates the M lead and checks for a response from the far end within 10 seconds.

For TN497, the test seizes a trunk and outpulses a pause. The port reports uplink the result of the seizure. This test can be disabled via the `Test` field on the trunk group administration form.

For TN439, Test #747 is run instead of #73. This test seizes a trunk and outpulses a pause digit. This test aborts on ports administered as access endpoints.

Table 9-708. TEST #73,#747 Tie Trunk Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The trunk may be busy with a valid call. Use the **display trunk xx** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active, but the port is not in use (no calls), then check the Error Log for Error Type 1025 (see Error Log table for description of this error and required actions). The port may be locked up. The far-end PBX may not be releasing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	This test is not valid for this trunk translation. Must be a wink-start or delay dial trunk and must be outgoing or two-way for this test to run. For the TN2140, the trunk must also be continuous-seize-ack or discontinuous-seize-ack. 1. Check trunk translation. If it is not a wink-start or delay dial trunk, this abort message should be ignored.
1018	ABORT	Test disabled via administration. 1. Verify that the ‘‘Maintenance Tests?’’ field on the Trunk Group Form is set to "n". To enable the test, issue the **change trunk-group x** command where ‘‘x’’ equals the number of the trunk group to be tested. Then change the entry in the ‘‘Maintenance Tests?’’ field on the form to “y.”
1040	ABORT	This test is not performed for trunk ports administered as access endpoints. 1. Verify this port is an access endpoint by using the **display port** command. 2. If the port has been administered as an access endpoint, then this test should abort.
2100	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-708. TEST #73,#747 Tie Trunk Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	No dial tone detected from the other end. (TN439 circuit packs only.) 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to fail, check the far-end PBX to ensure a translation match at both ends. 3. Check the facility.
2000	FAIL	Seizure message is not received back within 10 seconds. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, check the far-end PBX to ensure a translation match at both ends. 3. Check the facility.
	PASS	The Tie Trunk Seizure Test passes. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port, wiring, and stations.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Tie Trunk EPF Test (#74)

The first part of this test checks for proper activation and deactivation of the port's E lead. The second part checks the M lead electronic power feed current flow.

Table 9-709. TEST #74 Tie Trunk EPF Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The trunk may be busy with a valid call. Use the **display trunk xx** to determine trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active, but the port is not in use (no calls), then check the Error Log for Error Type 1025 (see Error Log table for description of this error and required actions). The port may be locked up. The far-end PBX may not be releasing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	This test is not valid for this trunk translation. Must be a type-1 standard trunk for this test to run. 1. Check trunk configuration. If it is not a type-1 standard trunk, this abort message should be ignored.
1014	ABORT	The test was aborted because the circuit pack has not been inserted into the system. 1. Use the **list configuration board** command to make sure the circuit pack is inserted in the carrier. 2. If the board is not inserted, make sure the circuit pack is inserted in the carrier and fully seated.

Continued on next page

Table 9-709. TEST #74 Tie Trunk EPF Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1040	ABORT	This test is not performed for trunk ports administered as access endpoints. 1. Verify this port is an access endpoint by using the **display port** command. 2. If the port has been administered as an access endpoint, then this test should abort.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	The E lead test failed due to an on-board port problem. 1. Replace the circuit pack.
2	FAIL	The M lead test failed. The EPF has experienced an overcurrent condition, perhaps due to the external M lead. 1. To make sure the problem is on-board, disconnect the facility from the pack and retry the test. 2. If the test fails, replace the circuit pack. Otherwise, check the external wiring toward the far-end PBX.
	PASS	Tie Trunk EPF test is successful. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Transmission Test (#844-848)

This test is non-destructive.

NOTE:
Tests #844-848 are not supported on a International switch.

These tests are run by the Automatic Transmission Measurement System (ATMS). They are not part of the long or short trunk test sequences. Instead, they are run on demand with the **test analog-testcall** command or as part of ATMS scheduled testing. For more information, see "Automatic Transmission Measurement System (ATMS)" in Chapter 6.

The test call is run from an analog port on a TN771 Maintenance/Test circuit pack. It attempts to seize a port and make a call to a terminating test line (TTL) on the trunk's far end. Transmission performance measurements are made and compared to administered thresholds. Errors are generated when results fall outside of "marginal" or "unacceptable" thresholds. Detail and summary measurement reports are obtainable via the **list testcalls** command.

Table 9-710. TEST #844-848 Transmission Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the trunk group/member number of the port. Use the "status trunk" command to determine the service state of the port. If the service state indicates that the port is in use, then the port unavailable for this test. (Refer to section on "status" commands for a full description all possible states). You must wait until the port is idle before retesting. 2. If the port status is idle, then retry the command at 1-minute intervals for a maximum of 5 retries.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM bus errors. 1. If system has no TDM bus errors and is not handling heavy traffic, repeat test at 1-minute intervals for a maximum of 5 retries.
1004	ABORT	The port has been seized by a user for a valid call. Use status trunk to determine when the port is available for testing. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.

Continued on next page

Table 9-710. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1005	ABORT	Trunk has been administered as incoming-only; transmission tests can only be run on outgoing trunks.
1115	ABORT	The near end test line on the TN771 circuit pack could not be allocated. 1. Verify that the TN771 circuit pack is in service and that port 1 is administered and in service with the **status port** command. 2. Retry the command at 1-minute intervals for a maximum of 5 retries.
1900	ABORT	The test completion message was not received from the TN771 circuit pack. 1. Test the TN771 circuit packs.
1901	ABORT	This error occurs when the TN771 circuit pack uplinks a message that is not the proper response for this test. The anticipated uplink messages are seize, ring or answer. 1. Verify that the Trunk is administered properly.
1905	ABORT	Intercept tone detected from far end. 1. Get the test line data and verify it with the far end. Dial the test number manually to see if the TTL is reached. If it is not, then either the number is wrong, or the far end is administered incorrectly.
1906	ABORT	Reorder tone detected from far end. 1. See actions for error code 1905.
1907	ABORT	Other unexpected tone detected from far end. 1. See actions for error code 1905.
1913	ABORT	Audible Ring detected from far end. 1. See actions for error code 1905.
1914	ABORT	Unidentified interrupted tone detected from far end. 1. See actions for error code 1905
1915	ABORT	Busy tone detected from far end. 1. Since the test line at the far end was busy. Try the test again. 2. If the test continues to abort, the problem is with the far end system.
1918	ABORT	Test progress tone not removed from far end (type 105 test line only). 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1919	ABORT	Unexpected far end release 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).

Continued on next page

Table 9-710. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1920	ABORT	No response from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1921	ABORT	No data returned from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1922	ABORT	Steady, unidentifiable tone from far end 1. See actions for error code 1905.
1923	ABORT	Broadband energy detected from far end (such as voice or announcement). 1. See actions for error code 1905.
1924	ABORT	No test tone from far end 1. See actions for error code 1905.
1938	ABORT	Near-end self test failed. 1. Test the TN771 circuit packs.
1939	ABORT	Loss self check at 0dBm at 1004 Hz failed. 1. Test the TN771 circuit packs.
1940	ABORT	Far end noise self check failed. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1941	ABORT	High frequency singing return loss self check failed. 1. Test the TN771 circuit packs.
1942	ABORT	Echo return loss self check failed. 1. Test the TN771 circuit packs.
1943	ABORT	Singing return loss self check failed. 1. Test the TN771 circuit packs.
1944	ABORT	Loss self check at -16 dBm at 1004 Hz failed. 1. Test the TN771 circuit packs
1945	ABORT	Loss self check at -16 dBm at 404 Hz failed. 1. Test the TN771 circuit packs.
1946	ABORT	Loss self check at -16 dBm at 2804 Hz failed. 1. Test the TN771 circuit packs.

Continued on next page

Table 9-710. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1947	ABORT	Noise with tone self check failed. 1. Test the TN771 circuit packs.
2000	ABORT	The test timed out while waiting for a response from the TN771 circuit pack. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2012	ABORT	An internal software error occurred. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2053	ABORT	The test call could not be established, but no information on why is available. 1. Retry the command at 1-minute intervals for a maximum of 5 retries.
2056	ABORT	An error occurred while trying to obtain results from the TN771 circuit pack. 1. Test the TN771 circuit packs.
	FAIL	Measured transmission performance was in the unacceptable range as administered on the trunk group form. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form. Besides the facility, test failures can be caused by faulty test lines or switch paths. If the measurements point to a facility problem, report the results to the trunk vendor.
8000	FAIL	Measured transmission performance was in the marginal range as administered on the trunk group form. This generally means that the trunk is usable but has an undesirable amount of noise or loss. If the user does not report unacceptable effects, it may not be necessary to take any action. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form.

TIME-DAY (Time of Day)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run	Full Name of MO
TIME-DAY	MINOR	set time	Time of Day

The time of day contains the current year, month, day of the week, day of the month, hour, minute, and second. The Time of Day maintenance object is responsible for monitoring the time-of-day clock and raising an alarm if the time-of-day clock is not set or cannot be read by the software. If the time-of-day clock is not set or cannot be read by the software, many features such as Time-of-Day Routing, CDR, ISDN Call-by-Call, Duplication, and so on will be either inoperative or incorrect. The time-of-day clock should be set using the **set time** command whenever the system is initially powered up or the TN1648 SYSAM circuit pack is replaced.

The time-of-day clock can be read with the **display time** command and set via the **set time** command. The time-of-day clock resides on the TN1648 SYSAM circuit pack and has a backup battery to save the time of day during power failures. If the TN1648 SYSAM circuit pack is physically removed from the carrier, the contents of the time-of-day clock is lost and the time of day must be set when the TN1648 SYSAM circuit pack is re-inserted.

Error Log Entries and Test to Clear Values

Table 9-711. Time of Day Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	display time
247[1]	0	none	MINOR	OFF	set time

1. This error indicates that software cannot read the time-of-day clock on the TN1648 SYSAM circuit pack. During this condition, all time stamps on Alarm Log entries, Hardware Error Log entries, and Software Error Log entries are potentially inaccurate. In addition, any features that are sensitive to the time of day (such as SMDR, Time-of-Day Routing, ISDN Call-by-Call) will not function correctly.

To resolve the alarm, do the following:

1. Use the **set time** command to set the time of day.
2. Use the **display time** command to display the time of day. If the time of day is displayed correctly, wait 15 minutes and verify that the alarm is retired. If the alarm has not been retired, continue with Step 3.
3. Test the active TN1648 SYSAM circuit pack using the **test maintenance [a | b] sh** command. If any tests fail, refer to the repair procedures for the SYSAM circuit pack before further investigating time-of-day problems. If all tests PASS and the alarm has not been retired, proceed to Step 4.
4. Replace the active TN1648 SYSAM circuit pack must be replaced. See "Replacing SPE Circuit Packs" in Chapter 5. The alarm should be resolved within 15 minutes of replacing the SYSAM and resetting the time with **set time**.

TONE-BD (Tone-Clock Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
TONE-BD	MAJOR	test tone-clock UUC short	Tone-Clock Circuit Pack
TONE-BD	MINOR	test tone-clock UUC short	Tone-Clock Circuit Pack
TONE-BD	WARNING	release tone-clock UUC	Tone-Clock Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E).

The Tone-Clock circuit packs house two independent components. The tone generator provides all the tones needed by the system, and the clock generates the system clocks for the Time Division Multiplex (TDM) Bus and the LAN Bus, and aids in monitoring and selecting internal synchronization references.

When resolving errors/alarms on the Tone-Clock circuit pack, the following sections should also be consulted:

- Use the **set tone-clock PC** command to establish the tone and synchronization resources for the system.
- TONE-PT (Tone Generator)
- TDM-CLK (TDM Bus Clock)
- SYNC (Synchronization)

The TN2182 is a combined Tone-Clock-Detector circuit pack which contains a third independent function not available on the TN768 or TN780. The TN2182 contains 8 ports used for all-purpose tone detection. These ports are called Enhanced Tone Receiver ports (ETR-PT) and are described in the documentation for ETR-PT.

Tone-Clock Circuit Packs and System Reliability Options

The following sections describe the relationship between the various System Reliability Options and Tone-Clock circuit pack configurations.

Standard Reliability Option

Systems with the Standard Reliability Option (no duplication options) have one Tone-Clock circuit pack in each port network (PPN and EPN). For the PPN or the first EPN of a cabinet this is in the A carrier. Cabinets containing a second EPN will also have a Tone-Clock circuit pack in the E carrier. This Tone-Clock circuit pack generates clocks and provides system tones for all carriers of the port network it resides on.

High Reliability Option

Systems with the High Reliability Option (duplicated SPE, simplex PNC) have one Tone-Clock circuit pack in each PPN control carrier, A and B. One Tone-Clock circuit pack will be actively generating system clock signals for PPN components, while the other will be in standby mode, ready to take over in the event of a Tone-Clock interchange. Similarly, one Tone-Clock circuit pack will be actively providing system tones for the PPN, while the other will be in standby mode. Normally, the same Tone-Clock circuit pack will be active for both tones and clock signals, but these responsibilities may be divided if neither circuit pack is able to perform both functions. The **status port-network** PN# command will indicate which Tone-Clock circuit pack is actively performing each function.

For systems using the TN2182 Tone-Clock-Detector circuit pack, tone generation and clock generation behaves the same as other clock boards with one being active and one being standby. But the tone detector ports (ETR-PTs) of the TN2182 are always considered available and in-service regardless of the active/standby state of the tones or clock for a specific circuit pack.

EPN Tone-Clock circuit pack configuration is the same as for the Standard Reliability Option. Each EPN Tone-Clock circuit pack will be active for both tones and clock signals for its port network.

Critical Reliability Option

Systems with the Critical Reliability Option (SPE duplication and PNC duplication) have two Tone-Clock circuit packs associated with the PPN, as in the High Reliability Option case, and two more Tone-Clock circuit packs for each EPN. For the first EPN in a cabinet, these are in carriers A and B; for the second EPN, where configured, they are in carriers D and E. As in the previous case, one Tone-Clock in each Port Network is active, supplying system clocks and tones, and the other is in standby mode.

Tone-Clock Interchange Strategy

Tone-Clock circuit pack interchanges are controlled both by manual intervention and by maintenance software strategies.

The manual interchange strategy for Tone-Clock circuit packs differs slightly between the PPN and any EPNs on a system.

Manual PPN Tone-Clock Interchange

In a PPN with more than one Tone-Clock circuit pack, the intention is to assure that the one considered most healthy is active at any given time. *This is independent of the SPE Duplication strategy*, in the sense that the active Tone-Clock circuit pack need not change with an interchange of SPE carriers. Rather, except for the effect of the manual intervention discussed earlier, Tone-Clock interchanges occur only as a result of changes in the health of Tone-Clock circuit packs, as perceived by maintenance software. When both Tone-Clock circuit packs are equally healthy, no preference is given to one over the other, regardless of which SPE carrier is active.

It is possible to manually control Tone-Clock interchanges in three ways.

1. The **standby** Tone-Clock circuit pack may be made unavailable for most purposes by using the **busyout tone-clock UUC** command. Such a Tone-Clock may not be selected with console commands, nor with normal maintenance software activities, until it has been made available again with the **restore tone-clock UUC** command.

   NOTE:
   busyout tone-clock is not allowed for active Tone-Clock circuit packs.

2. The SPE processor lock switches may be used to force a particular SPE to be active. *This method overrides all other Tone-Clock interchange controls*. If there is a Tone-Clock circuit pack in the same carrier as the active SPE, it will become active, regardless of its health. If the Tone-Clock circuit pack in the selected SPE was in the *busyout* state (see item 1 above), it will automatically be released and made active. While the lock switches are set for a particular carrier, *no manual intervention or software error detection* will cause an interchange of Tone-Clocks; the Tone-Clock circuit pack in the standby SPE carrier can never become active. If there is no Tone-Clock circuit pack in the selected SPE at the time the switches are set, but one is later installed, the system will interchange to it regardless of its health. If the Tone-Clock circuit pack is removed from an SPE while the switches are set, *no interchange will occur*; the system will have no active tone-clock. When the lock switches are restored to the neutral position, a tone clock interchange will occur only if the standby Tone-Clock circuit pack is healthier than the active one.

3. A particular Tone-Clock circuit pack can be made active by issuing the **set tone-clock UUC [override]** command. If the Tone-Clock to be made active is less healthy than the currently active one, no interchange will occur unless the **override** option is specified; without it a message will inform the user that it is required.

   Once a Tone-Clock circuit pack is made active by the **set tone-clock UUC** command, it will stay active until either the **set tone-clock UUC** command is issued again to make the other circuit pack active, or until a fault occurs in the active Tone-Clock circuit pack, which causes the system to interchange Tone-Clocks.

Manual EPN Tone-Clock Interchange

In an EPN with duplicated Tone-Clock circuit packs, one circuit pack is always *preferred* over the other. For the first Port Network in a cabinet, this is the Tone-Clock circuit pack in carrier **A**. If a second Port Network is configured in a cabinet, its preferred Tone-Clock is the one in carrier **E**. The intention is that the preferred circuit pack be active whenever it is healthy. Once a failing preferred Tone-Clock circuit pack has been replaced or repaired, the system will make it active as soon as possible.

Control over interchanges for an EPN is accomplished in essentially the same ways as items 1 and 3 in the PPN case above. In addition, when the non-preferred Tone-Clock circuit pack in an EPN is active, and the preferred circuit pack is repaired and proven capable of filling its roles, the system will automatically interchange back to it as soon as possible.

Software Maintenance Interchange

Interchanges may be instigated by software Tone-Clock maintenance in two ways.

1. A scheduled Tone-Clock circuit pack interchange occurs according to the parameters set by the **change system-parameters maintenance** command. This can be disabled or set to run weekly, but the standard (default) situation is for it to occur daily, at the time specified in the system-parameters list for scheduled maintenance to begin. This interchange will be blocked if the lock switches are set, if the non-preferred Tone-Clock circuit pack in an EPN has been selected with the **set tone-clock** command, if the standby Tone-Clock has been set to the busyout state, or if the clock generation capability of the standby Tone-Clock circuit pack is known to be impaired. When this scheduled interchange occurs, the standby Tone-Clock circuit pack becomes active for a period of 20 seconds to test its ability to generate clock signals, and then is returned to standby mode.
2. Unscheduled interchanges occur when on-board Tone-Clock circuit pack maintenance, or ongoing switch maintenance tests of **TONE-BD, TONE-PT**, or **TDM-CLK** uncover failures serious enough to raise any MAJOR or MINOR alarm against the active Tone-Clock circuit pack.

International Settings [G3r V2]

The TN780 Tone-Clock circuit pack uses three firmware configuration parameters for international support [G3r V2]. The following two are automatically set by the software load for the targeted country:

- The circuit pack's country-code (USA, ITALY, AUSTRALIA, etc.)
- The circuit pack's companding mode (mu-Law or A-Law)

The third configuration parameter is used only for Italy (country code: ITALY), and selects whether *new* versus *old* ISPT (Istituto Superiore Poste Telegrafi) tones will be used for dial and confirmation tones. Values for dial confirmation tone can be set independently on the **change system-parameters miscellaneous** form. Whenever such changes are made, the effects are immediately enforced on all TN780 Tone-Clock circuit packs without disrupting tone or timing services.

Tone	New ISPT Value(default)	Old ISPT Value
Dial	continuous	cadenced
Confirmation	cadenced	continuous

In addition the TN780 allows customization of up to six system tones in order to meet specific country needs. These changes are made via the **change system-parameters country-options** form.

The TN2182 allows the same internation changes as the TN780 but allows the customization of up to 24 system tones in order to meet specific country needs. These changes are made via the **change system-parameters country-options** form.

How to Replace the Tone-Clock Circuit Pack

Replacing the Tone-Clock circuit pack is a service-disrupting procedure on Port Networks with a single Tone-Clock, because the Tone-Clock circuit pack is always needed to generate clocks for its network. For EPN Tone-Clock replacement where no second Tone-Clock circuit pack exists, only that EPN is affected. When the circuit pack is removed, all calls are dropped immediately, the EPN enters emergency transfer within one minute, and no calls can be set up from or to that EPN. However, if the PPN Tone-Clock is removed for replacement in a Standard Reliability Option system, the System Emergency Transfer feature is activated within milliseconds, and the entire system is disrupted; no calls can be placed, and existing calls are dropped.

When replacing the Tone-Clock circuit pack, always make sure to replace it with the appropriate Tone-Clock circuit pack for the system. Three circuit pack codes are supported by G3r systems:

TN768	This is the general purpose Tone-Clock circuit pack for port networks on a G3r switch. It can be used in every situation except as the Master Tone-Clock circuit pack when a Stratum 3 Clock is administered.
TN780	The Stratum 3 Clock feature requires the use of this circuit pack code for the PPN (in both carriers of High and Critical Reliability systems). The Stratum 3 Clock will operate only with this code as the Master Tone-Clock circuit pack. The TN780 circuit pack is upward compatible with the TN768 code, and can be used in any place a TN768 would be allowed. The TN780 is used in many countries outside the U.S. where the TN768 does not provide local tones.
TN2182	This Tone-Clock-Detector may be used anywhere a TN768 or TN780 is used with the exception of configurations requiring Stratum 3 Clock. The TN2182 may be used in all country configurations.

Port Networks with a Single Tone-Clock Circuit Pack:

This procedure is destructive.

1. Pull out the defective Tone-Clock circuit pack. This will remove the clocks and cause the system to activate emergency measures:
   - For the PPN Tone-Clock, the system will immediately go into the Emergency Transfer state.
   - For an EPN Tone-Clock, all calls to and from the EPN will drop and the EPN will activate Emergency Transfer within about one minute, but the rest of the system should operate normally.
2. Insert a new Tone-Clock circuit pack. The system will detect the return of the clocks and will automatically recover as follows:
   - If the Tone-Clock circuit pack being replaced is in the Processor Port Network, the system will perform a **reset system 2 (system cold 2 restart)** automatically. First, all red LEDs of the PPN will come on and off within 30 seconds. Then, all red LEDs of any Expansion Port Networks will come on and go off within the next 30 seconds.
   - If the Tone-Clock circuit pack being replaced is in an Expansion Port Network, the system will reset the EPN **(EPN cold restart)** and all the red LEDs of the EPN will come on and go off within 30 seconds.
3. If the red LEDs come on but do not go off within 30 seconds, pull the circuit pack out and reseat it. If the LEDs perform as expected this time, continue with step 6. Otherwise, there may be a problem with the TDM Bus; possibly a bent pin in the Tone-Clock circuit pack slot. Follow the directions in the TDM-BUS maintenance section.
4. If the red LEDs did light, as explained above, then go to Step 6. If the red LEDs do NOT light, as explained above, then go on to Step 5.

5. Restart the affected Port Network:
   - In the PPN, restart the system via the **reset system 2** command.
   - In an EPN, restart the EPN by resetting its Expansion Interface circuit pack via the **reset port-network PN# 2** command, using the Port Network number of the affected EPN. (Use the **list cabinet** UU command to determine the Port Network number for a given cabinet and carrier.)
6. Test the new Tone-Clock circuit pack to verify that it is functioning properly, using the **test tone-clock UUC long** command, and verify that the system is operational by placing several phone calls. Where possible, try calls into, out from, and within the affected Port Network.

Port Networks with Two Tone-Clock Circuit Packs:

Table 9-712. LED Condition/Tone-Clock Circuit States (Two Tone-Clock Pack)

Condition	Tone-Clock Circuit State	Explanation
flashing yellow 2.7 seconds on .3 seconds off	active	An external timing source is being used as a synchronization reference[1].
flashing yellow .3 seconds on 2.7 seconds off	active	The local oscillator on the Tone-Clock circuit pack is being used as a synchronization reference.
yellow on continuously	active	The circuit pack has been reset but has not been told which synchronization source to use.
yellow LED off	standby	The circuit pack is in standby mode, (neither generating tones nor supplying clocks).
"jingle bells" green and yellow .1 sec on, .2 sec off, .1 sec on, .4 sec off, .4 sec on, .4 sec off	standby	Maintenance software is testing the standby circuit pack (the standby Tone-Clock is providing tones).

Continued on next page

Table 9-712. LED Condition/Tone-Clock Circuit States (Two Tone-Clock Pack) — *Continued*

Condition	Tone-Clock Circuit State	Explanation
"double blink" yellow .3 sec on, .3 sec off, .3 sec on, 2.4 sec off,	active	TN2182 has lost all external references and is in holdover mode.
other green and yellow patterns	active	Maintenance software is testing the active circuit pack.
random yellow	standby	If the circuit pack is a TN2182, the yellow LED may come on and off intermittently as ETR-PTs on the board are used for tone detection services.

1. For a Tone-Clock in the master port network, the external source is the primary or secondary DS1 source, or a Stratum 3 clock. For a Tone-Clock in a slave port network, the external source is the Expansion Interface circuit pack.

1. Use the **list cabinet** command to determine the Port Network number of the cabinet and carrier containing the Tone-Clock circuit pack to be replaced. If both Tone-Clock circuit packs in a Port Network need to be replaced, first replace and test the one that is in standby mode. Make sure that it is healthy and active before replacing the second one. Make sure the Tone-Clock circuit pack to be replaced is in Standby Mode by displaying its status via the **status port-network** command or making sure its yellow LED is off.

   The active/standby state of a Tone-Clock circuit pack may also be determined by looking at its LED. A continuously lit red LED on the Tone-Clock circuit pack indicates a reported fault on one or more of the maintenance objects on the circuit pack. Flashing patterns of the yellow and green LEDs correspond to the following service states:

2. If the Tone-Clock circuit pack to be replaced is active, then switch to the other Tone-Clock circuit pack by doing the following:
   - **set tone-clock UUC**—Where UUC is the Standby Tone-Clock circuit pack.

     NOTE:
     When Port Network Connectivity Duplication is active, the system generally expects an EPN to have its "preferred" Tone-Clock circuit pack active. For the first Port Network in a given cabinet, this is carrier A. For a second PN in a given cabinet this is carrier E. There is no "preferred" tone clock for the PPN, regardless of reliability options.

   - **status system**—Verify the Tone-Clock circuit pack switched to the other Tone-Clock circuit pack or check the LEDs. The yellow LED of the new Standby Tone-Clock circuit pack should be off (provided maintenance is not running on it) and the yellow LED of the active Tone-Clock circuit pack should be blinking.
   - If the interchange was not successful, the standby Tone-Clock circuit pack may be defective. In particular, if the error message "must use override" is displayed, fix the standby Tone-Clock circuit pack before attempting to replace the active one.
3. If the Tone-Clock circuit pack to be replaced is in the PPN, it is recommended, but not required, that the SPE carrier containing it be locked in standby mode by executing an interchange if necessary, and locking the SPE-Select switches. This protects you from disrupting service in case of inadvertent errors in replacing the circuit pack. See "Repairing SPE Components" in Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’.

   NOTE:
   If the SPE-Select switches are locked, be sure to release them at the conclusion of the replacement procedure.

4. Pull out the defective Tone-Clock circuit pack. No calls should be affected. If this is a TN2182 circuit pack, some ETR-PTs may be in use and removal of the pack will affect some individual users. It may be less disruptive to busyout the standby TN2182 before removing it.
5. Insert a new Tone-Clock circuit pack of the appropriate code in the same slot where the defective Tone-Clock circuit pack was removed.
6. Test the new Tone-Clock circuit pack via the **test tone-clock UUC long** command to make sure it is functioning properly. If the Tone-Clock circuit pack is being replaced due to loss of c locks, the Clock Health Inquiry (#46) will still report a failure, proceed with the next step.

7. To verify that the new Tone-Clock circuit pack can generate clocks for the system, switch to the new Tone-Clock with **set tone-clock UUC override**, and execute **test tone-clock UUC**. (In a PPN, the SPE-Select switches must be in the auto position.)

   ⚠ **CAUTION:**

   If the new Tone-Clock circuit pack is not able to generate system clocks, this procedure becomes destructive. The system will detect a loss of clock and recover accordingly.

   In this case if the Tone-Clock circuit pack being replaced is in the PPN the system will perform a reset system 2 (cold 2 restart) automatically. If the Tone-Clock circuit pack being replaced is in an EPN, the system will reset the EPN (EPN cold restart). After either type of restart, the faulty Tone-Clock circuit pack will be in standby mode.

   If the new Tone-Clock circuit pack is able to generate system clocks, there will be no system disruption.

8. Place several phone calls.

9. After replacing a Tone-Clock circuit pack in an SPE, if the SPE lock switches were set during the procedure, they should be released. Additionally, after repairs in an EPN, the **set tone-clock UUC** command should be used if required to make the preferred Tone-Clock circuit pack active.

Error Log Entries and Test to Clear Values

Table 9-713. Tone-Clock Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test tone-clock PC sh
1(a)	0	Circuit pack removed or SAKI Sanity Test (#53)	MINOR	ON	
18(b)	0	busyout tone-clock PC	WARNING	OFF	release tone-clock PC
23(c)	0	None	WARNING	OFF	
125(d)		None	MINOR	ON	
126(e)		None	MINOR	ON	
257	65535	Control Channel Test (#52)	MINOR	ON	test tone-clock PC r 20
257(f)	Any	None			
513(g)	Any	None			
769(h)	4358	None			
1025(i)	4363	NPE Audit Test (50)			test tone-clock PC sh
1538(j)	Any	None	MINOR	ON	
2049(k)	0	Clock Health Inquiry Test (#46)	MAJOR	ON	set tone-clock PC override
2305(k)	0	Clock Health Inquiry Test (#46)	MAJOR	ON	set tone-clock PC override
2561(l)	Any	None	MAJOR	ON	
3329(m)	0	None	MINOR/ WARNING[2]	OFF	set tone-clock PC
3840(n)	Any	None			
3848(o)	0	Clock Health Inquiry Test (#46)			set tone-clock PC override
3872(p)	0	None			set tone-clock PC override
3999 (q)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. Error Type 1—This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

NOTE:
The alarm is logged approximately 11-minutes after the circuit pack is removed/SAKI Sanity Test (#53) fails.

If the circuit pack is not present in the system, insert a circuit pack in the slot indicated by the error to resolve the error.

If the circuit pack is present in the system, it is faulty and must be replaced. See the preceding section, *How to Replace the Tone-Clock Circuit Pack*.

If the faulty circuit pack is in standby mode, a MINOR alarm is raised, but no other system action is taken. If the circuit pack is the active Tone-Clock, further effects of this error depend on the Reliability Option for the switch.

Table 9-714. Location of Tone-Clock Circuit Pack

Reliability Option	PPN	EPN
Standard	System Emergency Transfer (entire system affected)	Emergency Transfer in the affected EPN
High	Interchange to standby Tone-Clock in the PPN	Emergency Transfer in the affected EPN
Critical	Interchange to standby Tone-Clock in the PPN	Interchange to standby Tone-Clock in the affected EPN

If an interchange is attempted and the system is unable to activate the standby Tone-Clock, Emergency Transfer is activated. If the problem is in the PPN the entire system is affected. Otherwise only the EPN in question is affected. When this happens, both circuit packs are faulty and must be replaced. See the preceding section, *How to Replace the Tone-Clock Circuit Pack*.

If a successful interchange occurs in response to a failure of the active Tone-Clock, or if a standby Tone-Clock fails, the faulty Tone-Clock should be replaced.

b. Error Type 18—The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock PC** command. This error applies only to High or Critical Reliability systems (an active Tone-Clock may not be busied out). To resolve this error, execute **release tone-clock PC**.

c. Error Type 23—The circuit pack has been logically administered but not physically installed. Installing the circuit pack will resolve the alarm.

d. Error Type 125—A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

e. Error Type 126—The port network specified in the PORT field of the error log entry booted up without a Tone-Clock circuit pack, or with a one that cannot communicate at all with the system. The error is logged five minutes after the port network is restarted. If no circuit pack is present, install one of the proper code. If there is a circuit pack present, replace it. See the preceding section, *How to Replace the Tone-Clock Circuit Pack*.

f. Error Type 257—This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.

g. Error Type 513—This circuit pack has an on-board hardware failure. Replace the circuit pack using the procedure described in preceding section, *How to Replace the Tone-Clock Circuit Pack*.

h. Error Type 769—This error can be ignored, but look for other errors on this circuit pack.

i. Error Type 1025—This error is not service-affecting and no action is required.

j. Error Type 1538—The circuit pack was taken out of service because of an excessive rate of uplink messages. Use **test tone-clock PC long** to reset the circuit pack and put it back into service. If the command is not successful, replace the circuit pack using the procedure described in the preceding section, *How to Replace the Tone-Clock Circuit Pack*. If the alarmed circuit pack is the active Tone-Clock of a duplicated pair, first interchange Tone-Clocks via the **set tone-clock PC** command to avoid a service outage. If the error occurs again within 15 minutes, follow normal escalation procedures.

k. Error Type 2049 or 2305—These errors indicate the loss of one or more clock signals from the reported Tone-Clock circuit pack, which was active at the time of the error. The effect of any of these errors is described in the table for error type 1. Diagnosis of the problem is the same for all four error types, with the exception noted below.

   1. Examine the Hardware Error Log for errors reported against circuit packs in the same Port Network, especially TDM-CLK, TONE-BD, DUPINT, SW-CTL, and EXP-INTF. Follow the repair or replacement procedures indicated for any such errors found.

   2. If the error is not corrected by resolving errors found in step 1, the Tone-Clock circuit pack should be replaced. See the preceding section, *How to Replace the Tone-Clock Circuit Pack*.

NOTE:
Replacing the circuit pack and retesting it with the **test tone-clock** command is not adequate to retire this alarm and return the Tone-Clock Circuit Pack to full service; the Clock Health Inquiry test (#46) will continue to fail. Because the ability to generate clocks was considered lost, once any repairs have been made it is necessary to execute the **set tone-clock PC override** command, forcing the circuit pack to become active. If the problem has not actually been corrected, this action may cause a disruption in service for active digital facilities users.

3. If error 2305 or 3848 persists, all clock signals from the indicated board were lost. If the reported Tone-Clock circuit pack is in a Port Network with duplicated Tone-Clocks, the problem may lie with the circuit pack responsible for selecting the active Tone-Clock circuit pack (the *t/c selector*).

   - For a PPN, the t/c selector is the DUPINT circuit pack on carrier A.
   - For an EPN, the t/c selector is the active EXP-INTF circuit pack that is connected to the PPN. This is EXP-INTF 2A01 or 2B02 for EPN1 and 3A01 or 3B02 for EPN2.

   The t/c selector circuit pack of interest is the one which was active at the time the error was logged. This is the currently active t/c selector unless there has been an SPE interchange for PPN problem, or an EXP-INTF link switch for EPN problem, In order to determine whether an interchange has occurred since the TONE-BD error, examine the **display initcauses** log for SPE interchanges, and EXP-LNK entries in the hardware error log for expansion link interchanges.

   If the t/c selector circuit pack was not replaced as part of the previous step, replace it now. Follow procedures described in "Replacing SPE Circuit Packs" in Chapter 5; Chapter 7, ''LED Interpretation'', for the DUPINT circuit pack, or in the EXP-INTF section of this chapter for the Expansion Interface.

4. If the error has not been corrected at this point, there is a problem with the TDM Bus within the Port Network containing the reported Tone-Clock circuit pack. This may include TDM Bus intercarrier cables, Bus terminators, bent pins on the backplane, and errors on any circuit pack plugged into the same Port Network. Refer to the TDM-BUS section.

l. Error Type 2561—This error indicates that a Tone-Clock circuit pack, with a different circuit pack code as required for this system, has been inserted in the port slot as shown in the Hardware Error Log. To resolve this error, refer to the "How to Replace the Tone-Clock Circuit Pack" section for an appropriate circuit pack code and replace the Tone-Clock circuit pack according to the procedures indicated for this system. The meanings of the aux data values are as follows:

1001	A TN756 Tone-Clock circuit pack is in the PPN of a one port network system without High or Critical Reliability (Multicarrier Cabinet).
1002	A TN756 Tone-Clock circuit pack is in the EPN of a one port network system without High or Critical Reliability (Multicarrier Cabinet).
1003	Either a TN741 or TN714 Tone-Clock circuit pack (instead of a TN768, TN780 or TN2182) is in a one port network system without High or Critical Reliability (Multicarrier Cabinet).
1004	Either a TN741 or TN714 Tone-Clock circuit pack (instead of a TN768, TN780 or TN2182) is in a High or Critical Reliability system.
1005	Same as for aux value 1004.

m. Error Type 3329—The system attempted but failed to interchange Tone-Clock circuit packs. (This error occurs only in Port Networks with duplicated Tone-Clocks.) The fault may lie in the standby Tone-Clock or in the circuit pack that controls selection of the active Tone-Clock (the *t/c selector*). The goal of the following procedure is to ensure that both Tone-Clocks can be interchanged into while either t/c-selector circuit pack is active.

1. Examine the Error Log for errors reported against circuit packs in the same Port Network, paying special attention to TDM-CLK, TONE-BD, DUPINT, SW-CTL, and EXP-INTF. Follow the procedures indicated for any such errors found. After eliminating the above potential problem sources, proceed with the following steps.
2. Determine which circuit pack was controlling the choice of Tone-Clock at the time the error occurred.
   - For a PPN, the t/c selector is the DUPINT circuit pack on the A-carrier.
   - For an EPN, the t/c selector is the active EXP-INTF circuit pack that is connected to the PPN. This is EXP-INTF 2A01 or 2B02 for EPN1 and 3A01 or 3B02 for EPN2.

   The t/c-selector circuit pack of interest is the one which was active at the time the error was logged. An EXP-LNK interchange since the time of the error may have made that circuit pack the current standby. Determine whether an interchange affecting the t/c selector has occurred since the TONE-BD error. When investigation an EPN Tone-Clock, look for EXP-LNK entries in the hardware error log for PNC interchanges, which would affect the EXP-INTF.

3. If the t/c selector has not undergone an interchange since the error occurred, go to the next step. If such an interchange has taken place, interchange back to the formerly active t/c selector. Use the **set expansion-interface** command when investigating an EPN Tone-Clock.) If the interchange attempt fails due to other errors, resolve those problems first.
4. Interchange the Tone-Clock circuit packs using the **set tone-clock PC** command. If the command succeeds, the interchange which previously failed has been accomplished and the problem has been satisfactorily resolved. If it fails, proceed to the next step. (You may want to proceed in any case to definitively test all relevant components.)
5. Interchange the t/c selector using **set expansion-interface** if investigating an EPN. If errors prevent this interchange, resolve them first.
6. Attempt again to interchange Tone-Clocks with the **set tone-clock PC** command.

— If the Tone-Clock interchange failed for both t/c selectors:

Replace the standby Tone-Clock circuit pack which could not be interchanged into and return to this step. (See *How to Replace the Tone-Clock Circuit Pack*.) Test the new circuit pack as follows:

a. Execute the set tone-clock PC command.

b. Execute a set expansion-interface, if this is an EPN Tone-Clock.

c. Execute the set tone-clock PC command again.

If these commands successfully complete, the problem has been resolved.

— If these commands successfully complete, the problem has been resolved.

— If the Tone-Clock circuit packs successfully interchange when one EXP-INTF is active, but not when the other one is:

The t/c-selector circuit pack on the failing side is suspect.

a. Replace the A carrier DUPINT or EXP-INTF board that is active when the Tone-Clock interchange fails. (Follow procedures in "Replacing SPE Circuit Packs" in Chapter 5 for the DUPINT circuit pack; for the Expansion Interface, see “EXP-INTF (Expansion Interface Circuit Pack)”.)

b. Make sure the new t/c selector is active and execute the set tone-clock PC command.

— If both Tone-Clocks can be interchanged into, and interchanges succeed when either t/c selector is active, the problem has been resolved.

n. Error Type 3840—This error is not service-affecting and can be ignored. It indicates that the circuit pack has received a bad control message from the switch.

o. Error Type 3848—This error indicates that the Tone/Clock circuit pack had a loss of clock. If error 2305 is also logged, see note (j).

p. Error Type 3872—These errors indicate this Tone/Clock circuit pack had a loss of Data Clocks. This error will impact mainly users on station connected to Digital circuit packs. These users could be with out service. If error 2049 is also logged see note (i).

q. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *SAKI Reset Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
SAKI Reset Test (#53) (a)		X		D
Clock Health Test (#46)	X	X		ND
Control Channel Looparound Test (#52)(a)	X	X		ND
Tone Generator Crosstalk Test (#90) (b)		X		ND
Tone Generator Transmission Test (#40)(b)	X	X		ND
Tone Generator Audit/Update Test (#41)(b)	X	X		ND
TDM Bus Clock Circuit Status Inquiry Test (#148) (c)	X	X		ND
TDM Bus Clock Slip Inquiry Test (#149)(c)(e)	X	X		ND
TDM Bus Clock PPM Inquiry Test (#150)(c)	X	X		ND
TDM Bus Clock Parameter Update Test (#151) (c)	X	X		ND
Board Type Check Test (#574) (c)	X	X		ND
Standby Reference Health Check Test (#651) (c,d)		X		ND

1. D = Destructive; ND = Nondestructive

Notes:

a. Refer to XXX-BD for descriptions of these tests.

b. Refer to TONE-PT for descriptions of these tests.

c. Refer to TDM-CLK for descriptions of these tests.

d. This test runs only on the standby Tone-Clock circuit pack in a Port Network with duplicated Tone-Clocks (High or Critical Reliability systems). The circuit pack must be a TN780 with firmware version 2 or above.

Clock Health Inquiry Test (#46)

This inquiry reads special data stored in memory to determine if this Tone-Clock circuit pack had a loss of any of three clock types:

- SYSCLK
- SYSFM
- SYSDCLK

If this data indicates this Tone-Clock circuit pack had a loss of any of these clocks, the inquiry reports FAIL. In addition, if TDM-CLK error 1 is at threshold, this test will FAIL. TDM-CLK error 1 indicates a suspect clock is at the edge of its specified frequency. If the circuit pack did not have a loss of clock or TDM-CLK error 1 at threshold, the inquiry reports PASS.

This is not really a test, in the sense that it simply reports status held by the system, and does not generate new information or raise alarms. If this test fails with no error code, there is at least one Major alarm against a Tone-Clock circuit pack. If this test fails with an error code of 1, there is at least one Minor off-board alarm against a TDM-CLK.

Table 9-715. TEST #46 Clock Health Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error. 1. Retry the command at 11-minute intervals for a maximum of 5 times.
none	FAIL	This Tone-Clock circuit pack had an apparent loss of clock. One or more of error types 2049, 2305, 3834, and 3872 will appear in the error log. Correct the problem according to the appropriate error log entries. Once this test fails, the only way to make it pass, and to retire the associated alarm, is to repair the problem and to execute the **set tone-clock UUC override** command against the indicated Tone-Clock circuit pack.
1	FAIL	This Tone-Clock circuit pack is suspect of having a clock at the edge of its specified frequency. A Tone-Clock circuit pack with this problem can cause Expansion Interface circuit packs and SNI circuit packs to go out-of-frame or report no neighbor conditions, thus causing EPNs, Expansion Archangel Links (EALs), Remote Neighbor Links (RNLs), and/or Local Neighbor Links LNLs) to go down. 1. Replace the Tone-Clock circuit pack identified in the error log. Refer to the “How to Replace the Tone-Clock Circuit Pack” section.
	PASS	This Tone-Clock circuit pack has not reported a loss of clock.

TONE-PT (Tone Generator)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run[1]	Full Name of MO
TONE-PT	MAJOR	test tone-clock UUC short	Tone Generator
TONE-PT	MINOR	test tone-clock UUC short	Tone Generator
TONE-PT	WARNING	release tone-clock UUC	Tone Generator

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E).

NOTE:
Replacing the tone/clock circuit pack requires a special procedure which is described in the documentation for TONE-BD. That section also describes the LED display for this board.

The tone generator resides on the Tone/Clock circuit pack and provides all system tones such as dial tone, busy tone, and so on. If an active tone generator fails, its port network may not have tones (see the Tone Generator Transmission Test #40). For instance, a user may go off-hook and hear no dial tone. This problem will affect only users on the same port network in which the faulty Tone-Clock circuit pack resides. The system will be able to process certain type of calls (that is, internal calls will succeed while outgoing calls will not).

The Tone-Clock circuit pack also provides the clocks for the system and can serve as the synchronization reference. Therefore, when resolving alarms on the Tone-Clock circuit pack, the TDM-CLK (TDM Bus Clock) and SYNC (Synchronization) Maintenance documentation should be utilized as well as the TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation.

See the section on TONE-BD Maintenance in this manual for a discussion of the relationship of Tone-Clock circuit packs with the various Reliability Options.

Error Log Entries and Test to Clear Values

Table 9-716. Tone Generator Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test tone-clock UUC r 1
1(a)	17664	Tone Generator Audit/	MAJOR/	ON	test tone-clock UUC r 2
		Update Test (#41)	MINOR[2]		
18(b)	0	busyout tone-clock UUC	WARNING	OFF	release tone-clock UUC
130(c)		None	MINOR	ON	test tone-clock UUC Sh
257(d,f)	17667	None	MINOR	ON	
513(e,f)	17666	Tone Generator Audit/ Update Test (#41)	MINOR	ON	test tone-clock UUC r 3
769	Any	Transmission Test (#40)	MAJOR/ MINOR[2]	ON	test tone-clock UUC r 3
1025		Crosstalk Test (#90)	MAJOR/ MINOR[2]	ON	test tone-clock UUC l r 2
1281(g)	Any	Tone Generator Audit/ Update Test (#41)	MINOR	ON	test tone-clock UUC r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. MAJOR alarm if the alarmed Tone-Clock circuit pack is not duplicated; MINOR if it duplicated within the same Port Network.

Notes:

a. A failure in the tone generation facility on the indicated circuit pack has been detected. Replace the circuit pack. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

b. The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock UUC** command. It only applies to systems which have the High or Critical Reliability Option administered, because only a standby Tone-Clock circuit pack may be made busy by that command. To resolve this error, execute the **release tone-clock UUC** command for the alarmed circuit pack.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

d. The tone generation facility is having problems verifying that tones have been connected as requested.

e. The tone generation facility may or may not be able to generate tones.

f. Infrequent errors, at a rate which does not bring up an alarm, probably do not affect service, unless there are customer complaints of no tones, or incorrect tones which can not be explained in any other way. However, if an alarm is raised because this error is being repeatedly logged, then the circuit pack should be replaced. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

g. The system-parameters country-options administration are setup such that a TN780 or TN2182 are required and the existing tone-clock circuit pack will not provide the needed functionality. The Base Tone Generation Set on page 1 or the custom tones beginning on page 2 of the system-parameters country options form may have values not supported by the existing tone-clock.

This error (1281) indicates that the system parameters country-options form has custom tones translated and that the alarmed tone board does not support the customized tones. TN768 tone boards do not support any customized tones. TN780 tone boards support up to 6 customized tones using the following frequencies/levels only:

Silence

350Hz at 17.25 dB

425Hz at 4.0 dB

425Hz at 11.0 dB

425Hz at 17.25 dB

440Hz at 17.25 dB

350Hz+425Hz at 4.0 dB

350Hz+440Hz at 13.75 dB

480Hz at 17.25 dB

620Hz at 17.25 dB

440Hz+480Hz at 19.0 dB

404Hz at 11.0 dB

404Hz at 16.0 dB

480Hz+620Hz at 24.0 dB

404Hz+425Hz at 11.0 dB

375Hz+425Hz at 15.0 dB

404Hz+450Hz at 11.0 dB

1000Hz at 0.0 dB

1000Hz at +3.0 dB

525Hz at 11.0 dB

1400Hz at 11.0 dB

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *SAKI Reset Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
SAKI Reset Test (#53) (a)		X		D
Clock Health Test (#46) (b)	X	X		ND
Control Channel Looparound Test (#52) (a)	X	X		ND
Tone Generator Crosstalk Test (#90)		X		ND
Tone Generator Transmission Test (#40)	X	X		ND
Tone Generator Audit/Update Test (#41)	X	X		ND
TDM Bus Clock Circuit Status Inquiry Test (#148) (c)	X	X		ND
TDM Bus Clock Slip Inquiry Test (#149)(c)(e)	X	X		ND
TDM Bus Clock PPM Inquiry Test (#150) (c)	X	X		ND
TDM Bus Clock Parameter Update Test (#151) (c)	X	X		ND
Board Type Check Test (#574) (c)	X	X		ND
Standby Reference Health Check Test (#651) (c,d)		X		ND

1. D = Destructive; ND = Nondestructive

Notes:

a. Refer to XXX-BD (Common Port Circuit Pack) section for descriptions of these tests.

b. Refer to TONE-BD (Tone-Clock Circuit Pack) section for descriptions of these tests.

c. Refer to TDM-CLK (TDM Bus Clock) section for descriptions of these tests.

d. This test only runs on the Standby Tone-Clock circuit pack in a Port Network with more than one Tone-Clock circuit pack (High or Critical Reliability Option). The circuit pack must be a TN780 code with firmware revision 2 or above.

e. Test #149 does not run on the TN2182.

Tone Generator Transmission Test (#40)

The purpose of this test is to verify that the tone generation hardware on the tone-clock circuit pack is capable of generating a subset of system tones and a set of test tones. This test does not verify all system tones the tone generator produces during normal system operation.

The test is performed in two parts. For the first part, the Tone Generator is told to generate the touch-tone digits. The digits are received and checked by a Tone Detector touch-tone detector. If any of the digits fail, the test is repeated using a touch-tone detector in another Tone Detector circuit pack.

For the second part, the Tone Generator is told to generate call progress tones that are detected and identified by a tone detector. These tones are:

- 440 Hz
- 2225 Hz
- Digital Count

The tone generator is then told to generate a sequence of test tones whose output levels are measured by a tone detector. These tones are:

- 404 Hz at 0 dB
- 1004 Hz at -16 dB
- 1004 Hz at 0 dB
- 2804 Hz at 0 dB

A Tone Detector general purpose tone detector listens for the tones and measures the quality of the tone. If any of the measured values are not within limits, the test is repeated using a general purpose tone detector in a different Tone Detector circuit pack. If the values are still out of the limits, the test will fail.

For all the failure cases of Test #40, do the following:

1. Check that all Tone Detector circuit packs have the same companding mode as that administered for the system. Correct the situation if there is a mismatch.
2. Run the long test sequence: **test tone-clock PC long repeat 1**.
3. If the problem persists, replace the Tone-Clock circuit pack by following the steps outlined in the ‘‘How to Replace the Tone-Clock Circuit Pack’’ section

Table 9-717. TEST #40 Tone Generator Transmission Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	The system was not able to allocate all the resources needed for this test or there was an Internal system error.
1	ABORT	The system could not allocate all the resources needed to test the DTMF tones.
1001	ABORT	The system was not able to put the tone generation facility in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This can happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM Bus via the **test tdm port-network PN#** command. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test connection. This can happen when the system is heavily loaded or there is not a Tone Detector circuit pack in the port network where this test is being executed. 1. Make sure there is a Tone Detector circuit pack in the same port network. 2. If a Tone Detector circuit pack is missing, install one in the same port network. 3. Allow approximately 1-minute for Tone Detector maintenance to run on the newly inserted Tone Detector circuit pack. 4. Retry the command at 1-minute intervals a maximum of 5 times.
1022	ABORT	[G3r V2] Tone detection for the system is administered as wide broadband (tone detection mode 5), and the Tone Detector used for this test was not a TN420C. (the only circuit packs with this capability). GPTD ports on other types of Tone Detector circuit packs are taken out of service since they cannot provide the administered function. 1. Change the tone-detection mode administered on the system-parameters country-options form (see *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, Or 2. Remove all non-TN420C circuit packs from the system.
2000	ABORT	Response to the test request was not received within the allowable time period. System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-717. TEST #40 Tone Generator Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 (a)	FAIL	DTMF generation failed for the active tone generator.
105 (a)	FAIL	Generation of 440-Hz failed.
109 (a)	FAIL	Generation of 2225-Hz failed.
110 (b)	FAIL	Generation of 404-Hz level invalid.
111 (b)	FAIL	Generation of 1004-Hz low level invalid.
112 (b)	FAIL	Generation of 1004-Hz high level invalid.
113 (b)	FAIL	Generation of 2804-Hz level invalid.
115 (b,c)	FAIL	Generation of digital count sequence invalid.
120 (a)	FAIL	Generation of quiet tone failed.
1044 (a)	FAIL	DTMF generation failed to generate Digit 1 for the standby tone generator.
1045 (a)	FAIL	DTMF generation failed to generate Digit 5 for the standby tone generator.
1046 (a)	FAIL	DTMF generation failed to generate Digit 9 for the standby tone generator.
1047 (a)	FAIL	DTMF generation failed to generate Digit D for the standby tone generator.
	PASS	The tone generation facility is able to generate and transmit all the tones.

Notes:

Except in Port Networks containing more than one Tone-Clock circuit pack, replacing the circuit pack is a service disrupting procedure. The test should be run several times with more than one failure before the replacement policy specified in the following notes is executed. Use the procedure described in *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

a. All the failure error codes marked with (a) may affect users if the failure is on the active tone generator. When this type failure is detected, the system will attempt to move the tone generation function to the alternate Tone-Clock circuit pack, if one is present in the affected Port Network. When the tone generation facility fails in this way, especially in a Port Network without duplicated Tone-Clock circuit packs, the faulty Tone-Clock should be replaced promptly.

b. All the failure error codes marked with (b) are almost transparent to the user. Again, when this type failure is detected, the system will attempt to move the tone generation function to the alternate Tone-Clock circuit pack, if one is present in the affected Port Network. Users may or may not hear any noisy tones. This type of failure affects maintenance on other objects. Maintenance may not be able to run on other objects which use the tone generation facility (that is, Tone Detector Circuit Pack maintenance). In this case, the Tone-Clock circuit pack can be replaced as suitable to the customer.

c. Error code 115 may also be caused by TDM Bus corruption. This normally means a physical problem with bent backplane pins, TDM/LAN Bus cabling, or TDM/LAN Bus terminators. Such physical problems should especially be suspected if board replacement or other physical activity has occurred just before this error is observed.

   Use **display errors** to look for errors on other circuit packs in the carriers of the same Port Network as the indicated Tone-Clock. If any are found, they should be resolved if possible, and the Tone-Clock circuit pack retested. If this does not clear the problem, the Tone-Clock circuit pack should be replaced and the new one tested. If the problem persists, follow instructions for TDM Bus maintenance in this manual.

Tone Generator Update/Audit Test (#41)

The active tone generation facility is refreshed with all the time slot tone information. This test also triggers in-line error messages the Tone-Clock circuit pack generates when it detects problems by itself.

A check is also made between the type of tone-clock being tested and the type of tone-clock needed based on system administration. The administration on the system-parameters country-options form may imply that a TN780 is required.

Table 9-718. TEST #41 Tone Generator Update/Audit Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test.
2100	ABORT	System resources required for this test are not available.
1	FAIL	The system requires a TN780 tone-clock to support the administered country-options tone generation parameters. 1. Check the administration on the system-parameters country-option form. Specifically, the Base Tone Generation Set on page 1 and any custom tone administration beginning on page 2. 2. Replace existing tone-clock circuit packs with TN780.
	PASS	The tone generation facility has been successfully refreshed with its time-slot translation and system administration is consistent with this type of tone-clock. 1. Display the Hardware Error Log via the **display errors** command to make sure this circuit pack did not generate new errors.

Tone Generator Crosstalk Test (#90)

This test checks the ability of the Tone Generator to talk on a specific time slot. The tone generator is told to talk on a specific time slot. The other idle time slots are checked to make sure the Tone Generator put the tone on only the specified time slot.

Table 9-719. TEST #90 Tone Generator Crosstalk Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	The system was not able to put the tone generation facility in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This can happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the **test tdm port-network PN#** command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Tone Generator could be defective. In a Port Network with more than one Tone-Clock circuit pack, the system will attempt to move the tone generation function to the alternate one. 1. Test the Tone-Clock circuit pack again via the **test tone-clock UUC** command. 2. If the test fails again, look at the Hardware Error Log for Tone Detector circuit pack errors. 3. If there are Tone Detector circuit pack errors, refer to Tone Detector Maintenance documentation (DTMR-PT, GPTD-PT, CLAS-PT, ETR-PT) to resolve these errors first. 4. If there are no Tone Detector circuit pack errors, then the Tone-Clock circuit pack should be replaced. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.
	PASS	The tone generation facility is able to put tones out.

TR-LN-BD (Trunk Line Board)

The TN797 Analog Trunk and Line circuit pack provides 8 ports, any of which may be administered as one of the folowing:

Table 9-720. TN797 Analog Trunk and Line circuit pack – port administration

Function	Group Type	Trunk Type	LED MWI
Central Office trunk (CO)	co fx wats	loop start ground start	
CAMA/E911 trunk	cama		
Direct Inward Dialing (DID) trunk	did	wink start immed start	
Analog Line on-or-off premises	n/a	n/a	with/ without MWI

In the U.S., Canada, and like countries, all CO trunk ports of TN797 Analog Trunk and Line circuit pack should be administered as ground start (GS) trunks rather than as loop start trunks, because GS signaling provides disconnect supervision, and loop start does not. If for some reason, a port on the TN797 must be administered as loop start, it must be administered as one-way only – either incoming or outgoing – not only at the DEFINITY switch, but also at the CO switch. This is necessary to avoid collisions, i.e., “glare”, and other highly undesirable conditions.

The TN797 Analog Trunk and Line circuit pack does not support Neon Lamp Message Waiting Indication (MWI). No maintenance of the terminal connected to the Neon Analog Line circuit pack is performed.

For circuit pack problems, refer to the “XXX-BD (common port circuit pack)” maintenance documentation.

TSC-ADM (Administered Temporary Signaling Connections)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
TSC-ADM	none	none	Administered Temporary Signaling Connections

No alarms are generated for Administered Temporary Signaling Connections (TSC-ADM, also called ADM TSCs).

Administered temporary signaling connections provide a path through ISDN-PRI networks for supplementary D-channel messages. ISDN-PRI applications such as the Distributed Communications System (DCS) use temporary signaling connections to exchange user information across an ISDN-PRI network. What makes Administered TSCs unique is that these particular TSCs stay active for an extended period of time, similar to a permanent data connection. These ADM TSCs are used for DCS features that require Non-Call Associated (NCA) TSCs, and the ADM TSC provides the logical channel function in a DCS network.

An NCA TSC is a virtual connection established within a D-channel without associating any B-channel connections. The connection provides user-to-user service by exchanging USER INFORMATION messages without associated B-channel connections.

An Administered TSC is a special NCA TSC defined for the DCS over the ISDN-PRI D-channel. The ADM TSC has an administratively defined endpoint and is established for an extended period of time.

There are two types of ADM TSCs:

- Permanent

  These are established by the originating PBX (Near-end ADM TSC) or by the terminating PBX (Far-end ADM TSC). Once these ADM TSCs are established, they remain active.

- As-Needed

  These are established only when needed.

ADM TSC maintenance provides a strategy to verify that a far-end can respond to an ISDN-PRI USER INFORMATION TSC heartbeat message, thereby indicating that user-user signaling is functioning. In addition, maintenance can retrieve the status of the ADM TSC’s connection state.

Since ADM TSCs are administered on a per signaling group basis, the health of an ADM TSC also depends on the state of the D-channel or D-channel pair administered per signaling group. Refer to ISDN-SGR documentation for details on ISDN-PRI NFAS and D-channel Backup maintenance.

The two administration commands for ADM TSCs are as follows:

- **add signaling group** number
- **change signaling group** number

The two maintenance commands for ADM TSCs are as follows:

- **test tsc-administered signaling group** number [/tsc index]
- **status tsc-administered signaling group** number [/tsc index]

Error Log Entries and Test to Clear Values

Table 9-721. ADM TSC Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3840-3967 (a)	tsc index #	test tsc-administered			

Note:

a. There is no Test to Clear Value for error types 3840-3967. These error types provide the following additional data that may prove useful when tracking down problems.

Any of these errors indicates that a TSC Heartbeat Inquiry Test was run on an active far-end Administered TSC from the switch. Upon receiving the heartbeat message, the network communicated that the call was unable to complete. As a result, the error was logged. Check the signaling group status of the D-channel or D-channel pair via the **status signaling-group <group>** command for the Administered TSC. Check the status of the Administered TSC via the **status tsc-administered** command. Also check the administration of the Administered TSC on the switch.

This error may only be affecting service for some DCS customers. Upon receipt of this error condition, the switch will tear down and re-establish the ADM TSC within 20 minutes.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *TSC Heartbeat Inquiry Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
TSC Heartbeat Inquiry Test (#604)			ND

1. D = Destructive; ND = Nondestructive

TSC Heartbeat Inquiry Test (#604)

This test can be invoked by system technician personnel for any ADM TSC administered in the switch. Most of the error conditions on the following table will not log an error, but switched services may take some type of recovery action in certain instances.

This test sends a USER INFORMATION TSC heartbeat message inquiry across an ADM TSC to determine if the far-end can respond to a USER INFORMATION TSC heartbeat message.

Table 9-722. TEST #604 TSC Heartbeat Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Reissue the **test tsc-administered** command at 1-minute intervals a maximum of 5 times.
1005	ABORT	The Administered TSC does not exist. 1. Display the administration for the Administered TSC. 2. If an Administered TSC exists, reissue the **test tsc-administered** command.
1113	ABORT	The D-channel is out-of-service. 1. Refer to the “ISDN-LNK”.

Continued on next page

Table 9-722. TEST #604 TSC Heartbeat Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1145	ABORT	There is congestion in the network. 1. Issue the **status tsc-administered** command at 1-minute intervals a maximum of 5 times. 2. If the congestion does not clear, disable and enable the Administered TSC via the **change sig-group <group>** command. **NOTE:** To disable the Administered TSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where <group> refers to the number of the signaling group under which the suspect TSC is administered. Change the Enable field to "n." To enable the ADM TSC, change the "Enable" field to "y." 3. If the congestion still does not clear, check other nodes in the network.
1146	ABORT	The congestion just occurred in the network. 1. Issue the **status tsc-administered** command at 1-minute intervals a maximum of 3 times. 2. If congestion does not clear, disable and enable the Administered TSC via the **change sig-group <group>** command. **NOTE:** To disable the Administered TSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where <group> refers to the number of the signaling group under which the suspect TSC is administered. Change the Enable field to "n." To enable the ADM TSC, change the "Enable" field to "y." 3. If congestion still does not clear, check the other nodes in the network.
1147	ABORT	The ADM TSC is being torn down. 1. Issue the **status tsc-administered** command at 1-minute intervals a maximum of 3 times. 2. If ADM TSC is still down, disable and enable the ADM TSC via the **change sig-group <group>** command. **NOTE:** To disable the ADM TSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where <group> refers to the number of the signaling group under which the suspect TSC is administered. Change the Enable field to "n." To enable the ADM TSC, change the "Enable" field to "y." 3. If the ADM TSC is still down, check the other nodes in the network.

Continued on next page

Table 9-722. TEST #604 TSC Heartbeat Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1148	ABORT	The ADM TSC is enabled, but inactive (near-end). 1. Disable and enable the ADM TSC. 2. Reissue the **test tsc-administered** command. 3. If the ADM TSC is still inactive, check the other nodes in the network.
1149	ABORT	The ADM TSC is disabled. 1. Enable the TSC, and see if the status indicates "active." 2. Reissue the **test tsc-administered** command. 3. If the TSC still disabled, remove the ADM TSC from the system.
1181	ABORT	Ran out of ADM TSC resources. 1. Reissue the **test tsc-administered** command at 1-minute intervals a maximum of 3 times.
1182	ABORT	The BX.25 link is down at the gateway. 1. Disable the ADM TSC. 2. Check the status of the gateway link via the **status link link-no** command. 3. Once the gateway link indicates an "in-service" state, enable the Administered TSC. 4. Reissue the **test tsc-administered** command.
2000	ABORT	The Administered TSC is not responding to a TSC heartbeat inquiry. 1. Retry the **test tsc-administered** command at 1-minute intervals a maximum of 3 times. 2. If the problem continues to fail, obtain the status of the D-channel or D-channel pair associated with the ADM TSC via the **status sig-group <group>** command. If the D-channel is INS (i.e., in-service) and the status of the ADM TSC appears to be active, then disable and enable the ADM TSC through administration. **NOTE:** To disable the ADM TSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where <group> refers to the number of the signaling group under which the suspect TSC is administered. Change the "Enable" field to "n." To enable the ADM TSC, change the "Enable" field to "y." 3. Reissue the **test tsc-administered** command. 4. If the test fails, check the ADM TSC node on the other side of the network to verify that the ADM TSC is indeed active.

Continued on next page

Table 9-722. TEST #604 TSC Heartbeat Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal system error. 1. Reissue the **test tsc-administered** command at 1-minute intervals a maximum of 5 times.
1	FAIL	The Administered TSC is not active (far-end). 1. Reissue the **test tsc-administered** command. 2. Verify that the Administered TSC node on the other side of the network is active. 3. Disable and enable the Administered TSC. 4. Retry the **test tsc-administered** command.
2	FAIL	Facility IE (Information Element) reject. 1. Check all other nodes in the network, and make sure Administered TSC is active.
	PASS	The Administered TSC responded to a heartbeat.

TTR-LEV (TTR Level)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
TTR-LEV	WARNING	1	TTR Level
TTR-LEV	MINOR	1	TTR Level
TTR-LEV	MAJOR	1	TTR Level

1. See Repair Procedure for the TTR-LEV below.

TN748 and TN420 Tone Detector circuit packs and TN744 Call Classifier circuit packs provide tone receivers for detecting various types of signaling tones. These circuit packs are shared resources that serve all users of the PBX. This discussion uses the following terms and abbreviations (note that the maintenance-related system parameters form uses different names than the alarm and error logs):

Type of Tone Receiver	Maintenance Object	Also Known As	Alternate Abbreviation	Location
Dual-tone Multifrequency Tone Receiver	DTMR-PT	Touch Tone Receiver	TTR	4 per TN420/TN748
General Purpose Tone Detector	GPTD-PT	Call Progress Tone Receiver	CPTR	2 per TN420/TN748
Call Classifier	CLSFY-PT		CCTR	8 per TN744

TN748s and TN420s each have 4 DTMR-PTs and 2 GPTD-PTs. DTMR-PTs interpret dual-tone multifrequency (DTMF) calling signals and translate them into logical digits 0 through 9, *, and #. GPTD-PTs detect call progress tones, modem answer tones, and transmission test tones.

TN744 Call Classifier circuit packs have 8 CLSFY-PTs. These ports detect DTMF tones and classify network and MFC (multifrequency compelled) signaling tones. (That is, CLSFY-PTs can function as DTMR-PTs or GPTD-PTs, and have other additional capacities).

When a user goes off-hook to place a call, dial tone is returned to the user, indicating that a tone detector is connected and ready to receive and interpret tones. The tone detector is in use until the total number of digits needed is collected or until a time-out occurs. If all tone detectors in the system are being used simultaneously, the next user to go off-hook will not receive dial tone until a tone detector becomes available. It is therefore necessary to have a sufficient number of tone detectors in the system to prevent delays in receiving dial tone. The **list measurements tone-receiver** command shows the level of tone detector usage. For more information on this command, refer to the following documents:

- *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*
- *DEFINITY Communications System Generic 3 V2 Traffic Reports,* 555-230-511

In order to prevent dial-tone delays and other shortcomings in system performance, threshold levels for the 3 types of tone receivers are administered on the **change system-parameters maintenance** form. Whenever the number of tone receivers in service falls below the administered threshold for that type of tone receiver, an alarm is logged against the TTR Level maintenance object. At this point, the system is operating properly, but call processing capacity is reduced. Another alarm is logged if the number falls to zero. At this point, system operation is severely compromised.

Typical causes of these events are:

1. The threshold for GPTD-PTs or DTMR-PTs is administered incorrectly on the maintenance-related system parameters form.
2. Too many GPTD-PTs, DTMR-PTs, or CLSFY-PTs have been taken out of service, possibly by maintenance software or a demand busyout.
3. A tone detector circuit pack has been removed or suffered a fatal failure, resulting in the loss of all its ports.
4. The system has an insufficient number of TN748/TN744/TN420 circuit packs.

Repair Procedure for TTR-LEV

To resolve a TTR-LEV alarm:

1. **Display errors** and use the TTR-LEV Error Log Table to determine which type of tone receiver has fallen below its threshold.
2. Enter **change system-parameters maintenance**, and check the administered value. On the form, TTR represents DTMR-PTs, CPTR represents GPTD-PTs, and Call Classifier represents CLSFY-PTs. If the threshold value is set too high, change it to a lower value and wait a minute for the alarm to clear.

   To determine the correct thresholds, first find the total number of TN478/TN420 Tone Detector and TN744 Call Classifier circuit packs in the system using the **list configuration** command. Then calculate the total number of tone receiver ports of each type. Each Tone Detector circuit pack has 4 TTR (DTMR) ports and 2 CPTR (GPTD) ports. Each TN744 Call Classifier circuit pack has 8 Call Classifier (CLSFY-PT) ports.

   For each type of tone receiver, if the total number of ports installed in the system is less than the administered threshold, then either add more circuit packs to the system or reduce the threshold to match the number already in the system. If the TTR Level alarm is still present, then proceed to Step 3.
3. **Display errors** for error type 18 and look for GPTD-PTs, DTMR-PTs, or CLSFY-PTs that have been busied out.

   For each of the busied-out ports:

   - Determine why the port was busied out.
   - If the port can be placed back into service, then test the port via the **test port UUCSSpp** command.
   - If all tests pass, **release port** and wait 1-minute for the TTR Level alarm to clear.

   If this does not clear the TTR Level alarm, proceed to Step 4.
4. **Display alarms** and determine the location of the circuit pack with the alarmed GPTD-PT, DTMR-PT, or GPTD-PT.

   Test board UUCSS long rep 3 for that circuit pack.

   If this does not clear the TTR Level alarm, replace the Tone Detector or Call Classifier circuit pack with the alarmed GPTD-PT, DTMR-PT or CLSFY-PT.

Error Log Entries and Test to Clear Values

Table 9-723. TTR Level Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1 (a)	1	None			
2 (b)	2		WARNING (See WARNING message below)	OFF	
3 (c)	3	None			
4 (d)	4		WARNING	OFF	
5 (e)	5	None			
6 (f)	6		WARNING	OFF	
7 (g)	7		MAJOR	OFF	
8 (h)	8		MINOR	OFF	
9 (i)	9		MINOR	OFF	

WARNING:
The Alarm is upgraded to MAJOR if the Base Tone Generator is set to 12 (France).

Notes:

a. Error code 1 does not indicate a current error condition. It indicates that the number of DTMR ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.

b. The total number of DTMR ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure described above.

c. Error code 3 does not indicate a current error condition. It indicates that the number of GPTD ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.

d. The total number of GPTD ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure describe above.

e. Error code 5 does not indicate a current error condition. It indicates that the number of Call Classifier ports (CLSFY-PT) service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.

f. The total number of Call Classifier ports (CLSFY-PT) currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure described above.

g. There are currently no DTMR ports in service. To clear the alarm, refer to the repair procedure described above.

h. There are currently no GPTD ports in service. To clear the alarm, refer to the repair procedure described above.

i. There are currently no Call Classifier ports (CLSFY-PT) in service. To clear the alarm, refer to the repair procedure described above.

UDS1-BD (UDS1 Interface Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
UDS1-BD	MAJOR	test board UUCSS sh	UDS1 Interface Circuit Pack
UDS1-BD	MINOR	test board UUCSS l	UDS1 Interface Circuit Pack
UDS1-BD	WARNING	test board UUCSS sh	UDS1 Interface Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

2Mbit Japan trunk (TN2242)

The TN2242 2Mbit, 30-port trunk circuit pack supports Japanese TTC private networking environments. This circuit pack interfaces only with network equipment or other circuit packs of the same model and is incompatible with all other digital trunk circuit packs.

The maintenance strategy for the TN2242 is similar to that of the TN464F DS1 interface circuit pack. The TN2242 circuit pack is functionally the same as the TN464F (without ICSU) with the following exceptions:

- The Blue Alarm Inquiry Test (#139) always passes for the TN2242.
- The **test ds1-loop** command is not executed for the TN2242.
- A different initialization message is sent when the local looparound test (Test #135) is executed when **reset board** is run on a TN2242.
- Any tests associated with an Integrated Channel Service Unit (ICSU) are not executed, since ICSU is not supported on this circuit pack.
- Any tests associated with new functionality available with the video-enabled TN464F are not executed for the TN2242.
- Cyclical Redundancy Check (CRC) is not defined for this circuit pack.
- The D-Channel can be user-assigned to any port 1 - 30 when the signaling mode is ISDN-PRI.
- Wideband is not supported.
- Stations (OPS) are not supported.

The TN2242 circuit pack also supports specialized versions of CAS (Channel Associated Signaling) and ISDN-PRI signaling that pertain to the TTC private networking environment in Japan.

Upgrading to TN2242

Figure 9-111 shows the hardware connections for public network access in Japan. The upgrade procedure requires removing the JRC (Japan Radio Corporation) external converter in Figure 9-112.

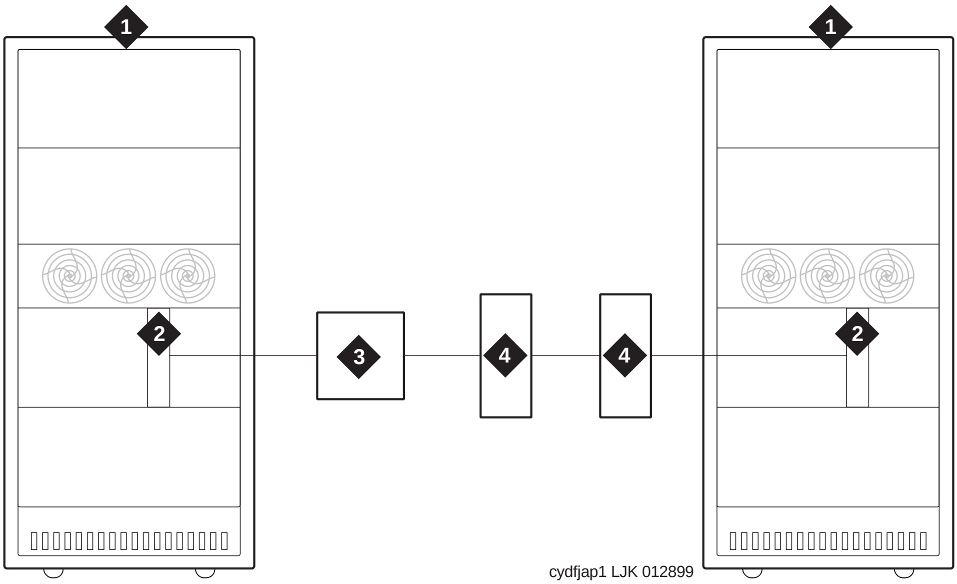

Figure Notes:

1. DEFINITY Release 7
2. TN464F DS1-CONV circuit pack (24-trunk digital tie-trunk)
3. JRC (Japan Radio Corporation) external converter
4. TDM facilities

Figure 9-111. Japanese TTC public network connections

Figure 9-112 shows the hardware connections for private network access using the TN2242 circuit pack.

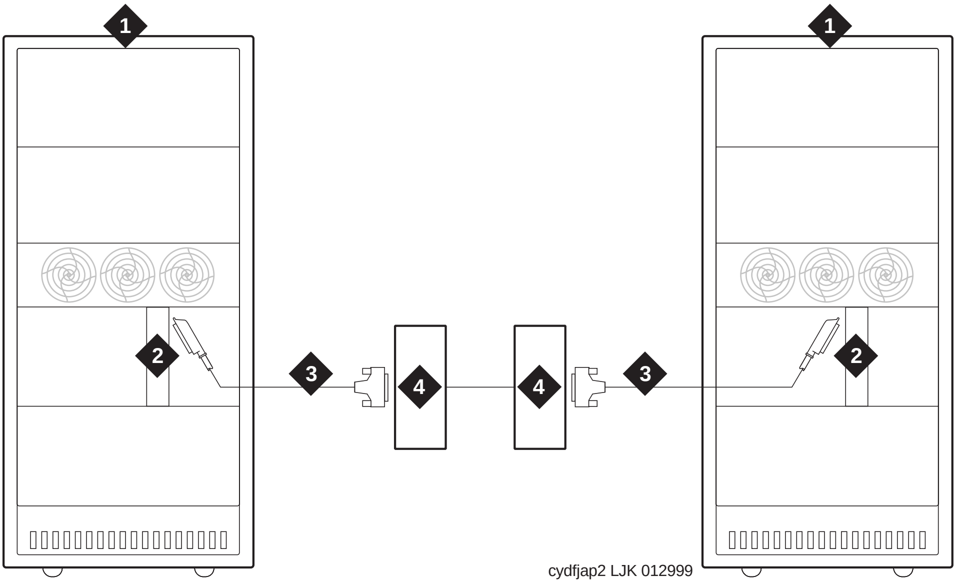

Figure Notes:

1. DEFINITY Release 7
2. TN2242 2Mbit Japan trunk circuit pack
3. H600-513 cable assembly cable. (See "H600-513 cable pinout").
4. TDM facilities

Figure 9-112. TN2242 Japan trunk TTC private network connections

To upgrade a system to the TN2242 circuit pack:

1. Busyout the TN464F DS1-CONV circuit pack (**busyout board UUCSS**).
2. Remove the TN464 administration (**change circuit pack, change ds1**, and **change trunk group *n***).
3. Remove the TN464F circuit packs.
4. Remove the JRC (Japan Radio Corporation) external converter and cable.
5. Insert the TN2242 circuit packs.
6. Connect the TN2242 to the TDM with the H600-513 cable assembly.
7. Administer the TN2242 circuit pack (see "Administration").

H600-513 cable pinout

Table 9-724 shows the pinout for the H600-513 cable assembly:

Table 9-724. H600-513 cable assembly pinout

TN2242			TDM	
50-pin connection pin number	**Color**	**Lead Designation**	**Color**	**15-pin connection pin number**
22	W-BL	Line in +	W-BL	4
23	W-O	Line out -	W-O	9
47	Bl-W	Line in -	Bl-W	11
48	O-W	Line out +	O-W	2

Administration

The TN2242 circuit pack requires board-level translation data. Before administering any ports on the circuit pack, administer the following forms:

- Circuit pack (**change circuit pack**)
- DS1 (**add ds1**)
- Trunk group (**add trunk group *n***)

Table 9-725 outlines the trunk group administration parameters that are required for this interface to operate successfully in Japan.

Table 9-725. TN2242 administration

Field	Value
Trunk Group form, Page 1	
Trunk Type (in/out)	wink, delay, immed (all permutations)
Trunk Signaling Type	blank
Answer Supervision Timeout	0
Receive Answer Supervision	y
Disconnect Supervision - In?	y
Disconnect Supervision - Out?	y

Continued on next page

Table 9-725. TN2242 administration — *Continued*

Field	Value
Incoming Dial Type	tone rotary mf (to other DEFINITYs only)
Wink Timer for wink type	300
Wink Timer for delay type	4500
Trunk Group form, Page 3 (Administrable Timers)	
Incoming Disconnect	100
Incoming Glare Guard	800ms or higher
Incoming Dial Guard	10
Incoming Incomplete Dial Alarm	25 or higher
Incoming Partial Dial	18
PPS	10 or 20
Make (for PPS 10)	35
Break (for PPS 10)	65
Make (for PPS 20)	15
Break (for PPS 20)	35
Outgoing Disconnect	100
Outgoing Glare Guard	800 or higher
Outgoing Rotary Dial Interdigit	800
Outgoing Seizure Response	5

LEDs

The LEDs on the faceplate of the TN2242 circuit pack indicate its status as described in Table 9-726.

Table 9-726. TN2242 LED interpretation

LED	Meaning
Red	■ MAJOR alarm ■ MINOR alarm ■ Firmware initialization during circuit pack insertion
Yellow	A port on the circuit pack is in use.
Green	Maintenance testing is in progress on the circuit pack or its ports.

Interactions with other MOs

The TN2242 maintenance object directly interacts with these maintenance objects:

- ''Synchronization''
- ''TN2242 trunk ports''
- ''Call processing''

Synchronization

The DS1 facility plays a vital role in the synchronization subsystem. The Tone/Clock circuit pack uses either the primary or secondary timing reference, whether internal (local -- Tone/Clock circuit pack) or external. TN2242 circuit packs can be administered as "primary" or "secondary" synchronization references.

TN2242 circuit pack sends DS1 link status information to the synchronization reference switching algorithm that determines whether timing references should be switched due to failure or restore conditions.

TN2242 trunk ports

The TN2242 circuit pack MO is responsible for monitoring the health of the DS1 facility. If a DS1 facility goes down, then that facility's DS1 circuit pack instructs all DS1 port MOs associated with the facility to place their trunks (or ISDN-PRI signaling link) in an out-of-service state.

Call processing

The **busyout board** command tears down all calls and signaling links associated with a TN2242 circuit pack.

TN2242 serviceability

Hardware connections

This circuit pack can be

- mated to another circuit pack of the same type when interconnecting two DEFINITYs.
- directly-connected to the TDM network device.
- directly-connected to another vendor PBX using ISDN PRI signaling.

Loopbacks

- There is no process to automatically signal the remote end to provide loopbacks for testing purposes. All loopbacks to be tested with a single circuit pack must be local loopbacks on the circuit pack.
- Remote loopbacks may be possible with the TDM network equipment with appropriate coordination between BCS Services Technicians and the service technicians of the TDM equipment (considered a CPE device).

The TN464C, D, E, and F Universal DS1 Interface circuit packs provide an interface to the DS1 facility and are designed to support 24 DS0 channels on a 1.544 Mbps DS1 link or 32 DS0 channels on a 2.048 Mbps link. (The 32-channel interface is not supported on G3r V1 systems.) The DS0 channels can be administered as trunks to other switches, lines to off-premises stations, ports to line-side PRI terminating devices, or ports to other line-side non-PRI terminating devices. (DS0 channels on TN464/Bs can only be administered as trunks to other switches.) For more information on how TN464 ports can be used, see the following sections in this chapter ISDN-SGR, ISDN-TRK, ISDN-LNK, PE-BCHL, TIE-DS1, CO-DS1, DID-DS1, OPS-LINE and WAE-PT. For information on other DS1 circuit packs, see DS1-BD.

Throughout this section on the UDS1-BD MO name, the term TN464 will mean any TN464C or later suffix UDS1 circuit pack. If part of this section refers to a specific suffix TN464 board, it will be noted as such.

The UDS1 maintenance strategy includes logging in-line errors reported by the UDS1 circuit pack, running tests for error diagnosis and recovery, and raising or clearing maintenance alarms.

TN464 circuit packs support the following:

- Digital Tie, CO, and DID trunks
- DS1 off-premises (OPS) lines
- Narrowband and wideband access endpoint ports
- ISDN-PRI trunks and accompanying signaling channel
- PRI endpoint ports (PE-BCHL) and accompanying signaling channel

The TN464 supports digital Tie, CO, and DID trunks, and OPS lines. On-board firmware performs call control signaling for the Tie, CO and DID trunks and OPS lines. ISDN-PRI trunk and PRI endpoint signaling (Q.921, Q.931) is received and generated by system software and is transmitted on a system link through the TN1655 Packet Interface and packet bus to the UDS1 where it is placed on the D-channel. Signaling over the DS1 link has to be synchronized between the transmitting and receiving ends to ensure error-free communication. Refer to ''SYNC (Synchronization)'' in this chapter for details.

Each trunk, line or endpoint has its own maintenance strategy but all depend on the health of the UDS1 Interface circuit pack. Refer to the following sections for details: TIE-DS1, CO-DS1, DID-DS1, OPS-LINE, ISDN-TRK, ISDN-LNK, ISDN-SGR, WAE-PT and PE-BCHL. The maintenance strategy for the TN464 UDS1 Interface circuit pack (UDS1-BD) is very similar to the maintenance strategy for the TN767 DS1 Interface circuit pack (DS1-BD). The same commands are used for administering and testing the boards. The differences in maintenance strategy between the boards are due to the UDS1 circuit pack's direct interface to the Packet Bus which is used for ISDN-PRI signaling (ISDN-LNK). While both the TN464 and TN767 can support ISDN-PRI B-channels, ISDN-PRI D-channel signaling applications require a TN464 UDS1 circuit pack.

The TN464F or later circuit pack combined with the 120A1 CSU Module forms an Enhanced Integrated CSU. The new 120A1 CSU Module, when combined with the functionality provided by the TN464F hardware and firmware, and new switch software, provides functionality equivalent to an external stand-alone Lucent ESF T1 CSU. The 120A1 CSU Module connects to the TN464F circuit pack on the I/O connector panel on the back of the port carrier. The new CSU Module, thus becomes an integrated part of the DEFINITY. system. Throughout the document, the term 120A1 will mean a 120A1 or later suffix CSU Module.

The Enhanced Integrated CSU is for use in the United States of America with 1.544 Mbps DS1 service. For further details on the 120A1 CSU Module see *DEFINITY Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 - Integrated CSU Module Installation and Operation*.

The TN464F and 120A1 CSU Module support on-demand loopback tests that assist in the detection of faults between the TN464F circuit pack and the CSU Module, between the Integrated CSU and the optional Customer Premises Loopback Jack, or between the Integrated CSU and remote CSU. These loopback tests are explained in detail later in this UDS1-BD section, but Figure 9-113 gives a high level overview of the loopback points.

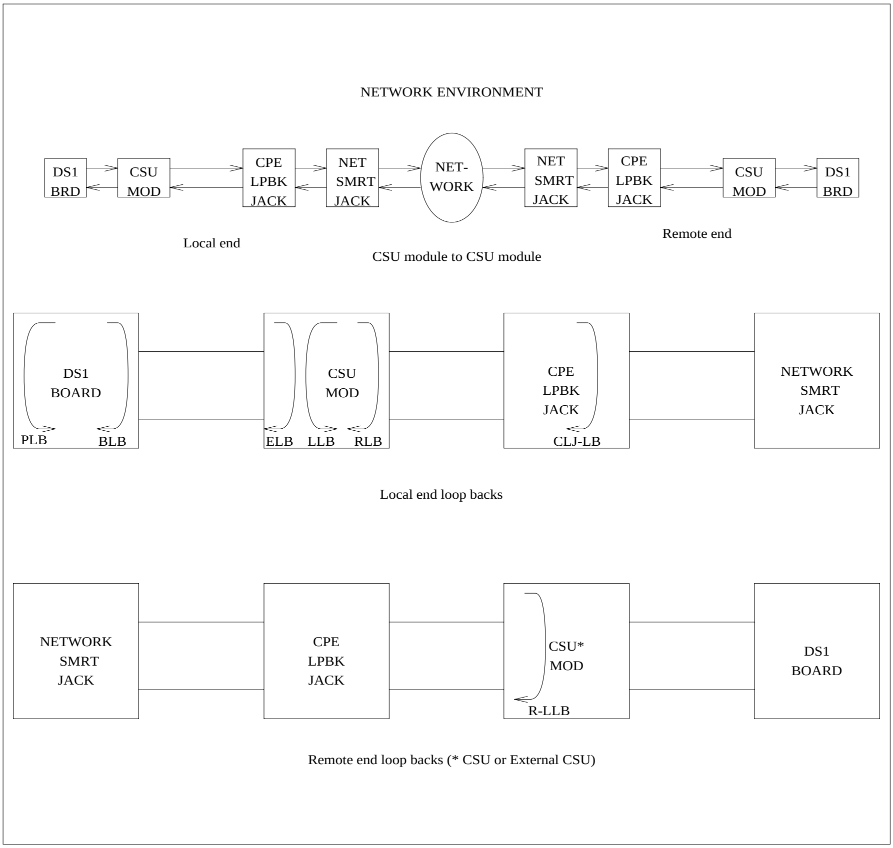

Figure 9-113. High Level Overview Of Loopback Points

The following list of acronym definitions are for the Figure 9-113:

- PLB = Payload Loopback
- BLB = Board Loopback
- ELB = Equipment Loopback
- LLB = Line Loopback
- RLB = Repeater Loopback
- CLJ = Loopback Jack Loopback
- R-LLB = Remote Line Loopback
- SMRT = Smart Jack
- LPBK = Loopback

Circuit Pack Administration and Options

The DS1 configuration for each circuit pack is administered on the DS1 Circuit Pack form. *Bit Rate* is set to 1.544 Mbps for 24-channel systems, and 2.048 Mbps for 32-channel systems. *Country Protocol* is used to drive layer 3 protocol decisions based on PRI specifications specific to a given country (not those related to specific features). This Country Protocol is independent of the *Country* parameter administered on the country-options system-parameters form. Different UDS1 circuit packs may be administered with different Country Protocols, allowing the switch to act as a gateway between two incompatible ISDN-PRI implementations (for example, between two different countries). US systems use country protocol 1. *Near-End CSU Type* is set to *other* for no CSU installed or for an external CSU such as an Lucent ESF T1 CSU, or *integrated* for the 120A1 CSU Module or the 401A T1 Sync Splilter. Answering *integrated* will cause additional fields to be displayed for administering the Enhanced Integrated CSU Module. *E1 Sync-Splitter?* is set to *y* if a 402A or 403A E1 Sync splitter is used to provide timing to an ATM switch. In addition to the above there are numerous other fields defining such parameters as framing modes, line coding companding mode and so on. For details, see *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, and *DEFINITY Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT/ISDN-PRI Reference*, 555-025-107.

Two option jumpers located on the side of the TN464C/D circuit pack must be installed correctly. The figures on the following page shows how to configure the circuit pack for 24-channel or 32-channel DS1, and for 75*W (coaxial) or 120*W trunk connections. The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

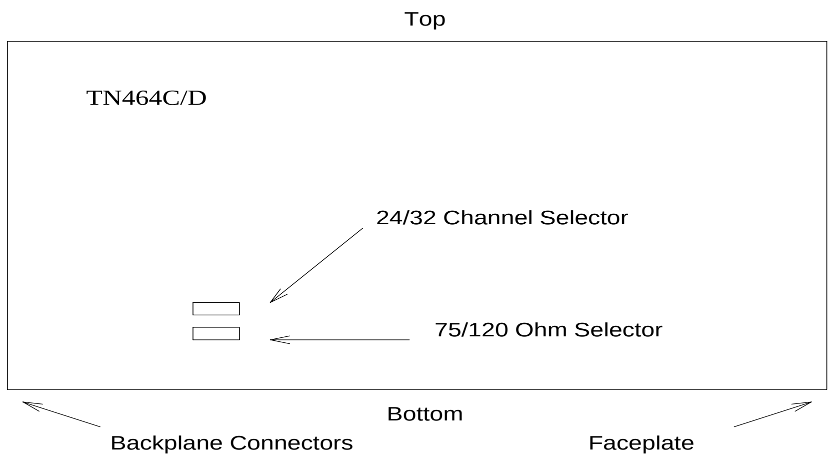

Figure 9-114. TN464C/D DS1 Option Jumpers

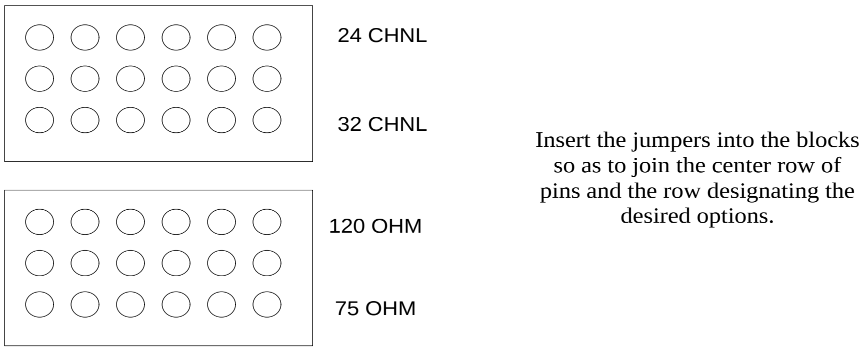

Figure 9-115. TN464C/D DS1 Option Jumpers (Continued)

The option switch located on the component side of the TN464E/F circuit pack must be set correctly. Figure 9-115 shows how to configure the circuit pack for 24-channel or 32-channel DS1. The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

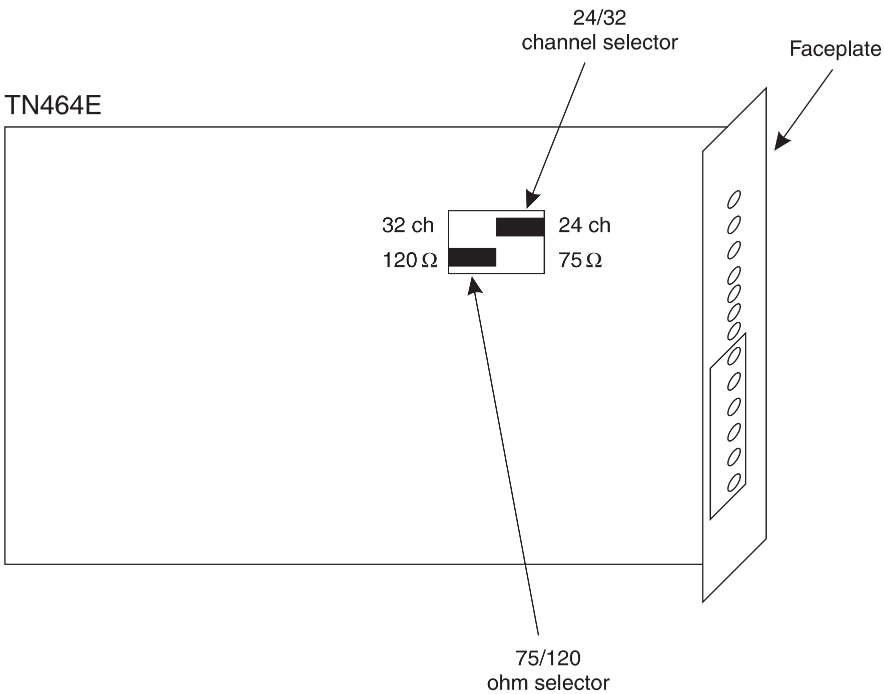

Figure 9-116. TN464E/F DS1 Option switches

Error Log Entries and Test to Clear Values

Table 9-727. DS1 Interface Circuit Pack Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS

Table 9-727. DS1 Interface Circuit Pack Maintenance Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3841(y)	4358				
3842(z)	46097				
3843(aa)	46081				
3900(ab)	Any	CPE Loopback Jack Test (#1212)			
3901(ac)	Any	Far CSU Loopback Test (#1213)			
3902(ad)	Any	One-Way Span Test (#1214)			
3999(ae)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pac
3. Minor alarms on this MO may be downgraded to warning alarms based on values set in the **set options** command.
4. Major alarms on this MO may be downgraded to minor or warning alarms based on values set in the **set options** command.

Notes:

a. Error 1 indicates that the circuit pack has totally stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11-minutes after the SAKI Test (#53) fails.

   To be fully administered, a UDS1 circuit pack must meet all of these 3 conditions:

   1. Have an entry in the circuit plan via the **change circuit pack** command
   2. Be administered via the **add ds1 UUCSS** command
   3. Be physically inserted into the correct slot

   If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

1. Make sure all conditions for administration are met and that a functioning UDS1 circuit pack is inserted in the correct slot, or
2. Completely remove the UDS1-BD from the system using the following steps:
   a. Remove any administered DS1 trunks, access endpoints or PRI endpoints associated with the circuit pack from their trunk groups.
   b. Execute the **remove ds1 UUCSS** and **change circuit pack UUCSS** commands.

If all the administration conditions are met for this circuit pack and the red LED is still on, follow the instructions for *LED Alarms with Error Type 1* in Chapter 7.

b. The UDS1 Interface circuit pack has been busied out by a **busyout board UUCSS** command.

c. The UDS1-BD circuit pack is not completely administered. To be fully administered, the UDS1 circuit pack must:
   1. Have an entry in the circuit plan via the **change circuit pack** command,
   2. Be administered via the **add ds1 UUCSS** command, and
   3. Be physically inserted into the correct slot.

A DS1 (UDS1-BD and DS1-BD) differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered with the **add ds1** command.

d. No Aux Data: A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

Aux Data 3: The 24/32-channel option jumper setting on the circuit pack does not match the option set on the DS1 circuit pack administration form. The circuit pack must be physically removed to see the setting of the jumper.

e. This error is associated with the Common Port Circuit Pack Maintenance Test. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for details.

f. The UDS1 Interface circuit pack has detected a transient hardware problem. The value in the Aux Data field indicates the type of hardware problem.

4352	External RAM failure
4353	Internal RAM failure
4355	Internal ROM failure

If the UDS1 board detects only one of these hardware problems, then the error will disappear when none of these faults are detected for 10 minutes. If the same Aux Data value is logged more than once in a 24 hour period, the circuit pack should be replaced.

g. LAN External RAM Error. This error occurs when there is a hardware fault in the PPE external RAM. The RAM is used for message buffering to and from the Packet Bus. This error should not occur regularly. If this error is seen quite frequently (10 times within 30 minutes), the circuit pack should be replaced.

h. Transmit FIFO Underflow Error. This error occurs when the circuit pack cannot find the "end of frame" bit when transmitting a frame to Packet Bus. An alarm will be raised if this error occurs three times within 10 minutes. Clear the alarm via the following commands: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long**, **release board UUCSS**. If the error recurs within 10 minutes, then replace the circuit pack.

i. Unable to Write LAN Translation RAM Error. This error occurs when a call is aborted because there are no available translation RAM locations for the call connection attempt. An alarm will be raised if this error occurs two times within 10 minutes. Clear the alarm via the following commands: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long**, **release board UUCSS**. If the error recurs within 10 minutes, then replace the circuit pack.

j. CSU Module/T1 Sync Splitter missing or E1 Synchronization Splitter (E1SS) missing.

CSU Module/T1 Sync Splitter missing: The `Near-End CSU Type` field on the **add ds1** form has been administered as `integrated` but the 120A1 CSU Module or the 401A T1 Sync Splilter is not physically connected (or is improperly connected) to the TN464F board on the back of the port carrier.

If using the 120A1 CSU Module or the 401A T1 Sync Spliltter, plug (or replug) the CSU Module/T1 Sync Splitter into the TN464F circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the `Near-End CSU Type` field using the **change ds1** form to `other`.

If this error remains after plugging the CSU Module/T1 Sync Splitter into the board's connector, there could be a problem with the I/O connector panel.

E1 Synchronization Splitter missing: The `E1 Sync-Splitter?` field on the **add ds1** form has been administered as `y`, but the 402A or 403A E1 Synchronization Splitter is not physically connected (or is improperly connected) to the TN464F board on the back of the port carrier.

If using the 402A or 403A E1 Synchronization Splitter, plug (or replug) the E1SS into the TN464F circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the `E1 Sync-Splitter?` field using the **change ds1** form to n.

If this error remains after plugging the E1SS into the board's connector, there could be a problem with the I/O connector panel.

k. CSU Module/T1 Sync Splitter not expected or E1 Synchronization Splitter not expected.

CSU Module/T1 Sync Splitter not expected: The 120A1 CSU Module or the 401A T1 Sync Spliltter is physically connected to the TN464F board on the back of the port carrier but the `Near-End CSU Type` field on the **add ds1** form has not been administered as `integrated`.

If the 120A1 CSU Module or the 401A T1 Sync Spliltter is to be used, use the **change ds1** command to change the `Near-End CSU Type` field to `integrated`. Otherwise, physically remove the 120A1 CSU Module or the 401A T1 Sync Spliltter from the back of the port carrier.

E1 Synchronization Splitter not expected: The 402A or 403A E1 Synchronization Splitter is physically connected to the TN464F board on the back of the port carrier but the `E1 Sync-Splitter?` field on the **add ds1** form has not been administered as y.

If the 402A or 403A E1 Synchronization Splitter is to be used, use the **change ds1** command to change the `E1 Sync-Splitter?` field to y. Otherwise, physically remove the 402A or 403A E1 Synchronization Splitter from the back of the port carrier.

l. DS1 configuration error. Attempting to use the 120A1 CSU Module with a TN464F circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America.

m. DS1 circuit pack suffix incorrect for CSU Module/T1 Sync Splitter or for E1 Synchronization Splitter.

DS1 circuit pack suffix incorrect for CSU Module/T1 Sync Splitter: The `Near-End CSU Type` field on the **add ds1** form has been administered as `integrated` but the DS1 circuit pack is not a TN464F or later suffix UDS1 board.

If the 120A1 CSU Module or the 401A T1 Sync Spliltter is to be used, remove the circuit pack and replace it with a TN464F or later suffix board. Otherwise, use the **change ds1** command to change the `Near-End CSU Type` field to `other`.

DS1 circuit pack suffix incorrect for E1 Synchronization Splitter: The `E1 Sync-Splitter?` field on the **add ds1** form has been administered as y but the DS1 circuit pack is not a TN464F or later suffix UDS1 board.

If the 402A or 403A E1 Synchronization Splitter is to be used, remove the circuit pack and replace it with a TN464F or later suffix board. Otherwise, use the **change ds1** command to change the `E1 Sync-Splitter?` field to n.

n. BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using the following commands: *busyout board UUCSS*, *test ds1-loop UUCSS ds1/csu-loopback-tests*, *release board UUCSS*. If the BLB test continues to fail, then the TN464F circuit pack needs to be replaced.

o. ELB failure. This error occurs when the Equipment Loopback (ELB) test fails for the Integrated CSU (I-CSU) Module/T1 Sync Splitter or for the 402A or 403A E1 Synchronization Splitter. This test is executed by the I-CSU/E1SS during I-CSU/E1SS power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module or the 401A T1 Sync Splilter, or the 402A or 403A E1SS is already installed) or when the 120A1 CSU Module or the 401A T1 Sync Splilter, or the 402A or 403A E1SS is plugged on to an already initialized TN464F DS1 board.

NOTE:
For the **I-CSU/T1 Sync Splitter only**, the ELB test is also executed as part of the command **test ds1-loop UUCSS ds1/csu-loopback-tests**. Attempt to clear the alarm via the following commands: **busyout board UUCSS, test ds1-loop UUCSS ds1/csu-loopback-tests, release board UUCSS**. If the ELB test continues to fail, then either the TN464F board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate where the failure is occurring by re-executing the test and by replacing one piece of hardware at a time.

p. RLB failure. This error occurs when the Repeater Loopback (RLB) test fails for the Integrated CSU (I-CSU) Module/T1 Sync Splitter or for the 402A or 403A E1 Synchronization Splitter. This test is executed by the I-CSU/E1SS during I-CSU/E1SS power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module or the 401A T1 Sync Splilter, or the 402A or 403A E1SS is already installed) or when the 120A1 CSU Module or the 401A T1 Sync Splilter, or the 402A or 403A E1SS is plugged on to an already initialized DS1 board.

NOTE:
For the **I-CSU/T1 Sync Splitter only**, the RLB test is also executed as part of the command **test ds1-loop UUCSS ds1/csu-loopback-tests**. Attempt to clear the alarm via the following commands: **busyout board UUCSS, test ds1-loop UUCSS ds1/csu-loopback-tests, release board UUCSS**. If the RLB test continues to fail, then the CSU Module needs to be replaced.

q. CPE Loopback Jack deactivation error. This error occurs when the TN464F circuit pack could not deactivate a CPE Loopback Jack on power-up/reset or upon software request.

Attempt to clear the alarm via the following commands: *busyout board UUCSS*, *test ds1-loopback UUCSS end-loopback/span-test*, *release board UUCSS*. If the attempt to deactivate the CPE Loopback Jack continues to fail, other steps must be taken to deactivate the loopback.

r. Far CSU Loopback deactivation error. This error occurs when the TN464F circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

   Attempt to clear the alarm via the following commands: *busyout board UUCSS*, *test ds1-loop UUCSS end-loopback/span-test*, *release board UUCSS*. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

s. LAN Bus Timeout Error. This error occurs when the circuit pack transmits too many bytes on the LAN bus for a single frame. This condition may be caused by an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those maintenance objects.

   If the error occurs three times within 10 minutes, the board will be isolated from the Packet Bus and the board will be alarmed. To clear the alarm and restore the board to the Packet Bus, use the following commands: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long**, **release board UUCSS**.

   If the problem persists, and there are no PKT-BUS alarms or port alarms, then replace the circuit pack.

t. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The common circuit pack level tests such as Test #50 and/or Test #52 are aborting with error code 2000.
   2. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
   3. A busyout/release of the circuit pack has no affect on test results.
   4. A **list configuration** command shows that the circuit pack and ports are properly installed.

   The circuit pack is isolated from the system and all trunks or ports on this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 20-30 minutes. When no faults are detected for 20-30 minutes, the UDS1 Interface circuit pack is restored to normal operation. All trunks or ports of the UDS1 Interface circuit pack are then returned to the in-service state. If the board is not restored to normal operation, or the error recurs after the board was restored to normal operation, escalate the problem.

u. For later releases of G3V4 and beyond, only error 3073 will show that this board is receiving slips and the AUX data shows the last slip count that was reported.

v. LAN Critical Error. A critical failure has been detected in the Packet Bus interface of the circuit pack. This failure may be due to an on-board fault or a Packet Bus fault. If the Packet Bus is alarmed, refer to the PKT-BUS Maintenance documentation for recommended repair procedures.

   This error will isolate the board from the Packet Bus and raise an alarm. If the Packet Bus is not alarmed, enter the following commands: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS**, **release board UUCSS**. This should clear the alarm and restore the board to the Packet Bus.

   If the problem persists, and there are no PKT-BUS alarms, then replace the circuit pack.

w. For later releases of G3V4 and beyond, only error 3585 will show that this board is receiving misframes and the AUX data shows the last misframe count that was reported.

x. These errors are not service-affecting. No action is required. These errors are reported by the circuit pack when it receives a bad control channel message from the switch. The auxiliary data identifies the following error events:

4096	Bad major heading
4097	Bad port number
4098	Bad data
4099	Bad sub-qualifier
4100	State inconsistency
4101	Bad logical link

y. The UDS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data field indicates the type of hardware problem.

z. Bad Translation RAM Location Found Error. This error is not service-affecting. No action is required. A Bad Translation RAM is detected, but the call continues by using another translation location.

aa. LAN Receive Parity Error. This error occurs when the circuit pack detects an error in a received frame from the Packet Bus. These errors are most likely caused by a Packet Bus problem, but may be due to a circuit pack fault.

   Refer to the PKT-BUS Maintenance documentation to determine if the problem is isolated to this circuit pack or if the problem is caused by Packet Bus faults.

ab. Error 3900 is used to give status information on a CPE Loopback Jack Test. The value in the Aux Data field indicates the status of the loopback test.

1. Test is currently running.
2. Test failed because loopback could not be activated.
3. Test failed because test pattern could not be detected.
4. Test has been terminated.

ac. Error 3901 is used to give status information on a Far CSU Loopback Test. The value in the Aux Data field indicates the status of the loopback test.

1. Test is currently running.
2. Test failed because loopback could not be activated.
3. Test failed because test pattern could not be detected.
4. Test has been terminated.

ad. Error 3902 is used to give status information on a One-Way Span Test. The value in the Aux Data field indicates the status of the span test.

1. Test is currently running.
2. Test has failed because test could not be activated.
3. Test pattern was not received from the far end.
4. Test has been terminated.

ae. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Investigate tests in the order they are presented in Table 9-728. By clearing error codes associated with the *NPE Connection Audit Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-728. System Technician-Demanded Tests

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	test ds1-loop	D/ND[1]
NPE Connection Audit Test (#50)		X			ND
Control Channel Loop Test (#52)		X			ND
Loss of Signal Alarm Inquiry Test (#138)	X	X			ND
Blue Alarm Inquiry Test (#139)	X	X			ND
Red Alarm Inquiry Test (#140)	X	X			ND
Yellow Alarm Inquiry Test (#141)	X	X			ND
Major Alarm Inquiry Test (#142)	X	X			ND
Minor Alarm Inquiry Test (#143)	X	X			ND
Slip Alarm Inquiry Test (#144)	X	X			ND
Misframe Alarm Inquiry Test (#145)	X	X			ND
Translation Update Test (#146)	X	X			ND
ICSU Status LEDs Test (#1227)	X	X			ND
SAKI Sanity Test (#53)			X		D
Internal Looparound Test (#135)			X		D
DS1/CSU Loopback Tests: DS1 Board Loopback Test (#1209) CSU Equipment Loopback Test (#1210) CSU Repeater Loopback Test (#1211)				X X X	D D D
CPE Loopback Jack Test (#1212)				X	D
Far CSU Loopback Test (#1213)				X	D
One-Way Span Test (#1214)				X	D
Inject Single Bit Error (#1215)				X	D
End Loopback/Span Test (#1216)				X	D

1. D = Destructive; ND = Nondestructive

NPE Connection Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for the SCOTCH-NPE chip on the circuit pack

Table 9-729. TEST #50 NPE Connection Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1019	ABORT	The test aborted because a test was already running on the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The circuit pack’s SCOTCH-NPE chip have been updated with its translation.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Control Channel Looparound Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 9-730. TEST #52 Control Channel Looparound Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The circuit pack failed to return the circuit pack code or vintage. 1. Retry the command a maximum of 5 times. 2. If the problem continues, and if the circuit pack is one of the Port circuit packs, replace the circuit pack. Otherwise, if the circuit pack is part of the SPE, use the procedure described in *Replacing SPE Circuit Packs* in Chapter 5. 3. Retry the command a few times a maximum of 5 times.
	PASS	Communication with this circuit pack is successful.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack. The test is highly destructive and can only be initiated by a system technician-demanded **reset board UUCSS** command.

Table 9-731. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Wrong circuit pack configuration to run this test. This error applies only to DS1 Interface circuit packs. It means the DS1 Interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions. 1. If the circuit pack needs to be reset, then set synchronization to another DS1 Interface circuit pack or to the Tone-Clock circuit pack and try again. Refer to "SYNC (Synchronization)" Maintenance documentation.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack. 2. Execute the **reset board** command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times.
1 2	FAIL FAIL	The circuit pack failed to reset. The circuit pack failed to restart. 1. Execute the **reset board** command again. 2. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.

Continued on next page

Table 9-731. TEST #53 SAKI Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Internal Looparound Test (#135)

This test is destructive.

The Internal Looparound Test is run by looping the transmitted DS1 bit stream back into the UDS1's board receiver. The loop occurs just before the DS1 facility interface. The test is highly destructive and can only be initiated by a system technician-demanded **reset board UUCSS** command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Internal Looparound Test. When the Internal Looparound Test is initiated, maintenance software sends appropriate messages to the UDS1 Interface circuit pack to start the test. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk or port are different, the test fails.

When the test is complete, the maintenance software sends a stop loop around message to the UDS1 Interface circuit pack to put the circuit pack back into the normal operation mode. All trunks or ports of the UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 9-732. TEST #135 Internal Looparound Test

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the **reset board** command at 1-minute intervals a maximum of 5 times.
1004	ABORT	Received an incoming call on a port of the UDS1 circuit pack during the test. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack to out-of-service state. 2. Retry the **reset board** command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the **reset board** command.
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Therefore, it cannot be reset without major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another UDS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this error type.
2012	ABORT	Internal system error 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-732. TEST #135 Internal Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the **reset board** command at 1-minute intervals for a maximum of 5 times.
	FAIL	The UDS1 Interface circuit pack failed in the Internal Looparound Test. If the UDS1 connects to a T1 network facility or another switch: 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 2. Enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the physical connectivity of DS1 Interface circuit packs and cable. 5. Replace the local UDS1 Interface circuit pack and repeat the test. 6. Contact T1 Network Service to diagnose the remote DS1 endpoint.
	FAIL *(cont'd.)*	If the UDS1 connects to a line-side terminating device such as a PRI terminal adapter: 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 2. Enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 4. Investigate the maintenance status of the line-side terminating device. Obtain the error seconds measurement on the terminating device (if possible). Refer to the line-side terminating device operating manual for information. 5. Check the physical connection of the UDS1 Interface circuit pack to the terminating device. Check premise distribution system (or intra-premise wiring) for physical connection failures. If the error seconds measurement is severe, investigate premise distribution system wiring for noise and distance limitation. 6. Replace the local UDS1 Interface circuit pack and repeat the test. 7. Contact the vendor of the line-side terminating device to diagnose the equipment.

Table 9-732. TEST #135 Internal Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	All administered trunks or ports of the UDS1 Interface circuit pack pass the Internal Looparound Test. The bit pattern consistency test is executed successfully over the path that covers a DS1 port, cable, and the external NCTE device.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Loss of Signal Alarm Inquiry Test (#138)

This test verifies the synchronization status and continuity of the DS1 link. The Loss of Signal alarm indicates that the UDS1 Interface circuit pack is unable to derive the synchronization clock from the DS1 facility. When the UDS1 Interface circuit pack detects a Loss of Signal alarm, it stops providing the synchronization clock for the system if it is administered as a timing source and transmits a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, the maintenance software places all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored.

The UDS1 Interface circuit pack raises a Loss of Signal alarm after the signal has been lost for about 1 second. It will not retire the alarm until the signal has returned for about 10 seconds.

This test is also used to maintain the Lucent 120A1 CSU Module or the 401A T1 Sync Spliltter, and the 402A or 403A E1 Synchronization Spllitter. The CSU Module, when combined with the functionality provided by the TN464F circuit pack, provides functionality equivalent to an external stand-alone Lucent ESF T1 CSU. The combination of the TN464F and 120A1 CSU Module is known as an Enhanced Integrated CSU (I-CSU).

The 401A T1 Synchronization Spllitter, when combined with the functionality provided by the TN464F circuit pack, allows an ATM switch to derive its timing from a T1 connected to the UDS1 in the DEFINITY.

The 402A or 403A E1 Synchronization Spllitter, when combined with the functionality provided by the TN464F circuit pack, allows an ATM switch to derive its timing from an E1 connected to the UDS1 in the DEFINITY.

If a TN464F circuit pack detects certain I-CSU/Sync Splitter hardware errors, it will notify maintenance. When the maintenance subsystem receives notification of the I-CSU/Sync Splitter error, it will execute this Loss of Signal Inquiry test. The test, in addition to querying for a Loss Of Signal alarm condition, will also query the TN464F board to confirm the I-CSU/Sync Splitter error. A Minor or Warning alarm will be raised depending on the severity of the I-CSU/Sync Splitter error. The trunks on the board may be taken out of service if the I-CSU/Sync Splitter error is deemed serious.

If a Loss Of Signal alarm and an I-CSU/Sync Splitter error co-exist, the Loss Of Signal alarm condition will take priority and the board and all trunks on the board will be put in the out-of-service state. Errors will be logged, however, for both.

When the maintenance subsystem receives notification that the I-CSU/Sync Splitter hardware error condition no longer exists, maintenance will restore the board and all trunks to their previous service state if the alarm can be cleared (no other I-CSU/Sync Splitter errors or Loss Of Signal alarm exist).

Table 9-733. TEST #138 Loss of Signal Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Table 9-733. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	UDS1 Interface circuit pack detects a Loss of Signal alarm. The physical link is broken or the remote DS1 endpoint is down. All trunks or ports of this UDS1 interface circuit pack are out-of-service. If the UDS1 Interface circuit pack is designated as the supplier of the system synchronization source, then the system synchronization maintenance will adopt a source elsewhere. Refer to the "SYNC (Synchronization)" section in this chapter for details. If the UDS1 connects to a T1 network facility: 1. Check the physical connection of the UDS1 Interface circuit pack and the cable. If a CSU Module or a Sync Splitter is physically connected to a TN464F board on the back of the port carrier, check the physical connection of the CSU Module/Sync Splitter and make sure the Network Interface cable is plugged into the CSU Module's/Sync Splitter's NETWORK jack. 2. If the UDS1 Interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the UDS1 Interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. If the UDS1 connects to a line-side terminating device such as a PRI terminal adapter: 1. Check the physical connection of the UDS1 Interface circuit pack to the terminating device. Check premise distribution system (or intra-premise wiring) for physical connection failures. If a CSU Module or Sync Splitter is physically connected to a TN464F board on the back of the port carrier, check the physical connection of the CSU Module/Sync Splitter and make sure the Network Interface cable is plugged into the CSU Module's/Sync Splitter's NETWORK jack. 2. Contact the vendor of the line-side terminating device to diagnose the equipment.

Table 9-733. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1300	FAIL	The CSU Module/T1 Sync Splitter or the E1 Sync Splitter is missing. The CSU Module/T1 Sync Splitter is missing: The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the 120A1 CSU Moduler or the 401A T1 Sync Splitter is not physically connected to the TN464F board on the back of the port carrier. 1. If using the 120A1 CSU Module or the 401A T1 Sync Splitter, plug the CSU Module/T1 Sync Splitter into the TN464F circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *Near-End CSU Type* field using the *change ds1* form to *other*. 2. Run the test again. The E1 Sync Splitter is missing: The *E1 Sync-Splitter?* field on the *add ds1* form has been administered as *y* but the 402A or 403A E1 Sync Splitter is not physically connected to the TN464F board on the back of the port carrier. 1. If using the 402A or 403A E1 Synchronization Splitter, plug the E1SS into the TN464F circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *E1 Sync-Splitter?* field using the *change ds1* form to *n*. 2. Run the test again.
1301	FAIL	The 120A1 CSU Module or the 401A T1 Sync Spliltter, or the 402A or 403A E1 Synchronization Splitter is not expected. The 120A1 CSU Module or the 401A T1 Sync Spliltter is not expected: The 120A1 CSU Module/T1 Sync Splitter is physically connected to the TN464F board on the back of the port carrier but the *Near-End CSU Type* field on the *add ds1* form has not been administered as *integrated*. 1. If the 120A1 CSU Module/T1 Sync Splitter is to be used, use the *change ds1* command to change the *Near-End CSU Type* field to *integrated*. Otherwise, physically remove the 120A1 CSU Module/T1 Sync Splitter from the back of the port carrier. 2. Run the test again. The 402A or 403A E1 Synchronization Splitter is not expected: The 402A or 403A E1 Synchronization Splitter is physically connected to the TN464F board on the back of the port carrier but the *E1 Sync-Splitter?* field on the *add ds1* form has not been administered as *y*. 1. If the 402A or 403A E1 Synchronization Splitter is to be used, use the *change ds1* command to change the *E1 Sync-Splitter?* field to *y*. Otherwise, physically remove the 402A or 403A E1 Synchronization Splitter from the back of the port carrier. 2. Run the test again.

Table 9-733. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1302	FAIL	Attempting to use the 120A1 CSU Module with a TN464F circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America. 1. If the 120A1 CSU Module is to be used, physically remove the TN464F circuit pack and reconfigure for 24-channel (1.544 Mbps) operation. 2. Reinsert the circuit pack and run the test again.
1303	FAIL	The DS1 circuit pack Suffix is incorrect for CSU Module/T1 Sync Splitter or E1 Sync Splitter administration. The DS1 circuit pack Suffix is incorrect for CSU Module/T1 Sync Splitter administration. The *Near-End CSU Type* field on the *add ds1* form has been administered as `integrated` but the DS1 circuit pack is not a TN464F or later suffix UDS1 board. 1. If the CSU Module/T1 Sync Splitter is to be used, and the *Near-End CSU Type* field is set to `integrated` to allow for CSU Module/T1 Sync Splitter administration, remove the circuit pack and replace it with a TN464F or later suffix board. Otherwise use the ***change ds1*** command to change the *Near-End CSU Type* field to *other*. The DS1 circuit pack Suffix is incorrect for E1 Sync Splitter administration. The *E1 Sync-Splitter?* field on the *add ds1* form has been administered as *y* but the DS1 circuit pack is not a TN464F or later suffix UDS1 board. 1. If the E1 Sync Splitter is to be used, and the *E1 Sync-Splitter?* field is set to *y* to allow for E1SS administration, remove the circuit pack and replace it with a TN464F or later suffix board. Otherwise use the ***change ds1*** command to change the *E1 Sync-Splitter?* field to *n*.
1310	FAIL	The DS1 Board Loopback (BLB) demand test (#1209) failed. 1. Repeat the test using the *test ds1-loop UUCSS ds1/csu-loopback-tests* command. 2. If the BLB test continues to fail, then replace the TN464F circuit pack. 3. Run this test again.

Continued on next page

Table 9-733. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1311	FAIL	The Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test (#1210) failed. This test is executed by the I-CSU during I-CSU power-up/reset (i.e., the TN464F board is physically inserted and a CSU Module or a Sync Splilter is already installed) or when the CSU Module/Sync Splitter is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command *test ds1-loop UUCSS ds1/csu-loopback-tests* for the CSU Module and T1 Sync Splitter. 1. Execute the *test ds1-loop UUCSS ds1/csu-loopback-tests* command. 2. If the ELB test continues to fail, then either the TN464F board, the CSU Module/T1 Sync Splitter, or the I/O cable between the backplane and the CSU module/T1 Sync Splitter (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module/T1 Sync Splitter and running the *test ds1-loop UUCSS ds1/csu-loopback-tests* command again. 3. If the ELB test continues to fail, then replace the TN464F board and run the *test ds1-loop UUCSS ds1/csu-loopback-tests* command again. 4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU module/T1 Sync Splitter.
1312	FAIL	The Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test (#1211) failed. This test is executed during I-CSU/Sync Splitter power-up/reset (i.e., the TN464F board is physically inserted and the CSU Module or the Sync Spliltter is already installed) or when the CSU Module/Sync Splitter is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command ***test ds1-loop UUCSS ds1/csu-loopback-tests*** for the CSU Module/T1 Sync Splitter. 1. Execute the ***test ds1-loop UUCSS ds1/csu-loopback-tests*** command. 2. If the RLB test continues to fail, then replace the CSU Module/T1 Sync Splitter. 3. Run this test again.
1313	FAIL	The TN464F circuit pack could not deactivate a CPE Loopback Jack loopback. 1. Execute the ***test ds1-loop UUCSS end-loopback/span-test*** command. 2. If the attempt to deactivate the CPE Loopback Jack is not successful, check the cabling and investigate the problem at the CPE Loopback Jack. 3. Run the test again.
1314	FAIL	The TN464F circuit pack could not deactivate a far-end CSU loopback. 1. Execute the ***test ds1-loop UUCSS end-loopback/span-test*** command.

Continued on next page

Table 9-733. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1320	FAIL	A CSU Module/Sync Splitter hardware failure, or an ICSU/Sync Splitter serial interface audit failure was detected by the TN464F UDS1 circuit pack. 1. Replace the CSU module/Sync Splitter, and then run the test again. 2. If the test continues to fail with this error code, replace the TN464F and run the test again. 3. If the test continues to fail with this error code, then the problem could be in the I/O cable between the backplane and the CSU module/Sync Splitter.
1321	FAIL	DTE LOS (loss of signal) was detected between the TN464F UDS1 board and the CSU Module or the Sync Splilter. Either the TN464F board, the CSU Module/Sync Splilter, or the I/O cable between the backplane and the CSU module/Sync Splitter (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. 1. Replace the CSU Module/Sync Splitter and run the test again. 2. If the test continues to fail with this error code, then replace the TN464F board and run the test again. 3. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module/Sync Splitter.
1322	FAIL	No 5 volts power detected from the TN464F circuit pack to the CSU Module or the Sync Splitter. Problem is probably due to an open fuse on the DS1 board or a faulty ICSU/Sync Splitter. **NOTE:** Do not immediately swap DS1 boards as this may blow the fuse on the new board. 1. If the test continues to fail with this error code, then replace the CSU Module/Sync Splitter and run the test again. 2. Remove the TN464F from the system and reinsert. 3. Run the test again once the board has finished its reset. 4. If the test continues to fail with this error code, then replace the TN464F board and run the test again. 5. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module/Sync Splitter.
1323	FAIL	A service-affecting CSU Module/Sync Splitter audit failure was detected by the TN464F UDS1 circuit pack. All administered ports on the UDS1 circuit pack are affected and maintenance software will place the ports into the out-of-service state. 1. Replace the CSU Module or the Sync Splitter.

Continued on next page

Table 9-733. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1324	FAIL	A non-service-affecting CSU Module/Sync Splitter audit failure was detected by the TN464F UDS1 circuit pack. No ports should be affected. No immediate action is required. These errors indicate that the CSU Module/Sync Splitter hardware may have a problem, and that it should be replaced when practical to avoid further deterioration.
	PASS	DS1 signal is present and the physical link is healthy. In addition, no Integrated CSU/Sync Splitter errors are detected.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Blue Alarm Inquiry Test (#139)

The Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the blue alarm status of the remote DS1 endpoint.

When the UDS1 Interface circuit pack detects a Blue Alarm signal from the remote DS1 endpoint, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a BLUE ALARM message to the maintenance software. When the Blue alarm is confirmed, the maintenance software places all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Blue alarm is cleared.

The UDS1 Interface circuit pack takes 1 seconds to recognize and report a Blue alarm and 16 seconds to recognize and report the resolution of a Blue alarm. When the Blue alarm is cleared, the UDS1 Interface circuit pack stops transmitting the Yellow alarm and places the trunks or ports back into the service state before the Blue alarm occurs.

Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the ICSU or DS1 board into a loopback mode. When the ICSU or DS1 board is in the LLB mode, the arriving bit pattern is regenerated and sent back. Line Loopback (LLB) Alarm is activated when the in-band activate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line. LLB is deactivated when the in-band deactivate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line.

Since LLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. PLB Alarm is activated when a network protocol activate bit pattern arrives over the 4Kbps ESF data link on the DS1 line. PLB is deactivated when a network protocol deactivate bit pattern arrives over the 4Kbps ESF data link on the DS1 line.

Since PLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm

Table 9-734. TEST #139 Blue Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The remote DS1 endpoint is out-of-service.
1 1794	FAIL	The UDS1 Interface circuit pack detects a Line Loopback Alarm (LLB). If the UDS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the UDS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. If the UDS1 interface circuit pack connects directly to a line-side terminating device (for example, a PRI terminal adapter), call the vendor of the terminating device to diagnose the equipment.

Continued on next page

Table 9-734. TEST #139 Blue Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1795	FAIL	The UDS1 Interface circuit pack detects a Payload Loopback Alarm (PLB). If the UDS1 Interface circuit pack connects to a leased T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the UDS1 Interface circuit pack connects directly to another DS1 board, call the system technician of the remote switch to diagnose the DS1 endpoint. If the UDS1 Interface circuit pack connects directly to a line-side terminating device such as a PRI terminal adapter contact the vendor of the terminating device to diagnose the equipment.
	PASS	Remote DS1 endpoint is in-service. Neither a Blue alarm nor a Line Loopback alarm nor a Payload Loopback Alarm is detected by the UDS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Red Alarm Inquiry Test (#140)

A UDS1 Interface circuit pack raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry Test checks the framing status of a UDS1 Interface circuit pack. A UDS1 Interface circuit pack takes 3 seconds to recognize and report a Red alarm and 10 seconds to recognize and report the resolution of a Red alarm.

When the UDS1 Interface circuit pack detects a Red alarm, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a RED ALARM message to the maintenance software. After the Red alarm is confirmed, the maintenance software places all trunks or ports of the circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Red alarm is cleared.

When the Red alarm is cleared, the UDS1 Interface circuit pack will stop transmitting the Yellow alarm to the remote DS1 endpoint. The maintenance software restores all trunks or ports of the UDS1 Interface circuit pack to the service state before the Red alarm occurs.

Loss of Multiframe Alarm

If the UDS1 Interface circuit pack is administered using DMI-BOS signaling, the UDS1 Interface circuit pack raises a Loss of Multiframe Alarm (LMA) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24th channel. Once the UDS1 Interface circuit pack detects an LMA, the circuit pack will transmit a Remote Multiframe Alarm (RMA) to the remote DS1 endpoint. Maintenance software handles both Red alarm and LMA alarm(s) using the same mechanism.

Table 9-735. TEST #140 Red Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 9-735. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The UDS1 interface circuit pack detected a red alarm. An out of frame condition occurred on the UDS1 interface circuit pack. The UDS1 interface circuit pack will transmit a yellow alarm to the remote UDS1 endpoint until the red alarm is retired. If the UDS1 connects to a T1 network facility or to another switch, do the following. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 2. Contact T1 Network Service or a technician at the far-end switch to diagnose the remote DS1 endpoint. 3. Check the physical connectivity of the UDS1 packs and of the cable. 4. Replace the local UDS1 interface circuit pack, and repeat the test. If the UDS1 connects to a line-side terminating device (for example, a PRI terminal adapter), do the following. 1. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 2. Investigate the maintenance status of the line-side terminating device. Refer to the 'Line-Side Terminating Device Operating Manual' for information. 3. Contact the vendor of the line-side terminating device to diagnose the equipment. 4. Check the physical connection of the UDS1 interface circuit pack to the terminating device, and check the premise distribution system (or the intra-premise wiring) for physical connection failures. 5. Replace the local UDS1 interface circuit pack and repeat the test.

Continued on next page

Table 9-735. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The test failed. The UDS1 interface circuit pack detected a loss of multiframe alarm (LMA). An out of frame condition occurred on the UDS1 interface circuit pack. The UDS1 interface circuit pack will transmit a remote multiframe alarm (RMA) to the remote UDS1 endpoint until the LMA is retired. If the UDS1 connects to a T1 network facility or to another switch, do the following: 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 2. Contact T1 Network Service or a technician at the far-end switch to diagnose the remote DS1 endpoint. 3. Check the physical connectivity of the UDS1 packs and of the cable. 4. Replace the local UDS1 interface circuit pack, and repeat the test. If the UDS1 connects to a line-side terminating device (for example, a PRI terminal adapter), do the following. 1. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 2. Investigate the maintenance status of the line-side terminating device. Refer to the 'Line-Side Terminating Device Operating Manual' for information. 3. Contact the vendor of the line-side terminating device to diagnose the equipment. 4. Check the physical connection of the UDS1 interface circuit pack to the terminating device, and check the premise distribution system (or the intra-premise wiring) for physical connection failures. 5. Replace the local UDS1 interface circuit pack and repeat the test.

Table 9-735. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	No Red alarm is detected on the UDS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Yellow Alarm Inquiry Test (#141)

Receiving a Yellow alarm from remote DS1 endpoint indicates that the remote DS1 endpoint has an out-of-frame condition. The Yellow Alarm Inquiry Test is used to determine whether the remote DS1 endpoint is transmitting a Yellow alarm. The UDS1 Interface circuit pack takes 500 msec to recognize and report a Yellow alarm and 500 msec to recognize and report that a Yellow alarm condition is cleared.

When the UDS1 Interface circuit pack detects a Yellow alarm from the remote DS1 endpoint, it will send a YELLOW-ALARM uplink message to the maintenance software. After the maintenance software receives the YELLOW-ALARM message, the Yellow Alarm Inquiry Test is run to confirm the Yellow alarm. Once the Yellow alarm is confirmed, the maintenance software places all trunks or ports on the circuit pack into the out-of-service state. The Inquiry Test will be run every 10 minutes until the Yellow alarm is cleared.

When the Yellow alarm is cleared, the maintenance software restores all trunks or ports on the UDS1 Interface circuit pack back to their previous service state before the Yellow alarm was raised.

This Yellow alarm corresponds to the yellow F2 state documented in CCITT Recommendation I.431.

Remote Multiframe Alarm

Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition while the UDS1 Interface circuit pack is administered using the DMI-BOS common channel signaling. The RMA is handled as a Yellow alarm.

Yellow F5 Fault Alarm

For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431.

Table 9-736. TEST #141 Yellow Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Major Alarm Inquiry Test (#142)

The Major alarm raised by a UDS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1000. The Major Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1000. The UDS1 Interface circuit pack takes 10 seconds to recognize and report a Major alarm and 10 seconds to recognize and report that a Major alarm condition is cleared.

When the UDS1 Interface circuit pack detects a Major alarm, it will send a MAJOR-ALARM message to the maintenance software. (32-channel interfaces send a YELLOW alarm to the far end). After the maintenance software receives a MAJOR-ALARM message, the Major Alarm Inquiry Test is initiated to confirm the Major alarm on the UDS1 Interface circuit pack. The Inquiry Test will be run every 10 minutes until the Major alarm is cleared. The maintenance software places all trunks or ports on the circuit pack in the out-of-service state if the Major alarm persists for more than 20 minutes.

When the Major alarm is cleared, the maintenance software restores all trunks or ports on the circuit pack to their previous service state before a Major alarm occurs.

Table 9-737. TEST #142 Major Alarm Inquiry Test

Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Minor Alarm Inquiry Test (#143)

The Minor alarm raised by a UDS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1,000,000, but less than 1/1000. The Minor Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. When D4 framing mode is selected, the UDS1 Interface circuit pack takes 41-minutes to recognize and report a Minor alarm and 41-minutes to recognize and report that a Minor alarm condition has cleared. If ESF framing mode is selected, the UDS1 Interface circuit pack takes 10 minutes to recognize and report a Minor alarm and 10 minutes to recognize and report that a Minor alarm condition has cleared.

When the UDS1 Interface circuit pack detects a Minor alarm condition, it will send a MINOR-ALARM message to the maintenance software. After the maintenance software receives a MINOR-ALARM message, the Minor Alarm Inquiry Test is initiated to confirm the Minor alarm. All trunks or ports on the circuit pack are kept in the in-service state after the Minor alarm is confirmed. The Minor Alarm Inquiry Test is run every 10 minutes until the Minor alarm is cleared.

Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 3. Investigate the maintenance status of the line-side terminating device. Obtain the error seconds measurement on the terminating device (if possible). Refer to the 'Line-Side Terminating Device Operating Manual' for information. 4. Contact the vendor of the line-side terminating device to diagnose the equipment. 5. Check the physical connection of the UDS1 interface circuit pack to the terminating device, and check the premise distribution system (or the intra-premise wiring) for physical connection failures. 6. Replace the local UDS1 interface circuit pack and repeat the test.

Continued on next page

Table 9-738. TEST #143 Minor Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	No Minor alarm is detected in the UDS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Slip Alarm Inquiry Test (#144)

Slips occur when transmitter and receiver are not running at precisely the same clock rate. The UDS1 Interface circuit pack can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test is used to acquire the total number of slips that have occurred on a DS1 link.

When the UDS1 Interface circuit pack detects a slip condition, the circuit pack will increase the on-board slip counter by 1. A SLIP-COUNT message is spontaneously sent to the system software after the counter reaches a threshold (for example, 88). When the maintenance software receives the SLIP-COUNT message, the Slip Alarm Inquiry Test is initiated to query the slip counters on a UDS1 Interface circuit pack and total the slip counts in the maintenance software.

If the count of slips is over the threshold, a Minor alarm is raised against the UDS1 Interface circuit pack. All trunks or ports of the UDS1 Interface circuit pack remain in the in-service state. If the UDS1 Interface circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See “TDM-BUS” and ‘‘SYNC (Synchronization)’’ for details.

Table 9-739. TEST #144 Slip Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-739. TEST #144 Slip Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 to 88	FAIL	The test failed because the UDS1 interface circuit pack and the remote DS1 endpoint are not synchronized to the same clock rate. The UDS1 interface circuit pack detected a slip alarm. The error code equals the number of slips detected by the UDS1 interface circuit pack since the last slip alarm inquiry test. If the UDS1 connects to a T1 network facility or to another switch, do the following: 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the DS1 interface circuit pack is a TN464C, enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors. 5. Contact T1 Network Service or the technician at the remote switch to diagnose the remote DS1 endpoint. 6. Check the physical connectivity of the UDS1 interface circuit packs and the cable. 7. Replace the local UDS1 interface circuit pack, and repeat the test. *Information continues on the next page.*
1 to 88 *(cont'd.)*	FAIL *(cont'd.)*	If the UDS1 connects to a line-side terminating device (for example, a PRI terminal adapter), do the following: 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. Enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 4. Investigate the maintenance status of the line-side terminating device. Refer to the 'Line-Side Terminating Device Operating Manual' for information. 5. Contact the vendor of the line-side terminating device to diagnose the equipment. 6. Check the physical connection of the UDS1 interface circuit pack to the terminating device, and check the premise distribution system (or the intra-premise wiring) for physical connection failures. 7) Replace the local UDS1 interface circuit pack and repeat the test.

Continued on next page

Table 9-739. TEST #144 Slip Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	No Slip alarm is detected on the UDS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Misframe Alarm Inquiry Test (#145)

Misframe Alarm indicates that framing bits observed on a UDS1 Interface circuit pack are in error. The Misframe Alarm Inquiry Test queries the total number of misframes that have occurred on a DS1 Interface circuit pack since the last inquiry.

When the DS1 Interface circuit pack detects a misframe error, it will increase its misframe counter by 1. If the counter reaches a specified threshold (i.e.- 17), a MISFRAME-COUNT message is automatically sent to the switch maintenance software. After the maintenance software receives the MISFRAME-COUNT message, the Misframe Alarm Inquiry Test is initiated to collect the misframe counts from the UDS1 Interface circuit pack.

When the threshold of misframes is reached, if the UDS1 Interface circuit pack is supplying the system synchronization source, then a switching synchronization source message is sent to the TDM Bus Clock. See TDM-BUS (TDM Bus) Maintenance documentation for details. A Minor alarm against the UDS1 Interface circuit pack is raised, but all trunks or ports of the UDS1 Interface circuit pack remain in the in-service state.

Table 9-740. TEST #145 Misframe Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-740. TEST #145 Misframe Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 to 17	FAIL	The test failed because the UDS1 interface circuit pack detected errors in the received framing bits pattern. The error code equals the number of misframes detected by the UDS1 interface circuit pack since the last misframe alarm inquiry test. Major bit and minor bit error rate (error types 2561 and 2817) error logs often accompany misframe alarms. Clearing the cause of these error logs may clear the misframes which are occurring. If the UDS1 connects to a T1 network facility or to another switch, do the following: 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the DS1 interface circuit pack is a TN464C, enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors. 5. Contact T1 Network Service or the technician at the remote switch to diagnose the remote DS1 endpoint. 6. Check the physical connectivity of the UDS1 interface circuit packs and the cable. 7. Replace the local UDS1 interface circuit pack, and repeat the test. *More information continues on the next page.*

Continued on next page

Table 9-740. TEST #145 Misframe Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 to 17 *(cont'd.)*	FAIL *(cont'd.)*	If the UDS1 connects to a line-side terminating device such as a PRI terminal adapter: 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. Enter the **list measurement ds1-log UUCSS** command to read the error seconds measurement. 3. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 4. Investigate the maintenance status of the line-side terminating device. Refer to the 'Line-Side Terminating Device Operating Manual' for information. 5. Contact the vendor of the line-side terminating device to diagnose the equipment. 6. Check the physical connection of the UDS1 interface circuit pack to the terminating device, and check the premise distribution system (or the intra-premise wiring) for physical connection failures. 7. Replace the local UDS1 interface circuit pack and repeat the test.
	PASS	No Misframe alarm is detected on the UDS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information specified by System Administration to the UDS1 Interface circuit pack. Translation includes the following data administered for a UDS1 Interface circuit pack (see output of **display ds1 UUCSS** command): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

In G3V3, if a TN464F or later UDS1 circuit pack is combined with a Lucent 120A1 CSU Module or the 401A T1 Sync Splitter to form an Integrated CSU Module/T1 Sync Splitter, this test will also send the administration for this Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU Module/T1 Sync Splitter is done using the DS1 circuit pack administration form. Translation for the CSU Module/T1 Sync Splitter includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power?, etc.

Table 9-741. TEST #146 Translation Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute interval s a maximum of 5 times.
	FAIL	Internal system software error. 1. Enter the **display ds1 UUCSS** command to verify the UDS1 Interface circuit pack translation.

Continued on next page

Table 9-741. TEST #146 Translation Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Translation data has been downloaded to the UDS1 Interface circuit pack successfully.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

DS1 Board Loopback Test (#1209)

This test is destructive.

The DS1 Board Loopback (BLB) Test causes a loopback at the TN464F DS1 board edge and tests DS1 board internal circuitry.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the BLB Test.

When the BLB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the BLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 9-742. TEST #1209 DS1 Board Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS ds1/csu-loopback-tests* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	DS1 Board Loopback Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the **test ds1-loop UUCSS end-loopback/span-test** command in order to execute this test.

Table 9-742. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	UDS1 Interface circuit pack failed the DS1 Board Loopback Test. 1. Retry the *test ds1-loop UUCSS ds1/csu-loopback-tests* command. 2. If the BLB test continues to fail, then replace the UDS1 circuit pack.

Continued on next page

Table 9-742. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The BLB test executed successfully. The test pattern was transmitted and received successfully up to the TN464F DS1 board edge.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

CSU Equipment Loopback Test (#1210)

This test is destructive.

The CSU Equipment Loopback (ELB) Test causes a loopback at the near-edge of the local Lucent 120A1 CSU Module or the 401A T1 Sync Splitter and tests the connection from the TN464F DS1 board to the CSU Module/T1 Sync Splitter (DS1 board edge interconnecting cable, and CSU Module/T1 Sync Splitter edge). This test will only be performed if the Lucent 120A1 CSU Module or the 401A T1 Sync Splitter is present, administered, and connected to a 1.544 Mbps TN464F DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the ELB Test.

When the ELB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the ELB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 9-743. TEST #1210 CSU Equipment Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS ds1/csu-loopback-tests* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	CSU Equipment Loopback Test cannot be executed in the current configuration. To run this test, the *Near-End CSU Type* field on the DS1circuit pack administration form must be set to *integrated* and the "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" (24-channel configuration). 1. Use the **change ds1 UUCSS** command to set the *Near-End CSU Type* field on the DS1 circuit pack administration form to *integrated*, and/or change the "Bit Rate" field to "1.544" if the board is to be used in 24-channel configuration. 2. Retry the ***test ds1-loop UUCSS ds1/csu-loopback-tests*** command.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.

Table 9-743. TEST #1210 CSU Equipment Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	UDS1 Interface circuit pack failed the CSU Equipment Loopback Test. 1. Retry the *test ds1-loop UUCSS ds1/csu-loopback-tests* command. 2. If the ELB test continues to fail, then either the TN464F board, the CSU Module/T1 Sync Splitter, or the I/O cable between the backplane and the CSU module/T1 Sync Splitter (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module/T1 Sync Splitter and running the *test ds1-loop UUCSS ds1/csu-loopback-tests* command again. 3. If the ELB test continues to fail, then replace the TN464F board and run the *test ds1-loop UUCSS ds1/csu-loopback-tests* command again. 4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU module/T1 Sync Splitter.
	PASS	The ELB test executed successfully. The test pattern was transmitted and received successfully over the connection from the TN464F DS1 board to the near-edge of the 120A1 CSU Module or the 401A T1 Sync Splitter.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

CSU Repeater Loopback Test (#1211)

This test is destructive.

The CSU Repeater Loopback (RLB) Test causes a loopback at the far-edge of the local Lucent 120A1 CSU Module or the 401A T1 Sync Splitter and tests the connection from the TN464F DS1 board to and including the CSU Module/T1 Sync Splitter circuitry. This test will only be performed if the Lucent 120A1 CSU Module or the 401A T1 Sync Splitter is present, administered, and connected to a 1.544 Mbps TN464F DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the RLB Test.

When the RLB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the RLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 9-744. TEST #1211 CSU Repeater Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS ds1/csu-loopback-tests* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	CSU Repeater Loopback Test cannot be executed in the current configuration. To run this test, the *Near-End CSU Type* field on the DS1circuit pack administration form must be set to *integrated* and the "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" (24-channel configuration). 1. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	UDS1 Interface circuit pack failed the CSU Repeater Loopback Test. 1. Retry the *test ds1-loop UUCSS ds1/csu-loopback-tests* command. 2. If the RLB test continues to fail, and the CSU Equipment Loopback Test (#1210) passed, then replace the CSU Module/T1 Sync Splitter.

Continued on next page

Table 9-744. TEST #1211 CSU Repeater Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The RLB test executed successfully. The test pattern was transmitted and received successfully over the connection from the TN464F DS1 board to the far-edge of the 120A1 CSU Module or the 401A T1 Sync Splitter.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

CPE Loopback Jack Test (#1212)

This test is destructive.

The CPE Loopback Jack (CLJ-LB) Test causes a loopback at the CPE Loopback Jack and tests the building wiring connection between the TN464F DS1 board and the CPE Loopback Jack.

The test is highly destructive and can only be initiated by a system technician demanded ***test ds1-loop UUCSS cpe-loopback-jack-test-begin [number-of-bits bit-pattern]*** command. The System technician has the choice of entering a loopback activation code on the command line or using the default code *0x47F*.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the CPE Loopback Jack Test.

The CPE Loopback Jack Test has the TN464F UDS1 Interface circuit pack transmit a loopback activation code to the CPE Loopback Jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully sent. If the loopback is not established within the 10 seconds, the test returns FAIL or abort.

The status of the CPE Loopback Jack test will be available in the hardware error log via error type 3900. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of Loopback/Span test executing (*Test* field), the type of pattern generated for the Loopback/Span test (*Pattern* field), and whether the pattern (*i.e. 3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop UUCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

Table 9-745. TEST #1212 CPE Loopback Jack Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS cpe-loopback-jack-test-begin* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	CPE Loopback Jack Test cannot be executed in the current configuration. To run this test, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command.

Continued on next page

Table 9-745. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop UUCSS end-loopback/span-test* command in order to execute this test.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Continued on next page

Table 9-745. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2	FAIL	The CLJ-LB test failed because it was not set up properly. The UDS1 interface pack could not successfully put the CPE loopback jack into loopback mode. 1. Rerun the **test ds1-loop UUCSS cpe-loopback-jack-test-begin** command. 2. If the test continues to fail, the problem could be with the TN464F board, the CPE loopback jack equipment, or somewhere between. Run the **test ds1-loop UUCSS ds1/csu-loopback-tests** command to determine if the loopback tests that are closer to the TN464F board are successful. If any of these tests fail, follow the maintenance strategy that is associated with the test that fails.
3	FAIL	The CPE Loopback Jack Test was not set up properly. The framed 3-in-24 test pattern, generated by the UDS1 Interface circuit pack and looped back through the CPE Loopback Jack, could not be detected properly by the UDS1 circuit pack. 1. Retry the *test ds1-loop UUCSS cpe-loopback-jack-test-begin* command. 2. If the CPE Loopback Jack test continues to fail, the problem could be with the TN464F board, the CPE Loopback Jack equipment, or somewhere in between. Run the *test ds1-loop UUCSS ds1/csu-loopback-tests* command to see if the loopback tests closer to the TN464F board are successful. If any of those loopback tests fail, follow the maintenance strategy associated with those loopbacks.

Continued on next page

Table 9-745. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The CPE Loopback Jack test has successfully began executing. The test will continue to run until the system technician enters the *test ds1-loop UUCSS end-loopback/span-test* command or the *release board UUCSS* command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Far CSU Loopback Test (#1213)

This test is destructive.

The Far CSU Loopback (R-LLB) Test causes a loopback at the far-end CSU and tests all circuitry and facilities from the local TN464F DS1 board to the far-end CSU.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS far-csu-loopback-test-begin* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Far CSU Loopback Test.

If the far-end CSU is not a Lucent 120A1 CSU Module or the 401A T1 Sync Splitter, and the DS1 is administered for ami-zcs line coding, one’s density protection must be disabled on the CSU/T1SS during the test due to the large number of zero’s in the 3-in-24 test pattern.

The Far CSU Loopback Test has the TN464F UDS1 Interface circuit pack transmit a loopback activation code to the remote CSU, waits up to 15 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result. If the loopback is not established within the 15 seconds, the test fails.

The status of the Far CSU Loopback test will be available in the hardware error log via error type 3901. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of Loopback/Span test executing (*Test* field), the type of pattern generated for the type of Loopback/Span test (*Pattern* field), and whether the pattern (*i.e. 3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop UUCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

Table 9-746. TEST #1213 Far CSU Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS far-csu-loopback-test-begin* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Far CSU Loopback Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command.

Table 9-746. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2	FAIL	The test failed because it was not set up properly. The UDS1 pack could not successfully put the far-end CSU into loopback mode. 1. Rerun the **test ds1-loop UUCSS far-csu-loopback-test-begin** command. 2. If the test continues to fail, the problem could be with the TN464F board, the CPE loopback jack equipment, or somewhere between. Run the **test ds1-loop UUCSS cpe-loopback-jack-test-begin** command to determine if the CPE loopback jack loopback test is successful. If a CPE loopback jack device is not being used, issue the **test ds1-loop UUCSS ds1/csu-loopback-tests** command instead. If the closer loopback test fails, follow the maintenance strategy associated with that test.
3	FAIL	The Far CSU Loopback Test was not set up properly. The framed 3-in-24 test pattern, generated by the UDS1 Interface circuit pack and looped back through the far-end CSU, could not be detected properly by the UDS1 circuit pack. 1. Retry the *test ds1-loop UUCSS far-csu-loopback-test-begin* command. 2. If the Far CSU Loopback test continues to fail with this error code, the problem could be with the TN464F board, the far-end CSU equipment, or somewhere in between. Run the *test ds1-loop UUCSS cpe-loopback-jack-test-begin* command to see if the CPE Loopback Jack test which is closer to the TN464F board is successful. (If a CPE Loopback Jack device is not being used, then run the *test ds1-loop UUCSS ds1/csu-loopback-tests* command to see if these even closer loopback tests succeed). If the closer loopback test fails, follow the maintenance strategy associated with that loopback.

Continued on next page

Table 9-746. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The Far CSU Loopback test has successfully began executing. The test will continue to run until the system technician enters the *test ds1-loop UUCSS end-loopback/span-test* command or the *release board UUCSS* command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

One-Way Span Test (#1214)

This test is destructive.

The One-Way Span Test allows one-way span testing to and from remote test equipment or another DEFINITY communications system. This will test all circuitry and facilities from the local TN464F DS1 board to the remote test equipment or other DEFINITY communications system.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS one-way-span-test-begin* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the One-Way Span Test.

The One-Way Span Test has the TN464F UDS1 Interface circuit pack transmit a framed 3-in-24 test pattern and attempt to receive and verify the pattern. If the TN464F board receives a framed 3-in-24 test pattern sent from another DEFINITY G3V3 or test equipment at the far-end of the DS1, it will begin counting bit errors within the received pattern.

The status of the One-Way Span test will be available in the hardware error log via error type 3902. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being sent cleanly over the span from the far-end, the number of bit errors should be very low. The *Test Duration* field will show *0* until the test pattern is received from the far-end. Upon receiving the test pattern, the board will begin calculating the test duration and number of bit errors. The command will also display the Loopback/Span test executing (*Test* field), the type of pattern generated for the Loopback/Span test (*Pattern* field), and whether the pattern (*i.e. 3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop UUCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

Table 9-747. TEST #1214 One-Way Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS one-way-span-test-begin* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	One-Way Span Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization UUCSS** command. 3. Lastly, issue the **enable synchronization-switch** command.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop UUCSS end-loopback/span-test* command in order to execute this test.

Continued on next page

Table 9-747. TEST #1214 One-Way Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-747. TEST #1214 One-Way Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The One-Way Span test has successfully began transmitting a framed 3-in-24 test pattern. The test will continue to run until the system technician enters the *test ds1-loop UUCSS end-loopback/span-test* command or the *release board UUCSS* command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Inject Single Bit Error Test (#1215). This test is destructive.

The Inject Single Bit Error Test will cause a single bit error to be sent within an active framed 3-in-24 test pattern.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS inject-single-bit-error* command. An attempt to use this command will be rejected if none of the three long-duration DS1 loopback/span tests (CPE Loopback Jack Test, Far CSU Loopback Test, One-Way Span Test) are active on a TN464F circuit pack.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Inject Single Bit Error Test.

The *list measurements ds1 summary* command displays the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). Injecting this single bit error should increment the bit error count of the loopback/span test by one.

Table 9-748. TEST #1215 Inject Single Bit Error Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS inject-single-bit-error* command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-748. TEST #1215 Inject Single Bit Error Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	A single bit error has been successfully injected into an active framed 3-in-24 test pattern.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

End Loopback/Span Test (#1216)

This test is destructive.

The End Loopback/Span Test will terminate an active loopback or span test on a TN464F UDS1 circuit pack. Bit error counting against the received test pattern stream is terminated and sending of the framed 3-in-24 test pattern is halted. If either the CPE Loopback Jack or the far-end CSU is looped, the appropriate loopback deactivate code is sent. If the loopback could not be deactivated, then the test will FAIL and a MINOR alarm will be noted in the alarm log until the loopback is cleared.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop UUCSS end-loopback/span-test* command. Since only one of these three different long-duration loopback/span tests can be active at a time, the TN464F circuit pack knows which loopback/span test to terminate.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running this End Loopback/Span Test.

The *list measurements ds1 summary* command will display the length of time the test ran (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field).

To restore the trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state, execute the **release board** command.

Table 9-749. TEST #1216 End Loopback/Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the *test ds1-loop UUCSS end-loopback/span-test* command at 1-minute intervals a maximum of 5 times.
1005	ABORT	End Loopback/Span Test cannot be executed in the current configuration. To run this test, the TN464F or later suffix DS1 board must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board UUCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command.

Continued on next page

Table 9-749. TEST #1216 End Loopback/Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1313	FAIL	The TN464F UDS1 circuit pack could not deactivate the loopback through the Customer Loopback Jack. 1. Retry the *test ds1-loop UUCSS end-loopback/span-test* command at 1-minute intervals for a maximum of 5 times.
1314	FAIL	The TN464F UDS1 circuit pack could not deactivate the loopback through the far-end CSU. 1. Make sure that the far-end DS1 is installed if the far-end CSU is a 120A1 Lucent CSU Module/T1 Sync Splitter. 2. Retry the ***test ds1-loop UUCSS end-loopback/span-test*** command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-749. TEST #1216 End Loopback/Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The active long-duration loopback or span test on the TN464F circuit pack was successfully terminated.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

ICSU Status LEDs Test (#1227)

The TN464F UDS1 circuit pack has four status LEDs on the faceplate in addition to the three standard faceplate LEDs. These four status LEDs are associated with the 120A1 Channel Service Unit (CSU) Module that can be connected to the TN464F board via the I/O connector panel on the back of the port carrier. The TN464F circuit pack combined with the 120A1 CSU Module or the 401A T1 Sync Splitter forms an Integrated CSU (I-CSU).

This test is a visual test. It will light the four status LEDs red for 5 seconds, then light them green for 5 seconds, then light them yellow for 5 seconds, then turn the LEDs off and returns control of the status LEDs to the circuit pack.

This test will only be executed on TN464F or later suffix UDS1 circuit packs administered for 24-channel operation (1.544 bit rate).

If the 120A1 CSU Module or the 401A T1 Sync Splitter is not physically installed, the status LEDs are always off and this test will abort.

Table 9-750. TEST #1227 ICSU Status LEDs Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	The ICSU Status LEDs test can not be executed for the current configuration. The test applies only to TN464F or later UDS1 circuit packs administered for 24-channel operation (1.544 bit rate). 1. If the circuit pack is a TN464F or later suffix UDS1 circuit pack, then retry the command.
1951	ABORT	The ICSU Status LEDs Test can not be executed because a 120A1 or later suffix CSU Module or a 401A or later suffix T1 Sync Splitter is not physically installed. If using a 120A1 CSU Module or the 401A T1 Sync Splitter, physically connect it to the TN464F board on the back of the port carrier. Otherwise, ignore this abort.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2500	ABORT	Internal system error. 1. Retry the command.

Continued on next page

Table 9-750. TEST #1227 ICSU Status LEDs Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The ICSU Status LEDs test executed successfully. A PASS result, however, does not necessarily mean that the status LEDs behaved properly. It only means that the software successfully attempted to light the status LEDs. This is a visual test. The service technician must visually exam the behavior of the LEDs while the test is running. The LEDs are functioning properly if the four status LEDs are lit red for 5 seconds, then lit green for 5 seconds, then lit yellow for 5 seconds. If the LEDs behave differently, the board should be replaced at the customer's convenience.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 UUCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

VC-BD

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
VC-BD	MAJOR	test board UUCSS l r#	Voice Conditioner Circuit Pack
VC-BD	MINOR	test board UUCSS l r#	Voice Conditioner Circuit Pack
VC-BD	WARNING[2]	test board UUCSS s r#	Voice Conditioner Circuit Pack

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).
2. Refer to XXX-BD (Common Port Board) Maintenance documentation.

CAUTION:
If the TN788 Voice Conditioner Circuit Pack (VC-BD) is not Vintage 2 or later, it must be replaced.

The TN788 Voice Conditioner Circuit Pack (VC-BD) is a service circuit pack that provides conditioning for the audio signals from multimedia equipment based on the CCITT H.221 standard. The TN788 transcodes, gain adjusts, and bridges the audio bit streams demultiplexed by the TN787 (MMI) circuit pack and transmits encoded, exclusive audio conference sums onto the TDM bus so that the MMI can multiplex the audio, video, and data streams for the H.221 endpoints.

Error Log Entries and Test to Clear Values

Table 9-751. VC-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS sh r 1
1 (a)	Any	None	MIN	ON	
18 (b)	0	busyout board UUCSS	WNG	OFF	release board UUCSS
257 (c)	Any	Control Channel Loop Test (#52)	MIN	ON	test board UUCSS r 20
513 (d)	4352 to 4357				
769 (e)	4358				

Continued on next page

Table 9-751. VC-BD Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1025 (f)	4363	NPE Audit Test (#50)			
1281 (g)	Any	SAKI Sanity Test (#53)	MAJ	On	
1293 to 1294 (h)	46088 to 46096	SAKI Sanity Test (#53)	MIN	ON	
1538 (i)	46082		MIN	ON	

1. Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The circuit pack stopped functioning or it was removed from the system. This alarm is logged approximately 11-minutes after the circuit pack is removed and/or the SAKI Sanity Test (#53) fails.

   To resolve this error, insert a circuit pack in the same slot as the error indicates, if the circuit pack is not already in the system. Or, if the circuit pack is in the system and the red LED is on, then follow instructions for Red alarms.

   CAUTION:
   If the TN788 Voice Conditioner Circuit Pack (VC-BD) is not Vintage 2 or later, it must be replaced.

b. This circuit pack is busied out by the **busyout board UUCSS** command.

c. Transient communication problems exist between the switch and this circuit pack. Execute the **test board UUCSS** command and refer to the repair procedures for the Control Channel Looparound Test (#52).

d. The circuit pack detected an on-board hardware failure. The reported aux data values correspond to the following detected errors:

Error	Description
4352	External RAM error
4353	Internal RAM error
4355	ROM Checksum error
4357	Instruction set error

Reset the circuit pack by executing the **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS** commands. When it is reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedures in footnote (a) for error type 1.

e. The circuit pack detects a program logic error. While no action is required, this error may lead to errors of other types being reported against this circuit pack.

f. The circuit pack cannot update NPE memory and read it back. This error type can be ignored, but it may lead to other error types being reported against this circuit pack.

g. A critical hardware failure has been detected on the circuit pack. Use **busyout board UUCSS, reset board UUCSS**, followed by **release board UUCSS**. If test #53 passes, the on-board circuitry is healthy. Use **test board UUCSS long clear** to retire the alarm. If test #53 fails, replace the circuit pack.

h. The circuit pack detected a critical hardware failure. Reset the circuit pack by issuing the **busyout board UUCSS**, **reset board UUCSS**, and **release board UUCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm by issuing the **test board UUCSS long clear** command. If the Circuit Pack Restart Rest (#594) fails, replace the circuit pack.

The reported error types correspond to the following detected errors:

Error	Description
1293	On-board auxiliary processor insane
1294	Internal memory access error

i. The circuit pack is hyperactive — it is flooding the switch with messages sent over the control channel. The circuit pack is taken out of service when a threshold number of these errors is reported to the switch. Clear the alarm by using **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long clear**, and **release board UUCSS**. If the error recurs within 10 minutes, then replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Code

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop-Around Test (#52)[2]	X	X	ND

1. D = Destructive; ND = Nondestructive
2. Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) maintenance documentation for a description of this test.

CAUTION:
If the TN788 Voice Conditioner Circuit Pack (VC-BD) is not Vintage 2 or later, it must be replaced.

Control Channel Looparound Test (#52)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) maintenance documentation as Control Channel Looparound Test (#52).

VC-DSPPT

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
VC-DSPPT	MAJOR	test port UUCSSpp	Voice Conditioner DSP Port
VC-DSPPT	MINOR	test port UUCSSpp	Voice Conditioner DSP Port
VC-DSPPT	WARNING	test port UUCSSpp	Voice Conditioner DSP Port

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).

Each Voice Conditioner Circuit Pack (VC-BD) provides two types of resources:

1. Transcoder Resources used for encoding and decoding audio formats
2. Summer Resources used for summing audio from different sources

The eight Voice Conditioner DSP ports are the transcoder resources on the VC-BD.

Error Log Entries and Test to Clear Values

Table 9-752. VC-DSPPT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/ Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
18 (a)	0	busyout port UUCSSpp	WNG	OFF	release port UUCSSpp
257 (b)	Any	NPE Crosstalk Test (#6)	MIN	ON	test port UUCSSpp 1 r 3
513 (c)	Any	VC DSP Port Local TDM Loopback Test (#1104)	MIN	ON	test port UUCSSpp sh r 3
778 to 781 (d)	Any	VC Port Reset DSP Test (#1106)	MAJ	ON	See note (d)
1025 (e)			WNG	ON	
1281 (f)	Any	VC DSP Port DSP Loopback Test #(1105)	MIN	ON	test port UUCSSpp sh r 3
3840 (g)					

1. Run the short test sequence first. If all test pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This port has been busied out by the **busyout port UUCSSpp** command.

b. The VC DSP Port NPE Crosstalk Test(#1103) failed.

c. The VC DSP Port Local TDM Loopback Test(#1104) failed. Run the Long Test Sequence.

d. A critical hardware failure has been detected on the circuit pack. Reset the port by the **busyout port UUCSSpp** and **reset port UUCSSpp** commands. If the VC Reset DSP Test (#1106) passes, then the on-board circuitry is healthy. Retire the alarm with the **test port UUCSSpp long clear** command.

e. The VC DSP port reported loss of framing on the Service Channel between the VC and MMI circuit packs.

f. The VC DSP Port DSP Loopback Test (#1105) failed.

g. The DSP corresponding to this port on the VC circuit pack reported a firmware error. No action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the DSP NPE Crosstalk Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
DSP NPE Crosstalk Test (#1103)		X	D
TDM Loopback Test (#1104)	X	X	D
DSP Loopback Test (#1105)	X	X	D

1. D = Destructive; ND = Nondestructive

DSP NPE Crosstalk Test (#1103)

This test is destructive.

The NPE Crosstalk test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of the port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 9-753. TEST #1103 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary resources for this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The NPE of the tested port was transmitting in error, causing noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test a maximum of 10 times. 2. If complaints still persist, examine the station, connections, and wiring.

VC DSP Port Local TDM Loopback Test (#1104)

This test is destructive.

This test verifies the connectivity of a VC DSP Port across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack. The Loopback Test runs the following tests:

1. A Looparound test across the TDM bus.
2. A conference Circuit Test.

The tests are run in the above order; if one test fails, an error code is returned and the remaining tests in the sequence are not executed.

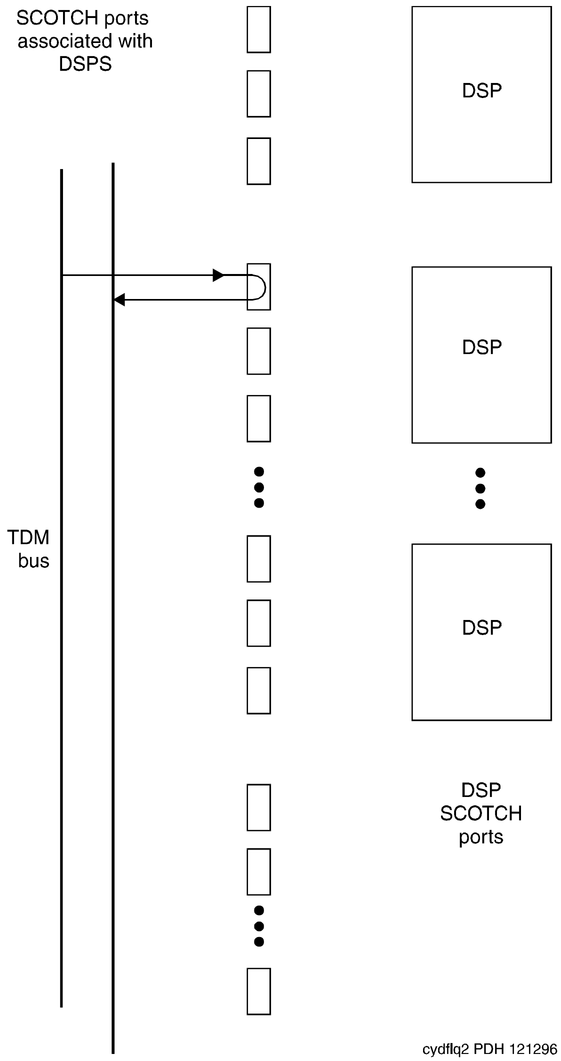

Figure 9-117. VC Circuit Pack DSP Port Local TDM Loopback Test

Table 9-754. TEST #1104 VC DSPPT Local TDM Loopback Test

Error Code	Test Result	Description/Recommendation
1000 1001	ABORT	System resources required to run this test are not available, or the port is busy with a valid call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The traffic load on the system is very high, or time slots may be out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a Tone Detector for the test. The system is oversized for the number of Tone Detectors present, or some Tone Detectors are out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port is seized by a user for a valid call. Use the **status station** command for the station associated with this port and determine if the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received from the VC-BD circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the port by using the **busyout port UUCSSpp** and **reset port UUCSSpp** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
0-3	FAIL	The TDM Looparound Test failed. 1. Replace circuit pack.
4-7	FAIL	The Conference Circuit Test failed. 1. Replace circuit pack.
	PASS	The VC DSP Port Local TDM Looparound Test passed.

VC-DSP Port DSP Loopback Test (#1105)

This test is destructive.

This test verifies the connectivity of a VC-DSPPT across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack.

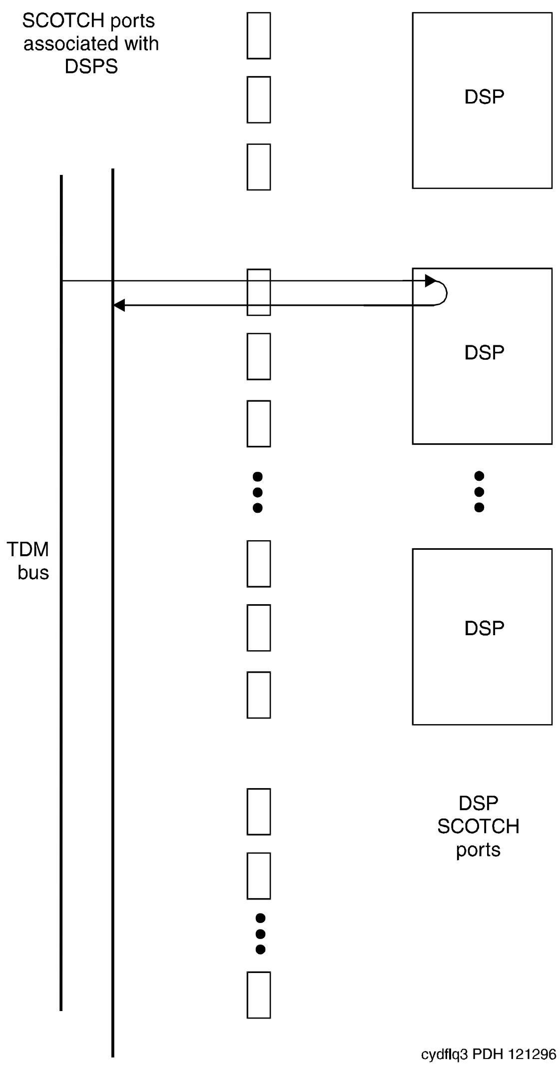

Figure 9-118. VC Circuit pack DSP Port DSP Looparound Test

Table 9-755. TEST #1105 VC-DSP Port DSP Loopback Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available, or the port is busy with a valid call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test, the traffic load on the system is very high, or time slots are out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a Tone Detector for the test, the system is oversized for the number of Tone Detectors present, or some Tone Detectors are out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status station** command for the station associated with this port and determine if the port is available for testing 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received from the VC-BD circuit pack within the allowable time period. 1. If this result occurs repeatedly, reset the circuit pack if the other ports are not in use by using the **busyout port UUCSSpp** and **reset port UUCSSpp** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
0, 1	FAIL	The VC-DSPPT DSP Loopback Test failed. 1. Replace the circuit pack.
	PASS	The VC DSPPT DSP Loopback Test passed

VC Port Reset DSP Test (#1106)

This test is destructive.

This test resets the VC-DSPPT and the DSP associated with it. As part of the reset procedure, the VC-DSPPT will execute a series of self- tests on the hardware. If these self- tests fail, the test will fail; otherwise the test will pass.

Before executing the test, the VC-DSPPT must be busied out by executing the **busy port UUCSSpp** command. After the completion of the test, the VC-DSPPT must be released by executing the **release port UUCSSpp** command.

Table 9-756. TEST #1106 VC Port Reset DSP Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available, or the port may be busy with a call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1015	ABORT	The VC-DSPPT is not busied out. 1. Busy out the VC-DSPPT by executing the **busy port UUCSSpp** command and then retry the test.
2000	ABORT	Response to the test was not received from the VC-DSPPT within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The reset of the VC-DSPPT was unsuccessful. 1. Replace circuit pack.
	PASS	The VC-DSPPT was successfully reset. 1. Release the VC-DSPPT by executing the **reset port UUCSSpp** command.

VC-LEV (Voice Conditioner DSP Port Level)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
VC-LEV	MAJOR	See "Resolving VC-LEV Errors/Alarms"	VC-LEV

Enable the MMCH feature on the *system-parameters customer-options* form before changing the fields.

The Voice Conditioner (VC) Port Level MO monitors VC efficiency by tracking the number of VC ports that are in-service, and then comparing that number with the value entered in the VC field on the System-Parameters Maintenance form. This VCs field is located under the Minimum Maintenance Thresholds section. The VCs field contains the minimum number of VC ports needed for the Multimedia Call Handling (MMCH) feature, and is an administrable field. The VCs field must contain a number between 0 and 126, and is entered by the system administrator. The MMCH feature must be enabled on the System-Parameters Customer-Options form before the VCs field can be changed to a number greater than 0. For example, administering 8 in that field means 1 circuit pack. The algorithm for determining that a low level of VC resources exists uses the number entered in the VCs field, and the number of VCs that are in-service in the system.

Each VC circuit pack contains 16 physical ports: 8 ports are reserved for VC-DSPPT ports, and the remaining 8 ports are designated as VC-SUMPT ports. The 8 DSP ports are made up of 4 encoder and 4 decoder resources that encode and decode audio formats. Thus, *one VC circuit pack is required for every 8 ports of MMCH port capacity*. If the number of in-service VC ports falls below the MMCH port capacity (value entered on the System-Parameters Maintenance form under the Minimum Maintenance Thresholds section and in the VCs field), a VEC-LEV error is logged. If this outage continues for 15 minutes a MAJOR alarm is raised.

Resolving VC-LEV Errors/Alarms

VC ports are a key part of the MMCH feature, any loss in the number of ports available for use degrades the MMCH customer defined service level.

If a VC circuit pack or port is busied out using the **busyout board** or **busyout port** command, these out-of-service ports are not included in the VC level calculation, thus allowing a technician to busy out a VC circuit pack for maintenance reasons without causing a MAJOR alarm to be raised.

NOTE:
When diagnosing a VC-LEV problem, resolve any alarms raised against VC-BD or VC-DSPPT maintenance objects. Clearing VC-BD or VC-DSPPT alarms may clear the VC-LEV alarm.

The VC circuit pack is maintained by the software similarly to the Tone Detector circuit pack. Tone Detector circuit packs may be removed and reinserted in any port board slot without administration. The same rule applies to VC circuit packs. If a VC circuit pack is removed from service logically (by failing the Archangel sanity scan test) or is removed from service physically (by physically removing the circuit pack from the carrier), no error/alarm is raised against VC-BD or VC-DSPPT maintenance objects. Therefore, if a VC-LEV error/alarm exists, and none has been raised against VC-BD or VC-DSPPT maintenance objects, a VC circuit pack may have been removed from service causing the VC-LEV error/alarm. To resolve a VC-LEV MAJOR alarm, restore the number of VC ports available for service to be equal to or more than the calculated port capacity (value entered in the `VCs` field).

To determine how many VC circuit packs are needed for the MMCH feature:

1. Display the System-Parameters Maintenance form by executing the command **display system-parameters maintenance**.
2. Locate the number listed in the Minimum Maintenance Threshold (`VCs`) field. The MMCH feature requires one VC circuit pack for each four ports listed in the Minimum Maintenance Threshold (`VCs`) field.
3. Divide the Minimum Maintenance Threshold value by 8 to determine the number of VC circuit packs needed. For example, a port capacity of 12 listed in the Minimum Maintenance Threshold (`VCs`) field would require 2 VC circuit packs.
4. Use the **list configuration** command to verify that the number of VC circuit packs listed agrees with the required number of VC circuit packs (determined in step 3). If the number of VC circuit packs listed in the step 3 differs from the calculated number, restore the number of VC circuit packs to the correct value, in order to resolve the VC-LEV alarm.

Error Log Entries and Test to Clear Values

Table 9-757. VC-LEV Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/ Off Board	Test to Clear Value
1 (a)	Any	None	MAJOR	OFF	

Notes:

a. The number of VC resources in the system that are in service has fallen below the calculated minimum value. If the number of in-service VC ports falls below the MMCH port capacity (value entered in the Minimum Maintenance Threshold VCs field on the system parameters maintenance form), a VEC-LEV error is logged. If this outage continues for 15 minutes a MAJOR alarm is raised. To resolve this alarm, correct the out-of-service problem by following the procedures below:

1. See “VC-DSPPT” and “VC-BD” and resolve any associated alarms.
2. If a VC-LEV error/alarm exist and none has been raised against VC-BD or VC-DSPPT maintenance objects, a VC circuit pack may have been removed from service causing the VC-LEV error/alarm. To resolve a VC-LEV MAJOR alarm, restore the number of VC ports available for service to be equal to or more than the calculated port capacity. See “Resolving VC-LEV ERRORS/ALARMS” for details.

System Technician-Demanded Tests: Descriptions and Error Code

There are no System Technician-Demanded test for VC-LEV.

VC-SUMPT

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
VC-SUMPT	MAJOR	test port UUCSSpp	Voice Conditioner Summer Port
VC-SUMPT	MINOR	test port UUCSSpp	Voice Conditioner Summer Port
VC-SUMPT	WARNING	test port UUCSSpp	Voice Conditioner Summer Port

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).

Each Voice Conditioner Circuit Pack (VC-BD) provides two types of resources:

1. Transcoder Resources that are used for encoding and decoding audio formats
2. Summer Resources that are used for summing audio formats from different sources.

The Voice Conditioner Summer ports (VC-SUMPT) are the summer resources on the VC-BD. There are 8 such ports on a VC-BD.

Error Log Entries and Test to Clear Values

Table 9-758. VC-SUMPT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
18 (a)	0	busyout port UUCSS	WNG	OFF	release port UUCSSpp
130 (b)			WNG	ON	test port UUCSSpp sh
257 (c)	Any	Control Channel Loop Test (#52)	MIN	ON	test board UUCSSpp 1 r 3
513 (d)	Any	VC Summer Port Local Loopback Test #(1100)	MIN	ON	test board UUCSSpp sh r 3

1. Run the short test sequence first. If all test pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This port has been busied out with the **busyout port UUCSSpp** command.

b. The circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, replace or reinsert the circuit pack.

c. The NPE Crosstalk Test(#1103) failed.

d. The VC Summer Port Local TDM Loopback Test(#1100) failed.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the NPE Crosstalk Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6) (a)		X	D
TDM Loopback Test (#1100)	X	X	D

1. D = Destructive; ND = Nondestructive

VC-SUMPT Port NPE Crosstalk Test (#6)

This test is destructive.

The NPE controls port connectivity and gain and provides conferencing functions. The NPE Crosstalk test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of the port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 9-759. TEST #6 VC-SUMPT Port NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1000 1001	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary resources for this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
0-3	FAIL	The NPE of the tested port was transmitting in error. This causes noisy and unreliable connections. 1. Replace circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. Verify that this is not an intermittent problem by repeating this test a maximum of 10 times. 2. If complaints continue, examine the station, connections, and wiring.

VC Summer Port Local TDM Loopback Test (#1100)

This test is destructive.

This test verifies the connectivity of a VC Summer Port across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack. The Loopback Test runs the following tests:

- A Looparound test across the TDM bus.
- A conference circuit test.

The tests are run in the above order. If the first test fails, the switch returns an error code, and the second test is not executed.

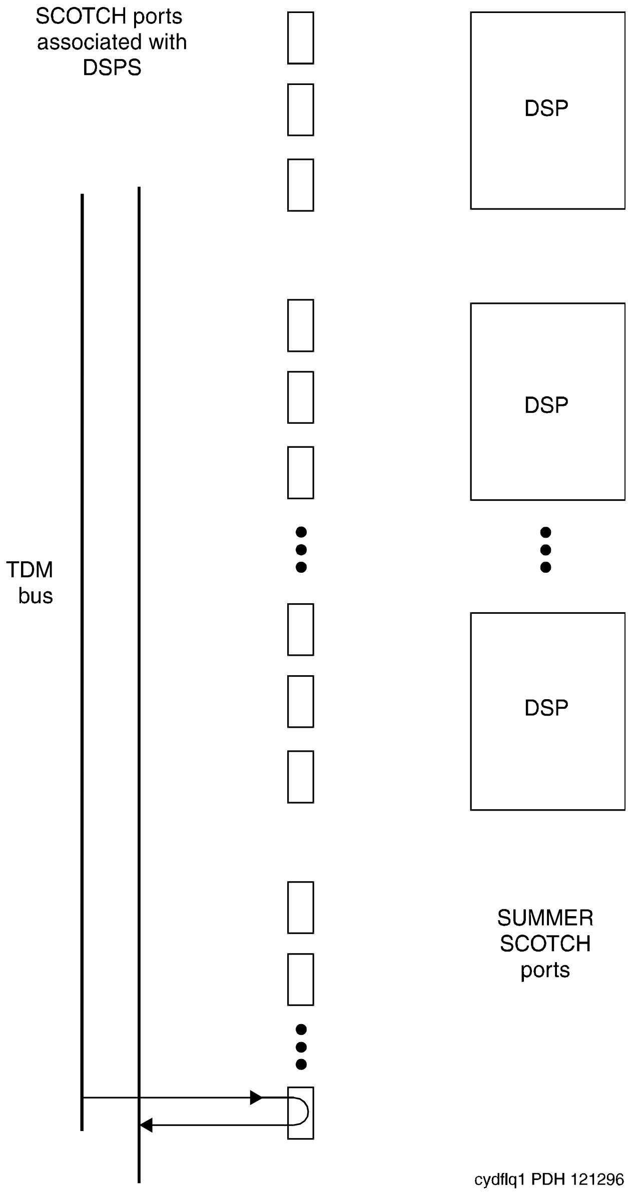

Figure 9-119. VC Circuit Pack Summer Port Loopback Test

Table 9-760. TEST #1100 VC Summer Port Local TDM Loopback Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available, or the port may be busy with a valid call. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The traffic load on the system is very high or time slots are out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a Tone Detector for the test, the system is oversized for the number of Tone Detectors present, or some Tone Detectors are out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status station** command for the station associated with this port to determine whether the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received from the VC-BD circuit pack within the allowable time period. 1. If this result occurs repeatedly, reset the circuit pack if the other ports are not in use. Reset the circuit pack by issuing the **busyout board UUCSS** and the **reset board UUCSS** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
0	FAIL	The TDM Looparound Test failed.
1	FAIL	The Conference Circuit Test failed. 1. Replace circuit pack.
	PASS	The VC Summer Port Local TDM Loopback Test passed.

WAE-PORT (Wideband Access Endpoint Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
WAE-PORT (a)	MINOR	test access-endpoint *extension* l	Wideband Access
WAE-PORT	WARNING	test access-endpoint *extension*	Endpoint Port

1. For additional repair information, see also DS1-BD (DS1 Interface Circuit Pack).

Wideband Switching supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. DEFINITY switching capabilities are extended to support wideband calls comprised of multiple DS0s that are switched end-to-end as a single entity.

Wideband Switching extends the Administered Connections feature to include non-signaling wideband access endpoints. Endpoint application equipment with direct T1 or E1 interfaces may connect directly to the switch’s line-side facilities; application equipment without T1 or E1 interfaces requires a terminal adapter such as a DSU/CSU. The terminal adapter or endpoint application equipment is connected to the TN464C Universal DS1 circuit pack.

These endpoints are administered as wideband access endpoints and have no signaling interface to switch; they simply transmit and receive data. (Some applications detect and respond to the presence or absence of data). Calls are initiated from these endpoints using the Administered Connections feature.

Multiple access endpoints on one line-side UDS1 circuit pack facility are separate and distinct within the facility. Endpoint application equipment must be administered to send and receive the correct data rate over the correct DS0s. All Administered Connections originating from wideband access endpoints use the entire bandwidth administered for the endpoint. An incoming call of a different data rate then that administered of the endpoint cannot be routed to the endpoint.

Although Wideband Access Endpoints are used primarily for line-side facilities, these endpoints can also be administered on network DS1 facilities to connect DEFINITY to non-switched network services, such as the Lucent fractional T-1 service. An example of this is the Lucent Static Integrated Network Access, where a trunk group to AT&T 4ESS Switched Services shares an access T-1 facility with a Wideband Access Endpoint. In this case, the Wideband Access Endpoint is connected to the AT&T fractional T-1 service, and it does not terminate on local endpoint equipment but is connected to a far-end CPE (for example, another DEFINITY PBX) via the dedicated fractional T-1. All Wideband Access Endpoint functionality and operation is identical on both line-side and network facilities. However, because maintenance capabilities are limited to the Wideband Access Endpoint interface, and because faults can occur end-to-end, troubleshooting procedures based on an end-to-end view of the network is required.

Wideband access endpoint port maintenance provides a strategy to maintain a wideband access endpoint port via a port on the Universal DS1 interface circuit pack hardware. The maintenance strategy covers logging wideband access endpoint port hardware errors, running tests for port initialization, periodic and scheduled maintenance, demand tests, and alarm escalation and resolution. Two different port service states are specified in the wideband access endpoint port maintenance:

- *out-of-service*: the port is in a deactivated state and cannot be used for calls
- *in-service*: the port is in an activated state and can be used for calls

  If the UDS1 Interface circuit pack is out of service, all ports on it are taken out of service and a Warning alarm is raised.

Error Log Entries and Test to Clear Values

Table 9-761. Wideband Access Endpoint Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test access-endpoint *extension* sh r 1
18(a)	0	busyout access-endpoint	WARNING	OFF	release access-endpoint *extension*
130(b)		None	WARNING	ON	test access-endpoint *extension*
1281(c)		Conference Circuit (Test #7)	MINOR	ON	test access-endpoint *extension* l r 4
1537(d)		NPE Crosstalk Test (#6)	MINOR	ON	test access-endpoint *extension* l r 3
1793(e)		None			test board *UUCSS* long
3840(f)	Any	Port Audit and Update (Test #36)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The wideband access endpoint has been busied out by a **busyout access-endpoint** extension command. No calls can be made to this extension.

b. The circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

c. The Conference Circuit Test (#7) failed on this port. See Test #7 for repair procedures.

d. The NPE Crosstalk Test (#6) failed on this port. See Test #6 for repair procedures.

e. The TN464C UDS1 Interface circuit pack has failed. See UDS1-BD.

f. The Port Audit and Update Test (#36) failed due to an internal system error. Enter **status access-endpoint** extension and verify the status of the port. If the wideband access endpoint port is out of service, enter **release access-endpoint** extension to put it back into service. Retry the test command.

Technician-Demand Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Port Audit and Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot, and does not cross over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of a port's long test sequence and takes 20 to 30 seconds to complete

Table 9-762. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status access-endpoint** extension or command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-762. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Use **status health** to determine if the system is experiencing heavy traffic. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be too big for the number of Tone Detectors present, or some Tone Detectors may be out of service. **List measurement tone-receiver** displays information on the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use **status access-endpoint** extension to determine when the port is available for testing. The port is available when it is in the **in-service/idle** state. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run because of a previously existing error on the specific port or a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. Investigate user-reported troubles on this port using other port tests and by examining the terminal adapter or external wiring.

Conference Circuit Test (#7)

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 9-763. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status access-endpoint** extension command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status access-endpoint** extension command to determine when the port is available for testing. The port is available when it is in the **in-service/idle** state. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to a previously existing error on the specific port or because of a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or circuit pack, and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. Even though wideband calls do not use the conferencing feature on the NPE, this failure indicates problems with the circuit pack hardware. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. 1. Investigate user-reported troubles on this port using other port tests and by examining the terminal adapter or external wiring.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the UDS1 Interface circuit pack to ensure that the wideband access endpoint port's translation is correct.

Table 9-764. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1006	ABORT	The port is out-of-service. If the port is busied out: 1. Issue **release access-endpoint <extension>** command to put the port back into in-service. 2. Retry the test command. If the port is not busied out: a. Check the error and alarm logs for WAE-PORT and UDS1-BD errors and alarms and follow the recommended repair procedures.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Port translation has been updated successfully.

XXX-BD (Common Port Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run [1]	Full Name of MO
XXX-BD[2]	MAJOR	test board UUCSS	Common Port Circuit Pack Maintenance
XXX-BD[2]	MINOR	test board UUCSS	Common Port Circuit Pack Maintenance
XXX-BD[2]	WARNING	test board UUCSS	Common Port Circuit Pack Maintenance

1. UU is the universal cabinet number (1 for PPN, 2-44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).
2. Refer to the appropriate circuit pack documentation for the correct MO name displayed in this field. It usually ends with BD.

Common Port Circuit Pack Maintenance is a set of common tests used by all the circuit packs listed in the tables below. The common portion of these circuit packs is the generic hardware that interfaces with the TDM Bus. The XXX-BD designation is also used on G3-MT displays when **reset board** is entered with an empty circuit pack slot, or with a circuit pack type that is in conflict with the actual board type administered for that slot. All circuit pack suffixes (B,C, D, and so forth) are supported by “XXX-BD.”

When any of the Common Port Circuit Packs are physically removed from the backplane, no alarm will be logged for approximately 11-minutes. (In the case of the TN754 Digital Line,TN566 DEFINITY AUDIX, and TN758 Pooled Modem circuit packs, Digital Line and Pooled Modem circuit packs, approximately 21-minutes will elapse before an alarm is logged.) When a circuit pack that has been removed is alarmed, the alarm type is minor and is classified as an on-board alarm. The time delay permits maintenance activity to be performed without triggering an additional alarm.

Alarms are logged against only those common port circuit packs on which ports have been administered. In a heavily loaded system, the interval between the removal of a Common Port Circuit Pack and the logging of the alarm may be several minutes longer. The circuit packs in the following list contain ports on the TDM bus. Suffixes are not shown; for a list of all circuit packs supported, see the table in Chapter 2. Those that appear in **bold** type are documented separately under their own maintenance object name. Only those with an asterisk are supported by G3r V1 systems.

XXX-BD Common Circuit Packs

The following list of circuit packs are listed by apparatus code.

Table 9-765. XXX-BD Common Circuit Packs

Apparatus Code	Name	Type
CPP1	Memory Expansion	Control

3999 (o)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Error type 1 indicates the circuit pack has stopped functioning or has been physically removed from the system. This error type does not apply to ANN-BD, DETR-BD, S-SYN-BD, M/T-BD, or CLSFY-BD. The alarm is logged approximately 11 minutes after removal of the circuit pack or failure of the SAKI Sanity Test (#53).

Check for the physical presence of the circuit pack in the slot indicated by the alarm. If the circuit pack is not present, insert one of the proper type. If the circuit pack is present and its red LED is lit, see *LED Alarm Without Alarm Log Entry* in Chapter 7.

b. This error indicates the circuit pack has been busied out. Release the circuit pack via **release board UUCSS**.

c. The circuit pack has been logically administered but not physically installed. The alarm should clear when the circuit pact is installed.

   If the circuit pack is already installed:

   1. Run **test board UUCSS long** and look at any test failures or error codes generated.
   2. If the test does not clear error 23, then execute **reset board UUCSS** and run the long test again.
   3. If the reset/test does not clear error 23, replace the circuit pack.

d. This error applies only to the Maintenance/Test circuit pack (TN771B or TN771C). The error indicates that the hardware associated with the Analog Trunk Testing port of the circuit pack failed to initialize. Note that when this error occurs, the Maintenance/Test circuit pack may report an invalid vintage. Although this error is not service-affecting, the Maintenance/Test circuit pack should be replaced.

e. The circuit pack physically installed in the slot does not match the type that is administered for that slot. Do one of the following:

   - Remove the incorrect circuit pack and replace it with one of the type that is administered for that slot.
   - Use **change circuit pack** to readminister the slot so that it matches the board that is installed, and follow with **reset board**.

f. This error applies to the Maintenance/Test circuit pack TN771D), Tone Detector (TN748B, TN748C, or TN748D), and Call Classifier (TN748) circuit packs. For the Maintenance/Test circuit pack, the error indicates that there is more than one Maintenance/Test circuit pack in the port network. For the Tone Detector or Call Classifier packs, the error indicates that there are more than 10 circuit packs in the system. Remove the circuit pack against which the error is logged.

g. This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.

h. This error, when reported with Aux data in the range of 4352 to 4358, indicates that the circuit pack has reported an on-board hardware failure. The circuit pack will continuously test the hardware and report the results approximately every 10 minutes. If the hardware problem is resolved, the “leaky bucket” strategy should clear the alarm in approximately 30 minutes. However, if the alarm does NOT clear in 30 minutes, then the circuit pack should be replaced.

i. This error can be ignored, but look for other errors on this circuit pack.

j. This error is not service-affecting and no action is required.

k. This error indicates that no ringing current is detected. Run Test #51, Ringing Application Test, and follow the procedures for Test #51. This error is only applicable to Analog Line circuit packs.

l. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with error code 2000.
   2. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
   3. A busy-out/release of the circuit pack has no affect on test results.
   4. A **list configuration** command shows that the circuit pack and ports are properly installed.

   If the XXX-BD is not a TN754 Digital Line Circuit Pack (DIG-BD), and if this error happens again within 15 minutes, then replace the circuit pack. If the XXX-BD is a TN754 Digital Line Circuit Pack (DIG-BD), then check the alarm level. If the alarm level is a WARNING, this indicates that users are probably causing the hyperactivity by playing with their digital stations. If the circuit pack is really hyperactive then this alarm will be upgrade to a MINOR alarm within 1 hour. If the alarm level is a MINOR alarm, then replace the circuit pack. To replace the circuit pack, refer to Replacing Circuit Packs in Chapter 5.

m. This error indicates that no neon current is detected. Run **test board UUCSS short** and follow the procedures for Test #220. This error is only applicable to TN769 and TN746 Analog Line circuit packs.

n. This error is not service-affecting and no action is required.

o. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

Technician-Demand Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Audit*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
NPE Audit Test (#50)		X		ND
Ringing Application Test (#51) (a)	X	X		ND
Control Channel Looparound Test (#52)	X	X		ND
SAKI Sanity Test (#53) (b)		X	D	
Neon Test (#220) (c)	X	X		ND

1. D = Destructive; ND = Nondestructive

Notes;

a. Only applicable to Analog Line circuit packs.

b. The SAKI Sanity Test is run in the Long Test Sequence for the Tone/Clock circuit packs (TN768, TN780) **only**. The test is run on other circuit packs only when they are reset via the **reset board** command.

c. Only applicable to TN746 and TN769 Analog Line circuit packs.

NPE Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

Table 9-767. TEST #50 NPE Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available.
1019	ABORT	Test already in progress.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The circuit pack's NPEs have been updated with their translation.
	EXTRA BD	Certain circuit packs have limitations on how many circuit packs can be in the system or port network such as the Maintenance/Test circuit pack (TN771B or TN771C), the Tone Detector circuit pack (TN748B, TN748C or TN748D) and the Call Classifier (TN744). The Maintenance/Test circuit pack allows only one circuit pack per port network. The Tone Detector and Call Classifier allow only 10 circuit packs in each system. All additional circuit packs will return EXTRA-BD and should be removed.
Any	NO BOARD	This is normal if the test is being done when (a) the board is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the board is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at 1-minute intervals for a maximum of 5 times.

Ringing Application Test (#51)

This test checks the ringing application circuitry common to all ports on an Analog Line circuit pack.

Table 9-768. TEST #51 Ringing Application Circuit Test

Error Code	Test Result	Description/ Recommendation
1000 2100	ABORT	Could not allocate the necessary system resources to run test.
	ABORT	Could not allocate the necessary system resources to run test. The circuit pack is not installed. Internal system error
2000	ABORT	There was no response from the board. 1. If error type 1538 (hyperactivity) is present in the error log, follow the maintenance strategy that is recommended for this error type. 2. Run the **busyout board**, **reset board**, and **release busy board** commands,and then retest. 3. If the test still aborts, dispatch with the circuit pack. 4. Check the off-board wiring and the terminal, and, if there are no problems found, replace the circuit pack.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to Chapter 8, for a full description of all possible states). You must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-768. TEST #51 Ringing Application Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1008	ABORT	Could not allocate a ringing circuit for one of the following reasons: all the ringing circuits are in use; the ringing generator is defective; ringing generator is not wired correctly. 1. If the test continues to abort, look for RING-GEN error in Error Log. a. If there are RING-GEN errors, refer to RING-GEN Maintenance documentation and try to resolve any problem(s). Then, go to Step 2. b. If there are no RING-GEN errors, and the test continues to abort, issue the **test board UUCSS** command on other TN742, TN769, or TN746 Analog circuit packs. If an ABORT with error code 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or may not be wired properly. Refer to RING-GEN Maintenance documentation for details. If an ABORT with error code 1008 does NOT occur on the other ports, then all four ring generators are in use. Exit from this documentation. 2. Retry the command.
	FAIL	No ringing current is detected. The ringing application circuitry on this circuit pack probably is not healthy. 1. Retry the command again. 2. If the test continues to fail, look for RING-GEN error in Error Log. a. If there are RING-GEN errors, refer to the RING-GEN Maintenance documentation and try to resolve any problem(s). b. If there are no RING-GEN errors, then replace the circuit pack. 3. Retry the command again.
	PASS	Ringing current is detected or this vintage of the Analog Line circuit pack does not support the Ringing Application Circuit Test. Analog Line circuit packs that DO NOT support Test #51 include TN712 Vintage 13 and earlier and TN742 Vintage 3 and earlier.
Any	NO BOARD	This is normal if the test is being done when (a) the board is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the board is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at 1-minute intervals for a maximum of 5 times.

Control Channel Looparound Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 9-769. TEST #52 Control Channel Looparound Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The test failed because the circuit pack failed to return the circuit pack code or vintage. 1. Retry the command for a maximum of 5 times. 2. If the test still fails, issue the **busyout board**, **reset board**, and **release busy board** commands, and then retest. 3. If the problem continues, replace the circuit pack. 4. Run the test again.
	PASS	Communication with this circuit pack is successful.
	EXTRA BD	This result should only appear when more than one TN771D Maintenance/Test circuit pack has been installed in this port network. Remove this circuit pack.
Any	NO BOARD	This is normal if the test is being done when (a) the board is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the board is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at 1-minute intervals for a maximum of 5 times.

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack. It is executed as part of the long test sequence only for the Tone-Clock circuit pack and DS1 interface circuit packs. Other common circuit packs can be reset with the **reset board UUCSS** command which also executes this test.

Table 9-770. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Wrong circuit pack configuration to run this test. This error applies only to DS1 interface circuit packs. It means the DS1 interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions. 1. If the circuit pack needs to be reset, then set synchronization to another DS1 interface circuit pack or the Tone-Clock circuit pack and try again. Refer to SYNC (Synchronization) Maintenance documentation.
1015	ABORT	Port is not out-of-service. 1. Busy out the circuit pack. 2. Execute command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	The circuit pack failed to reset.
2	FAIL	The circuit pack failed to restart. 1. Execute command again. 2. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the short test sequence.
Any	NO BOARD	This is normal if the test is being done when (a) the board is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the board is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at 1-minute intervals for a maximum of 5 times.

Neon Test (#220)

This test checks the voltage required to light the neon lamp on an analog terminal. A relay connects a 150V DC source from the backplane of the circuit pack onto the voltage bus, and another relay connects a 2K shunt from the bus to ground. Current in the line is then monitored to determine if the voltage is present. The neon test runs only for TN746 and TN769 Analog circuit packs. If the circuit pack is not a TN746 or TN769, the test will return PASS, but the test is not actually run.

Table 9-771. TEST #220 Neon Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Cannot get the list of translated ports on the circuit pack.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. Refer to the status commands described in Chapter 8 for a full description of all possible states.) You must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1008	ABORT	Could not allocate a ringing circuit. Either all the ringing circuits are in use, or the ringing generator is defective or is not wired correctly. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or is not wired correctly (see errors for RING-GEN). If it does not occur on port test 48 for ANL-16-L, then all four ring phases are in use.
2000	ABORT	Response to the request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Could not allocate the necessary system resources to run this test. Internal system error. 1. If Error Type 1538 is present in the Error Log, follow the recommended maintenance strategy.

Continued on next page

Table 9-771. TEST #220 Neon Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The test failed because no neon current was detected. 1. Determine if there is a TN755 or TN752 power unit circuit pack installed in the same carrier as the TN746 or TN769 analog line circuit pack that failed the test. Look for the failure of test 220 on other TN746 or TN769 circuit packs in the carrier. If test 220 fails on the other circuit packs, replace the TN755 or TN752 power unit circuit pack. 2. Retry the command again. 3. If the test continues to fail, replace the circuit pack. 4. Retry the command again.
	PASS	This circuit pack is a TN746 or TN769 Analog Line circuit pack and the neon current is detected. If this test passes, it can also mean that this circuit pack is not a TN746 or TN769 Analog Line circuit pack.
Any	NO BOARD	This is normal if the test is being done when (a) the board is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the board is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
