Enterprise Communications Server
Release 8.2
Maintenance for R8r
Volumes 1, 2, and 3

555-233-117
Comcode 108678442
Issue 1
April 2000

Notice
Every effort was made to ensure that the information in this book was complete and accurate at the time of printing. However, information is subject to change.

Your Responsibility for Your System's Security
Toll fraud is the unauthorized use of your telecommunications system by an unauthorized party, for example, persons other than your company's employees, agents, subcontractors, or persons working on your company's behalf. Note that there may be a risk of toll fraud associated with your telecommunications system and, if toll fraud occurs, it can result in substantial additional charges for your telecommunications services.

You and your system manager are responsible for the security of your system, such as programming and configuring your equipment to prevent unauthorized use. The system manager is also responsible for reading all installation, instruction, and system administration documents provided with this product in order to fully understand the features that can introduce risk of toll fraud and the steps that can be taken to reduce that risk. Lucent Technologies does not warrant that this product is immune from or will prevent unauthorized use of common-carrier telecommunication services or facilities accessed through or connected to it. Lucent Technologies will not be responsible for any charges that result from such unauthorized use.

Lucent Technologies Fraud Intervention
If you *suspect that you are being victimized* by toll fraud and you need technical support or assistance, call Technical Service Center Toll Fraud Intervention Hotline at 1 800 643-2353 or contact your local Lucent representative.

Federal Communications Commission Statement
Part 15: Class A Statement. This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to Part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio-frequency energy and, if not installed and used in accordance with the instructions, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference, in which case the user will be required to correct the interference at his own expense.

Part 68: Network Registration Number. This equipment is registered with the FCC in accordance with Part 68 of the FCC Rules. It is identified by FCC registration number AS593M-13283-MF-E.

Part 68: Answer-Supervision Signaling. Allowing this equipment to be operated in a manner that does not provide proper answer-supervision signaling is in violation of Part 68 Rules. This equipment returns answer-supervision signals to the public switched network when:

- Answered by the called station
- Answered by the attendant
- Routed to a recorded announcement that can be administered by the CPE user

This equipment returns answer-supervision signals on all DID calls forwarded back to the public switched telephone network. Permissible exceptions are:

- A call is unanswered
- A busy tone is received
- A reorder tone is received

Canadian Department of Communications (DOC) Interference Information
This digital apparatus does not exceed the Class A limits for radio noise emissions set out in the radio interference regulations of the Canadian Department of Communications.

Le Présent Appareil Nomérique n'émet pas de bruits radioélectriques dépassant les limites applicables aux appareils numériques de la class A préscrites dans le reglement sur le brouillage radioélectrique édicté par le ministére des Communications du Canada.

Call:	Lucent Technologies BCS Publications Center	
	Voice 1 800 457-1235	International Voice 317 322-6416
	Fax 1 800 457-1764	International Fax 317 322-6699
Write:	Lucent Technologies BCS Publications Center	
	2855 N. Franklin Road	
	Indianapolis, IN 46219	
Order:	Document No. 555-233-117	
	Comcode 108678442	
	Issue 1, April 2000	

For additional documents, refer to the section in "About This Document" entitled "Related Resources."

You can be placed on a standing order list for this and other documents you may need. Standing order will enable you to automatically receive updated versions of individual documents or document sets, billed to account information that you provide. For more information on standing orders, or to be put on a list to receive future issues of this document, contact the Lucent Technologies Publications Center.

European Union Declaration of Conformity
The "CE" mark affixed to the DEFINITY® equipment described in this book indicates that the equipment conforms to the following European Union (EU) Directives:

- Electromagnetic Compatibility (89/336/EEC)
- Low Voltage (73/23/EEC)
- Telecommunications Terminal Equipment (TTE) i-CTR3 BRI and i-CTR4 PRI

For more information on standards compliance, contact your local distributor.

Contents

About this Book

This document provides instructions and supporting information needed to monitor, test, and maintain the hardware components of the DEFINITY Enterprise Communications Server Release 8.2 systems.

These system's extensive background testing and technician-demanded tests allow many problems to be addressed before they severely disrupt call processing. Duplication options further enhance this reliability, giving the technician an opportunity to provide a high level of service while resolving problems or performing routine maintenance.

This book provides the necessary information to make full use of these capabilities and introduces some new components and strategies found in R8.2r.

NOTE:
This document is intended for Release 8.2 and later systems only. For previous DEFINITY systems (G3V5 and earlier), refer to *DEFINITY Enterprise Communications Server, Release 5 Maintenance for R5r,* 555-230-122.

Intended Use

- As a guide to diagnosing and repairing the Release 8.2r system for use by field technicians, remote service personnel, and user-assigned maintenance personnel
- As a training manual for teaching technicians how to maintain the system
- As a reference source on the system's maintenance capabilities

This document assumes that the technician has a working knowledge of telecommunications fundamentals and PBX maintenance practices. This document also assumes that the system was initially installed and tested properly and brought into service with all faults cleared. Adjuncts and other devices external to the switch are covered by their own service documentation.

How to Use this Document

Most maintenance sessions involve analyzing the Alarm and Error Logs to diagnose a trouble source and replacing a component such as a circuit pack. The information in Chapter 9, ‘‘Maintenance Object Repair Procedures’’ will generally suffice to address these needs. Certain complex elements of the system, such as fiber links and the packet bus, require a more comprehensive approach. Special procedures for these elements appear in Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’.

This document is not intended to solve all levels of trouble. When the limits of these procedures have been reached and the problem has not been resolved, it is the technician’s responsibility to escalate to a higher level of technical support. Escalation should conform to the procedures in the *Technical and Administration Plan*.

Organization

- Chapter 1, ‘‘Maintenance Architecture’’, describes the system’s design and maintenance strategy.
- Chapter 2, ‘‘Hardware Configurations’’, shows the locations and arrangements of the system’s cabinets, carriers, circuit packs, and cabling.
- Chapter 3, ‘‘Management Terminal’’, describes how to set up and use the management terminal.
- Chapter 4, ‘‘Initialization and Recovery’’, describes the various reset and reboot processes and how these are used to perform maintenance and recover systems or subsystems that are out of service. Use of the terminal SPE-down interface on non-functional or standby Switch Processor Elements is included here.
- Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’, describes general repair procedures such as replacing circuit packs and special troubleshooting procedures such as those for fiber link and packet bus faults.
- Chapter 6, ‘‘Additional Maintenance Procedures’’, describes preventive maintenance, software updates and other procedures not associated with specific alarms or components.

- Chapter 7, "LED Interpretation", is a guide to interpreting indications given by circuit pack and attendant console LEDs.
- Chapter 8, "Maintenance Commands", contains a description of each maintenance command available through the management terminal. The commands are ordered alphabetically. A general description of command syntax and conventions appears at the beginning of the chapter.
- Chapter 9, "Maintenance Object Repair Procedures", contains specific troubleshooting and repair instructions for every component in the system. The maintenance objects are listed alphabetically by name as they appear in the Alarm and Error Logs. Under each maintenance object appears a description of the object's function, tables for interpreting alarm and error logs, and instructions on how to use tests, commands, and replacements to resolve associated problems. Most of these procedures are complete and self-contained, while others rely upon procedures in Chapter 5, "Alarms, Errors, and Troubleshooting".

Safety Precautions

Before working on a system, the technician must be thoroughly familiar with the precautions and practices described at the beginning of Chapter 5, "Alarms, Errors, and Troubleshooting".

Class 1 Laser Device

The DEFINITY ECS contains a Class 1 LASER device if single-mode fiber optic cable is connected to a remote Expansion Port Network (EPN). The LASER device operates within the following parameters:

Power Output: -5 dBm
Wavelength: 1310 nm
Mode Field Diameter: 8.8 microns
CLASS 1 LASER PRODUCT
IEC825 1993

DANGER:

Use of controls or adjustments or performance of procedures other than those specified herein may result in hazardous radiation exposure.

Contact your Lucent Technologies representative for more information.

Electromagnetic Compatibility Standards

This product complies with and conforms to the following:

- Limits and Methods of Measurements of Radio Interference Characteristics of Information Technology Equipment, EN55022 (CISPR22), 1993
- EN50082-1, European Generic Immunity Standard
- FCC Parts 15 and 68
- Australia AS3548

NOTE:
The system conforms to Class A (industrial) equipment. Voice terminals meet Class B requirements.

- Electrostatic Discharge (ESD) IEC 1000-4-2
- Radiated radio frequency field IEC 1000-4-3
- Electrical Fast Transient IEC 1000-4-4
- Lightning effects IEC 1000-4-5
- Conducted radio frequency IEC 1000-4-6
- Mains frequency magnetic field IEC 1000-4-8
- Low frequency mains disturbance

The system conforms to the following:

- Electromagnetic compatibility General Immunity Standard, part 1; residential, commercial, light industry, EN50082-1, CENELEC, 1991
- Issue 1 (1984) and Issue 2 (1992), Electrostatic discharge immunity requirements (EN55024, Part 2) IEC 1000-4-2
- Radiated radio frequency field immunity requirements IEC 1000-4-3
- Electrical fast transient/burst immunity requirements IEC 1000-4-4

European Union Standards

Lucent Technologies Business Communications Systems declares that the DEFINITY equipment specified in this document bearing the “CE” mark conforms to the European Union Electromagnetic Compatibility Directives.

The “CE” (Conformité Européenne) mark indicates conformance to the European Union Electromagnetic Compatibility Directive (89/336/EEC) Low Voltage Directive (73/23/EEC) and Telecommunication Terminal Equipment (TTE) Directive (91/263/EEC) and with i-CTR3 Basic Rate Interface (BRI) and i-CTR4 Primary Rate Interface (PRI) as applicable.

The “CE” mark is applied to the following Release 8.2 products:

- Global AC powered Multi-Carrier Cabinet (MCC)
- DC powered Multi-Carrier Cabinet (MCC) with 25 Hz ring generator
- AC powered Single-Carrier Cabinet (SCC) with 25 Hz ring generator
- AC powered Compact Single-Carrier Cabinet (CSCC) with 25 Hz ring generator
- Enhanced DC Power System

Standards Compliance

The equipment presented in this document complies with the following (as appropriate):

- ITU-T (Formerly CCITT)
- ECMA
- ETSI
- IPNS
- DPNSS
- National ISDN-1
- National ISDN-2
- ISO-9000
- ANSI
- FCC Part 15 and Part 68
- EN55022
- EN50081
- EN50082
- CISPR22
- Australia AS3548 (AS/NZ3548)
- Australia AS3260
- IEC 825
- IEC950
- UL 1459

- UL1950
- CSA C222 Number 225
- TS001

Conventions Used in This Document

The following conventions are used in this document:

- DEFINITY Systems are called G3V4, G3 Release 5, G3vs, G3si, and G3r
  - — All occurrences of G3siV4, G3siV4+m, G3siV5, and G3siV5+m are called G3si unless a specific configuration is required to differentiate among product offerings
  - — All occurrences of G3 with out a suffix following the “3” refer to G3vs, G3si, and G3r
- A component of a DEFINITY System, such as a circuit pack, occurring without a reference to any specific system, is part of G3
- DEFINITY Communications Sever is abbreviated DEFINITY ECS
- All physical dimensions in this book are in English (Foot Pound Second) (FPS) followed by metric Centimeter Grams Second) (CGS) in parenthesis. Wire gauge measurements are in AWG followed by the diameter in millimeters in parenthesis.
- Information you type at the management terminal is shown in the following typeface: **list system-parameters maintenance**
- Information displayed on the management terminal screen is shown in the following typeface: `login`
- Keyboard keys are shown in the following typeface: Enter.
- Circuit pack codes (such as TN790 or TN2182B) are shown with the minimum acceptable alphabetic suffix (like the “B” in the code TN2182B).

  Generally, an alphabetic suffix higher than that shown is also acceptable. However, not every *vintage* of either the minimum suffix or a higher suffix code is necessarily acceptable.

  NOTE:
  Refer to *Technical Monthly: Reference Guide for Circuit Pack Vintages and Change Notices*, for current information about the usable vintages of specific circuit pack codes (including the suffix) in a Release 8.2 system.

- Admonishments used in this book are as follows:

CAUTION:
This sign is used to indicate possible harm to software, possible loss of data, or possible service interruptions.

WARNING:
This sign is used where there is possible harm to hardware or equipment.

DANGER:
This sign is used to indicate possible harm or injury to people.

Related Documents

The following documents are useful for system-related information:

***DEFINITY ECS Release 8.2 — Change Description,* 555-233-411**

Gives a high-level overview of what is new in DEFNITY ECS Release 8.2. Describes the hardware and software enhancements and lists the problem corrections for this release.

***DEFINITY ECS Release 8.2— System Description* , 555-233-200**

Provides hardware descriptions, system parameters, listing of hardware required to use features, system configurations, and environmental requirements.

***DEFINITY ECS Release 8.2— Administrator's Guide,* 555-233-506**

Provides descriptions of system features. Also provides step-by-step procedures for preparing the screens that are required to implement the features, functions, and services of the system. Includes the applications and benefits, feature interactions, administration requirements, hardware requirements, and procedures for voice terminal, data module, and trunk group administration.

***DEFINITY ECS Release 8.2— Reports,* 555-233-505**

Formerly titled *System Monitoring and Reporting*, this book provides detailed descriptions of the measurement, status, security, and recent change history reports available in the system and is intended for administrators who validate traffic reports and evaluate system performance. Includes corrective actions for potential problems.

***DEFINITY ECS Release 8.2 — Installation and Test for Single-Carrier Cabinets,* 555-233-120**

Provides procedures and information for hardware installation and initial testing of single-carrier cabinets. This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Castillian Spanish (SP), Italian (IT), Russian (RU), and Japanese (JA). To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

***DEFINITY ECS Release 8.2— Installation and Test for Multi-Carrier Cabinets,* 555-233-114**

Provides procedures and information for hardware installation and initial testing of multi-carrier cabinets.

***DEFINITY ECS Release 8.2— Installation for Adjuncts and Peripherals,* 555-233-116**

Provides procedures and information for hardware installation and initial testing of ECS adjunct and peripheral systems and equipment.

***DEFINITY ECS Release 8.2— Upgrades and Additions for R8.2r,* 555-233-115**

Provides procedures for an installation technician to convert an existing Generic 3 Version 4 DEFINITY Communications System to DEFINITY ECS and from DEFINITY ECS Release 5 and Release 7 to DEFINITY ECS Release 8.2. Included are upgrade considerations, lists of required hardware, and step-by-step upgrade procedures. Also included are procedures to add control carriers, switch node carriers, port carriers, circuit packs, auxiliary cabinets, and other equipment.

***BCS Products Security Handbook,* 555-025-600**

Provides information about the risks of telecommunications fraud and measures for addressing those risks and preventing unauthorized use of BCS products. This document is intended for telecommunications managers, console operators, and security organizations within companies.

***DEFINITY Wireless Business System Users Guide,* 555-232-105**

***DEFINITY Wireless Business System Installation and Test Guide,* 555-232-102**

***DEFINITY Wireless Business Systems System Interface*, 555-232-108**

***AT&T Network and Data Connectivity Reference*, 555-025-201**

Federal Communications Commission Statement

Part 68: Statement

Part 68: Answer-Supervision Signaling. Allowing this equipment to be operated in a manner that does not provide proper answer-supervision signaling is in violation of Part 68 rules. This equipment returns answer-supervision signals to the public switched network when:

- Answered by the called station
- Answered by the attendant
- Routed to a recorded announcement that can be administered by the CPE user

This equipment returns answer-supervision signals on all DID calls forwarded back to the public switched telephone network. Permissible exceptions are:

- A call is unanswered
- A busy tone is received
- A reorder tone is received

This equipment is capable of providing users access to interstate providers of operator services through the use of access codes. Modification of this equipment by call aggregators to block access dialing codes is a violation of the Telephone Operator Consumers Act of 1990.

This equipment complies with Part 68 of the FCC Rules. On the rear of this equipment is a label that contains, among other information, the FCC registration number and ringer equivalence number (REN) for this equipment. If requested, this information must be provided to the telephone company.

The REN is used to determine the quantity of devices which may be connected to the telephone line. Excessive RENs on the telephone line may result in devices not ringing in response to an incoming call. In most, but not all areas, the sum of RENs should not exceed 5.0. To be certain of the number of devices that may be connected to a line, as determined by the total RENs, contact the local telephone company.

NOTE:
REN is not required for some types of analog or digital facilities.

Means of Connection

Connection of this equipment to the telephone network is shown in the following table.

Manufacturer's Port Identifier	FIC Code	SOC/REN/ A.S. Code	Network Jacks
Off/On Premises Station	OL13C	9.0F	RJ2GX, RJ21X, RJ11C
DID Trunk	02RV2-T	0.0B	RJ2GX, RJ21X
CO Trunk	02GS2	0.3A	RJ21X
CO Trunk	02LS2	0.3A	RJ21X
Tie Trunk	TL31M	9.0F	RJ2GX
1.544 Digital Interface	04DU9-B,C	6.0P	RJ48C, RJ48M
1.544 Digital Interface	04DU9-BN,KN	6.0P	RJ48C, RJ48M
120A2 Channel Service Unit	04DU9-DN	6.0P	RJ48C

If the terminal equipment (DEFINITY® System) causes harm to the telephone network, the telephone company will notify you in advance that temporary discontinuance of service may be required. But if advance notice is not practical, the telephone company will notify the customer as soon as possible. Also, you will be advised of your right to file a complaint with the FCC if you believe it is necessary.

The telephone company may make changes in its facilities, equipment, operations or procedures that could affect the operation of the equipment. If this happens, the telephone company will provide advance notice in order for you to make necessary modifications to maintain uninterrupted service.

If trouble is experienced with this equipment, for repair or warranty information, please contact the Technical Service Center at 1-800-248-1234. If the equipment is causing harm to the telephone network, the telephone company may request that you disconnect the equipment until the problem is resolved.

It is recommended that repairs be performed by Lucent Technologies certified technicians.

The equipment cannot be used on public coin phone service provided by the telephone company. Connection to party line service is subject to state tariffs. Contact the state public utility commission, public service commission or corporation for information.

This equipment, if it uses a telephone receiver, is hearing aid compatible.

How to Order Documentation

In addition to this book, other description, installation and test, maintenance, and administration books are available. A complete list of DEFINITY books can be found in the *Business Communications System Publications Catalog*, 555-000-010.

This document and any other DEFINITY documentation can be ordered directly from the Lucent Technologies Business Communications System Publications Fulfillment Center toll free at 1-800-457-1235 (voice) and 1-800-457-1764 (fax). International customers should use 317-322-6791 (voice) and 317-322-6849 (fax).

How to Comment on This Document

Lucent Technologies welcomes your feedback. Please fill out the reader comment card found at the front of this manual and return it. Your comments are of great value and help improve our documentation.

If the reader comment card is missing, FAX your comments to 1-303-538-1741 or to your Lucent Technologies representative, and mention this document's name and number, *DEFINITY Enterprise Communication Server Release 8.2, Maintenance for R8r,* 555-233-117.

Where to Call for Technical Support

Use the following telephone number for the region in which the system is installed.

Organization	Telephone Number

Lucent Technologies Corporate Security	1-800-822-9009

Maintenance Architecture

1

The maintenance subsystem is that part of the software that is responsible for initializing and maintaining the system. This software continuously monitors system health and maintains a record of errors detected in the system. The maintenance subsystem also provides a user interface for on-demand testing.

This chapter provides a brief description of the R8r maintenance strategy, and presents background information on the system's overall functions. For detailed descriptions of components and subsystems, refer to related topics in Chapter 9, ''Maintenance Object Repair Procedures''. Sections on the following MOs are particularly useful for gaining an understanding of how the system works:

- STBY-SPE
- PNC-DUP
- EXP-PN
- SNI-BD
- DUP-INT
- SYNC

What's new for R8r

The following sections introduce new features in the Maintenance manuals:

- "H323-BCH"
- "H323-SGRP"
- "H323-STN"
- "DIG-IP-STN"
- "MEDPRO"
- "MEDPROPT"
- "AN-LN-PT (and TR-LN-BD)"
- "Administrable Loss Plan"
- "Traceroute"
- "Incomplete Command Timeout"

H323-BCH

H.323 signaling is very similar to ISDN Q.931 signaling. In order to take advantage of existing Definity ISDN call processing software, H.323 trunk call processing includes H.323 signaling groups, H.323 D-channels and H.323 B-channels. H.323 Signaling groups are similar in concept to ISDN PRI signaling groups. H.323 D-channels are an artificial fabrication created only to allow maximum re-use of system ISDN code. H.323 B-channels are also an artificial fabrication.

H323-SGRP

The H.323 Signaling Group (H323-SGRP) maintenance object supports a signaling channel for H.323 Trunk connections. The Media Processor (MedPro) TN802B circuit pack provides audio connectivity, working in concert with a C-LAN (TN799B) circuit pack that provides control signaling to support an H.323 connection.

The H.323 signaling group (323-SGRP) is a signaling channel that physically rides on a C-LAN ethernet port (socket) and the IP network. Unlike ISDN D-channels, the H.323 channel may actually come up and down on a call by call basis. The H.323 channel is actually a TCP/IP signaling channel. Layers 1 and 2 of this signaling channel are monitored by IP PING testing.

H323-STN

This maintenance object covers implementation of the maintenance for native mode H.323 endpoints. Native mode H.323 applications such as NetMeeting or Proshare only provide what is needed to support the H.323 standard. There is very little that Definity can invoke in the maintenance area. Definity will report errors as they are detected via the RAS registration and keep-alive mechanism. Definity will PING the endpoint both via the signaling path (i.e. via C-LAN) and via the media path (i.e. via Medpro).

This station type is not attached to a port board. Insertion of the station is not driven by board insertion, rather it is driven by successful registration of the endpoint. It is maintained via a set of explicit TCP/IP ping requests and errors reported by the switch software, which terminates the H.323 signaling portion of each endpoint. The MO follows standard maintenance methodology and supports test, busyout, release and status commands.

DIG-IP-STN

This maintenance object covers implementation of the maintenance for Lucent-provided IP Softphone or the Centre-Vu Remote IP Agent. The Lucent-provided endpoint consists of a service provider, an application layer called the Telephony Manager, and a registration application. The service provider terminates DCP signaling carried over TCP. The Telephony Manager provides the GUI emulating the DCP set. The registration application handles H323.RAS and is used to register and authenticate the endpoint with DEFINITY. This group of modules is called Vphone. Note that the Vphone does not include any type of audio path of bearer channel. The Vphone provides a DCP control plane for an alternate bearer channel. Tha alternate bearer channel is provided by either a native H.323 station or a POTS line or trunk. The Vphone is used only in a dual-connect arrangement.

The Vphone supports some level of existing DCP maintenance in the form of audits and updates.

This station type is not attached to a port board. Insertion of the station is not driven by board insertion, rather it is driven by successful registration of the endpoint. It is maintained via a set of explicit TCP/IP ping requests and errors reported by the User Manger software, which terminates the H.323 signaling portion of each endpoint. The MO follows standard mtce methodology and supports test, busyout, release and status commands.

MEDPRO

The TN802B MedPro circuit board is used by the DOLAN (Definity on the LAN) feature to provide voice over IP connectivity. The TN802B can run either:

- R8.1 IP Trunk application — allows the TN802B to emulate a DS1 circuit pack. In this mode, the circuit pack is maintained as a standard DS1 board with its associated Tie trunk ports. The TN802B operates as an integrated Internet Telephony Server. It communicates with other ITS boxes or IP trunk boards.
- the Media Processor (MedPro) application — allows the TN802B to act as a service circuit to terminate generic RTP streams used to carry packetized audio over an IP network. As part of the overall H.323 implementation, the TN802B or later circuit pack handles the audio streams while the TN799 C-LAN handles the TCP/IP signaling channels. This maintenance plan applies only to a TN802B MedPro running the Media Processor application.

The MedPro hardware combines an angel complex, a Windows NT PC and a TAP802 DSP card in a 3-slot package. When operating as an IP trunk circuit pack, the MedPro emulates a DS1 Tie Trunk circuit pack and blindly responds to DS1 trunk maintenance requests. Actual maintenance is accomplished via the windows NT interface and the ITS software diagnostics.

The Media Processor application is built upon the existing ITS software, and as such is not administered in DEFINITY as a DS1 trunk, and does not emulate a DS1 for maintenance purposes.

MEDPROPT

The MEDPROPT maintenance object monitors the health of the MEDPRO digital signal processors (DSPs).

The TN802B MAPD (Multi-Application Platform for DEFINITY) Media Processor circuit pack provides the audio bearer channels for H.323 voice over IP calls. One TN802B circuit pack has one MEDPROPT media processing resource. Based on system administration of audio codecs, a MEDPROPT can handle either 31 or 22 simultaneous channels of H.323 audio processing. If the **ip-parameters** form specifies only G.711 Mulaw or G.711 Alaw as the audio codecs, the MEDPROPT can service 31 channels. If any other codec type (G.723-5.3K, G.723-6.3K, or G.729) is administered, the MEDPROPT can only service 22 channels.

The MEDPROPT is physically made up of 11 individual DSPs, but is treated logically as one port. If individual DSPs on the TN802B MAPD fail, the MEDPROPT remains in-service at lower capacity.

The MEDPROPT is a shared service circuit. It is shared between H.323 trunk channels and H.323 stations. An idle channel is allocated to an H.323 trunk/station on a call-by-call basis.

AN-LN-PT (and TR-LN-BD)

The TN793B/TN2793B Analog Line circuit pack (w/ Caller ID), and the TN797 Analog Trunk and Line circuit pack both support this Maintenance Object.

The TN793B/TN2793B Analog Line circuit pack (w/ Caller ID) provides 24 ports for voice terminals and supports both on-premises and off-premises analog voice terminals.

The TN797 Analog Trunk and Line circuit pack provides 8 ports, each of which may be administered in any of several ways, as described in maintenance object TR-LN-BD.

NOTE:
The TN793B/TN2793B analog line circuit pack supports analog data modules. When assigned, analog data modules provide access to the NetPkt (TN794 circuit pack) data ports. To activate an analog data module you must assign the port location on the data form and connect a modem to the port. The analog data module can be used for connection to a CDR output, or other adjuncts as needed. These ports are tested the same as all other analog ports on the circuit pack.

Administrable Loss Plan

The administrable Loss Plan feature provides the user with the capability to administer the loss or gain applied on calls. This plan provides for dynamic administration of loss levels per station, using 2- party loss tables, and an algorithm that calculates 3, 4, 5, and 6-party conference loss plans. Such a feature can be used to provide additional gain, for example, on connections involving station sets whose users have hearing impairments.

Implementation of this plan involves the addition of a new field, `Digital Loss Plan Modifications`: on the **system-parameters customer options** form.

Traceroute

This command provides the ability to trace the route of packets originated from DEFINITY IP boards through the LAN. The output shows the ip address of each router or host (hop) that the packets encounter and the time elapsed between each hop. If a DEFINITY IP board has trouble communicating with a far-end device, the traceroute command can determine “how far” packets get toward the destination.

DEFINITY IP boards include:

- TN799B (or later suffix) CLAN board
- TN802B Medpro board

The output form lists:

- Hops traversed from source to destination
- IP addresses of the hop points and the final destination
- Observed round-trip delay from the source to each hop point

If no reply is received from a potential hop point, the `IP Address` field contains stars (*), which indicates a timeout condition.

The primary use of this command is to determine quickly and unambiguously if the fault lies within Lucent-provided equipment or if the fault is with the LAN or LAN administration to which the DEFINITY ECS switch is connected.

Incomplete Command Timeout

A time-out feature has been added to the MAINTENANCE-RELATED SYSTEM PARAMETERS form (accessed by the command **change system parameters maintenance**). This feature improves the operation of daily maintenance by allowing maintenance routines to run that might otherwise not run. It also helps to prevent the loss of translations that were not saved by the **save translation** command, and were also not saved because daily maintenance was prevented from running prior to the system reset. Highlights of the feature include:

- Options for blank, 1, 2, 3, 4, 5, or 6 hours (the default is 2 hours)
- The blank option indicates that the feature is not active
- Only commands that block the running of daily maintenance (add, change, duplicate, remove, and set) are affected
- All logins will time-out if any of these commands are active for the prescribed time (except for the “blank” option)
- The feature applies to all logins, regardless of type (init, dadmin, craft, inads) or permissions granted to the specific login ID of an administration or maintenance user

The corresponding “time-out” entry is appended to the list history log.

How to use the Maintenance book

This procedure begins with the system raising an alarm against a Maintenance Object (MO), a software module that monitors the components of a circuit pack. These components can include:

- Hardware
- System (processor) availability and conditions
- Presence of and physical connections (copper, fiber) to other components
- Presence of certain signals (synchronization, DS1) within specific parameters
- Environment (power, cabinet temperature sensors)

Table 1-1. Alarm levels, reporting conditions and action to take

Alarm level	Description	Reported to INADS?	Reported to console?	What action to take?
MAJOR	Critical service degradation	Y	Yes, after 4 attempts to call INADS	Immediate attention
MINOR	Some service degradation but does not render the system inoperable.	Y	Same as above	Check to see what service is affected
WARNING	Failure that causes no significant service degradation	N[1]	N	Monitor the situation. May be service or equipment interruption or failure outside the switch.

1. Some system-downgraded Warning alarms are reported to INADS.

Alarms are further classified as:

- On-board problems originate in the circuitry on the alarmed circuit pack.
- Off-board problems originate in a process or component that is external to the circuit pack.

To clear system alarms using the appropriate maintenance book:

1. Type **display alarms** and press Enter.
2. A query screen displays next (Screen 1-1), asking you if you want to see all alarms or if you want to restrict the list to certain kinds of errors.

```
                                ALARM REPORT
          The following options control which alarms will be displayed.
            ALARM TYPES
                       Active? y    Resolved? n
                        Major? y       Minor? y      Warning? y
            REPORT PERIOD
                     Interval: m      From:   /  /  :       To:   /  /  :
            EQUIPMENT TYPE ( Choose only one, if any, of the following )
                                   Cabinet:
                              Port Network:
                              Board Number:
                                      Port:
                                  Category:
```

Screen 1-1. Alarm Report query screen

a. The report can be restricted by typing either **y** (yes) or **n** (no) in these fields (shown above in bold):
   - Active
   - Major
   - Minor
   - Warning

CAUTION:
*If you choose **n** for major alarms and **y** for minor and warning alarms, you will not see the macro-level information that you may need to determine what is wrong with the system.*

b. The Cabinet, Port Network Board Number, Port and Category fields are described in the "Field descriptions" section.

3. After you have made your choices to tailor the report, press Enter.
4. The alarm log displays.

```
                                  ALARM REPORT
 Port        Maintenance On   Alt     Alarm    Svc    Ack?  Date         Date
             Name        Brd? Name    Type     State  1 2   Alarmed      Resolved
 01C1008     DID-TRK      y           MAJOR                 03/09/00:30 00/00/00:00
```

Screen 1-2. Alarm Report screen

A DID trunk port in slot 10, carrier C has a MAJOR alarm.

5. Note the value in the `Port` field (01C1008). This is the alarmed port address.
6. Type **display errors** and press Enter.
7. A query screen displays next, asking if you want to see all the errors or if you want to restrict the list to certain kinds of errors. Except for warning levels (Major, Minor, Warning), the screen is the same as Screen 1-1.

   Generally, unless you suspect a problem occurred within a certain time frame or with a particular component of the system, simply pressing Enter at the query screen displays the accumulated system errors (Screen 1-3).

```
                     HARDWARE ERROR REPORT - ACTIVE ALARMS
Port      Mtce     Alt     Err   Aux     First        Last        Err Err Rt/ Al Ac
          Name     Name    Type  Data    Occur        Occur       Cnt Rt  Hr  St
01C1008   DID-TRK          1547        03/09/00:20 03/15/01:18 255 1   7   a  y
```

Screen 1-3. Hardware Error Report - Active Alarms

8. Note the Error Type (`Err Type` field) value (1547) and the `Aux Data` value if present.
9. Find the DID-TRK MO in the Maintenance Object chapter of the appropriate maintenance book.
10. In the first table look up the initial command to run in the MAJOR row of the table (Step 4 indicated that a DID trunk in slot 10, carrier C has a MAJOR alarm).

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DID-TRK	MAJOR[2]	test port UUCSSpp long	DID Trunk
DID-TRK	MINOR	test port UUCSSpp long	DID Trunk
DID-TRK	WARNING	test port UUCSSpp	DID Trunk

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs), *C* is the carrier designation (A, B, C, D, or E), *SS* is the number of the slot in which the circuit pack resides (01 to 21), and *pp* is the two digit port number (01, 02, ...).
2. A MAJOR alarm on a truk indicates that alarms on these trunks are downgraded by the set options command and that at least 75% of the trunks in this trunk group are alarmed.

11. Type **test port 01C1008 long** and press Enter.

    "01C1008" is the address of the alarmed port (see Screen 1-2 and Screen 1-3)
12. While the port test is running, look up the Error Type (1537 from Screen 1-3) in the DID Trunk Error Log Entries table (example below).

Table 1-2. DID Trunk Error Log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1537		Port Diagnostic (#35)	MAJ/MIN/ WRN	OFF	test port UUCSSpp sh r 1
3840 (k)	40965	None			

13. Since the Test to Clear Value (**test port 01C1008 sh r 1**) is very similar to the initial test you ran in Step 11, wait for the results of the port test.
14. When the port test finishes, the following display appears (Screen 1-4):

```
                                   TEST RESULTS

Port       Maintenance Name  Alt. Name  Test No.  Result                 Error Code
01C1008    DID-TRK                      35        FAIL                   61472
```

Screen 1-4. Test Results screen

15. Find the Port Diagnostic Test (#35) [from the `Test No.` field) in the DID-TRK section of the Maintenance book. Note the `Error Code` (61472).
16. Look in Table 1-3 for Test #35 and then find “61472” in the Error Code column *and* “FAIL” in the Test Result column read the Description/Recommendation column.

Table 1-3. TEST #35 Port Diagnostic Test

Error Code	Test Result	Description/Recommendation
61472	FAIL	Battery feed test failed. A problem with the incoming CO line was detected. 1. Check the incoming CO line for proper operation. If warranted, refer the problem to the CO. 2. If the CO line checks out Ok, the failure must be on the DID port. Replace the circuit pack.

17. Perform both steps in the Description/Recommendation column.
18. Test the port (**test port 01C1008 long** and press Enter.) again after all of the recommendations are exhausted.

19. If all tests pass, wait approximately 3-5 minutes for the Alarm and Error logs to clear.
20. Type display alarms and press Enter twice.
21. Check that the DID-TRK alarm does not appear in the log.

Field descriptions

`Error type`	Enter error type, or blank
`Error List`	active-alarms, errors, or cleared-errors
`Interval`	h(our), d(ay), w(eek), m(onth), a(ll)
`From:/To:`	Specify time interval by date and time
`Cabinet`	Enter cabinet number (1 - 44)
`Port Network`	Enter port network number (1 - 44)
`Board Number`	Enter 5-character board number in **UUCSS** format: cabinet (1-44), carrier (A-E), slot (0-20)
`Port`	Enter 7-character port address in **UUCSSss** format: cabinet (1-44), carrier (A-E), slot (0-20), circuit (01-31)
`Category`	Enter category name (choose 1 from the list below:

adm-conn	announce	bri/asai	cdr	data-mod
detector	dup-spe	environ	exp-intf	ext-dev
generatr	inads-link	infc	maint	mass-st
mbus	memory	misc	mmi	mnt-test
modem	mssnet	pkt	pms/jrnl	pnc
pncmaint	pnc-peer	procr	quick-st	s-syn
spe	stabd	stacrk	stations	sys-link
sys-prnt	tape	tdm	tone	trkbd
trkcrk	trunks	vc	vsp	wideband
wireless				

`Extension`	Enter assigned extension, or blank
`Trunk`	
`Group`	Enter group number between 1-666
`Member`	Enter group member between 1-255, or blank

Maintenance Objects

The system is partitioned into separate entities called maintenance objects (MOs). Each MO is monitored by the system and has its own maintenance strategy. Most MOs are individual circuit packs such as the processor circuit pack (PROC) and expansion interface circuit pack (EXP-INTF). Some are hardware components that reside on part of a circuit pack. For example, the TDM bus clock (TDM-CLK) and tone generator (TONE-PT) circuits reside on the tone/clock circuit pack (TONE-BD). Others represent larger subsystems or sets of monitors, such as expansion port network (EXP-PN) and cabinet environmental sensors (CABINET).

Finally, some MOs represent processes or combinations of processes and hardware, such as synchronization (SYNC) and duplicated port network connectivity (PNC-DUP). The above abbreviations are *maintenance names* as recorded in the error and alarm logs. Individual copies of a given MO are further distinguished with an address that defines its physical location in the system. These addresses are described in Chapter 8, "Maintenance Commands". Repair instructions and a description of each MO appear alphabetically in Chapter 9, "Maintenance Object Repair Procedures".

Alarm and Error Reporting

During normal operations, software, hardware, or firmware may detect error conditions related to specific MOs. The system attempts to fix or circumvent these problems automatically, but if a hardware component incurs too many errors, an alarm is raised.

Alarm and Error Logs

The system keeps a record of every alarm detected in the system. This record, the alarm log, and the error log can be displayed locally on the management terminal or remotely by Initialization and Administration System (INADS) personnel. An alarm is classified as MAJOR, MINOR, or WARNING, depending on its effect on system operation. Alarms are also classified as ON-BOARD or OFF-BOARD.

- MAJOR alarms identify failures that cause critical degradation of service and require immediate attention. On high and critical reliability systems, MAJOR alarms can occur on standby components without affecting service since their active counterparts continue to function.
- MINOR alarms identify failures that cause some service degradation but do not render a crucial portion of the system inoperable. The condition requires attention, but typically a a MINOR alarm affects only a few trunks or stations or a single feature.

- WARNING alarms identify failures that cause no significant degradation of service or failures of equipment external to the system. These are not reported to INADS or the attendant console.
- ON-BOARD problems originate in circuitry on the alarmed circuit pack.
- OFF-BOARD problems originate in a process or component external to the circuit pack.

Multiple alarms against a given MO can change the level of a given alarm as it appears in the alarm log. If there is an active error against an MO that causes a MINOR alarm and an active error that causes a MAJOR alarm, then the alarm log would show two MAJOR alarms. If the MINOR alarm problem is resolved first, the error is still marked as alarmed until the MAJOR alarm problem is resolved, and the alarm log would still show two MAJOR alarms. If the MAJOR alarm problem is resolved first, the error is still marked as alarmed until the MINOR alarm problem is resolved, and the alarm log would now show two MINOR alarms. Similarly, the presence of an ON-BOARD alarm will cause all alarms against that MO to report as ON-BOARD.

NOTE:
To determine the actual level and origin of each alarm when there are more than one against the same MO, you must consult the *Hardware Error Log Entries* table for that MO.

The alarm log is restricted in size. If the log is full, a new entry overwrites the oldest resolved alarm. If there are no resolved alarms, the oldest error (which is not alarmed) is overwritten. If the log consists of only active alarms, the new alarm is dropped.

INADS Alarm Reporting

All Major and Minor alarms and some downgraded Warning alarms are reported to INADS. (Some classes of alarms can be downgraded to lower levels by INADS at the customer’s request). When the system raises one of these alarms, an attempt is made to call INADS. If the call to INADS fails, the call is retried in 7 minutes. This is repeated until four attempts have been made in a period of approximately 21 to 30 minutes. If all 4 attempts fail, the system waits 1 hour. Then it starts over again with 4 call attempts spaced 7 minutes apart. This cycle repeats until either the call to INADS successfully completes, or until the whole cycle is repeated 6 times. If, at any time during, a new alarm is raised by the system that should be reported to INADS, all timers and counts are reset and the strategy is repeated from the beginning.

During the 4 call attempts, the ACK lamp on the attendant console is turned off. Approximately 15 minutes into the hour interval between call attempts, the ACK lamp flashes, indicating the system is having trouble reporting alarms to INADS. At the end of the entire scenario described above, if the system could not report the alarm to INADS, the ACK lamp continues to flash.

Port Network Connectivity (PNC)

Port network connectivity is the equipment and controlling software that allows building large systems comprised of multiple Port Networks (PNs). Each PN is composed of Time Division Multiplexing (TDM) and packet (PKT) busses, and the port circuit packs connecting to them. A multi-carrier cabinet can contain more than one PN.

NOTE:
The terms LAN bus and PKT bus are interchangeable on the Release 8.1r. This document uses the term PKT bus, but “LAN” appears marked on some hardware components.

This section describes the hardware, software and firmware components that support the PNC. Knowledge of the service and maintenance functions of these components will aid in diagnosing and resolving troubles. Troubleshooting techniques for general PNC components such as busses appear in Chapter 6, “Additional Maintenance Procedures”.

PNC Configurations

The PNC is provided in one of two different configurations: Direct Connect and Center Stage Switch (CSS). In either configuration the TN570 Expansion Interface (EI) board provides the interface to the data on the TDM/PKT busses. In the direct connect configuration up to three PNs connect by hardware between each pair of PN EIs. See Figure 1-1.

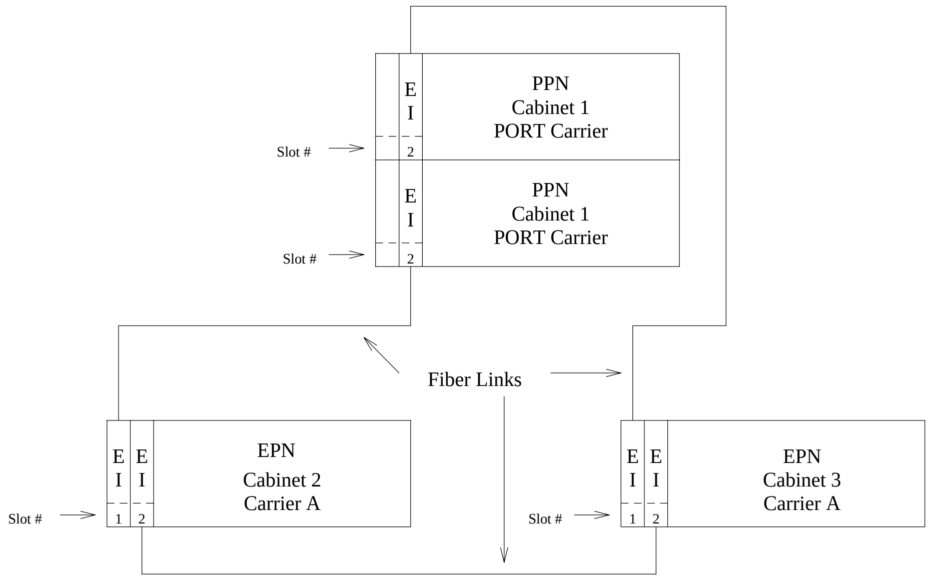

Figure 1-1. Direct Connect PNC

In the CSS configuration, up to 16 PNs (including the PPN) can connect to one switch node (SN). With two SNs, up to 22 PNs can be connected. Each SN consists of a carrier containing the following components (in critical reliability systems, each SN is duplicated on a second, identically configured carrier):

- 1 to 16 switch node interface (SNI) circuit packs (TN573)

  Each SNI serves as the interface for TDM/PKT data to and from its associated PN EI or to and from an SNI in the other switch node.

- 1 or 2 switch node clock (SNC) circuit packs (TN572)

  The SNCs provide timing for bit synchronized switching among the SNIs.

- Two power units

  Each power unit provides +5V to the circuit packs in its half of the SN and to both SNCs.

- Optionally in the PPN only, one Expansion Interface

- Optionally, 1 or 2 DS1 converter (DS1C) circuit packs

  The DS1 CONV circuit packs allow PNs to be located remotely up to 100 miles (161 km) between the two most distant PNs. The DS1 CONVs provide DS1 facility transport for a subset of the fiber timeslots between EIs in a direct connect system or between EIs and SNIs in CSS configurations. They can also be located on port carriers.

- TDM and PKT busses, and bus terminations

  There are 16 data busses in the SN. Each SNI has a slot dependent data bus on which it transmits data and has 16 inputs, one for each SN SNI slot, including its own. The data busses are terminated by 4 AHF105 paddle boards that mount on the backside of the backplane slots 2 and 20.

- Power distribution and control leads

Figure 1-2 shows two examples of CSS configurations. Illustrations of the switch node carrier hardware appear in Chapter 2.

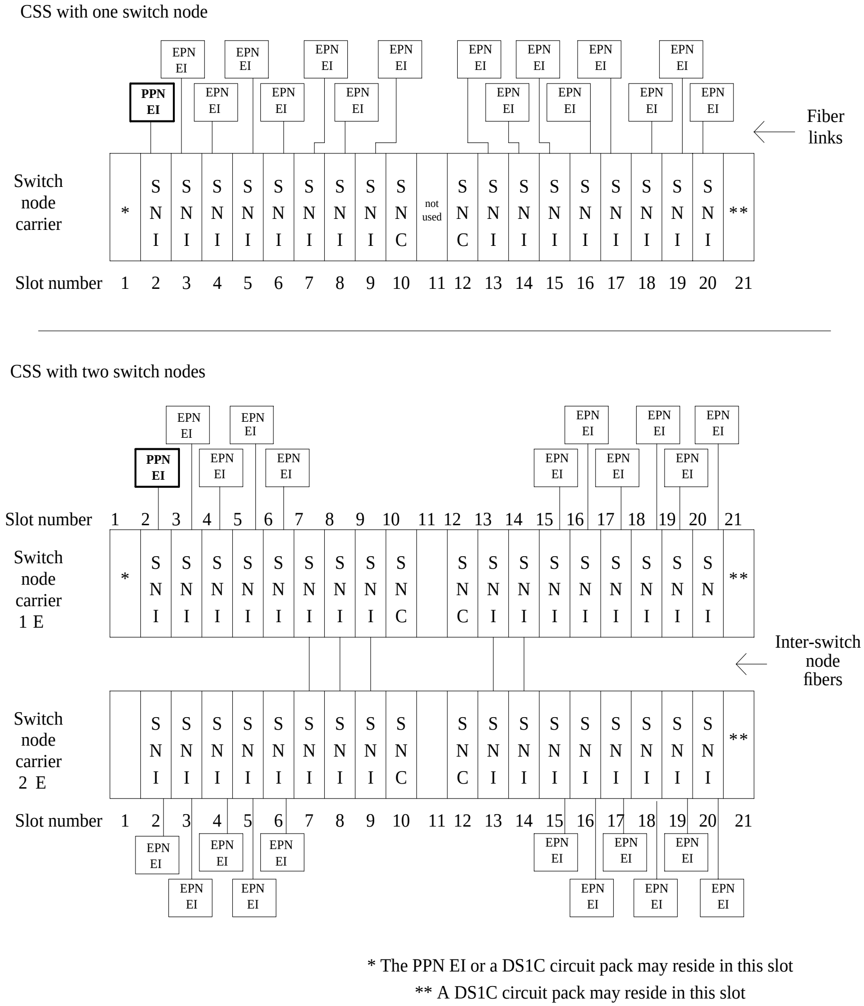

Figure 1-2. Center Stage Switch Configurations (Simplex Examples)

SPE Duplication

The Switch Processing Element (SPE) consists of the following circuit packs.

Table 1-4. SPE Circuit Packs and Maintenance Objects

Apparatus Code	Circuit Pack Name	Associated Maintenance Objects
TN1648	System Access and Maintenance	SYSAM
UN330B	Duplication Interface	DUPINT, DUP-CHL
UN331B	Processor	PROCR
TN1650B	Memory	MEM-BD
TN1655	Packet	PKT-INT
UN332	Mass Storage System/ Network Control (MSSNET)	H-ADAPTR, SW-CTL
TN1657	Disk Drive	DISK
TN1656 or TN2211	Tape Drive (Removable Media) Optical Disk (Removable Media)	R-MEDIA STBY-SPE STO-DATA

These circuit packs reside on the A carrier (control carrier) of the PPN in all systems, except for the UN330B which is found only in high and critical reliability systems. In high and critical reliability systems, the PPN B carrier duplicates exactly the configuration of the A carrier, making two identical SPE complexes. This duplication allows the system to recover from many faults, and enables troubleshooting and repairing of SPE components without interrupting service.

The Tone-Clock circuit pack also resides on the control carrier, and is also duplicated. However, it is not considered a part of the SPE. Although the SPE-Select switches control Tone-Clock selection, its duplication strategy differs from that of the SPE. See the ''TDM-CLK (TDM Bus Clock)'' and ''TONE-BD (Tone-Clock Circuit Pack)'' sections in Chapter 9, ''Maintenance Object Repair Procedures'' for details.

Duplicated SPEs employ an active/standby strategy. At any one time, one SPE, A or B, is designated active and controls the switch services network. The other SPE, designated standby, is not required for switch service but remains ready to become active and resume control of service should a service-affecting failure occur in the active SPE. This action is termed an SPE interchange. It is important that the standby SPE be kept as available as possible to allow for a rapid interchange.

Standby SPE Availability

The STBY-SPE maintenance object is responsible for testing of the standby SPE so that any faults that would prevent it from being available for service can be isolated and repaired. Various factors affect the availability of the standby SPE:

- The condition of the individual hardware components of the standby SPE, including circuit packs, power supplies, cables and other supporting components.

  Loss of power in an SPE due to power supply or power delivery components is discussed under the condition SPE-Down. If a circuit pack in the standby SPE that is critical to call service has failed, the standby will not be able to become active. Maintenance testing of the standby SPE allows isolation and repair of component problems so that the standby can be made available again.

- Standby memory content

  Each write operation in active memory is shadowed to the corresponding location in the standby SPE's memory. The standby memory should be in agreement with the active in order to support an interchange that will preserve call, feature and translation information. Maintenance software tracking the STBY-SPE MO aims to keep the two memories in agreement.

- Standby State-of-Health (SOH)

  The Duplication Interface circuit packs maintain a state-of-health value which reflects the availability of the standby SPE. If the Standby SPE's state-of-health level is too poor, it cannot automatically be interchanged into (made active).

- Standby SPE-Down

  If the standby SPE is completely dead and held reset by its SYSAM (in SPE-Down), or the standby SPE has no power, it is unavailable for service.

- System Time-of-Day

  If the Time-of-Day clock of the standby SPE is substantially out of synch with the active, interchanges could be more disruptive to service than desirable.

System software running on both active and standby SPEs attempts to ensure that the standby SPE is kept fully available in terms of the above factors. The health of both the active and standby is tracked as a State-of-Health (SOH) value.

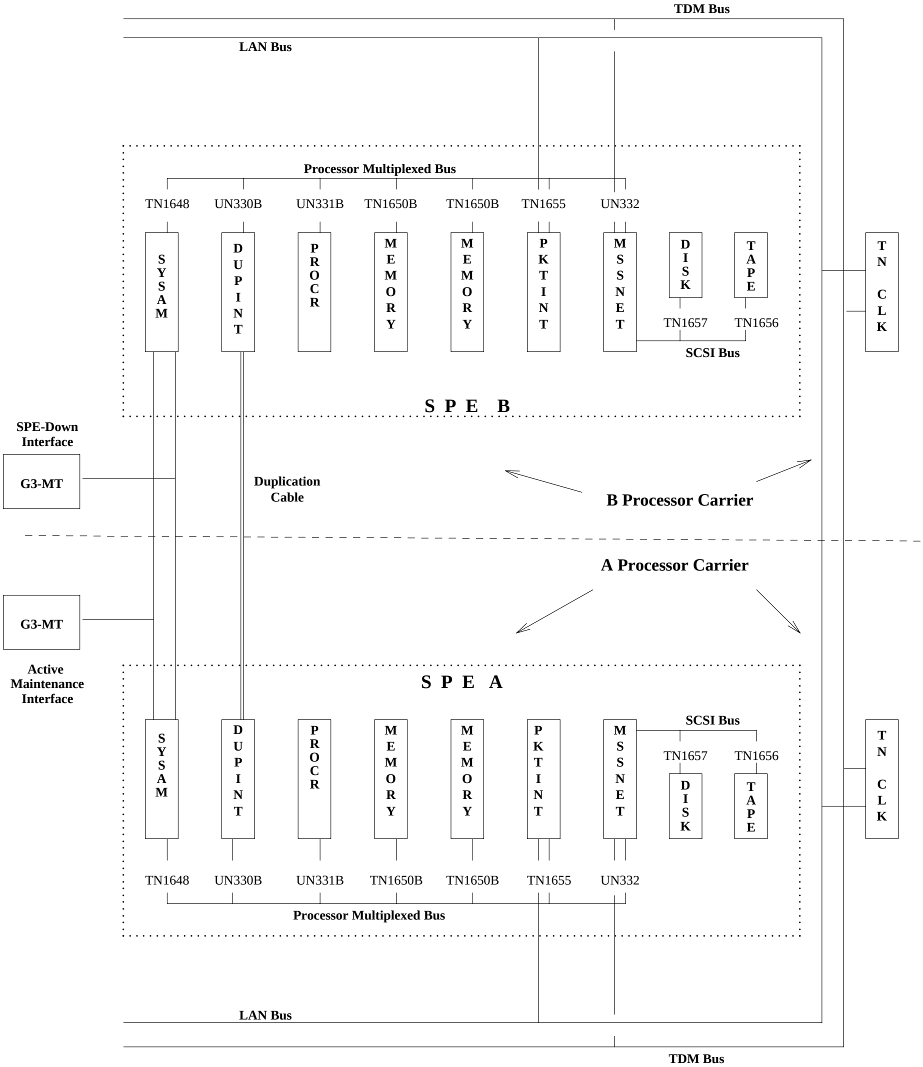

Figure 1-3. Duplicated SPEs — Hardware Configuration

Standby SPE State of Health

The Duplication Interface circuit packs on each of the two SPEs keep track of the State of Health (SOH) of each of the two SPEs. This circuitry ensures that, at any time, unless the SPE-select switches are locked:

- If the two SPEs have the same SOH, the current active SPE remains active.
- If the two SPEs have different SOH, the SPE with the better SOH becomes or remains the active SPE.

These descriptions apply to SOH levels on the standby SPE. Four possible levels of SPE SOH are supported and maintained by system hardware and software.

functional	The standby SPE is fully healthy with up-to-date memory content identical to active SPE memory content. An interchange into this SPE will cause minimal service disruption.
not refreshed	The standby SPE's hardware and operational software are fully healthy but the standby memory content is not currently identical to active SPE memory content. Typically either memory shadowing is off or a memory refresh operation is in progress to bring the memories' contents into agreement. Interchange into an SPE of this health level will lead to calls dropping and a service outage of several minutes.
partially-functional	One of the following conditions is in effect: — A failure of a critical standby SPE component has occurred. — The standby SPE has been busied out. — The SPE is in recent interchange mode (see "STBY-SPE (Standby SPE Maintenance)" in Chapter 9, "Maintenance Object Repair Procedures").
non-functional	This is the worst and most seriously disabled state of a standby SPE. The SPE has lost either power or basic sanity; the standby processor and its software are unable to cycle. Such an SPE cannot be made active by an interchange.

Standby SPE Maintenance Architecture

The maintenance strategy for the standby SPE is based on several independent components.

- Maintenance of handshake communication so that software on the active SPE can control maintenance of the standby SPE and its components.
- Controlling memory shadowing and performing the standby memory refresh operation.
- Activities, independent of handshake communication and memory shadowing, used to allow tracking of the standby SPE's condition. This includes reading of hardware status to determine the actual state of standby SPE.

As shown in Figure 1-4, all maintenance capabilities for the standby SPE are built upon these three strategies.

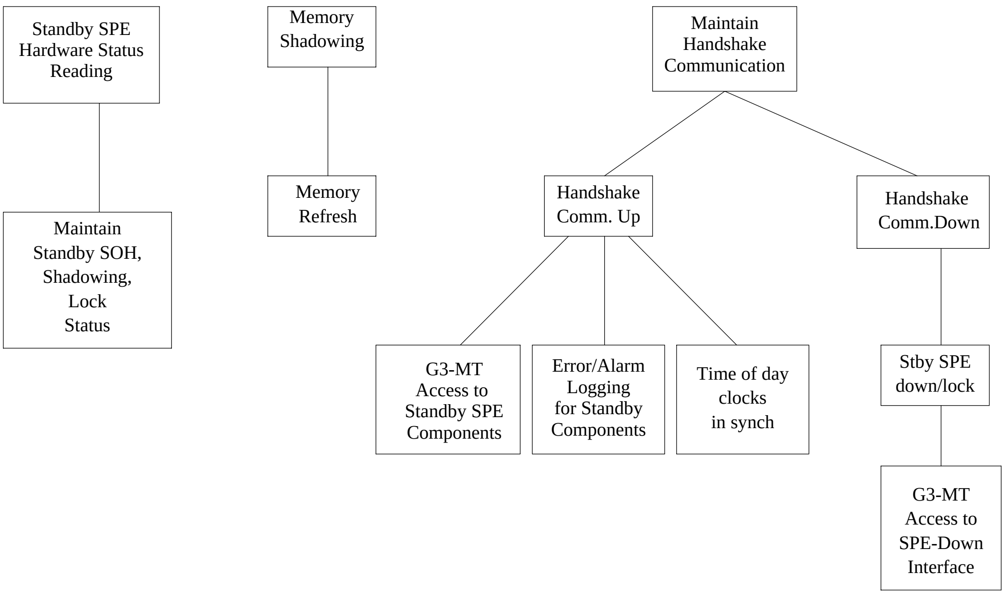

Figure 1-4. Components of Standby Maintenance

Standby SPE maintenance software is designed to attempt to self-correct problems. If a problem occurs, this software automatically tries to address the problem, bring the standby SPE back to a state of availability and clear all alarms which might have been raised. Typically, if a standby SPE problem has not cleared, it is of a hardware nature and some type of hardware component maintenance or replacement action is indicated. Once such corrections have been made, the system software will automatically bring the standby SPE back to full availability. There is no management terminal command to stimulate refresh of standby SPE memory; system software automatically accomplishes this itself when conditions are appropriate. The same is true of efforts to turn on shadowing where no explicit user interface command to turn on/off shadowing is available (note that busyout/release, below, can be used to indirectly accomplish this).

Standby Maintenance Monitor Software

The Standby Maintenance Monitor (SMM) is a software package that is *always* running on key components of the standby SPE to verify its competence. SMM tests individual standby SPE components and reports back to the active SPE, by the handshake message, any failures of individual tests. Failure reports trigger enhanced maintenance attention to standby SPE component problems by active SPE software. SMM also ensures that when handshake communication has been down for an extended period, the standby SPE will transition into the SPE-down state.

Handshake Communication

Every 30 seconds, the active SPE sends a handshake request message to SMM and waits for SMM to respond with a handshake response message. This message transmission occurs across the Duplication Interface circuit packs and their interconnecting cable. As long as SMM responds to these regular handshake request messages, handshake communication is considered *up* as reported on the **status spe** screen.

The physical path of handshake communication is illustrated below. Hardware problems at any point in this route could interfere with handshake communication. If the standby SPE fails to respond to four successive handshake requests, handshake communication is considered down. A major alarm is logged against STBY-SPE with error type 1 logged. The **status spe** screen will indicate that handshake is down. It is then no longer possible to communicate with the standby SPE. Maintenance testing of the standby by the active SPE (or by command) is discontinued, and the error and alarm logs become outdated for standby components.

Handshake communication failure is a severe and rare condition. It is due to either a failure of Duplication Interface hardware or a catastrophic failure of the standby SPE. As long as the active SPE is not locked by the switches, software attempts every 30 seconds, to re-establish handshake communication.

When the SPEs are locked with the switches, handshake communication is physically impossible, but no alarm is raised. When the standby is busied out, handshake communication should remain up, but in any case, only the busyout WARNING alarm will be raised.

Whenever the active SPE has undergone a restart (levels 1-5), handshake is technically considered down during and just after the restart. After a level 1 (hot) restart, if there are no standby SPE problems, handshake communication should be restored within 30 seconds. After active-SPE restarts of levels 2 and up, handshake should be restored within 3 minutes of G3-MT re-enabling.

The active SPE keeps hardware configuration and vintage data about the components of the standby SPE. This data can be accessed with **list configuration control**. Whenever handshake is down, this data may be out of date. Whenever handshake has been down and is restored, the active SPE requests standby SPE software to transmit the current version of this data. The data is then stored in active SPE memory.

Failure to use the lock-and-power- down method for standby circuit pack replacement can lead to incorrect standby component hardware configuration and vintage data.

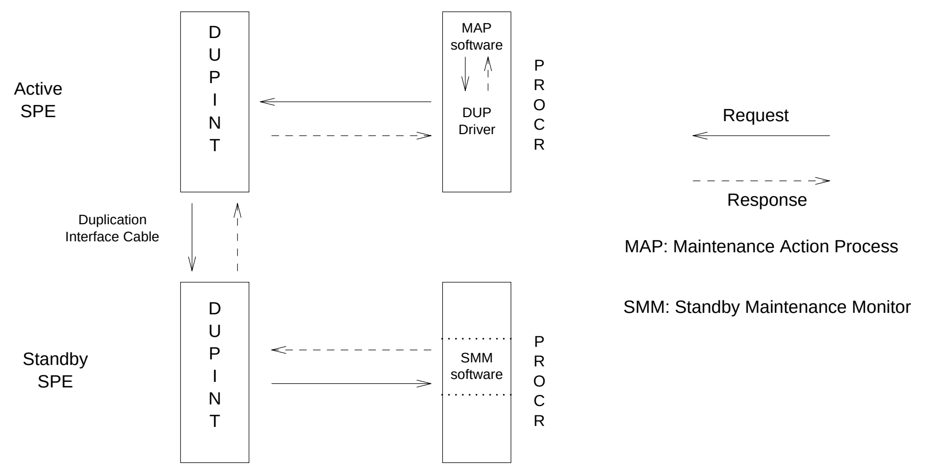

Figure 1-5. Handshake Communication Path

Maintenance of Standby Components

When handshake communication is up, maintenance for individual components of the standby SPE is the same as that for the active (except in some details for PKT-INT). The same commands are used to test standby and active circuit packs, and the error and alarm logs maintained on the active side record data for both.

If a major on-board alarm is raised against a standby SYSAM, Processor, Memory, MSSNET, or Packet Interface board, the standby SPE's SOH is lowered to *partially-functional*. Once that board's problem is fixed and the alarm cleared, system software automatically raises the standby SPE's SOH to *not-refreshed* or *functional*, depending on whether its memory is up to date.

Standby component faults can also affect memory shadowing. Certain faults can have negative effects on system operation if memory shadowing is left on. When these components get major alarms, memory shadowing is automatically kept off by system software. These are referred to as *shadowing relevant* components. Roughly, these include the hardware that provide shadowing or the hardware into which shadowed writes occur.

Table 1-5 below shows the effect often major on-board alarms against standby components on standby SOH and on memory shadowing. Note that off-board alarms, minor alarms and warning alarms have no effect on memory shadowing or on the SOH of the standby SPE.

Table 1-5. Effects of Major Alarms on Shadowing and Standby SOH

Alarmed Component	SOH Effect	Shadowing Effect
PROCR	partially functional	no effect
MEM-BRD	partially functional	shadowing kept off
SW-CTL	partially functional	shadowing kept off
SYSAM	partially functional	no effect
PKT-INT	partially functional	shadowing kept off
DUPINT	no effect	shadowing kept off
DUP-CHL	no effect	shadowing kept off
H-ADAPTR	no effect	no effect
DISK	no effect	no effect
R-MEDIA	no effect	no effect

When handshake communication is down, but the standby SPE is not in SPE-down mode (SOH is not *nonfunctional*), autonomous testing of standby SPE components by the SMM occurs on the standby SPE. If a component fails a test *while handshake is down,* its red LED is lit and the standby SOH is lowered to *partially-functional.*

A standby SPE component is considered to be testable if it can be tested with the usual maintenance commands from a management terminal connected to an ACTIVE connector on the SPE. In this condition, full maintenance software for it is running in the active SPE and the error/alarm data for it is up to date. Table 1-6 gives testability requirements for the various SPE components.

Table 1-6. Testability Requirements for Standby Components

Component	Required Condition
PROCR	handshake up
MEM-BD	handshake up
SW-CTL	handshake up
SYSAM	handshake up
PKT-INT	handshake up and Stby Refreshed
DUPINT	handshake up
DUP-CHL	handshake up
H-ADAPTR	handshake up
DISK	handshake up and Stby Refreshed
R-MEDIA	handshake up and Stby Refreshed

Locking the Active SPE

Duplication Interface hardware supports the ability to lock the active SPE in active mode by means of the SPE-Select switches. The procedure for safely doing this is described in Chapter 5, “Alarms, Errors, and Troubleshooting”, and in “STBY-SPE (Standby SPE Maintenance)” in Chapter 9, “Maintenance Object Repair Procedures”. In locked mode, the system operates as if it is simplex:

- The standby SPE is inaccessible to the active SPE and active G3-MT login.
- No SPE-interchange is possible.
- Handshake is down and memory shadowing is off.

The locked state is intended for temporary use to prevent interchanges during maintenance sessions. No alarm is raised when the switches are locked. However, alarms against SPE-SELE are raised later if the switches are left out of the AUTO position for an extended length of time.

Memory Shadowing

Memory shadowing is used to keep the standby SPE's memory content up-to-date relative to the active SPE's memory. Memory shadowing is turned on automatically when the standby SPE has booted up and completed its own memory testing. Each write operation in active memory is replicated in the corresponding location in standby memory.

When shadowing into the standby SPE has been off (as when the system first comes up), system software checks to see if it is safe to restore shadowing. Handshake communication must be up. Then software verifies (with Test #920) that the SPEs have identical hardware configurations. If this passes and there are no shadow-relevant component failures, system software turns on shadowing again.

Once shadowing is turned on, it is necessary to refresh the contents of standby memory to bring it into full agreement with the active's by copying every word of active SPE memory to the standby. This takes approximately 5 minutes, though traffic load can increase the duration. When completed, the standby SPE is said to be "refreshed". **status spe** or the *Standby SPE Status Query Test (#855)* in the STBY-SPE test sequence can be used to check the REFRESH status of the standby. Unless the standby SPE is refreshed, interchange into it can disrupt service for several minutes. Otherwise, interchanges are minimally disruptive. A standby SPE exiting lock mode or just released from busyout must undergo this full re-initialization.

System software tracks the operation and raises a major alarm when refresh failure occurs. If shadowing stays on, system software automatically tries to refresh again 5 minutes later.

Generally, memory shadowing should always remain on. But there are conditions when the system legitimately operates with shadowing off:

- The standby SPE is undergoing any restart.
- The active SPE is undergoing a restart level of 2 or greater.
- The active SPE is locked.
- The standby SPE is busied out.

In any other situation, it is an error condition for shadowing to be off. The first 2 situations are transitory and shadowing should automatically be restored within 10 minutes. If shadowing has been on for several minutes, it is an error condition for the standby not to be refreshed.

Initialization: Bringing the Standby SPE Up

When the standby SPE has been out of service or is first coming up, SPE software executes the following steps:

1. Establishes handshake communication.
2. When SMM answers handshake, raises the standby SPE's SOH to *not refreshed* if it has no critical component alarms, or *partially functional* there are critical component alarms.
3. Tests for component mismatch (test number 920).
4. If there is no mismatch, and no major alarms against shadow-relevant components, and if SMM permits, turns on memory shadowing
5. If memory shadowing is successfully turned on, initiates the process of overall memory refresh
6. When refresh completes, if there are no critical component major alarms, raises the standby SPE's SOH to level *functional*

Standby SPE initialization is a lower priority than initializing the active SPE and is therefore "paced" to lower CPU consumption. The above steps are carried out at 10 second intervals. During system initialization, the above sequence begins about 2 minutes after the terminal login prompt becomes available. Normally, the standby SPE should be fully initialized about 5 minutes after the availability of the login prompt. You can follow the execution of this sequence by repeatedly entering the command "status spe."

Should a step of this initialization sequence fail, system software retries that step at 30 second intervals until it succeeds. It does not proceed to the next step until the current one has succeeded. The failed condition is alarmed.

A procedure for bringing up the standby SPE after being in the SPE-down or locked modes is described at the end of Chapter 4, ''Initialization and Recovery''.

Power Interruptions

System cabinets and their associated power supplies can be powered by 110/208 volts AC either directly or from an Uninterruptible Power Supply (UPS) system. Alternatively, the cabinets and their power supplies may be powered by a -48 VDC battery power plant, which requires DC-to-DC conversion power units in the system.

If power is interrupted to a DC-powered cabinet or an AC-powered cabinet without optional backup batteries, the effect depends upon the decay time of the power distribution unit. If the interruption period is shorter than the decay time, there is no effect on service, though some -48V circuits may experience some impact. If the decay time is exceeded for a PPN, all service is dropped, emergency transfer is invoked and the system must reboot when power is restored. If the decay time is exceeded for an EPN, all service to that Port network is dropped and the EPN must be reset when power is restored. If the EPN contains a Switch Node carrier, all service to Port Networks connected to that Switch Node is dropped.

Single-carrier cabinets, which can be used for EPNs, also have no battery backup. If power is interrupted for more than 0.25 seconds, all service is dropped, and emergency transfer is invoked for the EPN.

In the above cases, the cabinet losing power is unable to log any alarms. However, in the case of an EPN going down while the PPN remains up, alarms associated with the EPN will be reported by the system.

Nominal Power Holdover

AC-powered multicarrier cabinets are equipped with an internal battery, powered by its own charger, that provides a short term holdover to protect the system against brief power interruptions. This feature, known as the Nominal Power Holdover, is optional on cabinets supplied by a UPS and required on all other AC-powered cabinets. The battery is controlled in such a manner that it automatically provides power to the cabinet if the AC service fails. The duration of the holdover varies according to the type of carrier and whether or not the system has a duplicated SPE. See Table 1-7 for duration times:

Table 1-7. Nominal Power Holdover

Cabinet Type	Control Carrier	Entire Cabinet
PPN, duplicated SPE	5 minutes	10 seconds
PPN, simplex SPE	10 minutes	10 seconds
EPN	10 minutes	15 seconds

Effects of Power Interruptions

Power holdover is controlled by software in the above manner in order to allow the system to sustain multiple brief power interruptions without exhausting the batteries before they have time to recharge. After power is restored, the batteries are recharged by a circuit that monitors current and time. If the batteries take more than 30 hours to recharge, a minor alarm is raised, indicating that the batteries must be replaced or the charger replaced.

The 397 Battery Charger Circuit immediately detects loss of AC power and raises a warning alarm against AC-POWER that is not reported to INADS. Certain maintenance objects such as external DS1 timing will report major alarms in this situation. When power is restored, the AC-POWER alarm is resolved.

PPN Cabinet with Power Holdover

When power is interrupted to a PPN cabinet, the effects depend upon the duration of the outage. Battery power is supplied to the whole cabinet for 10 seconds. If power is restored during that period, service is not affected. If the interruption exceeds the cabinet holdover period, but is restored before the control carrier holdover expires, all service is dropped and emergency transfer is invoked. The SPE is kept up allowing for a speedy restoration of service since a reboot is not required. All non-SPE circuit packs must be reinserted, taking about a minute, depending on the size of the system. If the interruption exceeds the control carrier holdover, all service is dropped and the system must reboot when power is restored, taking up to 15 minutes, depending on the size of the system. Human intervention may be required if central office equipment has been busied out.

EPN Cabinet with Power Holdover

When power is interrupted to an EPN MCC for less than 15 seconds, no service effect results. If the interruption exceeds 15 seconds, only the control carrier is kept up. Circuit packs on other carriers are powered down. Only calls and other services maintained by circuit packs on the control carrier are maintained. For this reason, critical services and those that require a long time to restore (for example, Announcement circuit packs) should be located on control carriers. All service to Port Networks connected to a Switch Node in the EPN is lost. When power is restored, all affected EPNs are reset by system software (see ''EXP-PN (Expansion Port Network)'' in Chapter 9, ''Maintenance Object Repair Procedures''). As with the PPN, a warning alarm is raised against AC-POWER.

External Alarm Leads

Each cabinet provides two leads for one major and one minor alarm contact closure that can be connected to external equipment. These are located on the SYSAM and Maintenance circuit packs. If the switch is under warranty or a maintenance agreement, EXT-DEV alarms are generated by the equipment connected to these leads and reported to INADS. These may be used to report failures of UPSs or battery reserves powering the switch. They are also commonly used to monitor adjuncts such as AUDIX.

Protocols

This section describes the protocols handled by the system and the points where these protocols change. Figure 1-6 is a pictorial guide through data-transmission state changes. Figure 1-6 illustrates the flow of data from DTE equipment, like a terminal or host, through DCE equipment, like a modem or data module, into a communications port on the system. The data flow is shown by solid lines. Below these lines are the protocols used at particular points in the data stream.

Not shown in the Figure 1-6 is the treatment of D-channels in ISDN-PRI and ISDN-BRI transmissions. PRI and BRI D-channels transport information elements that contain call-signaling and caller information. These elements conform to ISDN level-3 protocol. In the case of BRI, the elements are created by the terminal or data module; for the PRI, the elements are created by the system, which inserts them into the D-channel at the DS1 port.

For ISDN transmissions, therefore, BRI terminals and data modules, and DS1 ports insert, interpret, and strip both layer-2 DCE information and layer-3 elements. Also, the DS1 port passes layer-3 elements to the system for processing.

Layers

The Open System Interconnect (OSI) model for data communications contains seven layers, each with a specific function. Communications to and through the system concern themselves only with layers 1 and 2 of the model.

Layer 1, or the *physical layer,* covers the physical interface between devices and the rules by which bits are passed. Among the physical layer protocols are RS-232, RS-449, X.21, DCP, DS1, and others.

Layer 2, or the *data-link layer*, refers to code created and interpreted by the DCE. The originating equipment can send blocks of data with the necessary codes for synchronization, error control, or flow control. With these codes, the destination equipment checks the physical-link reliability, corrects any transmission errors, and maintains the link. When a transmission reaches the destination equipment, it strips any layer-2 information the originating equipment may have inserted. The destination equipment only passes to the destination DTE equipment the information sent by the originating DTE equipment. The originating DTE equipment can also add layer-2 code to be analyzed by the destination DTE equipment. The DCE equipment treats this layer as data and passes it along to the destination DTE equipment as it would any other binary bits.

Layers 3 to 7 (and the DTE-created layer 2) are embedded in the transmission stream and are meaningful only at the destination DTE equipment. Therefore, they are shown in the figure as ‘‘user-defined,’’ with no state changes until the transmission stream reaches its destination.

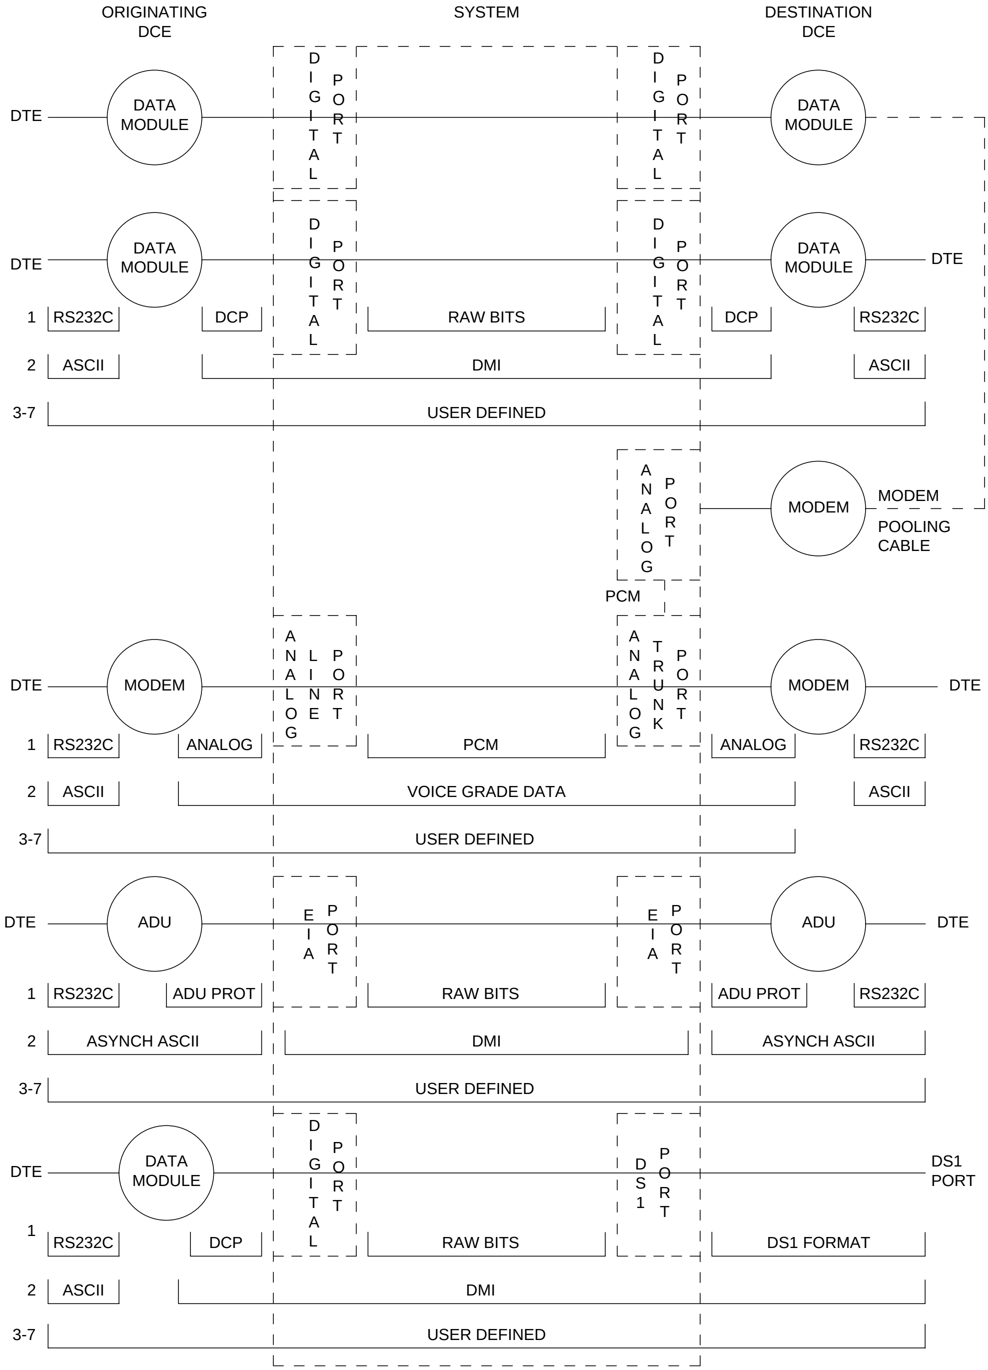

Figure 1-6. Data Transmission States

Usage

The following is a list of the protocols when data is transmitted to and through the system. The list is organized by protocol layers. Refer to Figure 1-6.

Layer-1 Protocols

Layer-1 protocols are used between the terminal or host DTE and the DCE, used between the DCE equipment and the system port, and used inside the system.

The following layer-1 protocols are used between the DTE equipment and the DCE equipment. DCE equipment can be data modules, modems, or Data Service Units (DSUs). A DSU is a device that transmits digital data to a particular digital endpoint over the public network without processing the data through any intervening private network switches.

- *RS-232* — A common physical interface used to connect DTE to DCE. This protocol is typically used for communicating up to 19.2 kbps
- *RS-449* — Designed to overcome the RS-232 distance and speed restrictions and lack of modem control
- *V.35* — A physical interface used to connect DTE to a DCE. This protocol is typically used for transmissions at 56 or 64 kbps

The following protocols are used at layer 1 to govern communication between the DCE equipment and the port. These protocols consist of codes inserted at the originating DCE and stripped at the port. The DS1 protocol can be inserted at the originating, outgoing trunk port and stripped at the destination port.

- *Digital Communications Protocol (DCP)* — A standard for a 3-channel link. This protocol sends digitized voice and digital data in frames at 160 kbps. The channel structure consists of two information (I) channels and one signaling (S) channel. Each I-channel provides 64 kbps of voice and/or data communication and the S-channel provides 8 kbps of signaling communication between the system and DTE equipment. DCP is similar to ISDN-BRI
- *Basic Rate Interface (BRI)* — An ISDN standard for a 3-channel link, consisting of two 64-kbps bearer (B) channels and one 16-kbps signaling (D) channel. For the implementation of this standard, see *DEFINITY Communications System and System 75 and System 85 ISDN BRI Reference*, 555-025-103

- *Primary Rate Interface (PRI)* — An ISDN standard that sends digitized voice and digital data in T1 frames at 1.544-Mbps or, for countries outside the United States, in E1 frames at 2.048-Mbps. Layer 1 (physical), layer 2 (link), and layer 3 (network) ISDN PRI protocols are defined in *AT&T System 75 and 85 — DS1/DMI/ISDN-PRI — Reference Manual*, 555-025-101. At 1.544 Mbps, each frame consists of 24 64-kbps channels plus 8 kbps for framing. This represents 23 B-channels plus 1 D-channel. The maximum user rate is 64 kbps for voice and data. The maximum distances are based on T1 limitations. At 2.048 Mbps, each E1 frame consists of 32 64-kbps channels
- *Analog* — A modulated voice-frequency carrier signal
- *ADU Proprietary* — A signal generated by an ADU. The signal is for communication over limited distances and can be understood only by a destination ADU or destination system port with a built-in ADU
- *Digital Signal Level 1 (DS1)* — A protocol defining the line coding, signaling, and framing used on a 24-channel line. Many types of trunk protocols (for example, PRI and 24th-channel signaling) use DS1 protocol at layer 1
- *European Conference of Postal and Telecommunications rate 1 (CEPT1)* — A protocol defining the line coding, signaling, and framing used on a 32-channel line. Countries outside the United States use CEPT1 protocol

Inside the system, data transmission appears in one of two forms:

1. Raw digital data, where the physical layer protocols, like DCP, are stripped at the incoming port and reinserted at the outgoing port.
2. Pulse Code Modulation (PCM)-encoded analog signals (analog transmission by a modem), the signal having been digitized by an analog-to-digital coder/decoder (CODEC) at the incoming port.

Layer-2 Protocols

Layer-2 protocols are given below:

- *8-bit character code* — Between the DTE equipment and the DCE equipment. Depending on the type of equipment used, the code can be any proprietary code set.
- *Digital multiplexed interface* proprietary — Family of protocols between the originating DCE and the destination DCE for digital transmission. See *DEFINITY Communications System and System 75 and System 85 DS1/DMI/ISDN PRI Reference*, 555-025-101; and *Digital Multiplexed Interface [DMI] Technical Specification,* 555-025-204
- *Voice-grade data* — Between the originating DCE and the destination DCE for analog transmission

Protocol States

Table 1-8 summarizes the protocols used at various points in the data transmission stream. See Figure 1-6.

Table 1-8. Protocol States for Data Communication

Transmiss-ion Type	Incoming DTE to DCE	OSI Layer	Protocols DTE to DCE	DCE to System Port	Inside System
Analog	Modem	1	RS-232, RS-449, or V.35	analog	PCM
		2	8- or 10-bit code	voice-grade data	voice-grade data
	ADU	1	RS-232	ADU proprietary	raw bits
		2	asynchronous 8-bit code	asynchronous 8-bit code	DMI
Digital	Data Module	1	RS-232, RS-449, or V.35	DCP or BRI	raw bits
		2	8-bit code	DMI	DMI
	Digital Signal Level 1 (DS1)	1	any	DS1	PCM or raw bits
		2	8-bit code	DMI or voice-grade data	DMI or voice- grade data

NOTE:
OSI means Open Systems Interconnect
PCM means Pulse Code Modulated
DMI means Digital Multiplexed Interface

Both the physical-layer protocol and the Digital Multiplexed Interface (DMI) mode used in the connection are dependent upon the type of 8-bit code used at layer 2 between the DTE equipment and DCE equipment, as listed in Table 1-9 and Table 1-10.

Table 1-9. Physical-Layer Protocol Versus Character Code

Protocol	Code
RS-232	Asynchronous 8-bit ASCII, and synchronous
RS-449	Asynchronous 8-bit ASCII, and synchronous
V.35	Synchronous

Table 1-10. Digital Multiplexed Interface (DMI) Mode Versus Character Code

DMI Mode	Code
0	Synchronous (64 kbps)
1	Synchronous (56 kbps)
2	Asynchronous 8-bit ASCII (up to 19.2 kbps), and synchronous
3	Asynchronous 8-bit ASCII, and private proprietary

Connectivity Rules

Figure 1-6 implies the following connectivity rules:

- Only the DS1 port and the analog trunk port are trunking facilities (all other ports are line ports). For communication over these facilities, the destination DCE equipment can be a hemisphere away from the system, and the signal can traverse any number of intervening switching systems before reaching the destination equipment.
- Data originating at any type of digital device, whether DCP or BRI, can exit the system at any type of digital port — BRI, digital-line, PRI, DS1, and others; as long as the call destination is equipped with a data module using the same DMI mode used at the call origin. This is because once the data enters the system through a digital port, its representation is uniform (raw bits at layer 1, and DMI at level 2), regardless of where it originated.
- Although data entering the system through an EIA port has not been processed through a data module, the port itself has a built-in data module. Inside the system, port data is identical to digital line data. Data entering the system at a DCP line port can exit at an EIA port. Conversely, data entering the system at an EIA port can exit at any DCP line port. The destination data module must be set for Mode-2 DMI communication.
- Voice-grade data can be carried over a DS1 facility as long as the destination equipment is a modem compatible with the originating modem

- If a mismatch exists between the types of signals used by the endpoints in a connection (for example, the equipment at one end is an analog modem, and the equipment at the other end is a digital data module), a modem-pool member must be inserted in the circuit. When the endpoints are on different switches, it is recommended that the modem-pool member be put on the origination or destination system. A modem-pool member is always inserted automatically for calls to off-premises sites via analog or voice-grade trunking. For internal calls, however, the systems are capable of automatically inserting a modem-pool member.
- Data cannot be carried over analog facilities unless inside the system it is represented as a Pulse Code Modulation (PCM)-encoded analog signal. To do this for data originating at a digital terminal, the signal enters the system at a digital port and exits the system at a digital port. The signal then reenters the system through a modem-pool connection (data-module to modem to analog-port) and exits the system again at an analog port.
- Although DS1 is commonly called a trunk speed, here it names the protocol used at layer 1 for digital trunks. Some trunks use different signaling methods but use DS1 protocol at layer 1 (for example, PRI and 24th-channel signaling trunks).

Disconnect Supervision

Disconnect supervision means the CO has the ability to release a trunk when the party at the CO disconnects, and the system is able to recognize the release signal. In general, a CO in the United States provides disconnect supervision for incoming calls but not for outgoing calls. Many other countries do not provide disconnect supervision on either incoming or outgoing calls.

The system must provide the assurance that at least one party on the call can control the dropping of the call. This avoids locking up circuits on a call where no party is able to send a disconnect signal to the system. Internal operations must check to be sure one party can provide disconnect supervision. An incoming trunk that does not provide disconnect supervision is not allowed to terminate to an outgoing trunk that does not provide disconnect supervision.

In a DCS environment, an incoming trunk without disconnect supervision can terminate to an outgoing DCS trunk connecting two nodes. The incoming trunk is restricted from being transferred to a party without disconnect supervision on the terminating node.

This is because, through messaging, the terminating node knows the originating node cannot provide disconnect supervision. This messaging is not possible with non-DCS tie trunks, and the direct call is denied.

Some two-wire loop start trunks outside the United States provide busy tone disconnect in place of line signals. For these trunks, an adjunct can be attached to the trunk to listen for busy or other disconnect tone. When a tone is detected, the adjunct sends line signals for disconnect to the system.

Administration is provided for each trunk group to indicate whether it provides disconnect supervision for incoming calls and for outgoing calls.

Transfer on Ringing

A station or attendant may conference in a ringing station or transfer a party to a ringing station. When a station conferences in a ringing station and then drops the call, the ringing station is treated like a party without disconnect supervision. However, when a station transfers a party to a ringing station, the ringing station party is treated like a party with disconnect supervision. Two timers (Attendant Return Call Timer and Wait Answer Supervision Timer) are provided to ensure the call is not locked to a ringing station.

Conference, Transfer, and Call-Forwarding Denial

If a station or attendant attempts to connect parties without disconnect supervision together, the following is possible:

- *Digital Station or Local Attendant Transfer*: if a digital station attempts to transfer the two parties together, the call appearance lamp flutters, indicating a denial. If transferring to a DCS trunk, the denial may drop the call since the transfer is allowed and the other system is queried for disconnect supervision.
- *Analog Station Transfer*: if an analog station attempts to transfer two parties together by going on-hook, the analog station is no longer on the call and the transfer cannot be denied.
- *Centralized Attendant Service (CAS) Attendant Transfer*: if a CAS attempts to transfer two parties together by pressing the release key, the release link trunk is released and the branch attempts a transfer by going on-hook
- *Station Conference/Dropout*: if a station conferences all parties, the conference is allowed since the station has disconnect supervision. When the station is dropped from the call, the call is dropped since the other parties do not have disconnect supervision.
- *Station Call Forwarding*: if a station is call forwarded off-premise to a trunk without disconnect supervision, the calling party without disconnect supervision is routed to the attendant

Table 1-11 lists the various protocols, with applications and maximum limitations.

Table 1-11. Protocols Used in DEFINITY

Protocol	Applications	Maximum Data Rate	Maximum Distance
DCP	Digital switch to data endpoints	64 kbps	5000 feet (1524 m) for data 3000 feet (915 m) for voice
RS-232	System to administration terminal. Data module to host computer	19.2 kbps	50 feet (15.2 m)
	Data module to printer	64 kbps	17 feet (5.9 m)
	Data module for downloading and high-speed data transfer	64 kbps	17 feet (5.9 m)
	EIA interface (Data line to ADU)	19.2 kbps 9.6 kbps 4.8 kbps 2.4 kbps 1.2 kbps 0.3 kbps	2000 feet (610 m) 5000 feet (1524 m) 7000 feet (2130 m) 12,000 feet (3654 m) 20,000 feet (6100 m) 40,000 feet (12200 m)
RS-449	Processor Interface to Processor Interface	19.2 kbps 9.6 kbps 4.8 kbps 2.4 kbps	200 feet (61 m) 400 feet (122 m) 800 feet (244 m) 1600 feet (488 m)
SSI	715 BCS-2 to Processor Interface 500 series printers to Processor Interface	56 kbps	5000 feet (1524 m)
BISYNC	Processor Interface line controller to host computer for terminal emulation (9.6 kbps)	2.4 kbps 4.8 kbps 9.6 kbps	
BX.25	Communication interface to MSA, DCS, ISDN, or AUDIX	9.6 kbps	
SDCPI	Data module to Processor Interface	64 kbps	17 feet (5.9 m)
RS-366	Host computer to ACU Data module to ACU	 64 kbps	50 feet (15.2 m) 17 feet (5.9 m)
V.35	Data module to data endpoints	56 kbps	50 feet (15.2 m)

Continued on next page

Table 1-11. Protocols Used in DEFINITY — *Continued*

Protocol	Applications	Maximum Data Rate	Maximum Distance
Category A	Data modules to terminals or cluster controller Data module in ASCII emulation mode	64 kbps 9.6 kbps	500 feet (152 m)
ISDN-BRI	Communication interface to ISDN-BRI S/T ISDN-BRI U	64 kbps 160 kbps	655 feet (199.3 m) to network interface or repeater 1310 feet (399.3 m) system to system 18,000 feet (5486.4 m) from system to network interface, and then ~2000 feet to phone
ISDN-PRI	Communication interface to ISDN-PRI	64 kbps	655 feet (199.3 m) to network interface or repeater 1310 feet (399.3 m) system to system

NOTE:
ADU means Asynchronous Data Unit
BCS means Business Communications System
MSA means Message Servicing Adjunct
ACU means Automatic Call Unit

Transmission Characteristics

The system transmission characteristics comply with the American National Standards Institute/Electronic Industries Association (ANSI/EIA) standard RS-464A (SP-1378A). The following tables list some general switch transmission characteristics.

Frequency Response

Table 1-12 lists the analog-to-analog frequency response for station-to-station or station-to-CO trunk, relative to loss at 1 kHz for the United States.

Table 1-12. Analog-to-Analog Frequency Response

Frequency (Hz)	Maximum Loss (dB)	Minimum Loss (dB)
60	—	20
200	5	0
300 to 3000	1	-0.5
3200	1.5	-0.5
3400	3	0

Table 1-13 lists the analog-to-digital frequency response of the system for station or CO-trunk-to-digital interface (DS0), relative to loss at 1 kHz for the United States.

Table 1-13. Analog-to-Digital Frequency Response

Frequency (Hz)	Maximum Loss (dB)	Minimum Loss (dB)
60	—	20
200	3	0
300 to 3000	0.5	-0.25
3200	0.75	-0.25
3400	1.5	0

Insertion Loss for Port-to-Port; Analog or Digital

Table 1-14 lists the insertion loss in the system for different connection types for the United States. Table 1-15 shows the overload and cross-talk characteristics.

Table 1-14. Insertion Loss for the United States

Typical Connections	Nominal Loss (dB) at 1 kHz
On-premises to on-premises station	6
On-premises to off-premises station	3
Off-premises to off-premises station	0
On-premises station to 4-wire trunk	3
Off-premises station to 4-wire trunk	2
Station-to-trunk	0
Trunk-to-trunk	0

Table 1-15. Overload and Crosstalk

Overload level	+3 dBm0
Crosstalk loss	>70 dB

Intermodulation Distortion

Table 1-16 lists the intermodulation distortion in the system for analog-to-analog and analog-to-digital, up to 9.6 kbps data

Table 1-16. Intermodulation Distortion

Four-Tone Method	Distortion
Second-order tone products	>46 dB
Third-order tone products	>56 dB

Quantization Distortion Loss

Table 1-17 lists the quantization distortion loss in the system for analog port to analog port.

Table 1-17. Quantization Distortion Loss

Analog Port-to-Analog Port	
Signal Level	Distortion Loss
0 to -30 dBm0	>33 dB
-40 dBm0	>27 dB
-45 dBm0	>22 dB

Table 1-18 lists the quantization distortion loss in the system for analog port to digital port and digital port to analog port.

Table 1-18. Quantization Distortion Loss

Analog Port-to-Digital Port or Digital Port-to-Analog Port	
Signal Level	Distortion Loss
0 to -30 dBm0	>35 dB
-40 dBm0	>29 dB
-45 dBm0	>25 dB

Terminating Impedance: 600 Ohms nominal
Trunk balance impedance (selectable): 600 Ohms nominal or complex Z [350 Ohms + (1 k Ohms in parallel with 0.215uF)]

Impulse Noise

On 95% or more of all connections, the impulse noise is 0 count (hits) in five minutes at +55 dBrnC (decibels above reference noise with C-filter) during the busy hour.

ERL and SFRL Talking State

Echo-Return Loss (ERL) and Single-Frequency Return Loss (SFRL) performance is usually dominated by termination and/or loop input impedances. The system provides an acceptable level of echo performance if the ERL and SFRL are met.

Station-to-station	ERL should meet or exceed 18 dB SFRL should meet or exceed 12 dB
Station to 4-wire trunk connection	ERL should meet or exceed 24 dB SFRL should meet or exceed 14 dB
Station to 2-wire trunk connection	ERL should meet or exceed 18 dB SFRL should meet or exceed 12 dB
4-wire to 4-wire trunk connection	ERL should meet or exceed 27 dB SFRL should meet or exceed 20 dB

Peak Noise Level

- Analog to analog — 20 dBrnC (decibels above reference noise with C-filter)
- Analog to digital — 19 dBrnC
- Digital to analog — 13 dBrnC

Echo Path Delay

- Analog port to analog port — $\leq$ 3 ms
- Digital interface port to digital interface port — $\leq$ 2 ms

Service Codes

Service codes (for the United States only) are issued by the Federal Communications Commission (FCC) to equipment manufacturers and registrants. These codes denote the type of registered terminal equipment and the protective characteristics of the premises wiring of the terminal equipment ports.

Private line service codes are as follows:

- 7.0Y — Totally protected private communications (microwave) systems
- 7.0Z — Partially protected private communications (microwave) systems
- 8.0X — Port for ancillary equipment
- 9.0F — Fully protected terminal equipment
- 9.0P — Partially protected terminal equipment
- 9.0N — Unprotected terminal equipment

- 9.0Y — Totally protected terminal equipment

The product line service code is 9.0F indicating it is terminal equipment with fully protected premises wire at the private line ports.

Facility Interface Codes

A Facility Interface Code (FIC) is a five-character code (United States only) that provides the technical information needed to order a specific port circuit pack for analog private lines, digital lines, MTS lines, and WATS lines.

Table 1-19 through Table 1-21 list the FICs. Included are service order codes, Ringer Equivalency Numbers (RENs), and types of network jacks that connect a line to a rear panel connector on a carrier.

Table 1-19. Analog Private Line and Trunk Port Circuit Packs

Circuit Pack	FIC	Service Order Code	Network Jack
TN742 and TN747B Off-Premises Station Port, and TN746B Off-Premises Station Port or On-Premises Station port	0L13C	9.0F	RJ21X
TN760/B/C/D Tie Trunk	TL31M	9.0F	RJ2GX

Table 1-20. Digital Trunk Port Circuit Packs

Circuit Pack	FIC	Service Order Code	Network Jack
TN1654 and TN574 DS1 Converter; TN722B DS1 Tie trunk; and TN767 and TN464 DS1 Interface	04DU9B,C	6.0P	RJ48C and RJ48M

Table 1-21. MTS and WATS Port Circuit Packs

Circuit Pack	FIC	Ringer Equivalency Number (REN)	Network Jack
TN742 and TN746B Analog Line	02LS2	None	RJ21 and RJ11C
TN747B Central Office Trunk	02GS2	1.0A	RJ21X
TN753 DID Trunk	02RV2-T	0,0B	RJ21X
TN790 Processor	02LS2	1.0A	RJ21X
TN1648 System Access and Maintenance	02LS2	0.5A	RJ21X

Multimedia Interface (MMI)

The Multimedia Interface handles the following protocols:

- International Telecommunications Union (ITU) H.221 — Includes H.230, H.242, H.231, and H.243 protocol
- American National Standards Institute (ANSI) H.221 — Includes H.230, H.242, H.231, and H.243 protocol
- BONDING (Bandwidth On Demand INoperability Group) Mode 1
- ESM HLP HDLC Rate Adaptation

The Vistium Personal Conferencing System is supported either through the 8510T BRI terminal or directly through the Vistium TMBRI PC board.

Using the World Class Core (WCC) BRI interface, most desktop multimedia applications are supported through a personal computer's BRI interface.

Hardware Configurations

2

The DEFINITY System supports a variety of configurations consisting of a PPN and up to 21 EPNs. In addition, the system may use a Center Stage Switch (CSS) consisting of one or two Switch Nodes. This chapter describes the PPN and EPN cabinets, and the configuration of carriers and circuit packs within these cabinets.

Multi-Carrier Cabinet

The Multi-Carrier Cabinet (J58890A) accommodates from one to five circuit pack carriers, and is always used for the PPN. EPNs may use either multicarrier cabinets or single-carrier cabinets.

The power unit in the bottom of the MCC cabinet supplies AC voltage or DC voltage from an external source to the power supply in each carrier. The AC powered cabinet optionally contains a battery charger and backup batteries to provide temporary power to the cabinet if the external source fails. The backup unit is optional for systems powered from an Uninterruptible Power Supply (UPS). The fan unit in the middle of the cabinet cools the carriers. AC-powered cabinets have two 120V AC receptacles in the back for use as an AC power source. These can be used to power the G3-MT.

Each cabinet must be connected to one of the following dedicated power sources:

- 120V AC 60 Hz at 50A from a National Electrical Manufacturing Association (NEMA) 5-50R power outlet or equivalent
- Single phase 240V AC, or three phase 208V AC, 60 Hz at 30A from a NEMA L 14-30R power outlet or equivalent

- -48V DC battery plant
- Global MCC uses 50-60 Hz at 200-240 VAC power source

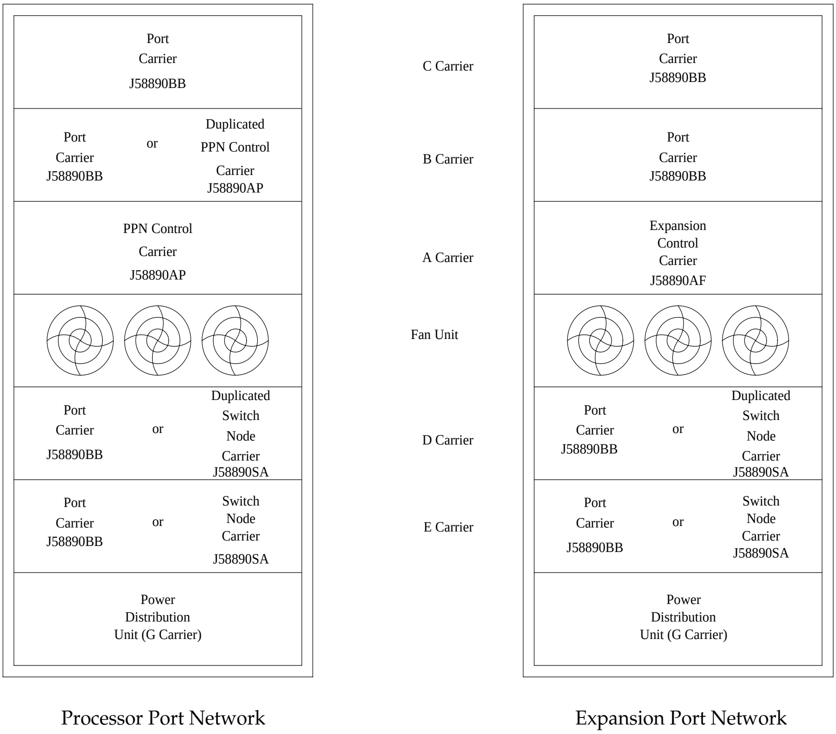

Figure 2-1. Multicarrier Cabinet (J58890A) Configurations

Processor Port Network Cabinet

The PPN cabinet, pictured above, is the primary cabinet in all G3r systems. It contains the Switch Processing Element (SPE) that controls the system and one Port Network that is interconnected by the daisy-chained TDM/LAN bus. If the system has a CSS, the PPN cabinet also contains a switch node. The individual carriers are described in following sections.

The A position always contains a PPN Control Carrier (J58890AP), also known as the Processor Carrier, which holds the SPE circuit packs. If the system has a duplicated SPE, the B position holds a second PPN Control Carrier. At least one, and up to four, Port Carriers (J58890BB) can be located in the other four carrier positions, depending on traffic needs and whether the system uses those positions for other types of carriers. In general, Port Carriers are added in the sequence, B-C-D-E, unless those positions are used otherwise, as follows.

If the system has a Center Stage Switch, the E position holds a Switch Node Carrier. In a CSS system with duplicated PNC, the D position holds a Switch Node Carrier that duplicates the one in E position. In large systems requiring a CSS with two Switch Nodes, the second SN is located in an EPN cabinet, for both simplex and duplicated systems. Systems that have added a CSS configuration after the original installation may have their first SN in an EPN cabinet.

Expansion Port Network Cabinets

When used for an EPN, the multicarrier cabinet supports one Port Network with a daisy-chained TDM/LAN bus, or, optionally, two separate PNs if the cabinet does not contain a Switch Node. A cabinet with two PNs has two separate TDM/LAN bus daisy-chains. One TDM/LAN bus between carriers in positions A, B and C supports the first PN, and another TDM/LAN bus between positions D and E supports the second PN. Figure 2-1 shows locations of carriers in EPN cabinets.

Each EPN cabinet contains one Expansion Control Carrier (J58890AF) located in the A position. In cabinets with one PN, up to four Port Carriers are added as needed in the sequence B-C-D-E, unless the D or E positions are used for a Switch Node. Cabinets with two PNs use optional Port Carriers in the B position, and then the C position for the first PN (above the fans). The second PN, (below the fans), is configured with the first Port Carrier in the E position and an optional second Port Carrier in D position.

In large systems with a CSS that requires two Switch Nodes, the second SN is located in an EPN cabinet (this is usually cabinet number 2, PN number 2). This EPN may not be remoted by a DS1CONV complex. An EPN with an SN has a Switch Node Carrier in E position. In systems with duplicated PNC, (Critical Reliability option), the D position holds another Switch Node Carrier that duplicates the one in E position.

Carriers in Multi-Carrier Cabinets

PPN Control Carrier (J58890AP)

The PPN Control Carrier contains dedicated slots used for circuit packs that compose the switch processing element (SPE). It does not contain port circuit pack slots. This carrier always resides in position A of the PPN cabinet. In a system with a duplicated SPE, a second PPN Control Carrier resides in the B position of the PPN cabinet.

Table 2-1 describes the function of each slot in the PPN Control Carrier.

Table 2-1. PPN Control Carrier Circuit Pack Slots

Slot Name	Circuit Pack	Code	Notes
POWER UNIT (right side)	Power Unit (+5V)	649A	Required for DC-powered systems. TRI PLS OUTPUT DC-Powered cabinets
SYS ACCESS/ MAINTENANCE	System Access and Maintenance	TN1648	Required
DUP INTFC	Duplication Interface	UN330B	Required for systems with duplicated SPE
PROCR	RISC Processor	UN331B	Required
TEST INTFC			Used by field support to connect diagnostic equipment
MEMORY 1 to 4	32 Mbyte Memory	TN1650B	Two required, up to four optional, Release 5 and higher requires 3
PACKET INTFC 1 to 3	Packet Interface	TN1655	One required, two slots reserved for future use; with duplicated SPE, both carriers must use same slot
TONE-CLOCK	Tone-Clock	TN780 TN2182	Required; TN780 required for interface to external Stratum 3 Clock
MSS/ NET CON	Mass Storage System/ Network Control	UN332	Required
DISK DRIVE	Disk Drive	TN1657	Required
R-MEDIA DRIVE	Tape Drive or Optical Disk Drive	TN1656 or TN2211	One or the other is required (removable media drive)

Port Carrier (J58890BB)

Table 2-2 describes the function of each carrier slot.

Table 2-2. Port Carrier Circuit Pack Slots

Slot Name	Circuit Pack	Code	Notes
POWER UNIT (right side)	Power Unit (+5V)	649A	Required for DC-powered systems. TRI PLS OUTPUT DC-Powered
POWER UNIT/ SERVICE	Power Unit, Neon	TN755B	This position is addressed as “00” in commands and displays. It does not provide tip and ring to the wall field. The following circuit packs are optional, depending on system features. One TN771D is required in all PPNs, and one in each EPN of Critical Reliability systems.
	Call Classifier	TN744	
	Integrated Announcement	TN750	
	Speech Synthesizer	TN725B, TN433, TN457	
	Tone Detector	TN748, TN420B	
	Maintenance/ Test	TN771D	
TONE-CLOCK 1	Tone-clock	TN768 TN2182	Required as follows: EPN with duplicated PNC: B carrier EPN cabinet with two PNs: D carrier E carrier of an EPN cabinet with two PNs and duplicated PNC; the Tone-clock slot is located with Port Slot #2. If the carrier does not contain a Tone-Clock board, any port board may be installed in this slot.
EXPN INTFC 2	Expansion Interface	TN570	Optional, depending on system’s connectivity and duplication configuration; if not used for an EI board, this slot can accept any common port board.
3			If the system’s connectivity and duplication configuration require a second EI on a port carrier, it resides in this slot; otherwise, this slot accepts any common port board.
4 to 20	Port Boards		Any common port board.

Expansion Control Carrier (J58890AF)

The Expansion Control Carrier is located in position A of each EPN. Table 2-3 describes the function of each carrier slot.

Table 2-3. Expansion Control Carrier Slots

Slot Name	Circuit Pack	Code	Notes
POWER UNIT (left side)	Power Unit (+5V)	631DA1	Required for AC-powered systems
		644A1	Required for DC-powered systems or empty
MAINTENANCE	Maintenance	TN775B	Required
TONE-CLOCK	Tone-Clock	TN2182	Required
EXPN INTFC	Expansion Interface	TN570	Required
2 to 19	Port Boards		Any common port board. Slot 2 may house a second EI if the configuration requires one.
POWER UNIT/ 18, 19	Power Unit, Neon	TN755B	Required for certain features; otherwise will accept any common port board.
POWER UNIT (right side)	Power Unit (-48V/-5V)	631DB1	Required for AC-powered systems
		645B1	Required for DC-powered systems
		649A	TRI PLS OUTPUT for DC-Powered cabinets

Switch Node Carrier (J58890SA)

Switch Node carriers house the components of a Center Stage Switch (CSS). The first switch node is located in carrier E of the PPN. If duplicated in a Critical Reliability configuration, its duplicate is located in carrier D of the PPN. The second switch node is located in carrier E of a non-remoted EPN. If duplicated in a Critical Reliability configuration, its duplicate is located in carrier D of the same EPN.

Table 2-4. Switch Node Carrier Circuit Pack Slots

Slot Name	Circuit Pack	Code	Notes
POWER UNIT (right side)	Power Unit (+5V)	649A	Required for DC-powered systems
EXPN INTFC DS1 CONV/ 1	DS1 Converter	TN574	Provides fiber connectivity from DS1 facilities to a remote EPN; this slot used in conjunction with an SNI in one of slots 2 to 9.
	Expansion Interface	TN570	Used for an EI board only in the PPN cabinet in a system with duplicated PNC (Critical Reliability); used in conjunction with adjacent SNI
2 to 9, 13 to 20	Switch Node Interface	TN573	SNIs are added sequentially as needed beginning with slot 2. If a second switch node is needed, (for more than 16 EPNs), up to 5 SNIs (those in slots 7, 8, 9, 13 and 14) are connected to corresponding SNIs in the other SN.
SWITCH NODE CLOCK / 10	Switch Node Clock	TN572	Required
SWITCH NODE CLOCK / 12	Switch Node Clock	TN572	Used in High Reliability option only (duplicated SPE, simplex PNC)
DS1 CONV/ 21	DS1CONV	TN574	Used as above in conjunction with an SNI in one of slots 13 to 20

PNC Cabling — Fiber Hardware

The term "fiber" is used to refer to all the hardware needed for the three basic types of connections used to form multi-PN systems. Fiber administration specifies the endpoints to be connected, optional DS1 CONV locations, and parameters for DS1 Facility Line encoding and equalization. The 3 connection types are:

1. EI-to-EI or EI-to-SNI Intercabinet hardware
2. EI-to-SNI or EI-to-EI intracabinet hardware
3. EI-DS1CONV or SNI-DS1CONV hardware

EI-to-EI or EI-to-SNI Intercabinet Fiber Optic Cables

EI-to-EI or EI-to-SNI intercabinet connections are implemented by installing a lightwave transceiver on the I/O connector plate for each of the administered fiber endpoints. Each lightwave transceiver has a receive and a transmit connector for a 62.5 micron or 50 micron fiber connection. Standard fibers are available in various lengths up to 150 feet (46 m) for single-mode fiber and up to 200 feet (61 m) for multi-mode fiber. These fibers are used to connect lightwave transceivers to each other when they are close enough together, or to optical cross-connect facilities for greater distances.

The lightwave transceivers are powered from I/O connector plate leads attached to TN570 Expansion Interface circuit pack or a TN573 Switch Node Interface circuit pack. The transceivers include loop-around capabilities to support fiber fault isolation. Either of two different 9823-type multi-mode transceivers may be used, depending upon the length of the fiber (table below), or the 300A single mode fiber transceiver. The transceivers at each end of a given fiber should match. Figure 2-2 illustrates the interconnection of fiber optic hardware.

Part Number	Maximum Fiber Length	Fiber Mode
9823A	4900 feet (1494 m)	Multi-mode
9823B	25,000 feet (7620 m)	Multi-mode
300A	22 miles (35.4 km)	Single mode

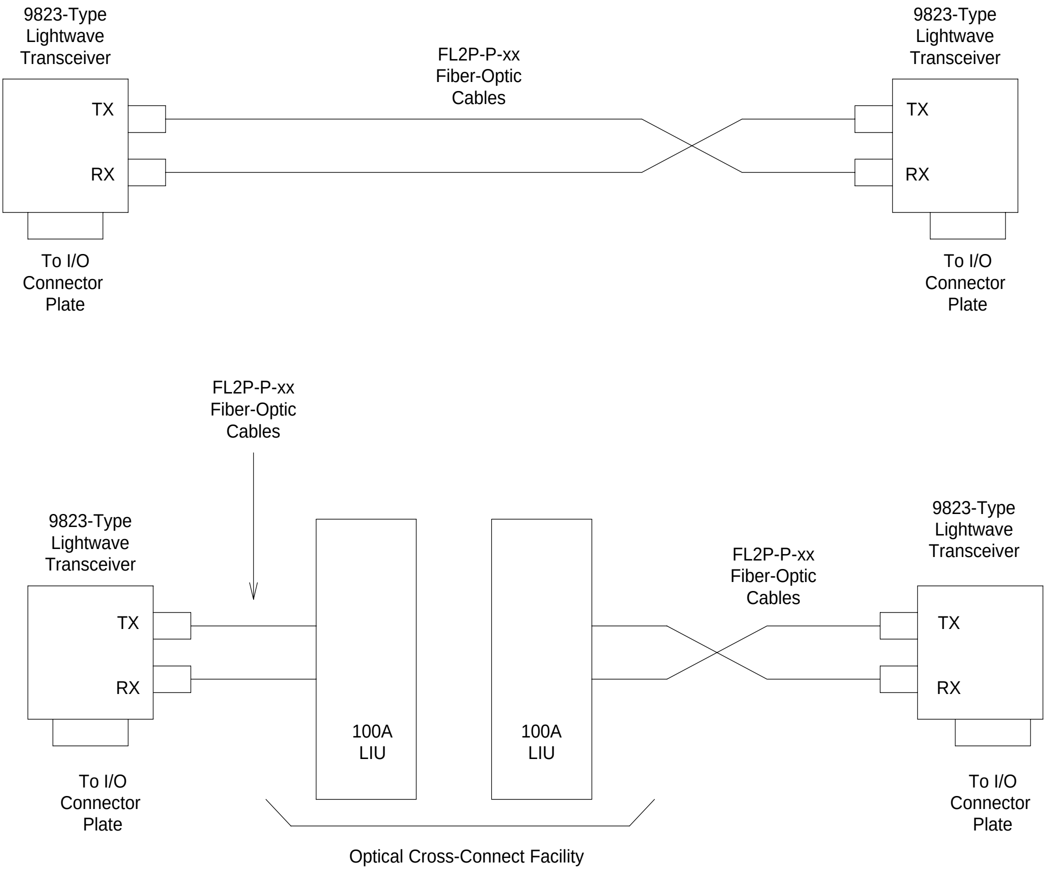

Figure 2-2. Fiber Link Connection Hardware

EI-to-SNI or EI-to-EI Intracabinet Metallic Cabling

Metallic cable may be substituted for optical cable for "fiber" connections between EIs or between an EI and an SNI in the same MCC cabinet. The same I/O plate connectors are used. The metallic cables should not be used for intercabinet connections, since doing so violates system ground integrity. The metallic cable comes in two lengths.

Part No.	Length	Intended use
H600-278,G1	13 inches (33 cm)	From an EI in slot 1 of a switch node carrier to an SNI in the same half of the carrier (usually the adjacent slot)
H600-278,G2	66 inches (168 cm)	From an EI to an SNI in the same cabinet, but in a different carrier or different half of a carrier

DS1 CONV Cabling

Digital services (DS1) can be used to connect PNs that are up to 100 miles (161 km) apart when fiber optic cabling is not practical. Multi-mode (fiber-connected PNs must be less than 25,000 feet (7620 m) and less than 22 miles (35.4 km) for single- mode fiber from the PPN.) A TN574 or TN1654 DS1 Converter (DS1 CONV) circuit pack serves as the interface between the network and an EI or SNI on the switch. DS1 cabling on a carrier consists of a Y-cable that connects a DS1 CONV to an EI or SNI and to the network. The following cables may be used, depending upon where the DS1 CONV and the EI or SNI are located:

Connection Type	Length	Comcode Number TN574	Comcode Number TN1654
On same half carrier	1 foot (30.48 cm)	846448637	847245750
On different half carriers in same cabinet	5.5 feet (1.68 m)	846448645	847245768
Between two adjacent cabinets	1 foot (30.48 cm), used with two 9823As, and 1 20-foot (6.1 m) fiber optic cable	846448652, and one 846885259 bracket	847245776 with one 846885259 bracket

The DS1 CONV to EI/SNI cable is a shielded metallic Y-cable held in place at the EI/SNI port connector by a 4B retainer and at the DS1 CONV port connector by a 4C retainer. The cable end with one 25-pair amphenol connector attaches to the I/O Plate connector for the EI or SNI. The end with two 25-pair amphenol connectors attaches to the DS1 CONV I/O Plate connector.

The 13-inch cable 846448652 or 847245776 connects the DS1 CONV to a fiber-optic cable, enabling the DS1 CONV to connect to an EI or SNI at a greater distance. The cable end with one 25-pair amphenol connector attaches to a lightwave transceiver using the 846885259 bracket. The end with two 25-pair amphenol connectors attaches to the DS1 CONV I/O Plate connector. The other end of the fiber-optic cable connects to a lightwave transceiver attached to the I/O plate connector of the EI or SNI.

An H600-348 cable connects the DS1 CONV cable to a Channel Service Unit (CSU), which connects to a wall field. (Alternatively, connection is sometimes made directly from the Y-cable to the wall field. See the pinout for the 50-pin connector at the end of the Fiber Fault Isolation Procedure in Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’.) This cable provides from one to four DS1 connections. One end of the H600-348 cable is plugged into the 50-pin amphenol piggy-back connector on the 8464486xx cable connected to the DS1CONV port connector. The other end of the H600-348 cable has four 15-pin sub-miniature D-type connectors that plug into the CSU. A pinout of this cable appears the end of the Fiber Fault Isolation Procedure in Chapter 5. H600-348 cables come in the following lengths:

Group No.	Length	Group No.	Length
G1	25 feet (7.62 m)	G5	125 feet (38.1 m)
G2	50 feet (15.24 m)	G6	200 feet (60.96 m)
G3	75 feet (22.86 m)	G7	400 feet (121.9 m)
G4	100 feet (30. 48 m)	G8	650 feet (198 m)

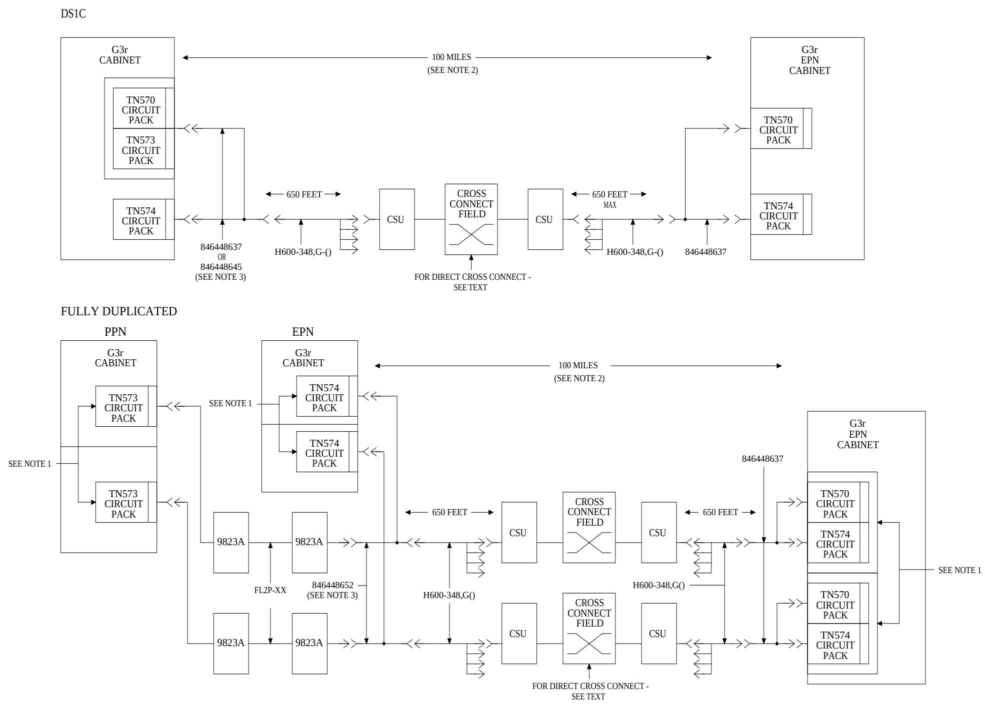

Figure 2-3. Typical DS1 CONV Connections to Remote EPNs

1. Place duplicate pairs in different carriers.
2. When removing two or more, the maximum cable distance between any two remoted end points is 100 miles (161 km). For example, if the EPN is 75 miles (121 km) from the PPN, then EPN 2 can only be 25 miles (40.2 km) from the PPN.
3. 846447637 is used within a carrier for a TN574, for TN1654 within a carrier use a 847245750.

   846448645 is used within a cabinet between carriers for a TN574, for TN1654 within a cabinet between carriers use a 847245768.

Circuit Packs

The following tables list all circuit packs supported by DEFINITY Systems. For information concerning vintages and current versions, see *Reference Guide for Circuit Pack Vintages and Change Notices* which is published periodically as a special edition of the *Lucent Technical Monthly*.

Duplication: Reliability Options

Standard Reliability Option

On Standard Reliability systems, the 512-time-slot TDM bus is divided into two duplicate 256-time-slot buses, A and B. Call traffic is shared between the two buses. The first 5 time slots on each bus are reserved for the control channel, which is active on only one of the two buses at a time. Likewise, the next 17 time slots are reserved for carrying system tones. The tone times slot are not necessarily on the same bus (A or B) as the control channel. If any failure takes place that affects the ability of the active control or tone time slots to function, the other bus becomes active for those time slots.

High Reliability Option

High Reliability systems duplicate components that are critical to the viability of the system as a whole to prevent a single failure from dropping all service:

- PPN control carrier and carrier power units (OLSs)
- All SPE circuit packs: Processor, Memory, MSSNET, Disk, Removable Media, SYSAM, Duplication Interface, and carrier power units (OLSs)
- PPN Tone Clock circuit pack (EPN Tone-Clocks are not duplicated)
- TDM buses (described above)

In addition to the above, the following are duplicated in Center Stage Switch (CSS) configurations:

- The PPN to CSS fiber link (consisting of the PPN Expansion Interface circuit packs, the Switch Node Interface circuit packs that connect to the PPN EIs, and cabling from the PPN EI to the CSS)
- Switch Node Clocks (SNCs) (two; on each Switch Node carrier)

The duplicated SPEs operate in active/standby fashion. Interchanges of the SPE and of PPN Tone-Clocks operate independently unless induced by use of the SPE-select switches. The 2 SNCs on each Switch Node carrier also operate in an active/standby manner.

The duplicated fiber link between the PPN EIs and the CSS (the cable may actually be metallic) do not use an active/standby strategy. Instead, both links simultaneously carry active call traffic and control connectivity in an equally distributed load-sharing manner. If a component fails one of these fiber links, all connectivity over it on it is torn down, resulting in some dropped calls and control and application links. Links and subsequent call service is immediately re-established over the other EI fiber link.

Critical Reliability Option

Critical Reliability systems include all of the features of the High Reliability option described above. Additionally, the duplicate components of Port Network Connectivity (PNC) and other components critical to the viability of each EPN.

- Switch Node carriers and carrier power supplies (OLSs)
- Switch Node Interface (SNI) circuit packs
- Switch Node Clock (SNC) circuit packs (one on each duplicated Switch Node carrier)
- PPN and EPN Tone-Clock circuit packs
- PPN and EPN Expansion Interface circuit packs
- Each EPN contains a TN771D Maintenance/Test circuit pack
- Inter-PN cabling
- DS1 Converter Complexes (circuit packs, cabling and DS1 facilities used to connect remote EPNs)

The entire PNC (whether direct connect or CSS connected) is duplicated as a whole, forming two identical sets which each function as a whole (A-PNC and B-PNC). The 2 PNCs operate in an active/standby manner with all inter-PN calls set up on both PNCs so that the active can assume control without disruption of service. Operation of PNC duplication is described under PNC-DUP in Chapter 9, ''Maintenance Object Repair Procedures''.

The Tone-Clocks in each EPN operate in an active/standby manner independently from other duplication strategies.

Management Terminal

3

The Management Terminal (MT) is used to enter commands and monitor operations through the maintenance user interface. Chapter 8, ''Maintenance Commands'' describes the commands available to the maintenance user. This chapter discusses the following topics:

- ''Terminals Supported''
- ''Highlights''
- ''Connecting the Management Terminal''
- ''Logging On''
- ''Password Aging''
- ''Administrable Logins''
- ''Logging Off''
- ''Switch-Based Bulletin Board''

Terminals Supported

The system supports the following terminal types: 513 BCT, 715 BCS, 4410 Data Terminal, 4425 Data Terminal, and DEC VT220. Refer to *DEFINITY Enterprise Communications Server Installation and Test for Multi-Carrier Cabinets*, and the user manual on your terminal model for detailed setup instructions.

Highlights

- Release 8r allows multiple users to perform maintenance and administration at the same time. Up to 5 maintenance and 5 administration commands can run concurrently. Some commands that use the same resources as others experience contention and cannot be run at the same time. For more information on contention, see ''Contention Between Simultaneous Commands'' in Chapter 8, ''Maintenance Commands''.

- Two maintenance logins are reserved for the SYSAM-RMT and SYSAM-LCL ports on the TN1648 SYSAM circuit pack located on PPN control carriers. SYSAM-RMT is a dial-up remote access port reserved for use by INADS. SYSAM-LCL is a local port accessed by RS232 connectors on the TN1648. Two additional maintenance users can log in by dial-up System Access Ports (SAPs) or by connecting directly to EPN Maintenance circuit packs.

- This system allows the customer to define their own logins and passwords, and to specify a set of commands for each login. It allows up to 20 customer, 1 dadmin, and 4 services logins. Each login name can be customized.

- The system is delivered to the customer with one "super-user" login and password defined. The customer then administers any additional logins/passwords. The super-user login has full customer permissions and can customize any login created. In addition, for a specific login, login permissions can be set by the super-user to allow or block up to 40 administration or maintenance objects (commands) that can affect the health of the switch.

- Following a security violation (a user defined security violation threshold), the security feature "Login Security Violation Notification Following a Security Violation" notifies a referral point, and the security feature "Login Kill after "N" Attempts" disables a login ID (Customer or Lucent Services logins). The Login Kill after "N" Attempts feature does not disable the last remaining initialization and administration (*inads*) type login. Lucent Services logins, disabled by a security violation or the command disable login, require a Lucent *init* level login ID to be re-enabled.

- During log off from the system administration and maintenance interface, ***Logoff Notification*** alerts system administrators of possible system maintenance problems. This notification also alerts the system administrators when features that present a significant security risk are enabled. A message displays on the system administration/maintenance interface during logoff, if a security risk feature is enabled. Additionally, the user can be required to acknowledge the alert notification before the logoff is completed.

Connecting the Management Terminal

The management terminal can be connected to the system in the following ways:

- SYSAM-LCL Local Access Port

  The management terminal can be connected directly to the SYSAM-LCL port of the TN1648 System Access and Maintenance (SYSAM) circuit pack in the PPN control carrier (or SPE). Two RS-232 connectors are located on the rear panel of the PPN control carrier beneath the label TERMINAL. To access the maintenance user interface running on the active SPE, connect an M25B (EIA) cord to the connector labeled ACTIVE. Connect the other end to the connector to the management terminal. On the 715 BCS terminal, use the port labeled P2(DCE); on most other terminals, use the connector labeled MAIN PORT. A null modem is not required for these ports. Refer to the user manual on your terminal model for detailed setup instructions.

On systems with duplicated SPEs, there are two PPN control carrier and two identical sets of connectors. Either connector labeled ACTIVE can be used, regardless of which SPE is active. The STANDBY connectors are described below.

- SYSAM-RMT Remote Access Port (RAP)

  One login can access the system by dialing in to the SYSAM-RMT port with a modem operating at either 1.2 or 2.4 kbps. This port is reserved for *inads* access.

- Parallel Printer Connection

  For parallel printer operation, connect the printer to the connector labeled with the printer icon. To enable parallel printer operation, use the following series of keystrokes:

  1. Cntl + F1 to access the Setup menu
  2. F4 to select the User Preferences sub-menu
  3. Down arrow to the Parallel Port field
  4. F4 to enable the option
  5. F1, F5, F1 to return to Setup, save selections, and exit

- Serial Printer Connection

  For serial printer operation, connect the printer to the connector on the back of the 715 BCS terminal labeled P1(DCE). A null modem is not required. Set the printer for 9600 baud, 7 data bits, and 1 stop bit. These are the default settings for the 715 BCS. If necessary, terminal settings for serial printer operations can be changed from the Communication Options sub-menu of the Setup menu.

Logging On

To log on to the system:

1. Connect and power up the Management Terminal (MT). The screen displays `login:`
2. Enter your login name, and press the Return key. The screen displays `password:`
3. Enter your password, and press the Return key.

For security reasons, the password does not display as you type it. The system verifies that a valid login and password name were entered. If an invalid login or password name was entered, the screen displays `login incorrect:`

In this case you must repeat the procedure. If your password has expired or is within 7 days of the expiration day, you see a error message:

```
Your Password has expired; enter a new one
Old Password:
New Password:
WARNING: your password will expire in xx days
```

If the system recognizes the login and password name, the screen displays the software version number followed by the prompt:

```
Terminal Type (Enter 513, 4410, 4425, or VT220):
[513]
```

4. Depending on your terminal type, enter one of the following:

Terminal Type	Entry
513 BCT	513 (default)
715 BCS	513 (default)
4410 Data Terminal	4410
4425 Data Terminal	4425
DEC VT220	VT220

5. After you supply the terminal type information requested, and if INADS alarm origination is activated on the Maintenance System-Parameters screen, the system displays the following:

   `Suppress Alarm Origination: [y]`

   The default answer is **yes**. If you do NOT wish to suppress alarm origination, enter **no**. Any other entry will default to yes. The **test inads-link** command will work regardless of whether you have overridden INADS alarm origination. You can deactivate INADS alarm origination whenever you log in as *craft*.

6. The screen displays:

   `enter command:`

   The system is now ready to execute maintenance commands. Press the HELP key to display a list of all valid entries.

   If you have a High-Priority Bulletin Board Message, the command line prompt includes the following notification to all users who are logged in:

   `-High-Priority Bulletin Board Messages Entered:`

NOTE:
If several “users” are logging in and out at the same time, a user may see the message “Transient command conflict detected; please try later”. After the “users” have completed logging in or out, the System Access Terminal is available for use. Try executing the command again.

Logging On When The SPE Is In SPE-Down Mode

If the system is in SPE-down mode when the Maintenance Terminal displays `login`, enter `INADS` as the MT login/name. Use the first INADS type password as your MT password.

NOTE:
You must identify the first INADS login before the system is in SPE down mode. The first INADS type login may be identified by entering the **list login** command and noting the first INADS login listed.

- System Ports

  MTs can log in via system ports (also known as system access ports or SAPs). if the system is so equipped. You can dial in to a data port located on a data line circuit pack that is administered as a system port. This type of port shows the entry `Type: system port` on the data module form. These ports operate at 9.6 kbps. For more information on system ports, see “PDATA-PT (Packet Data Line Port)” in Chapter 9, “Maintenance Object Repair Procedures” and *DEFINITY Enterprise Communication Server Administrator’s Guide*.

- EPN Maintenance Circuit Pack

  MTs can log in to the system by connecting directly to the TN775 Maintenance circuit pack in each Expansion Port Network. Connect an M25B (EIA) cord to the RS-232 connector labeled TERM on the rear panel of the expansion control carrier. This connection operates at a bit rate limited to about 1 kbps, because it communicates over system control links shared with call processing messages. This type of connection is useful for performing maintenance on a remotely located EPN.

- Standby SPE Connection

  With duplicated SPEs, there are two SYSAM connectors on each PPN control carrier (A and B). Either carrier's connectors may be used. Either ACTIVE connector accesses the active SPE, regardless of which carrier is active. Either STANDBY connector accesses the standby SPE through the SPE-Down interface. This interface is available when the SPEs are locked by the SPE-Select switches on a system with duplicated SPEs. Otherwise, the STANDBY connection is inactive. (On a simplex SPE, this interface is accessed when the SPE is down through the ACTIVE connector). Separate terminals may be connected to the two connectors, or one terminal may be switched back and forth between connections. The unused connectors should be capped.

  The SPE-down interface can only be accessed by SYSAM-LCL or SYSAM-RMT connections. This interface is described in *Chapter 4, Initialization and Recovery*.

To Display a Login

To display a specified login:

1. Enter the command **display login [login name]** and press the Enter key.

   The system displays the requested login data:

   - Name
   - Login type
   - Service level
   - Access to INADS Port value (V8)
   - Password aging cycle length
   - Facility test call notification and acknowledgment
   - Remote access notification and acknowledgment

To List Logins

To list all of the system logins and the status of each:

2. Enter the command **list logins**.

   The system displays the following information for all current logins:

   - Name
   - Service level
   - Status (active, inactive, disabled, svn-disabled, void)
   - Password aging cycle length

   The system displays only those logins with the same, or lower, service level as the requestor.

To Remove a Login

To remove a login from the system:

1. Enter the command **remove login [login name]**.

   The system displays the Login Administration form.

2. Press the Enter key to remove the login, or press Cancel to exit the remove login procedure without making a change.

To Test a Login

1. Enter your login name at the login prompt.

```
Login: telmgr
Password:vvvvvvvvcf
```

Screen 3-1. Login Prompt Form

After the user enters the correct login name and password, and if the login is administered correctly, the system displays the command line interface.

Password Aging

Password aging is an optional feature that the super-user administering the logins can activate. The password for each login can be aged starting with the date the password was created, or changed, and continuing for a specified number of days (1 to 99). The system notifies the user at the login prompt, 7 days before the password expiration date, that his/her password is about to expire. When the password expires the system requires the user to enter a new password before logging in. If a login is added or removed, the “Security Measurement” reports are not updated until the next hourly poll, or a **clear measurements security-violations** command is entered. Once a non-super-user has changed his/her password, the user must wait 24 hours to change the password again.

The Password Expiration screen is displayed when you log in. If your password is within 7 days of the expiration date, you are prompted to enter a new password. If your password has expired, you see the screen:

```
           Login: telmgr

        Password:
        Your Password has expired, enter a new one.

    Reenter Current Password:

                New Password:

        Reenter New Password:
```

Screen 3-2. Password Expiration Screen

Administrable Logins

The system is delivered to the customer with one customer "super-user" login/password defined. The customer then administers additional customer login/passwords as needed. The super-user login has full customer permissions and can customize any customer login that he/she creates.

Adding Customer Logins and Assigning Initial Password

The system provides enhanced login/password security by adding a security feature that allows users to define their own logins/passwords and to specify a set of commands for each login. The system allows up to 20 customer logins. Each login name is customized and must contain from 3 to 6 alphabetic/numeric characters, or a combination of both (characters 0-9, a-z, A-Z). A password must have from 4 to 11 characters and contain at least 1 alphabetic and 1 numeric symbol.

To add a customer login you must be a super-user, have administrative permissions, and:

1. Enter the **add login [name]** command to access the Login Administration form.
2. Enter your super-user password in the `Password of Login Making Change` field on the Login Administration form.

   The 3- to 6-character login name entered with the **add login [name]** command is displayed in the `Login's Name` field.
3. Enter **`customer`** in the `Login Type` field. The system default for the `Login Type` field is `customer`. The maximum number of customer logins of all types is 20.
4. Enter **`super-user`** or **`non-super-user`** in the `Service Level` field. Default is `non-super-user`.
   - **`Super-user`** gives access to the **add, change, display, list,** and **remove** commands for all customer logins and passwords. The super-user can administer any mix of super-user/non-super-user logins up to a total of ten additional system logins.
   - **`Non-super-user`** permissions are limited by restrictions specified by the super-user when administering the non-super-user login. A non-super-user can change his/her password with permission set by the super-user; however, once a password has been changed, the non-super-user must wait 24 hours before changing the password again. A non-super-user cannot change other user passwords, login characteristics, or permissions.

5. Enter **y** in the `Disable Following a Security Violation` field to disable a login following a login security threshold violation. This field is a dynamic field and only appears on the Login Administration form when the SVN Login Violation Notification feature is enabled. The system default for the `Disable Following a Security Violation` field is **y**.
6. Enter **y** in the `Access to INADS Port?` field to allow access to the remote administration port. This field only displays if Lucent has first enabled the customer super-user access to the INADS Remote Administration Port. The system default is **n**. This step is valid for V8 and higher systems only.
7. Enter a password for the new login in the `Login's Password` field (the system will not echo the password to the screen as you type). A password must have from 4 to 11 characters and contain at least 1 alphabetic and 1 numeric symbol. Valid characters include numbers, and !&*?;'^ (),.:- .
8. Re-enter the password in the `Login's Password` field. The system will not echo the password to the screen as you type.
9. In the `Password Aging Cycle Length` field, enter the number of days (1 to 99) from the current day that you want the password to expire. If you enter a blank in this field, password aging does not apply to the login.
10. Decide whether or not to leave the default of yes (**y**) in the `Facility Test Call Notification?` field. If you retain the default, the user receives notification at logoff that the facility test call feature access code is administered. If you do not want the notification to appear, set the field to **n**.

CAUTION:
Leaving The facility Test Call administered after logging off poses a significant security risk.

11. Decide whether or not to leave the default of yes (**y**) in the `Facility Test Call Notification Acknowledgment Required?` field. If you retain the default, the user is required to acknowledge that they wish to logoff while Facility Test Call is still administered. If you do not want to force the user to acknowledge, set the field to **n**. This field appears only if the `Facility Test Call Notification` field is set to **y**.
12. Decide whether or not to leave the default of yes (**y**) in the `Remote Access Notification?` field. If you retain the default, the user receives notification at logoff that remote access is still administered. If you do not want the notification to appear, set the field to **n**.

CAUTION:
To Leave Remote Access feature administered after logging off poses a significant security risk if you are using the feature in conjunction with the Facility Test Call feature.

13. Decide whether or not to leave the default of yes (**y**) in the `Remote Access Acknowledgment Required?` field. If you retain the default, the user is required to acknowledge that they wish to logoff while remote access is still administered. If you do not want to force the user to acknowledge, set the field to **n**. This field appears only if the `Facility Test Call Notification` field is set to **y**.

```
                          LOGIN ADMINISTRATION

                Password of Login Making Change:

            LOGIN BEING ADMINISTRATED
                               Login's Name:xxxxxxx
                                 Login Type:
                              Service Level:
     Disable Following a Security Violation?
                        Access to INADS Port?

           LOGIN'S PASSWORD INFORMATION
                           Login's Password:
                   Reenter Login's Password:
                Password Aging Cycle Length:

         LOGOFF NOTIFICATION
           Facility Test Call Notification? y     Acknowledgment Required? y
                Remote Access Notification? y     Acknowledgment Required? y
```

Screen 3-3. Login Administration

Changing a Login's Attributes

To change a customer login's attributes, you must be a super-user, have administrative permissions (specifically, the `Administration Permission` field must be set to **y** for the super-user), and:

1. Enter the **change login [name]** command to access the Login Administration form.
2. Enter your super-user password in the `Password of Login Making Change` field on the Login Administration form.

   The 3- to 6-character login name whose attributes are to be changed is displayed in the `Login's Name` field.
3. Enter **`customer`** in the `Login Type` field.
4. Enter **`super-user`** or **`non-super-user`** in the `Service Level` field.

   NOTE:
   You cannot change your own service level.
5. To disable a login following a login security threshold violation, enter **y** in the `Disable Following a Security Violation` field. This is a field that only appears on the Login Administration form when the SVN Login Violation Notification feature is enabled.
6. To allow access to the remote administration port, enter **y** in the `Access to INADS Port?` field. This field only displays if Lucent has first enabled customer super-user access to the INADS Remote Administration Port.
7. Enter a password for the new login in the `Login's Password` field (the system will not echo the password to the screen as you type). A password must have from 4 to 11 characters in length and contain at least 1 alphabetic and 1 numeric symbol. Valid characters include numbers, and !&*?;'^ (),.:-.
8. Re-enter the password in the `Login's Password` field. The system will not echo the password to the screen as you type.
9. In the `Password Aging Cycle Length` field, enter the number of days (1 to 99) from the current day when you wish the password to expire. If a blank is entered in this field, password aging does not apply to the login.

Administering Login Command Permissions

Login permissions for a specified login can be set by the super-user to block any command object that may compromise switch security. Up to 40 administration or maintenance command objects can be blocked for a specified login. When an object (administrative or maintenance command) is entered in the blocked object list on the Command Permissions Categories Restricted Object List form, the associated administrative or maintenance actions cannot be performed by the specified login.

There are 3 command categories. Each of the 3 command categories has a group of command subcategories listed under them, and each command subcategory has a list of command objects that the commands acts on. For a list of objects, see Tables 3-1 through 3-4 for Command Permissions Form Entries, in the areas of Display Administration and Maintenance, Administer Permissions, Administer Stations, and Administer Trunks, respectively. A super-user can set a user's permissions to restrict or block access to any command in these categories. The 3 categories are:

- Common Commands
  - Display Admin. and Maint. Data
  - System Measurements
- Administration Commands
  - Administer Stations
  - Administer Trunks
  - Additional Restrictions
  - Administer Features
  - Administer Permissions
- Maintenance Commands
  - Maintain Stations
  - Maintain Trunks
  - Maintain Systems
  - Maintain Switch Circuit Packs
  - Maintain Process Circuit Packs

These categories are displayed on the Command Permissions Categories form. To administer command permissions, log in as super-user and:

1. Access the Command Permissions Categories form by entering the command **change permissions login [login name]**. When the Command Permission Categories form opens for a login, the default permissions for that `login type` appear on the form. The super-user administering the login can then change a **y** to **n** for each subcategory field on the form.
2. Select a category for the login and enter **y** in each field where permission to perform a administrative or maintenance action is needed. The command object you select must be within the permissions for the login type you are administering.

   If the maintenance option is set to **y** on the Customer Options form, the super-user can enter **y** in the `Maintain Switch Circuit Packs?` or `Maintain Process Circuit Packs?` fields.
3. A super-user with full super-user permissions (super-user administering the login cannot have the `Additional Restrictions` field set to **y** for his/her own login) can restrict additional administrative or maintenance actions for a specified login by entering **y** in the `Additional Restrictions` field on the Command Permission Categories form. Enter the additional restrictions for a login in the `Restricted object list` fields on the Command Permission Categories Restricted Object List form. You can enter up to 40 command names (object names) to block actions associated with a command category for a specified login.

```

Logging Off

The terminal should be logged off whenever it is not in use to avoid accidental or malicious entries that could corrupt translations or disrupt operations. This also re-enables INADS alarm origination so that alarms will not go unreported.

To log off, simply enter **logoff** at the command prompt. The screen should then display:

```
login:
```

If no entry is made for 30 minutes during a craft login, the system automatically times out and terminates the login. At that time, any unresolved alarms that have not been reported to INADS will be reported. If you are logged in at more than one G3-MT terminal, the system waits until the last terminal times out or logs off before reporting such alarms to INADS.

Logoff Notification alerts system administrators of enabled features that present a significant security risk. The user may be required to acknowledge the notification before the logoff is completed. If facility test call notification or remote access notification are enabled for your login (see Adding Customer Logins and Assigning Initial Passwords, below), you receive a logoff screen. If either the facility test call or remote access acknowledgments are required, you need to respond to the `Proceed with Logoff?` prompt on the logoff screen. The response is defaulted to **n**; you must enter **y** to override the default.

CAUTION:
To leave the facility test call administered after you logoff poses a significant security risk.

CAUTION:
To Leave Remote Access feature administered after logging off poses a significant security risk if you are using the feature in conjunction with the Facility Test Call feature.

```
Facility Test Call Administered
Remote Access Administered

Proceed with Logoff? [n]
```

Screen 3-7. Logoff Screen

Switch-Based Bulletin Board

This feature allows a System Access Terminal (SAT) user to leave messages in the system in order to communicate with other system users. The bulletin board service provides an easy message interface between the customer and Lucent.

For example, when a new load is installed on a switch in the customer's system, Lucent can leave the customer messages that describe any new functions. It allows Lucent to keep the customer informed on the discovery of new problems. In addition, this feature provides additional information concerning problems that have already been escalated by the normal procedure.

NOTE:
This feature does not substitute for any existing procedures for escalating problems. It is only an aid to the existing process.

Accessing the Bulletin Board

Any user with the appropriate permissions can log into the system and access the bulletin board. Users that have "Maintain System" or "Administer Features" permissions can enter, change, display, print, or schedule to print a message. Users that have "Display Admin" and "Maintain Data" permission can display the bulletin board. Any user who has "Display" permission can display, print, or schedule to print the contents of the bulletin board.

When a user logs on to the system they the system notifies them of any messages on the bulletin board. The notification message indicates the last time the bulletin board was updated, if any "High-Priority" message exist, and if the bulletin board is 80% or more full. If a "High-Priority" message exists, the command prompt changes to the following message:

- `High-Priority Bulletin Board Messages Entered:`

After the next command, the default command prompt returns to the screen.

User Considerations

General considerations that apply to users are:

- Only one user at a time may edit a message on the bulletin board.
- The user must have the proper permissions to access the bulletin board.
- The user must maintain the information stored on the bulletin board. It is the user's responsibility to delete old messages. If the bulletin board is full, any new messages overwrite old messages.

System Considerations

The Bulletin Board feature provides up to three pages of text for each message. Each page is limited to 20 lines of text and 40 characters per line. The first ten lines of text on page one are reserved for Lucent Service's High-Priority messages.

System Bulletin Board Commands

The system commands **change bulletin board**, **display bulletin board**, and existing commands in the user interface can be used for the Switch Based Bulletin Board.

To edit or enter a message on the Switch Based Bulletin Board you must:

1. Log into the system with "Maintain System" or "Administer Features" Permissions.
2. Enter the command **change bulletin-board**.
3. Follow system prompts.

To display messages on the Switch Based Bulletin Board you must:

1. Log into the system with "Maintain System", "Display Admin," or "Maint Data" permissions.
2. Enter the command **display bulletin board**.
3. Follow system prompts.

Editing a Switch-Based Bulletin Board Message

A message may contain up to three pages of information with the first ten lines on page one reserved for Lucent Service's High-Priority messages (the *init*, *inads*, and *craft* logins can edit the first ten lines on page one). Pages two and three will allow up to 20 lines of 40 characters of text. Each line has a date field to show when the line is modified.

The control keys used to edit existing forms serve to edit a message in the Switch Based Bulletin Board. The following characters are allowed for use in the text field:

- Uppercase/lowercase letters, spaces, numerals, and !@#$%^ &*()_ -+=[]{};'"<>./?.

NOTE:
Tab characters are not allowed. The existing command line interface will cause the cursor to move to the next field if a Tab character is entered.

If a user changes any lines which cause 2 or more consecutive blank lines, the bulletin board automatically reorganizes (upon submittal). Two or more blank lines change to a single blank line. A blank line at the top of a form is deleted. These changes prevent holes from developing in the bulletin board screens as old entries are deleted.

To save a message entered into the bulletin board text field, you must execute the **save translation** command.

The following screen is an example of bulletin board messages between Lucent and a customer that is having trouble with trunk group translations:

```
display bulletin-board                             Page 1 of 3

                     Messages (* indicates high-priority)        Date
           * Lucent is in the process of                      02/02/95
           * investigating your trunk lockup problem.         02/02/95
           * The Bulletin Board will be updated as            02/02/95
           * information is found.                            02/02/95
           * We have identified the problem.                  02/02/95
           * The trunk you added does not provide             02/02/95
           * disconnect supervision, however your trunk       02/02/95
           * group was administered as such.                  02/02/95
           * Please call for details.                         02/02/95
           *
             We recently added a new trunk group (14)         02/03/95
             and have had trunk group members locking up.     02/03/95
             We see the error - Thanks for checking.          02/03/95
```

Initialization and Recovery

4

When the system is powered up, or when it experiences a catastrophic fault that interrupts its basic functions, it undergoes a reboot. In addition to reboot, there are several less severe resets available for the system to recover from less disrupting errors. The technician can also initiate these resets with a command.

CAUTION:
System resets can have wide-ranging disruptive effects. Unless you are familiar with resetting the system, follow normal escalation procedures before attempting a demand reset.

If a reset fails to recover normal system operation, the firmware that controls reset will escalate to the next higher level, up to reboot if necessary. A failure to reboot results in SPE-down mode, which is described in later in this chapter.

This chapter describes the causes, effects, and duration of each reset level. In a system with duplicated SPE, the standby SPE can undergo a reset without disrupting service since the active SPE remains in control. These resets can also be requested with the corresponding **reset standby-spe** *level* commands. All standby resets turn off memory shadowing, leaving the standby SPE temporarily unavailable for service. Refresh of the standby typically takes several minutes.

When resets occur, including interchanges, an error is logged against the maintenance object “SYSTEM.” The error code gives information about the cause of the reset. Information about the reset is also logged in the initcauses log. See **display initcauses** in Chapter 8, ‘‘Maintenance Commands’’.

The EPNs can also undergo individual resets. These are described in "EXP-INTF (Expansion Interface Circuit Pack)" and "EXP-PN (Expansion Port Network)" in Chapter 9, "Maintenance Object Repair Procedures". PNC interchanges are described under PNC-DUP in Chapter 9, and under **reset pnc interchange** in Chapter 8, "Maintenance Commands".

Multiple Offer Categories

When the system is initially powered up, or when it experiences a catastrophic fault that interrupts its basic functions, the system either initializes or reboots.

Initialization

Upon initialization, no forms (not even Customer Options) are available until the Offer Category is set. (The remote INADS channel is available.) To set the customer options, do the following:

1. Enter **change system-parameters offer-options** (init and inads logins only) and the following form displays:

```
change system-parameters offer-options

                         OFFER OPTIONS FORM

           Offer Category: _
           Activate Offer? _

WARNING: Need to save translations and reboot to make the change permanent.
```

Field descriptions

`Offer category`	Type either **A** or **B**.
`Activate offer?`	Type **y** if the entry for `Offer category` is correct and press Tab. Type **n** if there is an error in the `Offer category` field and press Tab. Re-enter the correct Offer Category.

2. After these two fields are filled and you press Enter, the system displays:

```
WARNING: Activating Offer Category may set unchangeable
limits.
```

   This is to let you know that the Offer Category along with the model determine the system capacities (limits) and allowable hardware.

3. Press the Submit key to submit the form.
4. Use the **save translations** command to make the changes permanent.

CAUTION:
To avoid potential loss of servce, ensure that your system's translations are protected by saving them to the PCM/CIA card.

Hot Restart

This reset occurs only on a duplicated SPE during a *planned* SPE interchange.

Duration	Up to 1.5 minutes
Causes	**reset system interchange** command
	(use of the **contention-override** or **health-override** options causes a reset level 1 or higher)
	SPE interchange requested by scheduled maintenance
Effects	Call service is unaffected.
	Yellow LEDs light on new active SPE and go out on the new standby.
	Memory shadowing is turned off.
	Remote access port (SYSAM-RMT) login is dropped.

Reset Level 1 (Warm Restart)

Duration	Up to 10 seconds, typically 2 seconds
Causes	**reset system 1** command
	Spontaneous SPE interchange (those caused by hardware faults)
	Software faults that are non-service affecting
	Abort of planned SPE interchange
	Hardware bus errors
	TN1655 Packet Interface faults
Effects	Stable calls are preserved.
	System links, and stable feature and service state data are preserved.
	Error and alarm logs are preserved, but all alarms are resolved except for STBY-SPE and busyouts.
	Transient calls (not yet connected), and some user stimuli, are dropped.
	New calls are not processed during the reset.
	G3-MT logins, including remote access and system port logins, are dropped.
	If the reset resulted from a spontaneous SPE interchange, memory shadowing is turned off, and the standby SPE will not be available for service until memory is refreshed (several minutes).
	Application links such as those to AUDIX and CDR are dropped and reestablished in under 2 1/2 minutes. (BX.25 links are not dropped, and CDR data is buffered during the outage.)
	MSS activity is aborted.
	Translation data is preserved, but if translation changes were in progress, the reset is escalated to Reset Level 3 (Cold-1).
	If core dump is enabled for this reset level, reset is delayed until the core dump is complete.

Reset Level 2 (Cold-2 Restart)

Duration	Up to 3.75 minutes
Causes	**reset system 2** command
	Escalation from reset level 1
	An attempted reset level 1 during a PNC interchange
	TDM-bus clock recovery on the PPN
	Spontaneous interchange into an unrefreshed standby SPE
Effects	**All system and application links are dropped**.
	All calls are dropped.
	Non-translation feature data, such as Automatic Wakeup calls, are lost and must be reentered.
	All G3-MT logins, including remote access and system port logins, are dropped.
	Initialization firmware runs diagnostics and displays results on the G3-MT screen.
	SPE memory shadowing is turned off, leaving the standby SPE unavailable for service for several minutes.
	All hardware components, except PNC components, are reset, including the EPNs. All standby Expansion Interfaces, and the active EI in the PPN are reset. SNIs, SNCs, DS1Cs and active EIs in the EPNs are not reset.
	If the PNC is duplicated, a global refresh of the standby PNC is performed after the reset.
	All busied out maintenance objects are released and must be rebusied, if so desired.
	Circuit packs are reinitialized, (translations are verified by comparison to physical board locations).
	If core dump is enabled for this reset level, reset is delayed until the core dump is complete.
	Error and alarm logs are preserved, but all alarms are resolved except for STBY-SPE and busyouts.

Reset Level 3 (Cold-1 Restart)

Duration	Up to 6.5 minutes
Causes	**reset system 3** command
	Escalation from reset level 2
	Translation loading fault
	Spontaneous interchange into an unrefreshed standby SPE
Effects	Actions and effects are the same as for reset level 2, plus the following:
	Emergency transfer is invoked.
	Translations are reloaded from disk or removable media.
	If core dump is enabled for this reset level, reset is delayed until the core dump is complete.
	Translations entered by users since the last save translation was executed by command or by scheduled maintenance are lost.

Reset Level 4 (Reboot)

Duration	Typically 8 to 11 minutes
Causes	**reset system 4** command
	Escalation from reset level 3
	Power up
	Recovery attempt from SPE-down mode (requested by reboot command, or automatically every 20 minutes)
	Spontaneous interchange into an unrefreshed standby SPE
Effects	System software (boot image) is reloaded, and all processes are reinitialized
	The disk, if present and healthy, is the default device from which the software is loaded. Otherwise, the reload is taken from removable media
	Before reboot, the system attempts to save the alarm and error logs to the disk on the active SPE
	After reboot, error and alarm logs are restored from the SPE that is active coming out of the reboot. (Note that this means that some error and alarm information may be lost if the last save before the reboot save does not succeed or if an SPE interchange takes place)

Other effects are the same as those in reset level 3, except that more extensive diagnostics are performed.

If reboot fails, SPE-down mode is invoked.

If a core dump is enabled for this reset level via the **set vector** command, the reboot is delayed until the core dump has completed.

Reset Level 5 (Extended Reboot)

Duration	Up to 25 minutes
Causes	**reset system 5** command
	This reset is invoked only by command
Effects	Effects are the same as for a level 4 reboot except that more extensive diagnostics are performed.
	This reset is used to diagnose SPE component failures not detected by level 4 reboot tests.

Initialization Diagnostics

For each reset level, the system performs a series of diagnostic tests on components of the SPE to confirm that the system can be brought into service. The management terminal displays the result of each test as it occurs. If a reboot fails, and the system cannot bring itself up, SPE-down mode is invoked. A description of this mode, with troubleshooting procedures available to it, appears in the following section.

Table 4-1 shows the diagnostic tests run during initializations. Level 1, 2 and 3 resets 4 perform the first 11 tests (through the Timer Test). Reboots complete all tests in the table except the last one. Only extended reboots execute the Memory Board Couple Test.

If a test fails, make the indicated repair. If more than one repair is indicated, perform them in the order shown until the problem is resolved. Follow procedures described in ''Replacing SPE Circuit Packs'' in Chapter 5, ''Alarms, Errors, and Troubleshooting''.

Table 4-1. Initialization Diagnostics for All Reset Levels

Test	Description/Recommendation
Internal Register Test	Replace processor.
Loop Data Test	Replace processor. Replace memory 1. Reseat all circuit packs in the processor carrier except SYSAM. The carrier may be defective. Follow normal escalation procedures.
Duart Test	Replace the processor board. Failure of this test will not prevent the system from running, but the processor is probably faulty.
Rom Checksum Test	Replace the processor.
Control Status Test	Replace the processor.
Dcache Test	Replace the processor. Failure of this test may not prevent the system from running, but degradation of service is probable.
Icache test	Replace the processor. Failure of this test may not prevent the system from running, but degradation of service is probable.
Write Buffer Test	Replace the processor. Replace the memory 1.
Bus Test	Replace processor. Replace memory 1. Reseat all circuit packs in the processor carrier except SYSAM. The carrier may be defective. Follow normal escalation procedures.
Parity Test	Replace the processor. Replace the SYSAM.
Timer Test	Replace the processor.
Bus Config Test	Replace processor.
Mem Config Test	Check memory boards for correct TN number and positioning on the carrier. Reseat memory boards.
Memory Functional Test	Replace memory boards one at a time until test passes.
Memory Board Stuck Bit Test	Replace memory board.
Memory Board EDC Test	Replace memory board.

Continued on next page

Table 4-1. Initialization Diagnostics for All Reset Levels — *Continued*

Test	Description/Recommendation
Memory Board Burst Test	Replace memory board Replace processor board The carrier may be defective. Follow normal escalation procedures.
Sysam Test	Replace the SYSAM board.
Vm Test	Replace the processor.
Exception Test	Replace the processor.
MSS Test	Replace the MSSNET board. Replace the processor.
Sanity Timer Test	Replace the SYSAM board.
Dupint Test	Replace the DUPINT board.
Disk Test	Replace the disk drive.
Loading Disk	Reformat disk. Replace the MSSNET board.
Ram Data Checksum Test	Reboot from whichever device (removable media or disk) was *not* used for the failed reboot. Replace memory.
Ram Text Checksum Test	Reboot from whichever device (removable media or disk) was *not* used for the failed reboot. Replace memory.
Removable Media Test	Replace the removable media cartridge. Replace the removable media drive. Replace the MSSNET board.
Pktint Reset Test	Replace the packet interface board.
Mem Board Couple Test (Extended reboot only)	Replace the indicated memory board.

SPE-Down Command Interface

A limited command interface called the SPE-down interface can be used to communicate with low level firmware when system software is unavailable for executing the usual maintenance commands. This is useful in three situations.

- The SPE is down in a system without duplicated SPEs
- The standby SPE is down in a system with duplicated SPEs
- One SPE is locked standby in a system with duplicated SPEs

SPE-Down Mode

Severe problems with components of the SPE may render a non-duplicated system incapable of call processing and other normal operations. When this happens, the system enters SPE-down mode and software is no longer in control. If the SPE is duplicated, this situation only occurs when *both* SPEs have fatal faults. Otherwise, if one SPE goes down, an interchange will occur and the system will run on the newly active SPE.

SPE Locked Standby or Standby SPE-Down

The SPE-down interface can be useful when repairing a standby SPE on a duplicated system. For example, if handshake communication is down, this is the only way to communicate with the standby SPE. Or, if a circuit pack on the standby has been replaced, this interface allows you to test both that circuit pack and the rest of the standby SPE before unlocking.

When the standby SPE on a duplicated system is down, or locked by means of the SPE-Select switches, it is no longer in communication with the active side, and the system is functionally unduplicated. In this state, the normal Maintenance User Interface is unavailable to the standby SPE. You can use the SPE-down interface to test the standby SPE and verify its health before rebooting or unlocking. A test of all SPE boards takes only a short time and ensures that all problems have been fixed and the SPE is ready to return to service.

Bringing Up the SPE-Down Interface

When SPE-down mode is in effect, the red LED will be lit on the Processor circuit pack and the system will present the following message:

```
*********** SPE DOWN MODE *************
```

An alarm-notification call already in progress will preempt input from the terminal. When the call is completed or dropped, the system displays the results of the call and a welcome message with one of the following prompts, indicating which SPE is currently connected to the terminal.

`SPE_A_DOWN>`	If SPE-A was active when the system went down
`SPE_B_DOWN>`	If SPE-B was active when the system went down
`SPE_DOWN>`	If the SPE is unduplicated

You can now enter SPE-down interface commands as described in ''Using the SPE-Down Interface''. If the prompt does not appear, check the connections between the terminal and the control carrier. Make sure the cable is connected to the connector labeled *ACTIVE*. If possible, try a different cable and/or terminal. If the prompt is still not present, replace the SYSAM circuit pack. If the SPE remains down with no prompt, follow normal escalation procedures.

To return the standby SPE to service, see the following section on ''Bringing the SPE Back into Service''.

SPE Locked Standby or Standby SPE-Down

To bring up the SPE-down interface on a functioning duplicated system, connect the terminal to the STANDBY terminal connector on the rear panel of either processor carrier. Assuming all cabling is intact, either connector will access the SPE which is standby. If the standby SPE is down, the message and prompt shown above are displayed. To enter SPE-locked-standby mode, carefully, and *one at a time*, move the SPE-Select switches to the position indicating the carrier of the currently active SPE. For example, if the SPE in carrier A is active, move the switches to position A. When the SPE is locked, SPE interchanges are prevented, memory shadowing is turned off, handshake is down, and maintenance activities normally controlled by software on the active SPE cease. The following message is printed, (in this example, A is locked standby):

```
*********SPE A locked standby************
```

One of the following prompts will appear, indicating which SPE is locked *standby* and whether the SPE is down.

```
SPE_A_LOCKED>

SPE_B_LOCKED>

SPE_A_DOWN_LOCKED>

SPE_B_DOWN_LOCKED>
```

You can now enter the commands described in "Using the SPE-Down Interface". If the prompt fails to appear, check your connections. Try connecting to the connector labeled STANDBY on the other PPN control carrier (A or B). If possible, try using a different cable and/or terminal. If the above actions do not produce a prompt, replace the SYSAM circuit pack on the standby SPE. If the prompt is still not present, follow normal escalation procedures.

If an SPE was down and the SPE-Select switches are set to lock, the down-and-locked-standby mode *replaces* the SPE-down mode. Normally, when the standby SPE is up and cycling, the yellow LED on the Processor circuit pack flashes on and off. If the SPE is locked standby *and* a terminal is connected to the STANDBY connector, the Processor LED remains unlit.

To return the standby SPE to service, see the following section on "Bringing the SPE Back into Service".

NOTE:
The physical connection of the terminal to the STANDBY connector while the SPE is locked standby with the SPE-Select switches prevents the Standby Maintenance Monitor (SMM) from running. Any reboot command to the standby while it is in the locked state will abort.

Using the SPE-Down Interface

When one of the above prompts appear, you may enter Spe-down interface commands. These are executed by the Low-level Maintenance Monitor (LMM), which is firmware resident on the processor board for controlling initialization and recovery actions, and processor and memory diagnostics.

Communications with the terminal are handled by the SYSAM board. If a remote access port (SYSAM-RMT) call is received while in this mode, it will preempt access by the local MT, and this message will be displayed:

```
Local Terminal session overridden by remote access
KEYBOARD LOCKED, WAIT FOR SYSAM OR LOGIN PROMPT
```

When the call is completed or dropped, the prompt will return. Note that the SPE-down interface to an SPE that is locked standby is never available to the remote access port, because the standby SPE is isolated from the active SYSAM circuit pack.

A limited set of commands is available to the SPE-down interface, as follows.

Table 4-2. SPE-Down Interface Commands

Keyboard Entry	Command
?	Help
r	Reboot
s	Secondary reboot
d	display alarms
t al or **t**	Test all standby SPE circuit packs
t sy	Test SYSAM circuit pack
t pr	Test Processor circuit pack
t m1	Test Memory circuit pack 1
t m2	Test Memory circuit pack 2
t m3	Test Memory circuit pack 3
t m4	Test Memory circuit pack 4
t ma	Test all Memory circuit packs
t du	Test DUPINT circuit pack
t ms	Test MSSNET circuit pack
t p1	Test PKTINT circuit pack 1
t p2	Test PKTINT circuit pack 2
t p3	Test PKTINT circuit pack 3
t pa	Test all PKTINT circuit packs

The following qualifier can be used with the test commands:

1 to **99**	Number of repetitions (default is 1)

Enter *only* the characters which appear in bold type. For instance, to test all memory boards ten times, enter **t ma 10** Entering **t** results in testing all boards once. You can abort the execution of a command by pressing ESC 3 times.

Test Commands

After a command is entered, various test result messages are printed on the terminal, indicating whether each test passes, fails or aborts. If any components fail, refer to the Maintenance Object documentation that applies. Additional information for interpreting these results can be found in the "Troubleshooting a Duplicated SPE" and "Testing the Standby SPE" sections in Chapter 5, "Alarms, Errors, and Troubleshooting". Note that the test memory command performs exhaustive tests and can be very time-consuming.

When testing is complete, the system readies itself for another command and the prompt appears. If testing does not complete within 20 minutes, the following message is displayed:

```
LMM did not finish test in time.
```

This is a serious error indicating that the processor, bus, and/or LMM are not working properly. Normally you will see initial test result output within a few seconds. If not, you can abort the test request by pressing ESC 3 times, and the command prompt will be returned.

If the SPE-down mode is entered or re-entered as a result of the test request, the screen displays:

```
Can't continue - test aborted.
```

Again, this is a serious error, but at least the processor is able to handle SPE-down reporting. Likely fault locations are memory board number 1, processor board, or processor/memory bus.

Display Alarms Command

The display alarms command asks for the alarms that caused the SPE to go down. It is valid only in the SPE-down or down-and-locked-standby mode. If **d** is entered while the SPE is in one of the down modes, the following header is displayed:

```
DISPLAY ALARMS:

Physical    Logical     On       Alternate   Alarm    Date       Date
Name        Name        Board?   Name        Type     Alarmed    Resolved
```

The header is followed by one and only one of the following lines (except that more than one Memory circuit pack failure may be displayed):

```
---     PROCR       y   -----  MAJOR  -----  -----
-----   MEM_BD_0    y   -----  MAJOR  -----  -----
-----   MEM_BD_1    y   -----  MAJOR  -----  -----
-----   MEM_BD_2    y   -----  MAJOR  -----  -----
-----   MEM_BD_3    y   -----  MAJOR  -----  -----
-----   MSS_NET     y   -----  MAJOR  -----  -----
-----   R-MEDIA     y   -----  MAJOR  -----  -----
-----   DISK        y   -----  MAJOR  -----  -----
-----   NO_R-MEDIA  y   -----  MAJOR  -----  -----
-----   BOOT_ERROR      -----  MAJOR  -----  -----
-----   SPE_SAN         -----  MAJOR  -----  -----
```

Note that the display is designed to approximate an alarm display from software maintenance, but is not populated with certain information, represented by dashed out fields. Only the first failed component detected is displayed.

In the absence of any other information about the cause of the failure, replace the indicated component using the procedures described in Replacing SPE Circuit Packs. After all tests pass, return the standby SPE to service, with procedures described in the following section on "Bringing the SPE Back into Service".

`BOOT_ERROR` indicates that the LMM was not able to either load, start, or keep the SPE running following a reboot request. `SPE_SAN` indicates that SYSAM detected enough sanity timeouts to exceed the threshold.

Reboot Commands

After all SPE-down interface tests have passed, an SPE can be brought back up by using the reboot commands. The reboot command, **r** starts a reboot using the boot image loaded on the disk device. The secondary reboot command, **s**, starts a reboot using the boot image loaded on the removable mediaremovable media device. The latter is useful if the boot image on the disk is corrupted, the disk device is faulty, or a different software load is desired. A reboot can be interrupted by pressing ESC 3 times.

As noted earlier, if an SPE is locked in the standby mode, the reboot commands cannot be entered and will abort.

Bringing the SPE Back into Service

WARNING:
In a system with duplicated SPEs, a spontaneous SPE interchange may occur if the active SPE is not in good health and either

— an unlocked SPE completes its reboot and handshake is reestablished

— a locked SPE in which the Standby Maintenance Monitor (SMM) is running is unlocked

WARNING:
Use the status spe command to determine the health of the active SPE and whether an interchange will occur.

Once all tests pass using the SPE-down interface, the SPE should be competent to return to service. There are however certain problems which will not show up in testing that may prevent this. Follow the appropriate procedure below to bring the SPE back up.

Simplex SPE

After the reboot command is entered, a series of diagnostics is run on the SPE. Results are displayed as they occur, as described in preceding sections. If all tests pass, the boot image is loaded and control is given to the operating system.

If you cannot get the SPE to reboot after replacing the components that failed SPE-down interface tests, follow normal escalation procedures.

Duplicated SPE

The physical connection of the terminal to the STANDBY connector, while the SPE is locked standby with the SPE-Select switches, prevents the Standby Maintenance Monitor (SMM) from running. Thus, any reboot command to the standby while in this state will abort. To reboot an SPE that is locked standby and has a terminal connected to it, simply move the SPE-SELECT switches to the AUTO position one at a time. This will automatically cause the standby SPE to reboot and its progress is displayed on the terminal. Moving the switches back to the locked position will cause the reboot to abort.

To reboot the standby SPE and have it remain locked standby following the reboot, use the following procedure:

1. Start the reboot by moving the SPE-Select switches one at a time to the AUTO position.
2. As soon as initialization diagnostics begin to appear on the screen, disconnect the MT cable from the STANDBY connector on the control carrier.
3. Return the SPE-SELECT switches to their previous locked position.

When the standby is back up and cycling, the yellow LED on the Processor circuit pack will begin flashing. It is then safe to unlock the SPE-Select switches if they were relocked. At this point, the system should re-establish handshake communication, turn on memory shadowing (assuming the standby is not busied out), and perform a refresh of the standby SPE’s memory. These steps can be monitored by using the **status spe** command at a terminal connected to the ACTIVE terminal connector. When these steps have been completed, the standby SPE should have a “functional” state of health and be fully in service.

If all tests pass, but the SPE does not return to service, there may still be problems on the standby which escaped detection by SPE-down testing. In this case, use the following steps, which describe a means of sequentially replacing circuit packs that are the most likely source of the problem.

1. First determine if memory shadowing is disabling handshake. With the standby locked, busyout the standby SPE; this prevents shadowing from turning on.
2. Bring up the standby as described above (unlock, unplug the STANDBY terminal and relock). If the yellow LED on the Processor fails to flash, follow normal escalation procedures. After the yellow LED begins flashing, unlock and monitor the recovery progress by repeatedly entering **status spe** on a terminal connected to the *active* SPE. If handshake is not established after 2 minutes, memory shadowing is not the problem. Proceed to step 4.
3. Release the standby and follow the progress of the refresh with **status spe**. If the refresh succeeds, the system should be fully functional. If the onset of shadowing or refresh coincides with handshake failure, replace the following circuit pack one at a time in the order shown and repeat this procedure from step 1 each time. (Use lock-and-power-down and DUP-CHL instructions).
    a. Standby DUPINT
    b. Standby PKT-INT
    c. Standby MSSNET
    d. Active DUPINT

    If the problem persists, follow normal escalation procedures.

4. If handshake has not come up after 2 minutes, replace each of the following circuit packs one at a time, in the order shown, and repeat this procedure from step 1 each time:

   a. Standby PKT-INT

   b. Standby DUPINT

   c. Standby SYSAM

   d. Standby PROCESSOR

   e. Standby MSSNET

   f. Standby MEMORY number 1

   g. Standby MEMORY number 2

   If the problem persists, follow normal escalation procedures.

Alarms, Errors, and Troubleshooting 5

Safety Precautions

By observing the prescribed safety precautions when working on the system, you can avoid unnecessary disruption of service and damage to the equipment. The items on this list should be a regular part of your routine.

WARNING:
Failure to comply with these procedures can have catastrophic effects on system service and hardware. Read the explanations following the list to ensure a complete understanding of these necessary procedures.

- Whenever touching any component inside the cabinet, ground yourself by means of the wrist strap attached to the cabinet, and avoid sources of static electricity.
- When logging on with the terminal, be aware that INADS alarm notification is normally disabled. Log off the terminal when leaving the system.
- Think carefully before moving SPE-SELECT switches. Always set them one at a time to the letter of the PPN control carrier that is *currently active* (unless a procedure specifically tells you to do otherwise).
- Never "hot plug" an SPE circuit pack, except for the removable media and disk drives on a simplex SPE. Lock and power down the PPN control carrier first.
- Do *not* power down switch node or port carriers to replace a board.
- Handle fiber optic cables with care. Bending, piercing, or cutting the cable can sever communications between major subsystems.
- When disconnecting fiber optic cables, grasp of both the lightwave transceiver and the cable connector.

- Before powering down a cabinet or carrier that contains DEFINITY AUDIX circuit packs (TN566), first power down the AUDIX unit to avoid damaging the AUDIX software. Instructions for powering down this unit are in the "DEFINITY AUDIX System Power Procedures" below, on the circuit pack, and in DEFINITY AUDIX documentation.
- When you are finished working on a cabinet, replace and secure all panels and covers to avoid disseminating electromagnetic interference.

DEFINITY AUDIX System Power Procedures

Manually Power Down AUDIX System

A yellow caution sticker on the system's power unit notifies technicians to shut down the DEFINITY AUDIX System prior to powering down the system.

1. Using a pointed object, such as a paper clip or pen (do not use a pencil), press the Boot/shutdown button. The button is located at the top right portion of the front panel.
2. Hold the boot/Shutdown button in until the LCD display flashes the message `MSHUT`.
3. Release the Boot/Shutdown button.

NOTE:
The DEFINITY AUDIX System takes about five minutes to shut down. The "heartbeat" indication on the display continues to flash.

Manually Power Up AUDIX System

1. Using a pointed object such as a paper clip or a pen (do not use a pencil), press the Boot/Shutdown button.
2. Hold the boot/Shutdown button in until the display indicates the message, BTEST, steady on.
3. Release the Boot/Shutdown button. the DEFINITY AUDIX system takes approximately 5 minutes to power up.
   - The display has the following sequence of steady on messages:
     — OSINIT
     — OS
     — AINIT
     — ADX

- The DEFINITY AUDIX System is now powered up. When the system is in the active state, the display indicates ADX, and the red LED is off.

NOTE:
When powering up, the DEFINITY ADUXI System automatically reboots. This sequence may show an MD or MJ ADX alarm in the display until the system how powered up. When the system has completed its power up sequence, the display reads: ADX.

Electrostatic Discharge

Whenever a circuit pack is inserted or removed, the grounding wrist strap attached to the cabinet must be used to avoid damage or disruption from ESD. Use of the wrist strap is also required whenever touching any components inside the switch cabinet, including the SPE-SELECT and EMERGENCY TRANSFER switches. While such actions may not cause a problem in a highly controlled environment, disruption to the system could result when conditions are not ideal, (for example, when the air is very dry).

If you *must* proceed when a wrist strap is not available, grab the outside panel of the cabinet with one hand *before* touching any components, and keep your extra hand grounded throughout the procedure.

Handle a circuit pack only by the faceplate, latch, or top and bottom edges. Do not touch board components, leads or connector pins. Keep circuit packs away from plastic and other synthetic materials such as polyester clothing. Do not set a circuit pack on a non-conductive surface such as paper. Use the anti-static bag, if available.

Never hand a circuit pack to another person unless that person is also using a wrist ground strap.

The body collects potentially damaging amounts of static electricity from many ordinary activities. The smallest amount of ESD that can be felt is far above that which can damage a sensitive component or disrupt service!

Figure 5-1 shows the location of the grounding jack.

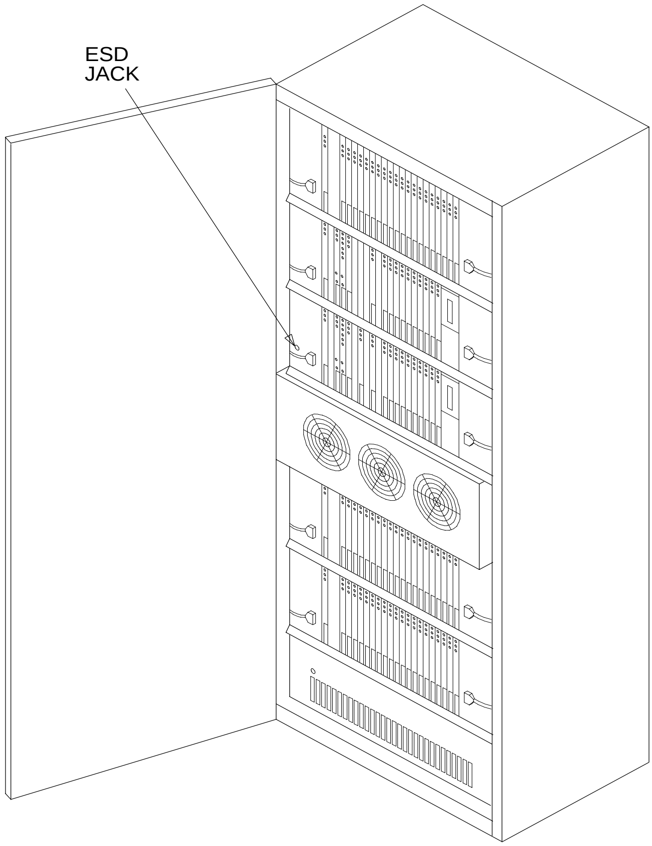

Figure 5-1. Multi-Carrier Cabinet ESD Grounding Wrist Strap Jack

Suppress Alarm Origination [y]

When logged in as “craft,” no alarms are reported to INADS. After logging off, INADS automatically reactivates, and any unresolved alarms are reported to INADS.

Also, when logged in as “craft,” an automatic logoff of the terminal occurs after 30 minutes of non-use. At that time, any unresolved alarms are reported to INADS. If you are logged in as “craft” at 2 different terminals, the logoff occurs when the second terminal remains unused for 30 minutes.

NOTE:
The **test inads-link** command functions even if INADS Alarm Origination is overridden.

Reseating and Replacing Circuit Packs

Most repair procedures involve replacing faulted circuit packs. In some cases, problems are resolved by reseating the existing circuit pack. Reseat a circuit pack *only* when explicitly instructed to do so by the documented procedures. Reseating is discouraged since it can put a faulty component back into service without addressing the cause, resulting in additional and unnecessary dispatches. After reseating a circuit pack, make sure the problem is really fixed by thorough testing and observing the component in operation.

When a port board is removed from the backplane, no alarm is logged for about 11 minutes to allow for maintenance activity to proceed. After that, a minor on-board alarm is logged. If the port board is not administered, no alarm is logged.

WARNING:
This procedure can be destructive, resulting in a total or partial service outage.

WARNING:
Proceed only after consulting and understanding the applicable service documentation for the component.

WARNING:
Observe all Safety Precautions described above.

WARNING:
If the yellow LED on the circuit pack to be removed is lit, the circuit pack is active and services using it will be interrupted.

WARNING:
Follow special procedures for the circuit packs listed below.

Special Procedures

The following circuit packs require special procedures.

For components of the SPE, see “Replacing SPE Circuit Packs”.

- UN331B Processor (SPE)
- TN1650B Memory (SPE)
- TN1655 Packet Interface (SPE)
- TN1648 SYSAM (SPE)
- UN332 MSSNET (SPE)
- TN1657 Disk (SPE)
- TN1656 Removable Media (SPE)
- TN2211 Optical Disk (SPE)
- TN768/780 Tone/Clock
- UN330B Duplication Interface
- TN750 Expansion Interface
- TN573 Switch Node Interface
- TN572 Switch Node Clock
- DS1 CONV

Replacing a BIU or Rectifier

To remove a Battery Interface Unit (BIU) or rectifier first attach a grounding strap from the cabinet to your bare wrist then follow the steps listed below:

1. Unlock the latch pin.
2. Pull down on the locking lever until the BUI or rectifier moves forward and disconnects from its socket.
3. Pull the BIU or rectifier out just enough to break contact with the backplane connector. Use steady even force to avoid disturbing the backplane.
4. Carefully slide the BIU or rectifier out of slot.

To install a BIU or rectifier first attach a grounding strap from the cabinet to your bare wrist than follow the steps listed below:

1. Insert the back edge of the BIU or rectifier making sure that it is horizontally aligned. Slide the unit in to the slot until it engages the backplane. Use extreme care in seating the backplane connectors.
2. Lift the locking lever until the latch pin engages.
3. Verify that the unit is seated correctly by observing the operation of the LED's.

Replacing SPE Circuit Packs

All circuit packs on the processor carrier of the PPN except for the Tone/Clock board are components of the SPE. In addition to the customary MO documentation, there are additional diagnostic techniques for these boards described in the following section, "Troubleshooting a Duplicated SPE". Instructions for replacing the Tone/Clock circuit pack can be found in the TDM-CLK MO documentation.

WARNING:
DO NOT "HOT PLUG" AN SPE BOARD. *Before removing any SPE circuit pack you must power down the carrier in which it resides, (except in the case of a removable media or disk drive in a simplex SPE). Powering down the processor carrier is destructive on a simplex system, causing a total service outage. Be sure you have consulted the appropriate documentation for the component you are replacing. Be sure you are familiar with the precautions at the beginning of this chapter.*

Simplex SPE

This procedure is destructive, resulting in a total service outage except for lines administered with Emergency Transfer. The processor *must* be powered down to avoid hardware damage. Arrange to perform this procedure when a service outage will have the least impact on the customer.

1. Attach the grounding strap to your wrist.
2. Remove power to the processor carrier, (carrier A), by unplugging the power cords located on the front of the power units located at *both* ends of the carrier.
3. Remove or reseat the circuit pack using the procedure described previously in "Reseating and Replacing Circuit Packs".
4. Restore power to the carrier by plugging both power cords back in.
5. Monitor the system reboot by observing the LEDs and G3-MT output.

   These indicators are described in Chapter 4, "Initialization and Recovery".
6. Test the replaced component(s) using the appropriate MO documentation.

7. If the same problem persists, reinstall the original circuit pack to avoid confusing further troubleshooting.

Replacing Circuit Packs on a Duplicated SPE: Lock-and-Power-Down

By following the lock-and-power-down procedure, components of a duplicated SPE can usually be replaced with no disruption of service.

WARNING:
In a system with duplicated SPEs, a spontaneous SPE interchange may occur if the active SPE is not in good health and either an unlocked SPE completes its reboot and handshake is reestablished, or a locked SPE in which the Standby Maintenance Monitor (SMM) is running is unlocked.

WARNING:
Use the ***status spe*** *command to determine the health of the active SPE and whether an interchange will occur.*

1. Enter **status spe** to verify that the component to be replaced is on the standby SPE. If it is, go to step 2.

   If the component is on the active SPE, initiate a planned SPE interchange by entering **reset system interchange**. If the interchange fails, there may be faults on the standby SPE preventing the interchange. You must either repair the fault on the standby SPE first, or force an interchange by using **reset system interchange health-override**.

   WARNING:
   Forcing an interchange may disrupt service. Arrange to do so at a time suitable for the customer.

2. Enter **status port-network 1** to check the health of the PPN Tone/Clocks.

   The Tone/Clock in the same carrier as the active SPE should have a service state of “in.” If not, repair it using “TDM-CLK” before proceeding.

3. Lock the active SPE.

   After grounding yourself, move the SPE-SELECT switches on both DUPINT boards, 1 at a time, to the carrier designation of the active SPE. For example, if the A carrier SPE is currently active, move the switches to position “A.”

4. Enter **status port-network 1** to verify that the active Tone/Clock is in the same carrier as the active SPE.

If not, repeat the command until this condition is met. If the active Tone/Clock has not migrated to the active carrier after 1 minute, there is a Tone/Clock problem. The Tone/Clock problem must be fixed first to avoid service disruption. See “TDM-CLK” maintenance object.

5. Power down the standby processor carrier by:
   a. Remove the power plug from the **left side** of the carrier first.
   b. Remove the second power plug from the **right side** of the carrier.
6. Remove the failed circuit pack and replace it with a new one of the same type.
7. Power up the standby processor carrier by:
   a. Insert the power plug in the right side of the carrier first.
   b. After inserting the first power plug in the right insert the second power plug in the left side of the carrier.

   The red and green LEDs will light indicating restoration of power and testing of the boards. These LEDs will go out as tests pass.
8. This step is optional. Use a terminal and the SPE-down interface to test the standby SPE as follows.

   If a terminal is connected to the STANDBY connector on the back of either PPN control carrier, the power-up reboot of the standby aborts and the SPE-Down interface can then be used to enter commands to the LMM firmware. Use **t al**, or the SPE-Down interface test command for the replaced component, to confirm that the problem is fixed. Repair any failures reported.

   When testing is finished, move the SPE-Select switches to the AUTO position *one at a time*. This unlocks the standby and begin a reboot which can be monitored from the terminal.
9. Verify that the standby is up.

   Regular flashing of the yellow LED on the Processor board indicates that the standby SPE is up and cycling. If the yellow LED is not flashing after five minutes, test the standby SPE as described in the above step. Relock the SPE standby, attach a terminal to the STANDBY connector on the back of either PPN control carrier and execute the SPE-down interface tests. All tests must pass before unlocking.
10. If the standby SPE is still locked, unlock it by returning both SPE-Select switches to the AUTO position *one at a time*.
11. Enter **status spe** to confirm that handshake is up. This should occur within 2 minutes. When it is, enter the **test long clear** command for the replaced component. If an alarm does not clear, consult the appropriate MO.
12. Verify that the standby SPE is brought into service.

Enter **status spe**. The standby SPE is fully operational when handshake is up, shadowing is on, and memory is refreshed. It can take up to 10 minutes after unlocking for the standby to be brought fully into service.

13. If the standby SPE does not fully return to service, consult "STBY-SPE (Standby SPE Maintenance)".

Troubleshooting a Duplicated SPE

The section on maintenance object "STBY-SPE (Standby SPE Maintenance)" contains procedures for troubleshooting specific problems such as handshake failure, memory shadowing failure, and poor state of health. The following procedures describe a method for determining the cause of a spontaneous SPE interchange and resolving any related problems.

If a spontaneous SPE interchange has occurred, assume that a serious fault has occurred on the SPE that is currently the standby. The following symptoms indicate that a spontaneous SPE interchange has taken place:

- A MINOR alarm with error type 103 is logged against STBY-SPE.
- An interchange entry is recorded in the initcauses log.
- The system is put into *recent interchange mode*, which prevents further SPE interchanges from taking place.

The presence of recent interchange mode is displayed on the **status spe** screen. The system is released from this mode, and the minor alarm is cleared, after 1 hour, or upon the execution of **test spe-standby long**, regardless of whether all tests pass.

There are three possible causes of a spontaneous interchange:

- Major hardware failure
- Failed recovery that has been software escalated
- Switching both SPE-SELECT switches to the standby carrier (not a recommended procedure)

In the last case, the interchange is not fault-driven, and no specific repair action is required. To determine whether this is the case, enter **display initcauses**. If the interchange was initiated by the SPE-SELECT switches, the `Cause` field will appear as in the following example.

```
Cause                Action  Escalated  Carrier  Time
SPE-SELECT switch      1        no         1B    11/27 14:53
```

If the interchange was fault-driven, there are two ways of finding the cause.

1. Using alarm and error logs in conjunction with the timestamp described above. After a spontaneous SPE interchange has occurred, the Alarm Log retains a record of any MAJOR ON-BOARD alarm against an SPE component that took place before the interchange. This record is retained for three hours and may indicate the cause of the interchange when testing is not possible or conclusive. Other information in the Error Log may also be helpful.
2. Testing the standby SPE when the logs do not identify the problem.

Start by determining the time of the interchange. Then, examine the alarm and error logs as described in the following section. If that does not identify the problem, proceed to the next section, which describes a sequence of tests of the standby SPE.

Determining the Time of a Spontaneous Interchange

There are 2 ways to tell at what time a spontaneous interchange has taken place:

- STBY-SPE Error 103

  This error is logged with a minor alarm whenever a spontaneous interchange takes place. The time recorded for the *first occurrence* of the error is the approximate time of interchange. The error is logged against the carrier of the SPE that was active before the interchange. This should now be the standby SPE, assuming no further interchanges have taken place.

- Display initcauses

  The **display initcauses** command displays a record of all system resets. In the following example, a spontaneous interchange *into* the B carrier SPE took place at 2:53 P.M. The standby SPE (B) transitioned into active mode with a WARM restart, (reset level 1).

```
Cause         Action  Escalated  Carrier  Time
Interchange   1       no         1B       11/27 14:53
```

Examining the Alarm and Error Logs

The system may have had time to log alarms or errors against the fault the caused the interchange. Proceed through the steps summarized in Figure 5-2. Examine only major alarms with a timestamp near the time of interchange, and whose carrier designation is the current standby SPE (the SPE interchanged out of). Include any resolved alarms meeting this description.

All relevant alarms must be timestamped at or near the time of interchange.

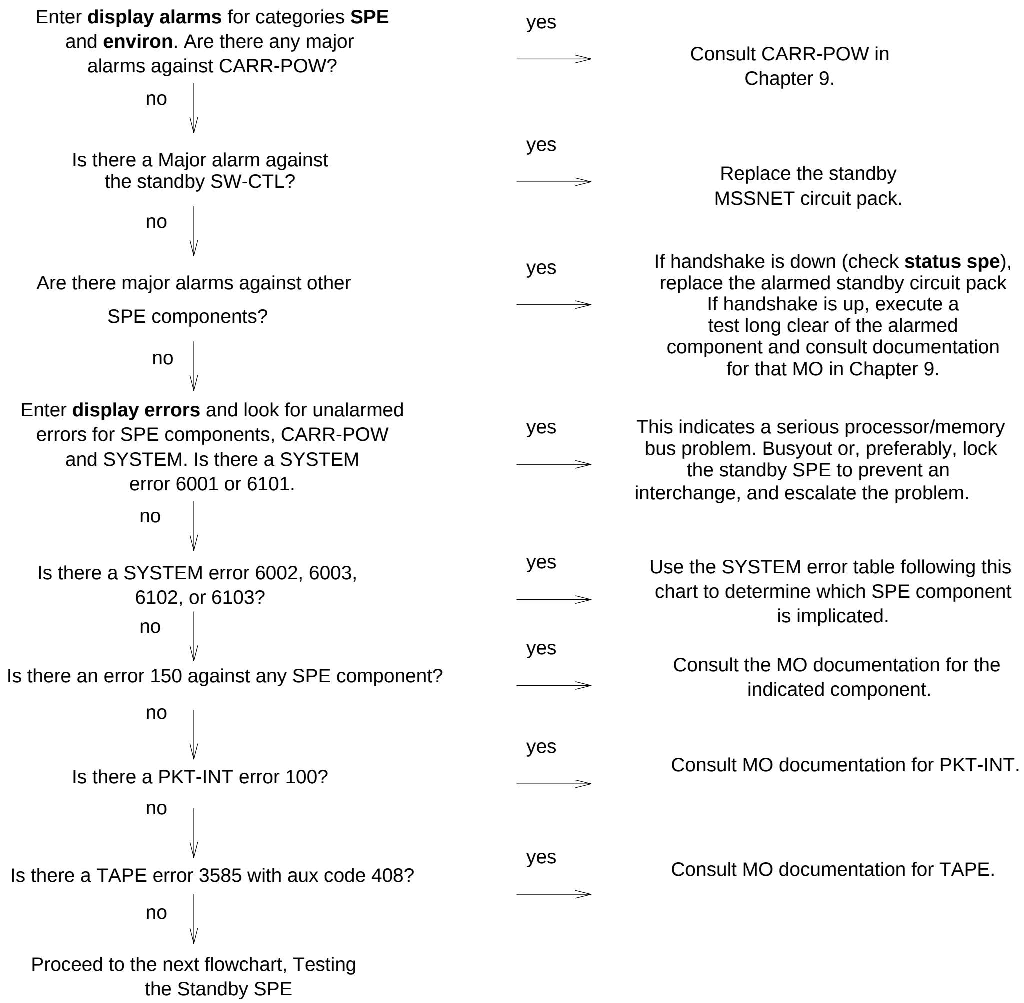

Figure 5-2. Determining the Cause of an SPE Interchange

Auxiliary Data for SYSTEM Errors 6002, 6003, 6102, and 6103

The following table shows which components are indicted by the auxiliary error codes found by using the preceding flowchart (Figure 5-2). Once you have identified the faulted component, consult the section for that MO.

Aux Data	Maintenance Object Implicated
16384	PROCR
16385	MEM-BD
4137	PKT-INT
16391	SW-CTL
16386	SYSAM
16389	DUPINT
16392	H-ADAPTR
16397	R-MEDIA
16398	DISK

Testing the Standby SPE

The system may not have had time to log errors against the failed component that caused the spontaneous interchange. If you have progressed through the preceding flowchart without determining the cause of interchange, test the standby for faults by proceeding through the following steps shown in Figure 5-3.

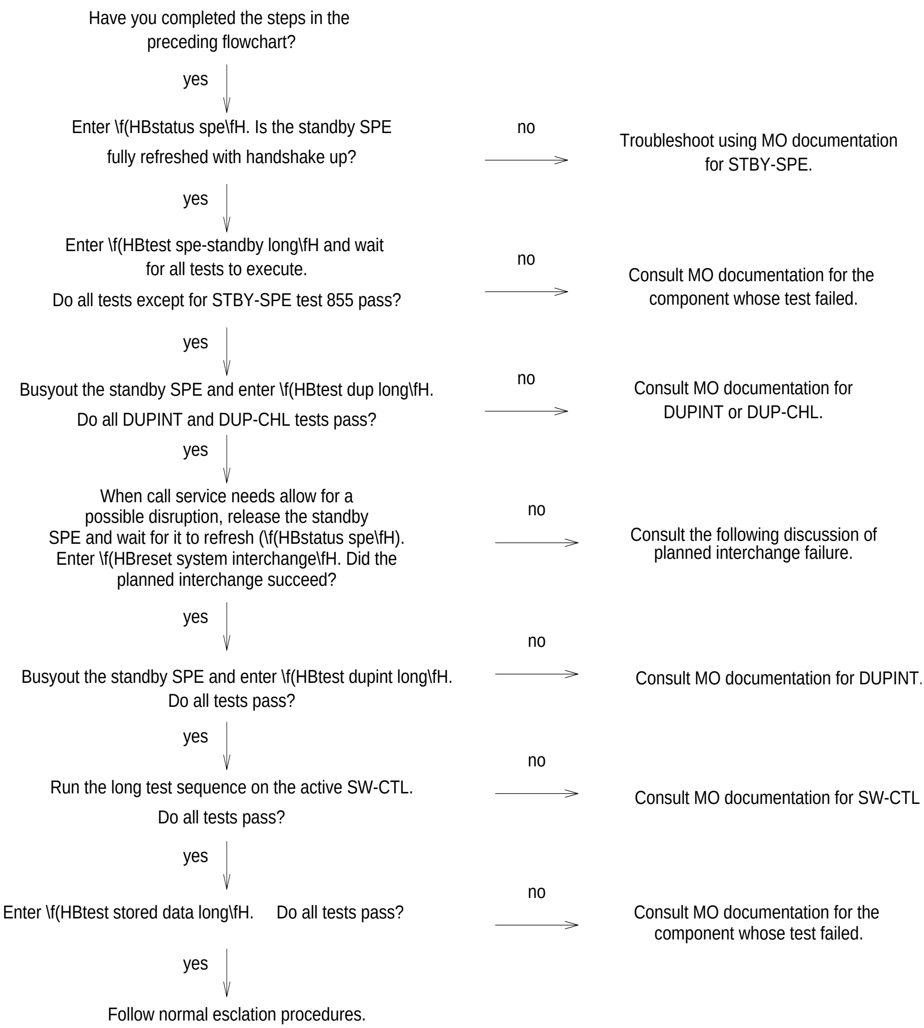

Figure 5-3. Testing the Standby SPE

Executing a Planned SPE Interchange

Planned SPE interchanges are initiated on demand by the **reset system interchange** command, or automatically by scheduled daily maintenance. The latter is administered with the system-parameters maintenance screen. A planned interchange normally has no perceivable effect on service. All active calls, transient calls, system links and stimuli, and data transmission are preserved. The SYSAM-RMT port (also called the Remote Access Port) is dropped, necessitating a re-login. The duration of the interchange is approximately one minute.

CAUTION:
Switching the SPE-select switches to the standby carrier causes a spontaneous interchange, not a planned one. This can disrupt service and is not a recommended procedure.

Prerequisites

Several conditions must be met to guarantee a non-disruptive interchange. If these are not met the system will not execute the interchange. All of these conditions, listed below, are expected to be met during normal operation.

- The SPE must not be locked by the SPE-SELECT switches.
- The standby SPE must be fully in service.

  That is, handshake is up, shadowing is on, memory is refreshed, and standby SPE state-of-health is "functional". "STBY-SPE (Standby SPE Maintenance)" describes how to correct a failure of any of these.
- There can be no minor alarms against the standby's PKT-INT or SYSAM circuit packs.
- There can be no ongoing disk or removable media operations on either active or standby MSS components.

  Wait until all such operations, such as translation saves or backup restores, are complete before requesting an interchange.

SPE Interchange Failures

If the above conditions are not met, or if any intermediate steps taken by the system in executing the interchange fail, the interchange is prevented. Usually, failure of a planned interchange has no effect on service.

If the interchange fails after the packet interface links have migrated, the system will require a reset level 1 (warm restart) to restore the links. In such a case, no calls are dropped, and new call service resumes within 5 seconds. However, it is probable that there is a severe system problem which predates the attempted interchange.

If the SPE is locked by means of the SPE-SELECT switches, error 607, auxiliary data 1153, is logged against SYSTEM. If the switches are not locked and the interchange fails, an unalarmed error 605 is logged against SYSTEM. The auxiliary code associated with this error indicates which aspect of the interchange failed. Table 5-1 explains the meaning of the auxiliary codes and what corrective action to take.

Table 5-1. SYSTEM Error 605 Planned Interchange Failure

Aux Data	See Note	Explanation
1352	1	Standby SOH “non-functional”
1353	1	Standby SOH not “functional”
1355	1	Handshake Communication with Standby SPE is down
1356	1	Memory Shadowing not enabled
1357	1	Standby memory not refreshed
1358	2	Mass Storage System was in use
1359	3	PKT-INT link migration failed
1360	1	Interchange failed[1]
1361	4	SW-CTL failure
1369	7	Could not suspend G3-MT connectivity[1]
1370	4	Could not freeze active SW-CTL[1]
1371	5	Internal Error associated with processor interrupts[1]
1372	6	Minor alarm on standby SYSAM or PKT-INT
1395		SPE Duplication not administered
1396	3	PKT-INT Link Migration failure in Begin Step[1]
1397	3	PKT-INT Link Migration denied, (peer test in progress)
1398	3	PKT-INT Link Migration failure in Completion Step[1]
1399	3	PKT-INT Link Migration failure in Finish Step[1]
1400	4	Could Not Idle SW-CTL dual port RAM[1]
1401	4	Could Not Refresh SW-CTL dual port RAM[1]
1402	5	Internal Error (could not get duplication status)
1403	5	Unable to inhibit Standby Maintenance Monitor
1404	5	Failure to determine Standby SPE alarm status

Continued on next page

Table 5-1. SYSTEM Error 605 Planned Interchange Failure — *Continued*

Aux Data	See Note	Explanation
1406	3	Active SPE's PKT-INT in held-reset state
1418	8	Active Duplication Interface circuit pack is in a bad state and needs to be reset.
2500	5	Internal Software failure[1] (sometimes)

1 A WARM restart is required.

Notes for SYSTEM Error 605 AUX Data:

1. Follow repair instructions in "STBY-SPE (Standby SPE Maintenance)" for the particular standby SPE problem. After fixing that problem, try the interchange again.
2. Mass Storage System is in use. Check Disk and Removable Media LEDs for activity. Wait until all MSS activity completes, then try the interchange again. If the problem persists, check for alarms and errors against MSS components and follow repair procedures for each Maintenance Object.
3. Test the PKT-INT on both carriers with the long test sequence. Follow procedures for "PKT-INT (Packet Interface Circuit Pack)". Once *all* tests of both PKT-INTs pass, try the interchange again.
4. Consult SW-CTL service documentation. Test SW-CTL on both carriers with the long test sequence. Follow repair instructions for any failures. Once *all* tests of both SW-CTLs pass, try the interchange again.
5. Make sure the standby SPE is refreshed Then try the interchange again.
6. Examine alarm log to determine which of PKT-INT or SYSAM circuit packs has a minor alarm against it. Consult service documentation of whichever is alarm to clear
7. Check for errors/alarms against active SPE's SYSAM. If you find any, consult the "SYSAM (Circuit Pack)" documentation. If you find none, and if all tests of the SYSAM long sequence pass, try the interchange again.
8. Run **test duplication-interface long** and follow instructions for any test that does not pass.

LA85 Port Tester

The LA85 port tester (Comcode 105138424) is recommended for troubleshooting all DEFINITY station troubles involving analog, DCP, MFET, MFAT, or BRI configuration. The port tester detects the presence of voltage from equipment ports and is degined to indicate the status of the wiring at the:

- Wall field in the equipment room
- Wall field in any intermediate closet
- Wall jack at the station
- Terminal and terminal station cord

Use the information in Table 5-2 to isolate problems with the port tester.

Table 5-2. Port fault isolation using the LA85 Port Tester

To begin the isolation procedure at the	You may need this preliminary information or equipment	And if	Then
Wall field in equipment room	Use **display errors** command	Off-board errors indicated	Verify wiring from switch to equipment room wall field.
Station (terminating end)			1. Unplug station cord from terminal and plug it into the “BRI” or “Other” jack on the tester, as applicable. 2. If the readings are OK, the terminal, handset, or handset cord may be faulty.
Station wall jack	1. Wrong or incorrect reading from the terminal end of the station cord (from Step 1 above) 2. D8W line cord (Comcode 103786761) used at station wall jack		1. If the reading from the jack is OK, then the terminal cord may be faulty.

Continued on next page

Table 5-2. Port fault isolation using the LA85 Port Tester — *Continued*

To begin the isolation procedure at the	You may need this preliminary information or equipment	And if	Then
Intermediate closet wall field			1. Isloate part of the wiring span (either to the switch or to the terminal)

The port tester is equipped to check 110-type wall field hardware with the three 1-pair patch cords that are color-coded blue (1), orange (2), or green (3).

NOTE:
If the wall field has 66-type blocks, a 66-type block adapter (Comcode 405546474) is needed.

DANGER:
The port tester should not be plugged into an active circuit for an extended period of time. Resistors in the tester can burn out.

LED indications for the various port types are listed in Table 5-3. Abbreviations are as follows:

- R = Red
- G = Green
- N = Not lighted
- N/A = Not applicable

Table 5-3. LED indications for the LA85 Port Tester

Port	W-BL Bl-W	W-O	O-W	W-G	G-W	Bl-W	W-BL
Analog	G[1]	N	N	N	N	N/A	N/A
DCP	N	G	G	G	G	N/A	N/A
DCP (2-wire)	G	N	N	N	N	N/A	N/A
MFET	G	G	G	G	G	N/A	N/A
MFAT	N	R[2]	R	R	G[3]	N/A	N/A
BRI	N/A	N/A	N/A	G	G	G	G

1 The red LED lights on a reversal. If the analog set contains a polarity guard, the set is still operable. Determine whether an off-hook pulls a dial tone that can be broken by dialing.

2 Some LA85 port testers may indicate that W-O should appear green. Information in this chart is correct.

3 Some LA85 port tesers may indicate that G-W should appear red. This chart is correct.

Fiber Fault Isolation Procedure

Use the following procedure to isolate faults on a fiber-link. When troubleshooting a system with duplicated Port Network Connectivity (PNC), first **busyout pnc-standby** before busying out a standby Fiber-Link (FIBER-LK), Expansion Interface (EXP-INTF), Switch Node Interface (SNI) or DS1 Converter (DS1C). At the end of this section is a description of the loopback tests run and a pinout of the cable used to connect the DS1 C to DS1 facilities.

- A busyout of any of these components on a simplex PNC is destructive.
- Be sure to release all busied out components after completing the tests.

Steps:

1. Enter **display alarms** with category **pnc**.

   Are there any on-board alarms? If so, replace the circuit pack(s).

2. Enter **display errors** for category **pnc**.

   Check for any of the following errors:

Maintenance Object	Error Type
FIBER-LK	Any
SNI-BD	513
EXP-INTF	257 769 770 1281 1537 3073 3074 3075 3076 3585 3841 3842

   If *one or more* of the above errors are present go to step 3.

   If *none* of the above errors are present, look for SNI-PEER errors.

   - If there is one SNI circuit pack with many different SNI-PEER error types, replace the indicated SNI circuit pack
   - If there are many SNI-PEER errors of the same error type, replace the indicted SNI circuit pack using the following table.

Error Type	SNI slot
1	2
257	3
513	4
769	5
1025	6
1281	7
1537	8

Error Type	SNI slot
1793	9
2049	13
2305	14
2561	15
2817	16
3073	17
3329	18
3585	19
3841	20

- After replacing an SNI circuit pack, clear alarms by executing **test board** UUCSS**long clear** for all alarmed EXP-INTF circuit packs. Wait 5 minutes for any SNI-BD or SNI-PEER alarms to clear. (You can speed this process with **clear firmware counters [a-pnc | b-pnc]** for the PNC that was repaired).
- Exit this procedure.

3. Enter **list fiber-link** to get the physical location of the fiber-link endpoints. If a DS1 CONV is administered to the fiber-link (DS1 CONV is "y"), use the **display fiber-link** command to get the physical location of the DS1 CONV circuit packs on the fiber-link.
4. Execute **busyout fiber-link** FP followed by **test fiber-link** FP **long**.

   If any tests in the sequence fail, proceed with step 5.

   If all of the tests pass, clear alarms by executing **test board** UUCSS **long clear** for all alarmed EXP-INTF circuit packs. Wait 5 minutes for any SNI-BD, SNI-PEER, FIBER-LK, or DS1C-BD alarms to clear. You can speed this process with **clear firmware counters [a-pnc | b-pnc]** for the PNC that was repaired. You are finished with this procedure.
5. For each endpoint of the fiber-link, follow this flowchart:

   Busyout and **test board UUCSS long** and record all test failures. When looking at test results, consult the explanations and illustrations of the tests, which appear at the end of this procedure.

   Is `Board Not Assigned` displayed for an EXP-INTF in an EPN? If yes, **test maintenance long** to release an EXP-INTF that may be held reset by an EPN Maintenance circuit pack.

   If No, did EXP-INTF test 242 fail? If yes, replace the EXP-INTF circuit pack and the lightwave transceiver (if present) and go back to Step 4. (EXP-INTF test 242 runs an on-board looparound if no lightwave transceiver is connected to the EXP-INTF.)

If No, did SNI test 757 fail? If yes, replace the SNI circuit pack and go back to step 4 of this procedure.

If No, did SNI test 756 fail? If yes, replace the SNI circuit pack and the lightwave transceiver (if present) and go back to Step 4.

If No, did EXP-INTF test 240 fail? If yes, replace the EXP-INTF circuit pack and go back to Step 4.

If No, did tests 238 (EXP-INTF) or 989 (SNI) fail? If yes, replace the lightwave transceivers and fiber-optic cable, or metallic cable, and go back to Step 4. The faulted component can be further isolated by using the Manual Loopback Procedure described at the end of this procedure.

NOTE:
If a fiber out of frame condition exists and lightwave transceivers are used, check that both lightwave transceivers are of the same type, (9823a or 9823b). If they are not both the same, replace one of the lightwave transceivers so that they match. (9823A is used for distances up to 4900 feet (1493 m) and 9823B is used for distances up to 25,000 feet (7620 m)).

If No, is a DS1 CONV administered on the fiber-link? If no, follow normal escalation procedures.

If Yes, is there an SNI-BD 513 alarmed error (**display errors ,** `category` = pnc)? If yes, replace cabling between the SNI circuit pack and the DS1C circuit pack.

If the alarm persists, replace the DS1C and the SNI circuit packs. and go back to Step 4.

If No, if the connected circuit pack is an EXP-INTF, did Test #238 fail?

If Yes, replace cabling between the EXP-INTF circuit pack and the DS1C circuit pack. If Test #238 continues to fail, replace the DS1C and the EXP-INTF circuit packs and go back to Step 4.

If No, **busyout** and **test board UUCSS long** for both DS1C circuit packs and note all test failures and aborts.

Did the test return `Board not inserted` for the near-end circuit pack (nearest the SPE), or for the far-end circuit pack in a simplex PNC? If so, replace the cabling between the DS1C circuit pack and the SNI or EXP-INTF circuit pack.

Wait 1 minute and retest.

If the board is still not inserted, replace the DS1C circuit pack and the EXP-INTF or SNI connected to it and go back to Step 4.

If No, check to see if any of the CSU devices are looped back. **Busyout** and **test ds1-facility UUCSS external-loop** for each DS1 facility. The tests should fail.

If any test passes, the facility is looped back, and the loopback should be removed. If the DS1C Complex has only one DS1 facility, this test cannot be executed at the far-end circuit pack (farthest from the SPE).

Did test 788 pass and test 789 fail? If yes, replace the DS1C and lightwave transceiver (if present) at the other end of the DS1C complex. See Figure 5-4 and Figure 5-5. Go back to Step 4.

If No, did test 788 fail or abort and test 789 fail or abort? If yes, execute **test ds1-facility UUCSS long** command for each administered and equipped DS1 facility.

If No, did test 797 fail?

If Yes, run the **test ds1-facility UUCSS external-loopback** command for each administered and equipped DS1 facility.

This test requires manually altering the external connections of the DS1 facility. Place the loopbacks at as many points as your CSU capabilities will allow (see Figure 5-5).

- If Test #799 fails at LB1, problem is with DS1C #1, CSU #1, or the connections in between.
- If test 799 passes at LB1 and fails at LB2, the problem is with CSU #1.
- If test 799 passes at LB1 and at LB2, the problem is with the DS1 facility, CSU #2, connections to CSU #2, or DS1C #2.

SNI/EI Manual Loop Back Procedure

Use this procedure to isolate a fault in the cables or lightwave transceivers of SNI/EI links. (Do not use this procedure on a connection with a DS1C as an endpoint.) By performing the loopback at both endpoints and, if applicable, at the cross-connect field, the failure point can be identified. If both endpoints pass, but the link remains inactive (with the boards not busied out), the fault should lie in the cabling in between. If the test passes at a transceiver, but fails at the cross-connect field, the cable or connectors in between are at fault.

A short optical fiber jumper with connectors is required for this procedure. If the link uses metallic cable, the metallic connector must be removed from the back of the carrier, and a lightwave transceiver connected in its place.

1. Note the condition of the yellow LED on the circuit pack.
2. Busyout the circuit pack.
3. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the circuit pack. Note which is the transmit fiber and which is the receive fiber for proper re-connection at the end of this procedure.

4. Connect the transmit and receive jacks of the lightwave transceiver with the jumper cable.

   NOTE:
   Make sure that the total length of the fiber jumper cable does not exceed the maximum length recommended for the fiber link connections between cabinets. Otherwise, test results may be influenced by violation of connectivity guidelines.

5. At the front of the cabinet, observe the yellow LED on the looped back circuit pack.
   - If the yellow LED flashes once per second, the circuit pack or transceiver should be replaced.
   - If the yellow LED flashes five times per second, the circuit pack or its lightwave transceiver may need replacement. This condition may also be due to a faulty system clock on the port network (for an EI) or the switch node carrier (for an SNI).
   - If the yellow LED was flashing before starting this procedure, and it is now either solid on or solid off, this circuit pack and its lightwave transceiver are functioning properly.
6. Replace the faulty component(s) and reconnect the original cables in their correct positions. Be sure to use a lightwave transceiver that matches the one at the opposite end.
7. Release the circuit pack.

Loopback Tests for fiber fault isolation

Figure 5-5 shows the loopbacks performed on the SNI circuit pack for test 756 and test 757. Test 756 reports the result of the off-board loopback; test 757 reports the result of the on-board loopback. Test 756 and test 757 can run individually or as part of the **test board UUCSS long** command for an SNI circuit pack.

Test 242 can be run as part of the **test board UUCSS long** command for an Expansion Interface circuit pack. Besides testing on-board components, this test is helpful for isolating problems between a circuit pack and the lightwave transceiver. The loopback shown in this diagram shows only part what test 242 does. If no lightwave transceiver is connected to the Expansion Interface circuit pack, an on-board loopback is performed on the Expansion Interface circuit pack. For more information about test 242, see “EXP-INTF (Expansion Interface Circuit Pack)”.

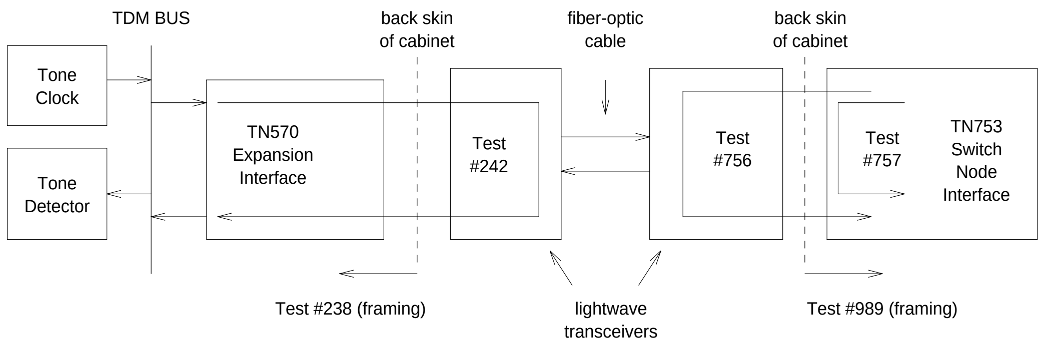

Figure 5-4. Fiber fault isolation tests

If DS1Cs exist on the fiber link (check with **list fiber-link**), then additional DS1CONV loopback tests can be run to further isolate the problem. The loopback tests are shown in Figure 5-5. For more information about loopback tests 788 and 789, see the "DS1 CONV-BD" section in. For more information about DS1 facility loopback tests 797 and 799, see the "DS1-FAC (DS1 Facility)" section.

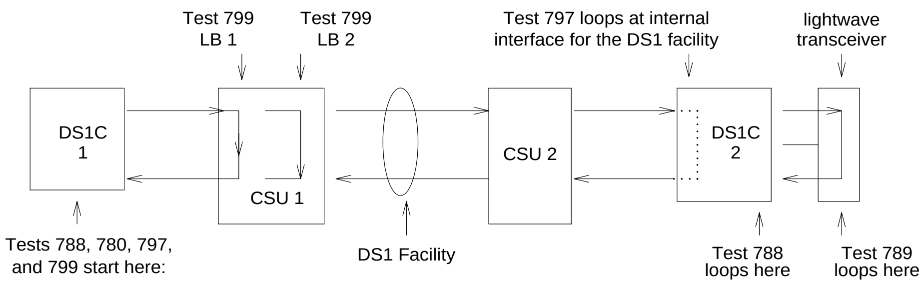

Figure 5-5. DS1 CONV Loopbacks

Table 5-4 shows the pin assignments for the cable used to connect the TN574 DS1 CONV circuit pack to DS1 facilities.

Table 5-4. DS1 Interface Cable Connectors

ATM Tips

This section provides tips for DEFINITY ATM PNC when interfacing with the ATM switch. Throughout this section, refer to Figure 5-6.

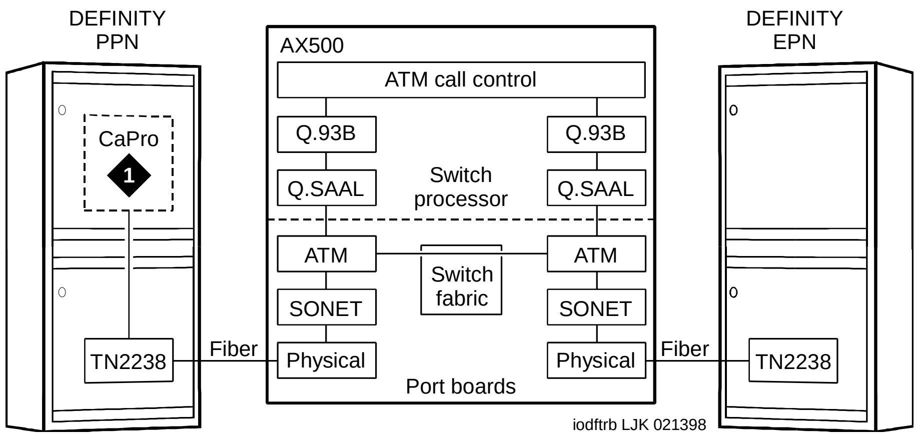

Figure 5-6. ATM troubleshooting schematic

NOTE:
The CaPro element (Note 1 in Figure 5-6) is a software module within the DEFINITY PPN.

Initial LED inspection

Visually inspect the LEDs on both the TN230X (Table 5-5) and the ATM switch (Table 5-6) for a high-level status of the system.

Table 5-5. TN230X LED reference

LED color			Interpretation
Red	Green	Yellow	
Off	Off	Steady on	Normal state for active ATM EI board on PPN.
Off	Off	Off	Normal state for standby ATM EI board on PPN and EPN.
Off	Off	2 sec on / 2 sec off	Normal state for active PNC archangel ATM EI board on EPN.

Continued on next page

Table 5-5. TN230X LED reference — *Continued*

LED color			Interpretation
Red	Green	Yellow	
-	-	100ms on / 100ms off	Loss of signal on the OC-3 fiber. Either the TN230X-receive (top) or TN230X-transmit (bottom) fibers are not working.
N/S	Fast blink	-	Running DSP diagnostics or downloading code to DSPs (typical during boot process).
-	Slow blink	-	Board insertion has not yet completed.
-	Steady on	-	Running maintenance tests. May appear to be blinking if several short tests are run one after another.
Steady on	-	-	Hardware alarm. Does not necessarily take the TN230X out of service, for example, if one of the 24 DSPs fails diagnostics.

Table 5-6 shows the various LEDs on the A500 ATM switch and the meanings of the different states.

Table 5-6. A500 LED Quick Reference

Component	Label	Color	State	Meaning
Switch Processor Board	LK	Green	Intermittent blink	Normal state. Traffic is being sent or received over the Ethernet LAN link.
	RX	Green	Steady on	Normal state. Carrier is received over the Ethernet LAN link.
	DIAG	Green	Off	Normal state.
	NBOOT	Green	Off	Normal state.
	MGT	Green	Off	Normal state.
	RUN	Green	Steady on	Normal state. The switch processor is running.
	PWR	Green	Steady on	Normal state. The switch processor board is powered up.
	VOLT	Yellow	Off	Normal state
	TEMP	Yellow	Off	Normal state
	FAN	Yellow	Off	Normal state

Continued on next page

Table 5-6. A500 LED Quick Reference — *Continued*

Component	Label	Color	State	Meaning
	SYSERR	Yellow	Off	Normal state
	FAULT	Yellow	Off	Normal state
Switch Fabric Board	PWR	Green	Steady on	Normal state. The switch fabric board is powered up.
	FAULT	Yellow	Off	Normal state
Port Board	PWR	Green	Steady on	Normal state. The port board is powered up.
	FAULT	Yellow	Off	Normal state
Port Board Per Port	RX	Green	Off	No ATM cells are being received. This is not a normal state if the terminating port network is supposed to be up and running.
	RX	Green	Intermittent blink	ATM cells are being received intermittently. This is a typical pattern for DEFINITY if only Variable Bit Rate (VBR) signaling connections are present but no talk paths are up, perhaps because no calls are in progress.
	RX	Green	Steady on	ATM cells are being received frequently enough that the LED is lit constantly. This is a typical pattern for DEFINITY if Constant Bit Rate (CBR) talk paths are present.
	CD	Green	Off	Loss of carrier on the fiber. The A500 detects only if the A500-receive (right-hand) fiber is not working. The state of the A500-transmit (left hand) fiber is not detected.
	CD	Green	Steady on	Normal state. There is a optical carrier detected on the fiber from the TN230X.
	RPRD	Yellow	Off	Normal state
Power Supply	AC OK	Green	Steady on	Normal state. AC power is okay.
	DC OK	Green	Steady on	Normal state. DC power is okay.

Cajun A500 Diagnostics

The first step in any diagnostic procedure involving the A500 is to identify the OC-3 ports on the A500 that have DEFINITY port networks attached.

- Be aware that customers may use other ports on the A500 for applications unrelated to DEFINITY (LAN traffic or multimedia applications, for examples).
- These other applications may manifest themselves in the output of the troubleshooting commands you run on the A500. DEFINITY port networks must be identified by their A500 port numbers.

NOTE:
The following examples show DEFINITY port networks connected to A500 ports A1.1 and A1.2.

Has the A500 been installed and configured correctly?

Diagnostics

- Is the A500 powered up?
- If you are administering the A500 through a locally-attached console, is there a local console terminal connected to the console port on the A500 switch processor board with the correctly-pinned RS232 serial cable?
- If you are administering the A500 through telnet over the Ethernet, is there an 10BaseT Ethernet drop plugged into the Ethernet port on the A500 switch processor board? (Note that a few A500 commands are only permitted over the local console terminal.)
- Has the A500 been booted using either the recessed reset button or by turning the power off, then on again?
- Did the A500 go through a normal power up sequence, including testing all of the LEDs?
- Are any A500 yellow fault LEDs lit?
- Are the remaining A500 LEDs in a normal state (Table 5-6 above)?
- Can you log into the A500 console using the diagnostic account **root** from the local console terminal or through telnet? (See Figure 5-7 below.)

Figure 5-8. A500 screen output for status command

a. If the customer is providing an Ethernet connection to the A500, does the `Ethernet IP address` field have the customer-provided Internet address (configured using the **admin address** command)?

   If you are adminstering the A500 through a telnet connection over the Ethernet, this works, but it is worthwhile making sure the Ethernet address is correct anyway.

b. If the customer is providing an Ethernet connection to the A500, does the `Ethernet IP mask` field have the customer-provided mask (typically something like `255.255.255.0`, although other values are valid), as configured with the **admin address** command?

c. If the customer is providing an Ethernet connection to the A500, does the `IP default router` field have the customer-provided Internet address, as configured using the **admin gateway** command?

d. If the customer is providing an Ethernet connection to the A500 and intends to upload to or download from a TFTP server, does the `TFTP server` field have the customer-provided Internet address, as configured using the **tftp setserver** command?

e. Does the `ATM address` field have the customer- or Lucent-provided network prefix (the first thirteen bytes and set by using the **modify atmprefix** command)?

DEFINITY Administration

Is ATM PNC administered correctly?

1. Enter **list atm pnc** on the DEFINITY SAT. The cabinet, carrier and slot positions of each administered TN230X board display as shown in Figure 5-9. Ensure that each board's physical location matches the display.

```
list atm pnc                                                   Page   1   SPE A
                                   ATM PNC
PNC                   A-PNC                      B-PNC
Connection #          LOC                        LOC

 1                    01B02
 2                    02A01
```

Figure 5-9. Screen output for list atm pnc command

Alternatively, use the **list configuration UUC** command (non-control cabinets) to confirm the PPN and EPN board locations and correct insertion.

2. Enter **status pnc** at the DEFINITY SAT. This display tells you which TN230X board is active in a duplicated system and how many alarms (if any) of each severity level have been logged for the board. Figure 5-10 shows the output from this command.

```
status pnc
                          PORT NETWORK CONNECTIVITY

                                 Duplicated? no
                            Software Locked?
                             Standby Busied?

                          Standby Refreshed?
                       Interchange Disabled?

              A-PNC                                  B-PNC

              Mode: active                           Mode:
   State of Health:                       State of Health:
    Inter PN Index:                        Inter PN Index:

      Major Alarms: 0                        Major Alarms:
      Minor Alarms: 0                        Minor Alarms:
    Warning Alarms: 0                      Warning Alarms:
```

Figure 5-10. Screen output for status pnc command

3. Enter either **list configuration UUC** (for the carrier in which the ATM-EI packs reside) or **display circuit-packs *cabinet*** (non-control cabinet) at the DEFINITY SAT. This command tells you in more detail what boards are in which slots in each cabinet and carrier. Verify that the TN230Xs are physically located in the slots indicated on the display. Figure 5-11 shows the output for the **display circuit-packs 1** command; Figure 5-12 shows the output for the **display circuit-packs 2** command.

```
display circuit-packs 1

  10: TN754  B    DIGITAL LINE

  '#' indicates circuit pack conflict.
```

Figure 5-12. Screen output for display circuit-packs 2

4. Enter **display atm pnc *portnetwork*** on the DEFINITY SAT.

   This display tells you the ATM addresses that have been administered for each TN230X. Verify that each ATM address (the concatenation of the five displayed hexadecimal fields) is correct and match those administered in the A500. See "A500 Administration" for more information.

   Administered with hard coded PNNI routes

   If the port networks are addressed using *hard coded PNNI routes* in the A500, the display looks like Figure 5-13 (pnc 1) and Figure 5-14 (pnc 2).

```
display atm pnc 1
                                    ATM PNC

                             Connection Number: 1

      Location: 01B02
          Name:

Address Format: ICD ATM

           AFI: 47
           ICD: 0005
        HO-DSP: 80FFE1000000F2071B02
           ESI: 000000000000
           SEL: 00
```

Figure 5-13. Screen output for display atm pnc 1

```
display atm pnc 2
                                    ATM PNC

                             Connection Number: 2

      Location: 02A01
          Name:

Address Format: ICD ATM

           AFI: 47
           ICD: 0005
        HO-DSP: 80FFE1000000F2072A01
           ESI: 000000000000
           SEL: 00
```

Figure 5-14. Screen output for display atm pnc 2

Administered with End System Identifiers

If the port networks are addressed using End System Identifiers, the display looks like Figure 5-15 (pnc 1) and Figure 5-16 (pnc 2).

```
display atm pnc 1
                                  ATM PNC

                           Connection Number: 1

            A - PNC
      Location: 01B02
          Name:

            A - PNC

      Location: 02A01
          Name:

Address Format: E.164 ATM Private

           AFI: 45
         E.164: 0001013035381053
        HO-DSP: 00000000
           ESI: 000000000012
           SEL: 00
```

Figure 5-16. Screen output for display atm pnc 2 with End System Identifiers

A500 Administration

Is the A500 administered correctly?

1. Enter **show signaling summary** on the A500 console. Figure 5-17 shows the screen output.

```
A500:show signaling summary

Port     loc VCI    SAP    IntType     Signaling    ILMI   SAP State      State
------   -------    ---    -------    -----------   ----   ------------   -----
A1.1        1        1     Network    UNI3.1        No     UP             UP
A1.2        2        2     Network    UNI3.1        No     UP             UP
```

Figure 5-17. Screen output for the show signaling summary command

   a. If an A500 port to which a DEFINITY port network is attached is not listed in this display, it is likely that the port was administered incorrectly as having no UNI signaling (**admin link** command).

   Ensure that fields listed have the values indicated below.

Field	Value
`IntType`	`Network` If it is `User`, links will not come up between the PPN and the EPN.
`Signaling`	`UNI3.1` If it is `UNI3.0`, links will not come up between the PPN and the EPN.
`ILMI`	Preferred value of is `No`, however this alone does not prevent links from coming up between the PPN and an EPN.
`SAP State`	May or may not be `UP`. Their values depend on more than just whether the port was marked as **UP**. (See highlighted data for SAP State in Figure 5-17.)

2. If the A500 was administered using hard-coded PNNI routes to identify each endpoint, enter **show signaling routes** on the A500 console. Figure 5-18 shows the screen output from the command.

```
A500:show signaling routes

Number of Local Static Routes Allowed: 30
Current number of Local Static Routes: 2

Address: 47.00.05.80.ff.e1.00.00.00.f2.07.2a.01.00.00.00.00.00.00.00
mask:152  cost:   0  node:self  port:A1.2 state:UP

Address: 47.00.05.80.ff.e1.00.00.00.f2.07.1b.02.00.00.00.00.00.00.00
mask:152  cost:   0  node:self  port:A1.1 state:UP
```

Figure 5-18. Screen output from the show signaling routes command

Check that the `Address` field (administered using the **admin signaling route add** command) matches those administered in DEFINITY.

3. If the A500 was administered using End System Identifiers, enter **show signaling esi** on the A500 console. Figure 5-19 shows the command output.

```
A500:show signaling esi
Addresses registered on A1.1
----------------------------
* 45.0001.01303538105300000000.000000000011.00

Addresses registered on A1.2
----------------------------
* 45.0001.01303538105300000000.000000000012.00

( * - configured )
```

Figure 5-19. Screen output A500: show signaling esi command

Check that the `Addresses registered` (use the **admin signaling esi add** command) match those administered in DEFINITY.

- If an address or End System Identifier is missing or incorrect on the A500 port associated with the PPN, the EAL and PACL links will come up, but one-way talk paths may result. (The ATM network can route from the PPN to the EPN, which creates the bidirectional EAL and PACL signaling channels and one side of the talk path.)
- If an address or End System Identifier is missing or incorrect on the A500 port associated with the EPN, the links will not come up between the PPN and the EPN.

4. Enter **show sys interfaces** on the A500 console. Figure 5-20 shows the screen output.

```
Device      Oper        Admin       State        Type
            Status      Status

```

Figure 5-20. A500 screen output for show sys interfaces command

- For each administered port used by a DEFINITY port network, the `Admin Status` should be up (using the **admin up** command).
- The state of `Oper Status` is not pertinent to administration of the A500 and is discussed in a later section.

- `State` should be `present`, indicating that A500 port board insertion was successful. If `State` is `invalid`, then the A500 believes that the corresponding port board slot is empty or the port board is not recognized.

  It may be necessary to re-administer the A500 port boards. Refer to the *Cajun A500 Quick Reference* for further information.

- If `Admin Status` or `State` is incorrect, the links will not come up between the PPN and the EPN.

TN230X

Did the TN230X come up correctly?

1. Review the LED conditions for the TN230X:
   - Do the TN230X LEDs (see Table 5-5) indicate a normal operational state (any of the following):
     — Active in the PPN
     — Standby in the PPN
     — Archangel mode in the EPN
     — Standby in the EPN?
2. If after board insertion or a demand reset:
   - Do the TN230X LEDs indicate that it is booting?
   - Do the TN230X LEDs indicate it is downloading its DSPs?
   - Do the TN230X LEDs indicate that board insertion has not yet occured?
   - Do the TN230X LEDs indicate a maintenance alarm?
3. Enter **list configuration carrier *cabinetcarrier*** on the DEFINITY SAT. See Figure 5-21 (1b) and Figure 5-22 (2a) below.

```
list configuration carrier 1b

                              SYSTEM CONFIGURATION

Figure 5-22. List configuration carrier 2a screen

- The TN230X board should be shown in the correct slot.
- Fields should have values as indicated below:

Field	Value
`Board Type`	`ATM PNC EI`
`Vintage`	The TN230X vintage. If `Vintage` is `no board`, then either the board is in the incorrect slot or board insertion was not completed correctly. Refer to ''Reseating and Replacing Circuit Packs'' in this chapter.

4. If the TN230X is inserted and shows a vintage number, enter **test board *cabinetcarrierslot*** for this board on the DEFINITY SAT, as shown in Figure 5-23 (1b02) and Figure 5-24 (2a01).

```
test board 1b02

                                  TEST RESULTS

  Port       Maintenance Name  Alt. Name Test No. Result              Error Code

  01B02      ATM-EI                      316      PASS
  01B02      ATM-EI                      598      PASS
  01B02      ATM-EI                      1258     PASS
  01B02      ATM-EI                      241      PASS
  01B02      ATM-EI                      304      PASS
  01B02      ATM-EI                      1259     PASS
```

Figure 5-23. Screen output for the test board 1b02 command

```
test board 2a01

                                  TEST RESULTS

  02A01      ATM-EI                      316      PASS
  02A01      ATM-EI                      598      PASS
  02A01      ATM-EI                      1258     PASS
  02A01      ATM-EI                      241      PASS
  02A01      ATM-EI                      304      PASS
  02A01      ATM-EI                      1259     PASS
```

Figure 5-24. Screen output for the test board 2a01 command

- The `Result` should be PASS for each test number. If the any of the tests fail, refer to "ATM-BCH (ATM B-Channel Trunk)" in Chapter 9.

Possible Causes

1. The TN230X board is in a slot different from the DEFINITY administration.
2. The TN230X did not complete board insertion.

Physical Layer

Is there an optical signal between the TN230X and the A500?

1. Does the TN230X's yellow LED flash 100ms on/100ms off, indicating a loss of signal on the fiber? Recall that the TN230X detects continuity problems with either the Transmit (bottom) or the Receive (top) fibers.

   If there is loss of signal on the fiber, refer to the "Fiber Fault Isolation Procedure" in this chapter.

2. Is the A500 port's CD LED off, indicating a loss of signal on the fiber? Note that the A500 detects continuity problems only with the Receive (right-hand) fiber; the state of the Transmit (left-hand) fiber is not detected.
3. Enter **show signaling summary** on the A500 console. Figure 5-25 shows the screen output.

```
A500:show signaling summary

Port     loc VCI    SAP    IntType     Signaling    ILMI   SAP State      State
------   -------    ---    -------    -----------   ----   ------------   -----
A1.1        1        1     Network    UNI3.1         No     UP             UP
A1.2        2        2     Network    UNI3.1         No     UP             UP
```

Figure 5-25. A500: show signaling summary screen

Ensure that the fields have the values indicated below.

`SAP State`	Up If it is `PHY_DOWN` or `DOWN`, then there is probably a loss of signal on the port in question. This command detects a continuity problem only with the Receive (right-hand) fiber; it does not detect the state of the Transmit (left-hand) fiber.
`State`	The value of may be `UP` or `DOWN`, depending on the administration of the port. It may be necessary to re-administer the A500 port boards. Refer to the *Cajun A500 Quick Reference* for further information.

4. Enter **show system interfaces** on the A500 console. Figure 5-26 shows an example of the screen output.

```
Device      Oper        Admin       State        Type
            Status      Status

```

Figure 5-26. A500: show sys interfaces

— `Oper Status` should be up. If it is down, there is likely a loss of signal on the port in question (`State` of `present`), or the A500 does not recognize the port board (`State` of `invalid`). This command detects a continuity problem only with the Receive (right-hand) fiber; it does not detect the state of the Transmit (left-hand) fiber.

Possible Causes

- The fiber is disconnected from the A500 and/or the TN230Xs.
- The Transmit and Receive fibers are swapped at the A500 or the TN230X (but not both).
- There is a break in the fiber.
- The TN230X is not transmitting a carrier (not inserted, not powered, or not administered). See "ATM-BCH (ATM B-Channel Trunk)".
- Hardware safety interlocks on optical transceivers may cut transmitter power if no carrier is received, so lack of a receive carrier could indicate a transmitter problem at the same end.
- The A500 does not recognize that there is a port board in the slot. It may be necessary to re-administer the A500 port boards. Refer to the *Cajun A500 Quick Reference* for further information.

Recommended Action

1. Plug in, swap, repair, or replace the fiber as necessary.
2. Verify that the port board is inserted.

SONET Layer

Are SONET frames reaching the A500?

Is the A500 port's green RX LED solid off, indicating no cell traffic?

1. Enter **show stats sonet *port*** on the A500 console. Figure 5-27 shows the screen output.

NOTE:
The following examples point to port A1.2 as the port of interest.

```
    Sonet per Port Statistics
---------------------------------

 Receive Cell Count:       80654
 Transmit Cell Count:      79555

 Section Level Bit Err:    1
 Line Bit Err:             1
 Line FEB Err:             168
 Path Bit Err:             1
 Path FEB Err:             98
 Correctable HCS Err:      0
 Uncorrectable HCS Err:    0
 Loss of Frame Err:        1
 Loss of Signal Err:       0
 Out of Frame Err:         0

 Path Signal Label:        19
```

Figure 5-27. A500: show stats sonet a1.2 screen

Ensure that the fields have the values indicated below.

`Receive Cell Count`	Each field's values should be increasing if the TN230X is actively sending and receiving cells with the A500. (Even if a TN230X did not achieve board insertion, it will still try to talk to the A500.)
`Transmit Cell Count`	If neither field is increasing, the A500 port may have been marked down using the **admin down** command. Use the **show system interfaces** command to verify that the `Admin Status` is up. If the `Receive Cell Count` is increasing but the `Transmit Cell Count` is not increasing, this may be because the port was administered with no UNI signaling (**admin link** command). Use the **show signaling summary** command to ensure that `Signaling` is `UNI3.1`. The error counters may not be zero, but should not be large either compared to the receive and transmit cell counters. If the counters are large and increasing, check the fiber integrity. Make sure the fiber pairs are securely plugged into both the TN230X and the A500. If the fiber has been pulled and reinserted as part of fault diagnosis, the non-zero `Loss of Signal Err` counter may be correct.

Q.SAAL (Data Link) Layer

Are ATM signaling messages reaching A500 Call Control?

1. Enter **show signaling stats *port* qsaal** on the A500 console. Figure 5-28 shows the screen output.

```
A500: show signaling stats a1.2 qsaal

------------------------Q.SAAL Statistics------------------------
Port A1.2:
----------
Type:  UNI3.1
VPI: 0x00, VCI: 0x05
                       Tx          Rx
                    --------    --------
BGN PDUs:                  0           1
BGAK PDUs:                 1           0
END PDUs:                  0           0
ENDAK PDUs:                0           0
RS PDUs:                   0           0
RSAK PDUs:                 0           0
BGREJ PDUs:                0           0
SD PDUs:                  81          78
SDP PDUs:           Supported only for UNI 3.0
ER PDUs:                   0           0
POLL PDUs:              6259        5720
STAT PDUs:              5720        6259
USTAT PDUs:                0           0
ERAK PDUs:                 0           0
Discarded PDUs:            0           0
Errored PDUs:              0           0
Buffers in use:            0           0
High buffer mark:          3           0
```

Figure 5-28. A500: show signaling stats a1.2 qsaal screen

NOTE:
If there is no connection between the TN230X and the A500 at the Q.SAAL protocol layer, then no report is displayed.

— If `Port A1.2` (or the port of interest) is `not configured for UNI signaling`, then the port was administered for no UNI signaling (**admin link** command). Use the **show signaling summary** command to verify that `Signaling` is `UNI3.1`.

— The `Supported only for UNI 3.0` line for the `SDP PDUs:` field means that the port was administered for UNI3.0 signaling (**admin link** command). Use the **show signaling summary** command to verify that `Signaling` is `UNI3.1`.

— The `POLL PDUs` and `STAT PDUs` counters should be increasing if the TN230X is actively sending and receiving Q.SAAL Protocol Data Units with the A500. This occurs even if the TN230X did not achieve board insertion.

Q.93B (Network) Layer

Are connection requests being received by A500 Call Control?

1. Enter **show signaling stats *port* q93b** (or the port of interest) on the A500 console. Figure 5-29 shows the screen output.

```
A500:show signaling stats a1.2 q93b

-------------------------Q.93B Statistics------------------------
Port A1.2:
----------
                       Tx          Rx

Current Connections:       3
```

Figure 5-29. A500:show signaling stats A1.2 q93b

NOTE:
If there is no connection between the TN230X and the A500 at the Q93B protocol layer, then no report displays.

Ensure that the fields have the values indicated below.

`Port A1.2` (or the port of interest)	If this field is `not configured for UNI signaling`, then the port was administered for no UNI signaling (**admin link** command). Use the **show signaling summary** command to verify that `Signaling` is `UNI3.1`.

`Connect Messages`
`Setup Messages`
`Release Messages`
	These counters should be non-zero if the A500 is handling Q.93B protocol layer messages sent by the PPN and EPN. They may not increase during troubleshooting unless calls are being made, since the PPN initially sets up control connections to the PPN and then sets up talk path connections as needed.

2. If connections are being rejected, the `Last Cause Code` may give a clue to why. The Cause Code (Table 5-7 below) indicating the error may be on the PPN port even though the EPN port is the one misbehaving, and vice versa.

   Enter **show signaling cause *causecode*** on the A500 console. Figure 5-30 shows the screen output for this command.

```
A500:show signaling cause 31

Cause 31: Normal, unspecified
```

Figure 5-30. A500:show signaling cause 31

3. At the DEFINITY SAT type **display errors** and press Enter.

   Set the `Error List` to **errors** and `Category` to **PNC** on the input screen (Figure 5-31) and press Enter to display any Cause Codes (see Table 5-7 below) returned from the ATM network to a TN230X on the PPN (and to a TN230X on an EPN). This is successful only if the links between the PPN and the EPN remain up so that the message from the EPN is logged.

   Refer to "ATM-BCH (ATM B-Channel Trunk)" in Chapter 9 for detailed information regarding Cause Codes for this Maintenance Object.

```
display errors                                          Page   1 of   1   SPE A

```

Figure 5-32. Screen output for display errors command

In this example the errors that have `ATM-NTWK` for `Name` and `1` for `Data` indicate an error returned to the TN230X from the ATM network. In this case, Type indicates the Cause Code returned by the ATM network (see Table 5-7 below). In the example above, two Cause Codes (41 and 3) are reported from the ATM network. For more information about these Cause Codes and repair information see "ATM-NTWK (ATM Network Error)" in Chapter 9.

Table 5-7. Observed Cause Codes

Cause Code	Definition	Observed Cause
3	No route to destination	The ATM addresses administered in the ATM switch (**show signaling routes** or **show signaling esi**) or in DEFINITY (**display atm pnc**) are incorrect.
31	Normal, unspecified	This is a normal return.
41	Temporary failure	This "try again later" Cause Code has been observed when the source of the problem is on another port (for example, a routing problem on another port that displays Cause Code 3).
47	Resources unavailable, unspecified	DEFINITY call volume is too high for the available resources in the ATM network.
63	Service or option unavailable, unspecified	DEFINITY call volume is too high for the available resources in the ATM network.

ATM Call Control

Are ATM signaling connections being setup to A500 Call Control?

1. Enter **show switch circuittable** on the A500 console. Figure 5-33 shows the screen output.

```
A500:show switch circuittable

Figure 5-33. A500: show switch circuittable screen

- The `pp UBR` virtual circuits between A500 ports `A1.1` (PPN) and `Self` (A500) and between `A1.2` (EPN) and `Self` (A500) are ATM signaling channels between the port network and the A500.
- They are used to request connection setups and releases to other end points such as another port network.
- These are established by each TN230X when it comes up, independent of DEFINITY Call Processing.
- Other UBR virtual circuits may exist between A500 ports that are not associated with DEFINITY port networks and may be signaling channels for other applications (for example, data network traffic).

CaPro Layer

Are control channels being established from the PPN to the EPN?

Diagnostics

- Do you get a dial tone on a set on the port network in question?
- Can you ring a set on the EPN dialing from the PPN and vice versa?

1. Enter **list sys-link** on the DEFINITY SAT. Figure 5-34 shows the screen output.

```
list sys-link

                               SYSTEM LINKS INFORMATION

Location   Link Type/    State   Current      Faulted     Last Fault
           Channel               Path         Path        Recorded

Figure 5-36. A500:show switch circuit screen

— The pmp CBR (Constant Bit Rate) virtual circuits (VCs) between A500 port A1.1 (PPN) and A500 port A1.2 (EPN) are used for talk paths between port networks (PPN to EPN, EPN to PPN, or EPN to EPN).

— They are established when calls are first setup between port networks. Each virtual circuit represents one party of a complete multiparty talk path.

— The report above shows one complete talk path: one unidirectional point-to-multipoint virtual circuit from A1.1 to A1.2, and another from A1.2 to A1.1.

— These virtual circuits may persist beyond the duration of a phone call. The DEFINITY Call Processing software saves virtual circuits for a few seconds after the end stations have hung up in case the VC can be used again for another call between the same two port networks.

— In early version of the Release 2 A500 firmware, these connections incorrectly identified as `pmp UBR`.

— There may be other CBR virtual circuits between A500 ports that are not associated with DEFINITY port networks. A common CBR application is Circuit Emulation, in which T-1, T-3, etc. circuits are carried over ATM.

Unusual ATM trouble conditions

There are a few failure modes in the DEFINITY/A500 combination that are particularly difficult to diagnose. One example might be that you can't make a completely successful call, even though most indications from DEFINITY and the A500 look pretty good. This section documents some hints and clues that may help diagnose the following failure modes:

- Incorrectly typed or omitted EPN Route or End System Identifier (A500)
- Swapped Routes, End System Identifiers, or Fiber between a PPN and an EPN
- Swapped Routes, End System Identifiers, or Fiber between A and B side TN230Xs on an EPN
- Swapped Routes, End System Identifiers, or Fiber between two EPNs

Incorrectly typed or omitted EPN Route or End System Identifier (A500)

Symptoms

Talk paths are one-way, from the PPN to the EPN: you can hear tones from the PPN end station to the EPN end station but not vice versa. Because the signaling channels are bidirectional virtual circuits (VCs) established from the PPN to the EPN, these can be routed correctly and come up just fine. Talk paths are two unidirectional virtual circuits, so a single call has one VC from the PPN to the EPN (which is routed correctly) and one VC from the EPN to the PPN (which cannot be routed).

Diagnostics

1. At the A500 use the **show signaling routes** or **show signaling esi** command(s) as appropriate to check the ATM addresses.
2. Use **show signaling stats *port* q93b** on the EPN port and look for Cause Code 3 (`No route to destination`).

Action

1. Correct the ATM address translations in the A500.

Swapped Routes, End System Identifiers, or Fiber between a PPN and an EPN

Symptoms

- An incorrectly-connected EPN TN230X does not complete board insertion.
- Dial tone is present on end stations on the PPN and on correctly-connected EPNs, but no dial tone is present on the affected EPN end stations.
- Calls cannot be made between the PPN and the correctly connected EPNs, because talk paths cannot be routed correctly.

Diagnostics

1. The **show switch circuittable** command on the A500 shows VBR control channels from the A500 port intended for the incorrectly-connected EPN (but actually connected logically or physically to the PPN) that should not exist.

Action

1. Correct the ATM addresses (or swap fibers) on the A500 between the incorrectly-connected PPN and EPN.

Swapped Routes, End System Identifiers, or Fiber between two EPNs

Symptoms

- All TN230Xs complete board insertion.
- The PPN cold starts both incorrectly connected EPNs as usual.
- Both EPNs log many `WRONG BOARD INSERTED` errors (use **list configuration all** or **display circuit-packs *<carrier>***) providing the EPNs actually do have different boards configured in the same slots.
- Some end stations may work if they are connected to the correct board in the same slot on both EPNs. Otherwise, end stations on the PPN have dial tone, while end stations on the EPNs do not.
- All A500 diagnostic commands look good.

Diagnostics

1. Check log for `WRONG BOARD INSERTED` errors (use **list configuration all** or **display circuit-packs *<carrier>***).

Action

1. Correct the ATM addresses (or swap fibers) on the A500 between the incorrectly connected EPNs.

Swapped Routes, End System Identifiers, or Fiber between A and B side TN230Xs on an EPN

Symptoms

- The PPN establishes links to what it thinks is the active TN230X on the EPN.
- As normal, it reboots this TN230X, and when complete, it resets the EPN. When this happens, the active (instead of the standby) TN230X reboots, dropping the links.
- To recover, the PPN re-establishes links to what it thinks is the active TN230X and the cycle repeats indefinitely.

Diagnostics

1. The **status pnc** command on the DEFINITY SAT shows both the A-side and B-side `State of Health` field as `partially functional`.

Action

1. Correct the ATM addresses (or swap fibers) on the A500 between the A and B side of the EPN.

Multimedia Call Handling (MMCH)

Expansion Services Module

The Expansion Services Module (ESM) provides T.120 data sharing capability on a MMCH multipoint H.320 video conference. Each conference participant must have endpoints administered and a personal computer with the H.320 video application installed. The DEFINITY ECS must have the expansion service module installed.

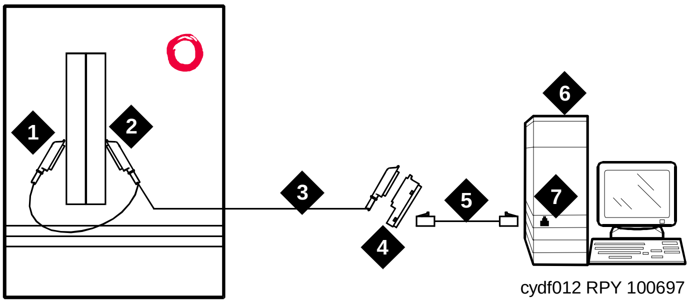

Figure Notes

1. Port B Y-cable connector to a TN787 Multimedia Interface (MMI) circuit pack
2. Port A Y-cable connector to a TN2207 PRI circuit pack
3. 25-pair Y-cable
4. 356A adapter
5. D8W cord connected to 356A adapter port 1
6. Expansion Service Module (ESM)
7. Port B on compatible primary rate interface (PRI) card

Figure 5-37. Typical ESM connections

CAUTION:
The TN2207 circuit pack is the only pack allowing connection of an ESM to the DEFINITY ECS switch.

Troubleshooting

Before troubleshooting any problems associated with the DEFINITY MMCH, always be sure that the endpoint is operating correctly (audio, video, and data) by making point-to-point test calls. If possible, make the test calls over the network to test the connectivity and routing of network calls from the endpoint. This eliminates problems such as disconnected audio or video cables and network troubles.

64 Kbps Calls Terminate but Far End Receives 56 Kbps Indication

Description

Some 2x64 Kbps conferences on the DEFINITY MMCH do not establish because of framing, audio, or video problems.

For calls that are routed in the network through a Lucent Technologies/LEC interface, the originating equipment may launch a 64 Kbps call attempt, and the far end receives either a 56 Kbps or 64 Kbps indication. If the far end receives a 64 Kbps indication, the call may have used 56 Kbps facilities. If so, the call may exhibit any of the following conditions:

- No handshaking in one direction or both (call disconnects after timeouts)
- Call connects, but audio or video is corrupted (audio noise or no video)
- Call succeeds without disruption (this is the least likely since one endpoint must be aware that the call is really 56 Kbps to connect)

If any of the above conditions occur, then 64 Kbps calls from the site are blocked.

Solution

Administer the conference for connection at 56 Kbps.

Calls Terminate with No Audio

Description

To support endpoints that do not support Multipoint Command Conference (MCC), the DEFINITY MMCH changes its capability set and initiates a capability set exchange with the endpoint when the Selected Communications Mode (SCM) changes. If the endpoint does not follow the SCM audio mode, the MCU may include the endpoint as a secondary (audio only) endpoint. If the endpoint sends an unknown or unsupported audio mode, then the TN788B decoder port mutes the endpoint from the conference. The user may hear the conference but may not be heard by other parties in the conference.

Solution

1. Use the Status Conference x form and check the Audio Mode field for the current operating mode of the conference.
2. Another indication of the audio modes is in the “Incoming Mode Commands from Endpoint and Outgoing Commands from MMI” on page 3 of the Status Conference x Endpoint y form. Check the `Audio` fields under the Mode Commands/Communication Modes section of the form.

Some Parties Cannot Be Heard by Others (Audio Subsetting)

Description

Problems where varying subsets of the conference hear different things may have problems with the various summing resources/groups that are in use. Traditionally theses faults are caused by the SPE not cleaning up the connections properly. Isolation and diagnosis should focus on the VC resources in use by that conference.

Solution

1. Use the **status conference** command to list the VC resources in use by this conference. Try a hot replacement of any VC boards in use, which refreshes the VC translations and move all of the audio connections to different VC ports.
2. If the problem still exists, try dropping the conference and then bringing the conference back up again. Not only does this refresh VC translations, but uses different timeslots as well.
3. If the problem still exists, suspect a hardware problem. If practical, wait for the DEFINITY MMCH to be idle (no active conferences), and then check the circuit packs for active (yellow) LEDs. If any of these are unexpected, such as on a VC board, try replacing the board and then bringing the conference up again.

Calls Terminate with No Video

Description

Generally, loss of video can be divided into 2 types. The first occurs when the DEFINITY MMCH switches to the endpoint, but nobody sees them. The receivers see either “black” video or a frozen image of the previous speaker depending on the codec of the manufacturer. The type occurs when the DEFINITY MMCH does not switch to an endpoint.

Solution

In the first type described above, wiring problems, power to the camera, or video encoder circuit pack problems in the codec are typical causes.

In the second type, no video from an endpoint typically occurs because it is not a valid video source. This can be checked by looking at page 1 of the Status Conference x Endpoint y Vid form under the Capability section. In this section, a “y” or “c” suggests that the endpoint has video. An “e” means ept has not declared any video capability in cap set, “n” is audio only, and “blank” means audio add-on.

Also check page 1 of the Status Conference x Endpoint y Vs form for indication of the video state for the endpoint values.

Calls Terminate Correctly but Are Unstable

A number of conditions will lead to some or all endpoints having stability problems during the course of a conference. A lack of stability from an endpoint is noticeable by a lack of a video switching while the party is the only talker or excessive disconnects from that endpoint.

Synchronization

Generally, the most common problem is a mismatch in synchronization sources between the endpoint and the DEFINITY MMCH. This typically causes low-level (Px64) handshake problems that can trigger the endpoint/MMCH to disconnect the call. The MCCH's timers are set to sufficiently high values so that, normally, the endpoint will timeout and disconnect first. If installed in a customer network, it is a good idea to perform an audit of the path synchronization is being supplied. If there are different clock sources between endpoints and the DEFINITY MMCH, some problems are sure to occur. The severity of these problems can range from a handshake failure every few seconds to one per day. Depending on the type of endpoint, this can cause the endpoint to disconnect or just freeze video until the main problem is resolved.

Specifically, PictureTel System 4000 endpoints seem to be the most sensitive to instability. The Lucent Technologies Vistium also disconnects fairly infrequently. Last, the CLI Rembrandt II VP freezes video and waits for framing to be recovered.

Network Configuration Concerns with Synchronization

When auditing a network for synchronization, avoid unnecessary hops. Thus, a switch providing star-configuration synchronization is preferred over a daisy-chain configuration. Additionally, if there are DEFINITY PBXs that have EPNs, synchronization should be provided to sub nodes from the same port network through which the PBX receives its synchronization. Passing synchronization through the PBX Expansion Interface adds an unnecessary hop to the path and creates another potential point of failure.

Expansion Interface Duplication

If a customer's network uses PBX EPNs with duplicated Expansion Interfaces, scheduled switching of the Expansion Interface links should be disabled on the PBX via **change system-parameters maintenance**. When scheduled maintenance runs and switches the links, there is a brief corruption of the data path. If endpoints have active calls when the switch occurs, this corruption of the data path causes Px64 handshake problems, which lead to the endpoints losing video source status, and sometimes disconnecting as described above. Disabling the EI switching is in the customer's best interest to prevent the disruption of the Px64 data stream. The customer will get the same level of alarm indications and maintenance on the EI links, regardless of the status of scheduled switching.

PRI D-Channel Backup

A somewhat unlikely source of call stability problems occur where the translations for PRI D-channel Backup between two non-MCU switches were incorrect. As an example, on switch A, DS1 1A10 was designated as the primary source, and on switch B, the corresponding DS1 was designated as the secondary source. When scheduled maintenance was run on the switch that had an active standby D-channel, an audit disconnected some calls using the link. The problem was corrected when the the D-channel primary/secondary assignments matched.

Processor Duplication on the PBX

Do not enable the PI link switch on scheduled maintenance. This can cause link stability problems on the Accunet Bandwidth Controller (ABC).

Voice-Activated Switching Problems

Voice-activated switching on the DEFINITY MMCH does not follow the loudest talker. The MMCH queues all speaking parties and selects a new video broadcaster (the second-oldest speaking party) when the oldest speaking party has stopped talking. The new broadcaster will see the last speaker as its video. The system can also “learn” about the noise coming from an endpoint to help prevent false switches, adapting both to noise level and repetitive sounds such as a fan. This adaptation occurs over approximately 10 seconds.

No Switching, Full Motion Video

If a room is excessively noisy, the DEFINITY MMCH may receive sufficient audio signal to conclude that there is a speaker present. Use the Status Conference x form to determine if the MMCH thinks an endpoint is talking. The MMCH sets the `Ts` field to `t` for each endpoint if there is voice energy detected. This endpoint may have to mute when nobody at the site is speaking to allow the conference to proceed normally. Remind the customer that it may be necessary to mute if a side conversation is going on in the background, just as one would do in an audio conference. If the system does not switch broadcasters even after the current broadcaster has muted, check the conference administration using the **display conference X** command to ensure that the conference is in voice-activated mode. Also verify that parties who were speaking are valid video sources as described in the “Calls Terminate with No Video” section above.

The See-Me feature (MCV) can also cause VAS to “lock-up.” An endpoint can activate MCV to force their site to become the broadcaster. If they do not disable the feature when finished, the system remains in this mode indefinitely. Beginning with Release 3.0, the **status conference X** command shows that MCV is in effect by displaying `av` in the Video Status (Vs) column. Page 3 of the Status Conference X Endpoint Y form also has a `Broadcaster` field that indicates MCV is in effect with (SEE-ME) as the broadcaster. The same scenario can occur in a CHAIR or UCC-controlled conference with a designated broadcaster. In this situation the CHAIR/UCC has not released the designated broadcaster and returned to VAS mode. If there is a UCC-designated broadcaster, **status conference X** indicates a Video Status of u. Also, for UCC rollcall the return video may appear to be stuck. Check the Video Status for an "R," indicating rollcall.

If none of the examples above appears to be the cause, and if the room was quiet, all speakers are valid video sources, the conference is voice-activated, and the speaker can be heard, then escalate the problem.

Video Never Switches to a Particular Party

Description

Verify that the endpoint is a valid video source as described in the "Calls Terminate with No Video" section above. If it is, then the audio from the endpoint may not have sufficient voice signal for the hardware to determine the parties at the endpoint are speaking. Check the `Talk` field on page three of the Status Conference X Endpoint Y form to see if the `talking bit` is y. Next, check the audio by standing adjacent to the microphone and speaking at a normal level.

Solution

If the audio is not muffled:

1. Use the **status conference** command to determine which port on the TN788B (VC board) is connected to this endpoint.
2. Check the VC (TN788B) board using the **test board xxyy long** command.
3. Drop the call.
4. Find another available port, then:
   a. Busyout the port to which the endpoint was connected.
   b. Make another call to the same conference. If the problem corrects itself, then the previous port may be bad. If there are other VC boards with sufficient available ports to replace calls on the current VC, then pull the board that has the bad endpoint on it (the **status conference** command displays the encoder port associated with the call). The system will automatically reestablish the VC connections without dropping the call. If this fixes the problem, then replace the board, as it has at least one bad port. Reseating the board may temporarily fix the problem due to the hard reset done to the board.

Audio Echo

Echo in conference calls, particularly those with large delay characteristics, is totally disruptive. When Voice Activated Switching is taken into account, the effects are disastrous. Various arrangements of the microphone(s) and room speaker(s) may be needed.

For some Lucent Technologies Vistium endpoints, if an external speaker is attached or was attached when the system was last rebooted, this endpoint will cause audio echo throughout the conference. First, isolate the offending endpoint by asking each endpoint to mute, one at a time, until the echo disappears.

If the input from an endpoint is located too close to the speakers of an endpoint, then acoustic echo is created. The microphone must be moved away from the speakers.

Normally, if any microphone in the room is moved relative to the speakers, that site will cause echo until the echo canceller in the codec retrains itself, some will require a manual reset. If a PictureTel keypad is configured with external microphones connected to the keypad, then the internal microphone and external microphone(s) “sing” to each other if the “ext mic” bat switch is set to “int mic” on the back of the keypad. In this configuration, VAS locked on that site, and the acoustic “singing” was inaudible.

Rate Adaptation

Because of a lack of a clear explanation in standards, sometimes endpoints do not work well with each other and the DEFINITY MMCH. The MMCH will only allow a conference to downgrade from 64kbps to 56 kbps operation on conferences that have the `Rate Adaptation` flag set to y.

When a downgrade does occur, information on the Status Conference form indicates the success or failure of the 64kbps-endpoints that are participants to properly rate adapt to 56kbps. As a general indication that the conference has rate adapted, the `Conference Transfer Rate` and `Effective Transfer Rate` fields show initial and current transfer rates, respectively. For each 64-kbps endpoint the column that indicates `Rate Adapt` shows an n if the endpoint did not follow the procedures as specified by the H.221. If an endpoint shows y, it did successfully rate adapt. If an endpoint shows c, it joined the conference at 56kbps.

Once the conference rate adapts, the endpoints that do not properly follow suit, will become audio-only endpoints. A conference will not rate adapt from 56 kbps back to 64 kbps until all endpoints disconnect from the conference and it idles.

The PictureTel 1000 Release 1.1C, PictureTel 6.01 software, and the Vistium 2.0 software successfully rate adapt with the MCU. External rate adaptation techniques used by VTEL and CLI are known to cause problems with the endpoint when used with this feature.

Endpoint or I-MUX in Loopback Mode

Some endpoints have a loopback enable feature. This makes DEFINITY MMCH data loopback at the MMCH when a connection is in progress. The loopback can be enabled prior to or during a connection.

The MMCH does not detect the loop and continues to VAS. In most scenarios, the switch occurs, but within a few seconds, the broadcaster's return video becomes its own image. Once the broadcaster stops speaking, the system "false" switches to an apparently random port that was not speaking.

Troubleshooting ISDN-PRI Problems

The following flow chart defines a layered approach when troubleshooting ISDN-PRI problems. Since a problem at a lower layer affects upper layers, layers are investigated from low to high. In the flowchart, the DS1 facility is layer 1, the ISDN-PRI D-channel is layer 2, and the ISDN trunks are layer 3. Transient problems are diagnosed on Page 2 of the flowchart. For problems with PRI endpoints (wideband), see the following section.

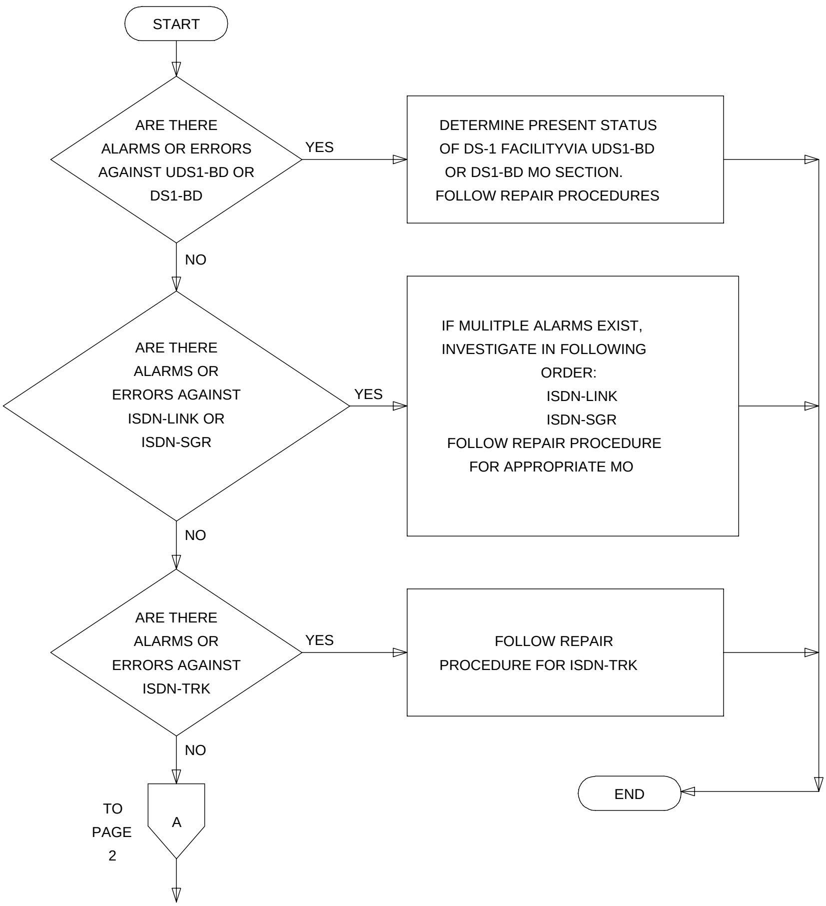

Figure 5-38. Troubleshooting ISDN-PRI (Page 1 of 2)

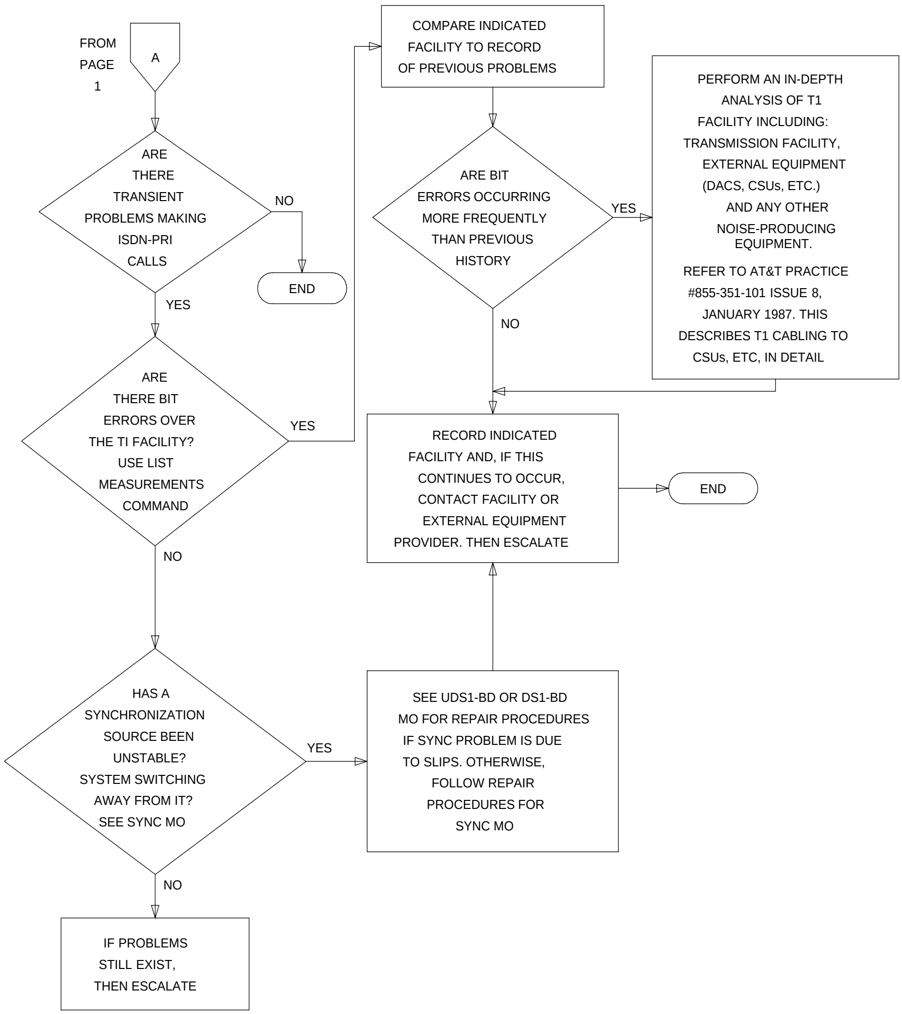

Figure 5-39. Troubleshooting ISDN-PRI (Page 2 of 2)

Troubleshooting ISDN-PRI Endpoints (Wideband)

The following flow chart defines a layered approach when troubleshooting PRI endpoint problems. Because problems at lower layers affect upper layers, layers are investigated from low to high. In this procedure, the DS1 facility is layer 1, the TN1655 Packet Interface is layer 2, and the PRI endpoint ports are layer 3.

The troubleshooting procedure described here is limited to diagnosing faults between the switch and the line-side PRI terminal adapter or ISDN-PRI endpoint equipment. Problems encountered on the network-side of a wideband connection or problems with end-to-end equipment compatibility are beyond the scope of this section.

Are there alarms or errors against any of the following maintenance objects: UDS1-BD PKT-INT SYS-LINK ISDN-LNK ISDN-SGR PE-BCHL	YES →	Resolve those alarms or errors in the order listed at left by following procedures for the appropriate maintenance object in Chapter 9.
↓ NO		
Check out the status of the endpoint equipment or Terminal Adaptor. Do this at the endpoint, not at the G3-MT on the switch. Does the adaptor or endpoint indicate problems?	YES →	Follow repair procedures recommended by the provider of the Terminal Adapter or endpoint equipment.
↓ NO		
Check administration at the endpoint and on the switch (for example, port boundary width). Are they inconsistent?	YES →	Correct the administration so that both ends match.
↓ NO		
Does every call fail or are the failures transient? ↓ Transient Failures	Always Fails →	Check the health of the application equipment (for example, the video codec) and that of the DEFINITY network. If constant failures persist, follow normal escalation procedures.
Use **list measurements ds1** to check for bit errors over the DS1 interface between the switch and the terminal adapter or endpoint equipment. ↓ No bit errors	Bit Errors →	Perform an in-depth analysis of the DS1 interface including premises distribution wiring, endpoint equipment, and any other possible source of noise. If the problem cannot be isolated, follow normal escalation procedures.

Check for alarms and errors against SYNC. Has a synchronization source been unstable? Has the system switched synch sources?	YES →	Follow procedures described in SYNC in Chapter 9.

↓ NO

Follow normal escalation procedures.

Troubleshooting ISDN-BRI/ASAI Problems

Troubleshooting ISDN-BRI/ASAI problems can be a complex and involved procedure. The reason for this is that ISDN-BRI devices communicate with the SPE over the Packet Bus, as opposed to the TDM Bus. Therefore, it is possible for failures of other Packet Bus-related system components to cause problems with ISDN-BRI devices. Figure 5-40 shows the connectivity of the Packet Bus as it applies to ISDN-BRI signaling.

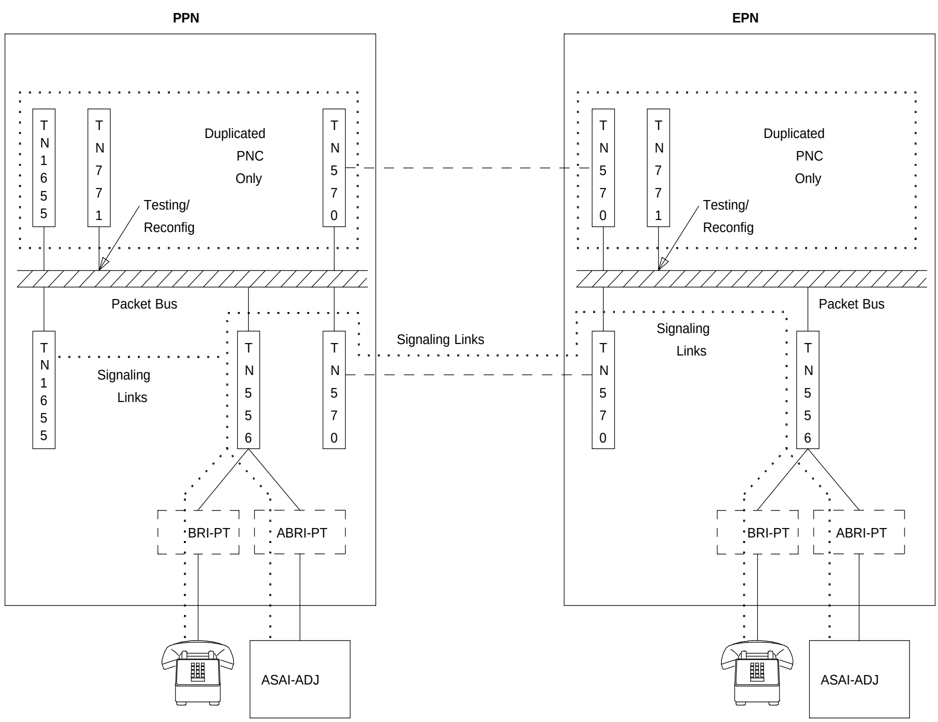

Figure 5-40. ISDN-BRI/Packet Bus Connectivity

The flowchart in Figure 5-41 describes the steps needed to isolate and resolve ISDN-BRI problems. The order in which you should examine the maintenance objects is determined by looking at how widespread the failure is. For example, since all ISDN-BRI devices communicate with the TN1655 Packet Interface circuit pack, this MO should be examined early in the sequence. On the other hand, a failure of an Expansion Interface (TN570) circuit pack may cause ISDN-BRI failure in an EPN, but could not be the cause of a failure in the PPN.

NOTE:
If the flowchart query ‘‘Is the problem affecting MOs on multiple BRI-BD circuit packs?’’ is reached and the port network in question has only one ISDN-BRI circuit pack, then assume that the answer is ‘‘Yes’’ and follow the repair procedure for PKT-BUS.

When directed by the flowchart to refer to the Maintenance documentation for a specific MO, keep in mind that the repair procedure for that MO may refer you to another MO’s repair procedure. The flowchart tries to coordinate these activities so that a logical flow is maintained if the ISDN-BRI problems are not resolved with the first set of repair procedures.

These following **status** commands may also be useful when diagnosing ISDN-BRI problems:

- **status port-network**
- **status packet-interface**
- **status bri-port**
- **status station**
- **status data-module**

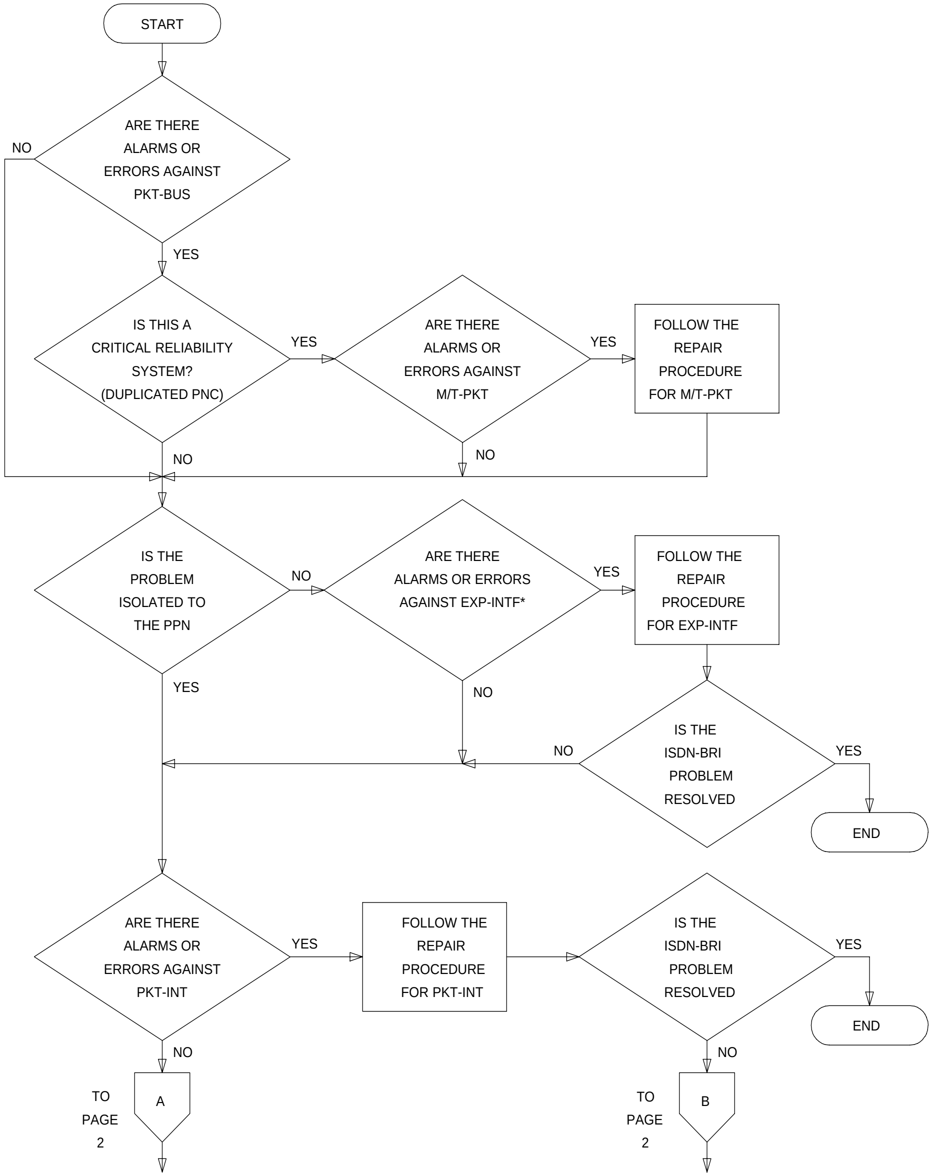

Figure 5-41. Troubleshooting ISDN-BRI Problems (Page 1 of 2)

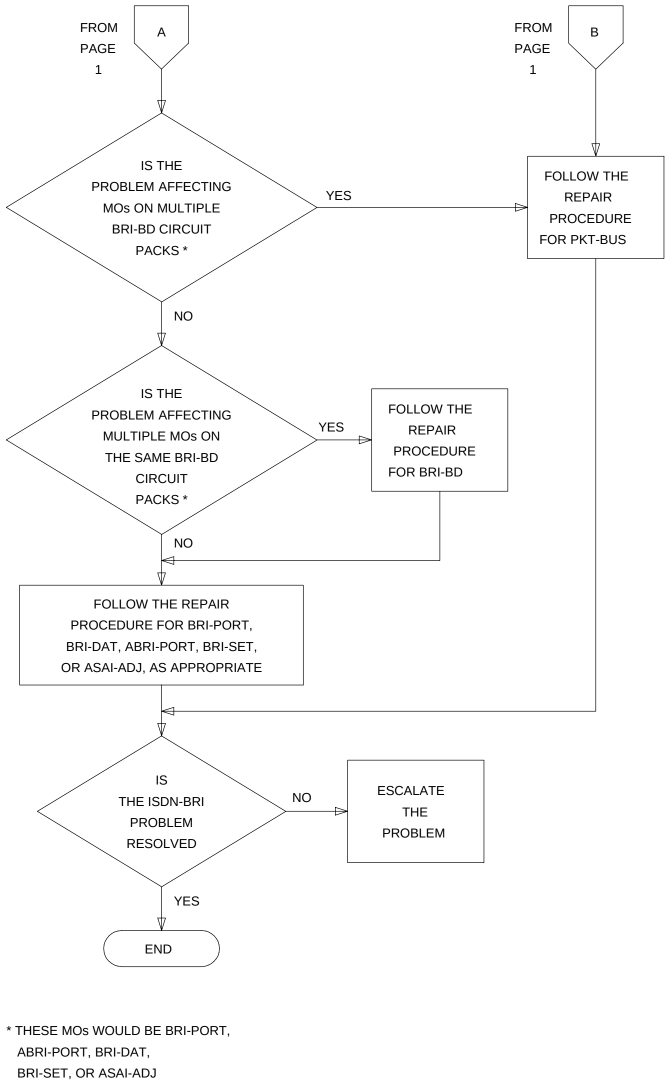

Figure 5-42. Troubleshooting ISDN-BRI Problems (Page 2 of 2)

Troubleshooting ISDN-PRI Test Call Problems

An ISDN-PRI test call is placed across an ISDN-PRI user-network interface to a previously designated number in order to test ISDN capabilities of the switch, the trunk and the far end. An ISDN-PRI test call is also a maintenance procedure concerned with the identification and verification ISDN-PRI user-network interface problems. The ISDN-PRI test call can access ISDN-PRI trunks only.

An ISDN-PRI test call can be placed only if the circuit translates to an ISDN-PRI trunk. An ISDN-PRI test call can be originated via either the *synchronous* or the *asynchronous* method. Each method is described below.

NOTE:
Before attempting to make an ISDN-PRI test call to the public network (the far-end), make sure that test call service is provisioned by the network. The user must subscribe to Test Type 108 service and have the correct far-end test call number administered on the trunk group form for the call to be allowed.

Synchronous Method

One command is used in this method to start, stop and query an ISDN-PRI test call. In the synchronous method, an outgoing ISDN-PRI test call may be part of one of the following *long* test sequences entered at the terminal:

- **test trunk grp/mbr long [repeat #]**
- **test port UUCSSpp long [repeat #]**
- **test board UUCSS long [repeat #]**

The **long** qualifier must be entered in the above commands in order for the ISDN test call to run. The repeat number (#) can be any number from 1 through 99 (default = 1).

The following information is displayed in response to the above commands:

- Port: The port address (UUCSSpp) is the port network number, carrier designation, slot, and circuit of the maintenance object under test.
- Maintenance Name: The type of maintenance object tested.
- Test Number: The actual test that was run.
- Test Results: Indicates whether the test passes, fails, or aborts.
- Error Code: Additional information about the results of the test (See the ISDN-TRK section of Chapter 9 for details.

Asynchronous Method

The asynchronous method requires a Maintenance/Test circuit pack to be present in the system. In this method, 4 commands are used to start, stop, query, and list an outgoing ISDN-PRI test call:

Start:	**test isdn-testcall grp/mbr[minutes]**
Stop:	**clear isdn-testcall grp/mbr**
List:	**list isdn-testcall**
Query:	**status isdn-testcall <grp>/<mbr>**

Before placing an outgoing ISDN-PRI test call, verify that the Feature Access Code has been administered on the System Features Form, and that the Far End Test Line Number and TestCall Bearer Capability Class (BCC) have been administered on the Trunk Group Administration Form. Furthermore, if the ISDN-PRI trunk is of the cbc (call by call) service type, then the Testcall Service field on Trunk Group Administration Form must have been administered also.

To initiate an outgoing ISDN-PRI test call with the asynchronous method, issue the start command listed above, which enables you to specify a specific the trunk on which to originate the ISDN-PRI test call. An optional qualifier can be used that specifies in minutes (1 to 120) the duration of the test call. If no duration is specified, the default is either 8.4 or 9.6 seconds.

Screen 5-1 shows a typical response to the **test isdn-testcall** command:

```
test isdn-testcall

Port     Maintenance Name    Test Number    Test Result  Error Code
1B1501   ISDN-TRK              258            PASS
```

Screen 5-1. Test ISDN-TestCall Response

The displayed fields have the following meanings:

`Port`	The port address (UUCSSpp) is the port network number, carrier designation, slot, and circuit of the maintenance object under test.
`Maint. Name`	The type of maintenance object tested.
`Test Number`	The actual test that was run.
`Test Results`	Indicates whether the test passes, fails, or aborts.
`Error Code`	Additional information about the results of the test (See the ISDN-TRK section in Chapter 9 for details).

The functions of the **clear**, **list**, and **status** commands associated with the ISDN Testcall are summarized below.

clear isdn-testcall: enables you to cancel an in-progress ISDN-PRI test call and allow another test call to start.

list isdn-testcall: enables you to list all the ISDN-PRI trunks in use for an ISDN-PRI test call in the system.

status isdn-testcall: enables you to check on the progress of an outgoing test call. When an outgoing ISDN-PRI test call completes in a specific port network, another ISDN-PRI trunk from the same port network is available for testing (regardless of whether the **status** information has been displayed).

Troubleshooting the Outgoing ISDN-Testcall Command

If the TestCall BCC field appears on the Trunk Group Administration Form, make sure the TestCall BCC field indicates the correct BCC for the service provisioned on the ISDN-PRI trunk. The TestCall BCC values are defined as follows:

`0`	Voice
1	Digital Communications Protocol Mode 1
2	Mode 2 Asynchronous
3	Mode 3 Circuit
4	Digital Communications Protocol Mode 0 (that is usually the default).

If the ISDN-PRI trunk is of type `cbc` make sure the TestCall Service field on the Trunk Group Administration Form indicates the correct service so that a network facility message can be sent across the ISDN-PRI network.

If the outgoing ISDN-PRI test call keeps aborting, make sure that the far-end device can handle DCP Mode 0 or DCP Mode 1.

NOTE:
Before attempting to make an ISDN-PRI test call to the public network (that is, the network is the far-end), make sure that test call service is provisioned by the network. The user must subscribe to Test Type 108 service and have the correct far-end test call number administered on the trunk group form for the call to be allowed.

Packet Bus Fault Isolation and Repair

The following procedures provide a means of isolating and correcting faults on both the packet bus and the various maintenance objects that use the packet bus. The packet bus is shared by all circuit packs that communicate on it, and a fault on one of those can disrupt communications over the packet bus. Furthermore, a circuit pack that does not use the packet bus can also cause service disruptions by impinging on the backplane or otherwise modifying the configuration of the bus. (this is discussed in more detail later). For these reasons, isolating the cause of packet bus failure can be complicated. This discussion provides a flowchart and descriptions of the tools and procedures used to isolate and correct packet bus faults.

This discussion is organized into the following sections which provide background information and troubleshooting procedures. The Packet Bus Fault Isolation Flowchart is intended to be the normal starting point for isolating and resolving packet bus problems. Before using it you should familiarize yourself with packet bus maintenance by reading the introductory sections.

- "Remote Maintenance versus On-Site Maintenance"discusses the strategy and the requirements for performing remote maintenance and on-site maintenance for the packet bus.
- "Tools for Packet Bus Fault Isolation and Correction" discusses the tools that are needed to isolate and correct packet bus faults.
- "What is the Packet Bus?" describes the packet bus, its use in G3r, and the types of faults that can occur on the packet bus. A diagram shows the physical and logical connections between circuit packs connected to the packet bus.
- "Circuit Packs That Use the Packet Bus" describes the various circuit packs, ports, and endpoints that use the packet bus. The section discusses how these maintenance objects interact, how a failure of one maintenance object can affect another, and failure symptoms of these maintenance objects.
- "Maintenance of the Packet Bus" describes the strategy of maintenance software for packet bus. Similarities and differences between the packet bus and the TDM Bus are discussed. An overview of the Fault Isolation and Correction Procedures is also presented.
- "The Maintenance/Test Circuit Pack (TN771)" discusses the use of the Maintenance/Test circuit pack in both packet bus fault isolation and other switch maintenance. The standalone mode of the Maintenance/Test circuit pack, which is used to perform on-site packet bus fault isolation and correction, is discussed in detail.

- "Packet Bus Fault Isolation Flowchart" is the starting point for the troubleshooting process. It is used to determine if a failure of service is caused by the packet bus itself or by another maintenance object on the packet bus.
- "Correcting Packet Bus Faults" presents the procedures required to correct either a problem with the packet bus itself or one that is caused by a circuit pack connected to the Packet Bus.

Remote Maintenance versus On-Site Maintenance

Most packet bus fault isolation and repair procedures require a technician to be on-site. This is because a packet bus failures are caused by a hardware failure of either the packet bus itself or a circuit pack that is connected to it. Initial diagnoses can be made via use of the Packet Bus Fault Isolation Flowchart, but the Maintenance/Test Standalone Mode Procedure and the Packet Bus Fault Correction Procedure require that a technician be on-site. These procedures are presented with this requirement in mind.

The flowchart refers to the repair procedures in Chapter 9, "Maintenance Object Repair Procedures" for various maintenance objects. When a decision point is reached, a remotely located technician can refer to the appropriate section and attempt to resolve any fault conditions. Some procedures require on-site repair action. Keep in mind that failure of a maintenance object appearing early in the flowchart can cause alarms with maintenance objects that appear later in the flowchart. Multiple dispatches can be prevented by remotely checking subsequent stages on the flowchart and preparing the on-site technician for replacement of several components if necessary.

The Maintenance/Test packet bus port described below provides status information that is accessed with the **status port-network P** command and the PKT-BUS test sequence. The Maintenance/Test circuit pack may or may not be present at a customer site, depending on the configuration of the switch. If a Maintenance/Test circuit pack is not present, one must be taken to the site for diagnosing packet bus problems.

In a system with duplicated SPEs, an SPE interchange may resolve the packet bus problem. This operation can be executed remotely, and is discussed in *Packet Bus Fault Correction Procedures* below.

Tools for Packet Bus Fault Isolation and Correction

The following tools may be required on-site to perform packet bus fault isolation and correction.

- TN771D Maintenance/Test circuit pack for use in standalone mode, and the connectors and cables necessary to install it (see the *Maintenance/Test Circuit Pack* section).
- A replacement for the TN771D Maintenance/Test circuit pack in the system may be needed. See the *A Special Precaution Concerning the TN771D* section.
- A backplane pin-replacement kit may be required (see *Packet Bus Fault Correction*) If the kit is not available, replacement of a carrier may be required.

What is the Packet Bus?

The packet bus is a set of 24 leads in the backplane of each Port Network. Twenty of these leads are data leads, three are control leads, and one lead is a spare. This distinction is important only for understanding why some circuit packs are able to detect only certain faults; the distinction does not affect fault isolation and repair. Each Port Network has its own packet bus and there is one packet bus maintenance object (PKT-BUS) in each port network. The packet bus is not duplicated as is the TDM Bus. There are however several spare leads on the packet bus and, in Critical Reliability systems (duplicated PNC), these spare leads are used to recover from some failures on the packet bus.

The packet bus carries various types of information:

- Signaling and data traffic destined for other port-networks and/or Center Stage Switches. The TN570 Expansion Interface circuit pack provides packet bus access for these connections.
- ISDN-BRI signaling information for ISDN-BRI stations, data modules and ASAI adjunct connections. The TN556 ISDN-BRI circuit pack provides packet bus access for these connections.
- X.25 signaling information and data traffic to support system adjunct applications. The TN577 Packet Gateway circuit pack provides packet bus access for these connections.
- ISDN-PRI signaling information carried in the D-channels of ISDN-PRI facilities connected to the switch. The TN464F Universal DS1 circuit pack provides packet bus access for these connections.
- System Port traffic to support various input/output devices such as dial-up modems and printers, as well as system adjunct applications. The TN553 Packet Data circuit pack provides packet bus access for these connections.

The SPE interface to the packet bus is the TN1655 Packet Interface circuit pack. When SPEs are duplicated, there is one TN1655 in each SPE. The TN771D Maintenance/Test Circuit Pack (discussed in detail later) provides packet bus maintenance testing and reconfiguration capabilities.

Packet Bus Faults

Two types of packet bus faults occur:

Shorts — A short occurs when different leads on the packet bus become electrically connected to each other. This can occur due to failures of circuit packs, cables between carriers, TDM/LAN terminators, or bent pins on the backplane. A fault occurring during normal operation is usually caused by a circuit pack. A fault that occurs while moving circuit packs or otherwise modifying the switch is usually due to bent pins on the backplane.

Opens — An open occurs when there is a break on the packet bus such that the electrical path to the termination resistors is interrupted. Usually, this break is caused by a failed TDM/LAN cable or terminator. A less likely possibility is a failure in the backplane of a carrier.

Shorts are far more common than opens, since they can be caused by incorrect insertion of a circuit pack. It is possible for a circuit pack to be the cause of a packet bus fault but still operate trouble-free itself. For example, the insertion of a TDM-only circuit pack such as a TN754 Digital Line could bend the packet bus pins on the backplane, but remain unaffected since it does not communicate over the packet bus.

Packet bus faults do not necessarily cause service interruptions, but shorts on it usually do. Depending on what leads are defective, the system may be able to recover and continue to communicate. While this allows uninterrupted service, it makes isolating the fault difficult. The Maintenance/Test circuit pack provides the capability to detect, and, in some cases, correct packet bus faults.

Packet Bus Connectivity

Various circuit packs communicate on the packet bus (see the next section). For more details, refer to Chapter 9, ‘‘Maintenance Object Repair Procedures’’ for the following circuit packs:

- TN1655 Packet Interface: PKT-INTF
- TN570 Expansion Interface: EXP-INTF
- TN556 ISDN-BRI: BRI-BD, BRI-PORT, ABRI-PORT, BRI-SET, BRI-DAT, ASAI-ADJ
- TN577 Packet Gateway: PGATE-BD, PGATE-PT
- TN553 Packet Data: PDATA-BD, PDATA-PT
- TN464F Universal DS1: UDS1-BD, ISDN-LNK

- TN771D Maintenance/Test: M/T-BD, M/T-DIG, M/T-PKT

Circuit Packs That Use the Packet Bus

This section describes the circuit packs that use the packet bus and the effects of circuit pack and bus failures on each other.

Seven circuit packs can use the packet bus: The maintenance objects pertaining to each circuit pack, (described further in Chapter 9), are listed in brackets.

- **TN1655 Packet Interface** [PKT-INTF] provides the SPE interface to the packet bus (as the UN332 MSSNET does to the TDM Bus). All traffic on the packet bus passes through the Packet Interface. The Packet Interface can detect some control lead failures and many data lead failures via parity errors on received data.
- **TN570 Expansion Interface** [EXP-INTF] connects the Port Networks (PNs) in the system. (Only TN570s can be used in Release 5r). All Packet traffic between PNs passes through a pair of TN570s (one in each port network). The Expansion Interface can detect some control lead failures, and many data lead failures via parity errors on received data.
- **TN556, TN2198, and TN2208 ISDN-BRI circuit packs** [BRI-BD, BRI-PORT, ABRI-PORT, BRI-SET, BRI-DAT, ASAI-ADJ] carries signaling information for ISDN-BRI station sets and data modules, as well as signaling information and ASAI messages between the SPE and an ASAI adjunct. The ISDN-BRI circuit pack has the same fault detection capabilities as the TN570 Expansion Interface.
- **TN577 Packet Gateway circuit pack** [PGATE-BD, PGATE-PT] provides X.25 connectivity to support external system adjuncts such as Audix® and DCS. The packet bus carries both signaling and customer traffic. The Packet Gateway circuit pack has the same fault detection capabilities as the TN570 Expansion Interface.
- **TN553 Packet Data circuit pack** [PDATA-BD, PDATA-PT] connects via a backplane cable to a TN726B Data Line circuit pack in an adjacent carrier slot. Together, the two circuit packs perform a protocol conversion from mode 3 packet bus traffic originating in the SPE to mode 2 TDM Bus traffic destined for external system devices and adjuncts. This connectivity is referred to as a *System Port*. System Ports support devices and adjuncts such as the System Printer, the PMS Journal Printer, the PMS Wakeup Log Printer, data terminals, remote administration terminals, and equipment to support the Call Detail Recording (CDR) feature. System Ports are also used for saving and restoring System Announcements. The packet bus carries both signaling and data for the Packet Data circuit pack. The Packet Data circuit pack has the same fault detection capabilities as the TN570 Expansion Interface.

- **TN464F Universal DS1 circuit pack** [UDS1-BD, ISDN-LNK] supports ISDN-PRI communications over an attached DS1 facility. It transports of D-channel signaling information over the packet bus, and B-channel data over the TDM bus. The Universal DS1 circuit pack has the same fault detection capabilities as the TN570 Expansion Interface.
- **TN771D Maintenance/Test circuit pack** [M/T-BD, M/T-DIG, M/T-PKT, M/T-ANL] is the workhorse of packet bus maintenance. This circuit pack can detect all packet bus failures for the Port Network in which it resides. In Critical Reliability systems (duplicated PNC), this circuit pack enables the reconfiguring of the packet bus around a small number of failed leads. The TN771D circuit pack provides a standalone mode (one that does not involve communication with the SPE), for inspecting the packet bus for faults. Standalone mode is a critical tool for troubleshooting packet bus faults.

NOTE:
All Maintenance/Test circuit packs must be of vintage TN771D or later. This circuit pack is also used for ISDN-PRI trunk testing (M/T-DIG) and ATMS trunk testing (M/T-ANL).

Effects of Circuit Pack Failures on the Packet Bus

Certain failures of any of the above circuit packs can disrupt traffic on the packet bus Some failures cause packet bus failures with corresponding alarms, while others cause service outages without alarming the packet bus, (although the failed circuit pack should be alarmed).

Packet bus circuit pack failures affect the bus in the following ways:

- **TN1655 Packet Interface**. A failure of the Packet Interface typically causes all Packet traffic in the system to fail. As a result,
  - — Expansion Port Networks and Center Stage Switches are disabled.
  - — ISDN-BRI sets are not able to make or receive calls.
  - — Communication with ASAI adjuncts fail
  - — X.25 communications with external adjuncts fail.
  - — System Ports are disabled.
  - — ISDN-PRI D-channel signaling is disabled.

  If the failure is on the packet bus interface, the packet bus may be alarmed as well.

  In a system with duplicated SPEs, there is one TN1655 Packet Interface in each SPE. If a Packet Interface failure in the active SPE causes a packet bus disruption, an SPE interchange may restore service. In other cases, replacement of the circuit pack may be required before service is restored.

- **TN570 Expansion Interface**. A failure of the Expansion Interface typically causes all packet traffic in the connected EPN or Center Stage Switch to fail. If the failure is on the packet bus interface, the packet bus may be alarmed as well.

  If an active Expansion Interface failure causes a packet bus disruption in a Critical Reliability system (duplicated PNC), a PNC Interchange may restore service. In other cases, replacement of the circuit pack may be required before service is restored.

- **TN556 ISDN-BRI Circuit Pack**. A failure of the ISDN-BRI circuit pack typically causes some or all ISDN-BRI sets and data modules and/or an ASAI adjunct connected to the circuit pack to stop functioning. If the failure is on the circuit pack's packet bus interface, the packet bus may be alarmed.
- **TN577 Packet Gateway Circuit Pack**. A failure of the Packet Gateway circuit pack disrupts communications with the adjunct (for example, Audix, DCS) connected to the far end of the X.25 link. If the failure is on the circuit pack's packet bus interface, the packet bus may be alarmed.
- **TN553 Packet Data Circuit Pack**. A failure of the Packet Data circuit pack disrupts System Port traffic. If the failure is on the circuit pack's packet bus interface, the packet bus may also be alarmed. Applications that use System Ports include:
  - — Saving and restoring announcements
  - — Call Detail Recording (CDR)
  - — Journal Printer for the Property Management System (PMS)
  - — Wakeup Log Printer for the Property Management System (PMS)
  - — System Printer
  - — Data Terminals
  - — Remote administration terminals
- **TN464F Universal DS1 Circuit Pack**. A failure of the Universal DS1 Circuit Pack disrupts ISDN-PRI signaling traffic carried on the D-channel. The loss of that signaling may impact the pack's 23 B-channels. If the D-channel supports Non Facility Associated Signaling (NFAS), the B-channels of up to 20 other DS1 circuit packs may also be affected. In cases where all 24 channels of the circuit pack are B-channels, packet bus related failures may not affect the B-channels, since only D-channel signaling is carried on the packet bus. If the failure is on the circuit pack's packet bus interface, the packet bus may be alarmed as well.
- **TN771D Maintenance/Test**. A failure of the Maintenance/Test may cause an incorrect indication of a packet bus failure or the inability to detect such a failure. If the failure is on the packet bus interface, the packet bus may be alarmed as well.

Failure of any circuit pack's bus interface may alarm the packet bus due to shorting of the packet bus leads. This typically disrupts *all* packet bus traffic in the affected PN. A failure of the packet bus in the PPN affects packet traffic in the EPNs as well. Some packet bus failures do not affect all endpoints, so a packet bus failure cannot be ruled out just because some packet service is still available.

A circuit pack can fail in a manner such that it transmits bad data on the packet bus. If the Packet Interface so fails, all Packet traffic is disrupted. Such a failure on an Expansion Interface may disrupt all Packet traffic in that port network. If an ISDN-BRI circuit pack fails such that it transmits bad data, all devices connected to the circuit pack fail to function. This failure may also disrupt the entire packet bus whenever the circuit pack tries to transmit data. Such a disruption may be indicated by packet bus alarms that occur and go away, intermittent failures of other packet circuit packs, and/or interference with other connected endpoints. These failures are difficult to isolate because of their intermittent nature. In most cases, the failed circuit pack is alarmed, and all connected endpoints on the circuit pack are out of service until the circuit pack is replaced. These symptoms help in isolating the fault.

Maintenance of the Packet Bus

The following topics are covered in this section:

- "Packet Bus and TDM Bus: a Comparison"
- "Packet Bus Maintenance Software"
- "Fault Correction Procedures: Overview"

Packet Bus and TDM Bus: a Comparison

The packet and TDM busses have several similarities and differences. There are two physical TDM buses in each PN. One of the buses can fail without affecting the other, but half of the call-carrying capacity is lost. There is *one* packet bus in each PN. A failure of that bus can disrupt all packet traffic in that PN.

In critical reliability systems, the Maintenance/Test circuit pack provides packet bus reconfiguration capabilities. This allows the packet bus to remain in service with up to 3 lead failures. There is no corresponding facility on the TDM Bus. Instead, the second physical TDM Bus continues to carry traffic until repairs are completed.

System response varies according by type of bus failure and whether or not the failure occurs in the PPN or an EPN. In an EPN, a catastrophic TDM Bus failure (one that affects both TDM Buses) disables *all* traffic in the PN. A catastrophic packet bus failure affects only packet traffic, so that TDM traffic is unaffected, while all ISDN-BRI, ASAI, X.25, and ISDN-PRI signaling traffic is disrupted. The significance of this distinction depends on the customer's applications. A customer whose primary application requires ASAI would consider the switch to be out of service, while a customer with a large number of Digital/Analog/Hybrid sets and a small number of ISDN-BRI sets would probably not consider the packet bus failure a catastrophic problem. The only way an EPN packet bus failure can affect TDM traffic is via possible impact on system response time in a large switch due to running of ISDN-BRI endpoint maintenance. This should rarely happen because the packet bus maintenance software is able to prevent this for most faults (see the next section).

If packet bus failure occurs in the PPN, the impact is much more widespread. Because the PPN packet bus carries the signaling and control links for all EPNs, PPN packet bus failure effectively removes all the EPNs from service, including both TDM and packet busses. Packet bus traffic in the PPN is also disrupted.

CAUTION:
Packet bus fault correction and fault isolation often involve circuit pack removal, which is destructive to service. Minimize time devoted to destructive procedures by the use of non-destructive ones where possible.

Packet Bus Maintenance Software

Packet bus maintenance software involves the usual set of maintenance object error conditions, tests, and alarms. These are described in “PKT-BUS” in Chapter 9. Because a packet bus failure can cause all BRI/ASAI endpoints in the affected Port Network, and all their associated ports and circuit packs, to report failures, special care must be taken to ensure that the flood of error messages does not overload the system and interfere with TDM Bus traffic. *When such a failure occurs*, circuit pack maintenance is affected in the following manner:

- In-line errors for the following MOs which indicate possible packet bus failures are logged but *not acted upon:* BRI-BD, PGATE-BD, PDATA-BD, UDS1-BD.
- In-line errors for the following MOs which indicate possible packet bus failures are *neither logged nor acted upon:* BRI-PORT, ABRI-PORT, PGATE-PT, PDATA-PT, ISDN-LNK.
- All in-line errors for the following MOs are *neither logged nor acted upon:* BRI-SET, BRI-DAT, ASAI-ADJ.
- Circuit pack and port in-line errors that are not related to the packet bus, or that indicate a circuit pack failure, are acted upon in the normal fashion.
- Periodic and scheduled background maintenance is not affected.
- Foreground maintenance (for example, commands executed from the terminal) is not affected.

These interactions allow normal non-packet system traffic to continue unaffected, and they reduce the number of entries into the Error/Alarm Logs. If the packet bus failure is caused by a failed circuit pack, errors against the circuit pack should appear in the Error/Alarm Logs as an aid for fault isolation. The above strategy is implemented when:

- In-line errors indicate a possible packet bus failure reported by two or more Packet circuit packs.

- A packet bus Uncorrectable report is sent from the Maintenance/Test packet bus port (M/T-PKT).

When such a failure occurs, a PKT-BUS error is logged. Refer to the PKT-BUS section in Chapter 9 for more detailed information.

Fault Correction Procedures: Overview

This section gives an overview of the procedures used to isolate the cause of and correct packet bus faults. Details are presented in following sections.

1. Procedure 1 attempts to determine if a circuit pack that interfaces to the packet bus is the cause of the packet bus problem. This involves examination of the Error and Alarm logs followed by the usual repair actions.
2. If the packet bus problem persists, remove port circuit packs (those in purple slots) to look for circuit packs that have failed and/or damaged the packet bus pins.
3. If the packet bus problem persists, perform the same procedure for control complex circuit packs.
4. If the problem persists, or if the packet bus faults are known to have open leads, replace bus terminators and cables. If this does not resolve the problem, reconfigure the carrier connectivity of the port network to attempt to isolate a faulty carrier.

The Maintenance/Test Circuit Pack (TN771)

The TN771 Maintenance/Test circuit pack provides the following functions:

- Analog Trunk (ATMS) Testing
- Digital Port Loopback Testing
- ISDN-PRI Trunk Testing
- Packet Bus Testing
- Packet Bus Reconfiguration (Critical Reliability systems only)

The PPN always contains a TN771D. Critical Reliability systems have a TN771D in each EPN. A TN771D is optional in EPNs of other configurations. The ISDN-PRI Trunk Testing functions are discussed in the ''ISDN-PLK (ISDN-PRI Signaling Link Port)'' section in Chapter 9, ''Maintenance Object Repair Procedures''.

The Digital Port Testing functions are discussed in the ''DIG-LINE (Digital Line)'', "DAT-LINE (Data Line Port)", ''PDMODULE (Processor Data Module) TDMODULE (Trunk Data Module)'', ''TDMODULE (Trunk Data Module)'', ''PGATE-PT (Packet Gateway Port)'', ''PDATA-PT (Packet Data Line Port)'', and ''MODEM-PT (Modem Pool Port)'', sections in Chapter 9, ''Maintenance Object Repair Procedures''.

The Analog Trunk Testing functions are discussed in the ''TIE-TRK (Analog Tie Trunk)'', ''DID-TRK (Direct Inward Dial Trunk)'', ''CO-TRK (Analog CO Trunk)'', and

"AUX-TRK (Auxiliary Trunk)", sections in Chapter 9, "Maintenance Object Repair Procedures".

NOTE:
All Maintenance/Test circuit packs must be of TN771D vintage or later.

TN771D Packet Functions

The Maintenance/Test packet bus port (M/T-PKT) provides the packet bus testing and reconfiguration capabilities. When the port is in service, it continuously monitors the packet bus for faults and fault recoveries, and reports results to PKT-BUS maintenance.

The yellow LED on the TN771D Maintenance/Test circuit pack provides a visual indication of the state of the packet bus:

Flashing — Flashing of the yellow LED once per second indicates that there are too many faults for the Maintenance/Test packet bus port to recover by swapping leads. *The packet bus may be unusable*. If the failures detected are open lead failures, the packet bus may still be operating.

On steady — The Maintenance/Test packet bus port has swapped leads on the packet bus to correct a fault. *The packet bus is still operating*. Or, one of the other ports on the Maintenance/Test circuit pack is in use.

NOTE:
First busy out the Maintenance/Test circuit pack ports used for other than packet bus testing before using the Maintenance/Test circuit pack to help resolve packet bus faults. This is done by entering **busyout port** UUCSS**01, busyout port**UUCSSl**02**, and **busyout port** UUCSS**03**. Be sure to release these ports when the process is completed.

Off — There is no packet bus fault present.

NOTE:
It takes 5 to 10 seconds for the LED to respond to a change in the state of the packet bus.

During normal switch operation, the Maintenance/Test provides visual feedback of the packet bus state. When in standalone mode (see the next section), these visual indications are still present, but the packet bus is never reconfigured. The yellow LED either blinks or is off.

TN771D in Standalone Mode

In TN771D standalone mode, a terminal is connected to the Maintenance/Test circuit pack with an Amphenol connector on the back of the cabinet. This setup allows direct inspection of the packet bus and identifies shorted or open leads. This mode does not use the usual MT Maintenance User Interface and is thus available even if switch is not in service. When in standalone mode, the TN771D does not reconfigure the packet bus.

Required Hardware

- TN771D: Standard or High Reliability systems may not have a TN771D in each EPN. (Use **list configuration** to determine if this is so.) When this is the case, one must be taken to the site. See the following section, "Special Precaution Concerning the TN771D".
- Terminal or PC with terminal-emulation software: The EIA-232 (RS-232) port should be configured at 1200 baud, no parity, 8 data bits, and one stop bit. This is *not* the same configuration as for the G3-MT. If a terminal configured as a G3-MT is used, change the SPEED field from 9600 to 1200 on the terminal's options setup menu. (This menu is accessed on most terminals by pressing the CTRL and F1 keys together. On the 513 BCT, press SHIFT/F5 followed by TERMINAL SET UP). Remember to restore the original settings before returning the G3-MT to service.
- 355A EIA-232 Adapter (Comcode 105 012 637).
- 258B Six-Port Male Amphenol Adapter (Comcode 103 923 025). A 258A Adapter and an extension cable can also be used.
- D8W 8-wire modular cable of an appropriate length to connect the 258A on the back of the cabinet to the 355A adapter. The relevant Comcode is determined by the length of the cable, as follows:
  - — 103 786 786 (7 feet)(2.1 m)
  - — 103 786 802 (14 feet)(4.3 m)
  - — 103 786 828 (25 feet)(7.6 m)
  - — 103 866 109 (50 feet)(15.2 m)

Slot Selection for Standalone Mode

When selecting a carrier slot to use for standalone mode in a port network that does not already contain a TN771D, keep the following points in mind:

- A port circuit slot (indicated by a purple label) should be used. The service slot (slot 0) *cannot* be used for standalone mode, although a TN771D may normally be installed there.
- -5 volt power supply must be available in the carrier. (Refer to "CARR-POW (Carrier Power Supply)" in Chapter 9, "Maintenance Object Repair Procedures" for a description of carrier power supply units.)
- A slot in the A carrier is preferable for EPNs if the above conditions are met.

Entering and Exiting Standalone Mode

When in standalone mode, the red LED on the TN771D is lit This is normal and serves as a reminder to remove the TN771 from standalone mode.

CAUTION:
The TN771D in standalone must be the only TN771D in the port network. If a TN771D is already in the port network, place that TN771D in standalone mode. Do not insert a second TN771D. Otherwise, the system is not able to detect the extra circuit pack and will behave unpredictably.

CAUTION:
If the TN771D packet bus port has reconfigured the packet bus in a Critical Reliability system (indicated by error type 2049 against PKT-BUS), placing the Maintenance/Test in standalone mode causes a loss of service to the packet bus. In this case, this procedure disrupts service.

For port networks with a TN771D already installed:

1. Ensure that Alarm Origination is suppressed either at login or via **change system-parameters maintenance**.
2. Attach the 258A 6-Port Male Amphenol Adapter to the Amphenol connector on the back of the carrier corresponding to the TN771D's slot. Connect one end of a D8W 8-wire modular cable to port 1 of the 258A. Connect the other end of the cable to a 355A EIA-232 Adapter. Plug the EIA-232 Adapter into the terminal to be used, and turn the terminal on.

3. Reseat the TN771D circuit pack.

NOTE:
On a Critical Reliability system, this causes a MINOR OFF-BOARD alarm to be raised against PKT-BUS. This alarm is not resolved until the TN771D's packet bus port (M/T-PKT) is returned to service. To ensure that PKT-BUS alarms have been cleared, it may be necessary to restore the TN771D to normal mode.

For port networks without a TN771D installed:

1. Attach the 258A 6-Port Male Amphenol Adapter to the Amphenol connector on the back of the carrier corresponding to the slot into which the TN771D is to be inserted. Connect one end of a D8W 8-wire modular cable to port 1 of the 258A. Connect the other end of the cable to a 355A EIA-232 Adapter. Plug the EIA-232 Adapter into the terminal to be used, and turn the terminal on.
2. Insert the TN771D circuit pack into the slot. The system will not recognize the presence of the circuit pack.

If the standalone mode is entered successfully, the following is displayed on the connected terminal:

```
                    TN771 STANDALONE MODE

              (Type "?" at the prompt for help)

Command:
```

CAUTION:
If the above display does not appear, check the wiring between the terminal and the TN771D, and the terminal parameters settings. If these are correct, the TN771D may be defective. In such a case, use the following procedures to exit standalone mode and then test the Maintenance/Test circuit pack. Refer to M/T-BD and M/T-PKT in Chapter 9, "Maintenance Object Repair Procedures"*. If the TN771D fails while in standalone mode, the message* `TN771 circuit pack failed` *is displayed, and no further input is accepted on the terminal. The circuit pack must be replaced.*

To exit standalone mode:

1. Remove the 258A Adapter from the Amphenol connector.
2. If the TN771D was installed for this procedure, remove it. Otherwise, reseat the TN771D.
3. If **change system-parameters maintenance** was used to disable alarm origination, re-enable it now.

Using Standalone Mode in Packet Bus Fault Isolation and Correction

When the TN771D is in standalone mode, three commands are available:

ds	Displays the current state of the packet bus leads.
dsa	Toggles auto-report mode on and off. In auto-report mode, the state of the packet bus leads are displayed and the terminal beeps whenever a change occurs.
?	Displays the available commands.

Below is an example of a standalone mode display. The symbols above the line represent specific leads on the backplane. The bottom line indicates the following:

```
     L L L L L L L L L L H H H H H H H H H H S S S L
     P 0 1 2 3 4 5 6 7 8 P 0 1 2 3 4 5 6 7 8 S F B F
     _______________________________________________
     S S                 O

   Command:
```

O	Open lead
S	Shorted lead
blank	No fault

NOTE:
This information is available only from the standalone mode. It is not available from the MT or a remote login.

Figure 5-43 shows the location of the packet bus leads for a given slot as seen from the front and back of the carrier.

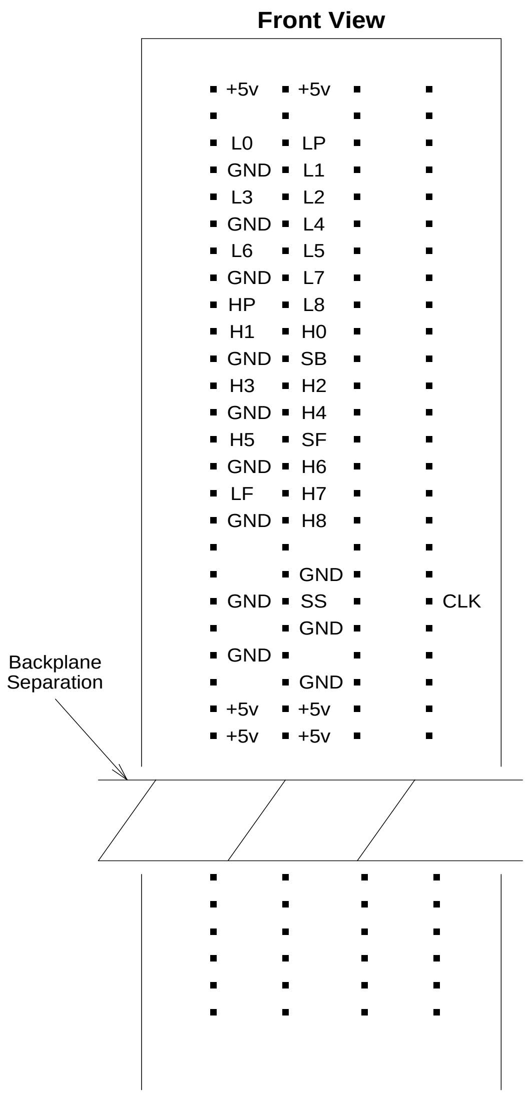

Figure 5-43. Packet Bus Leads on the Backplane

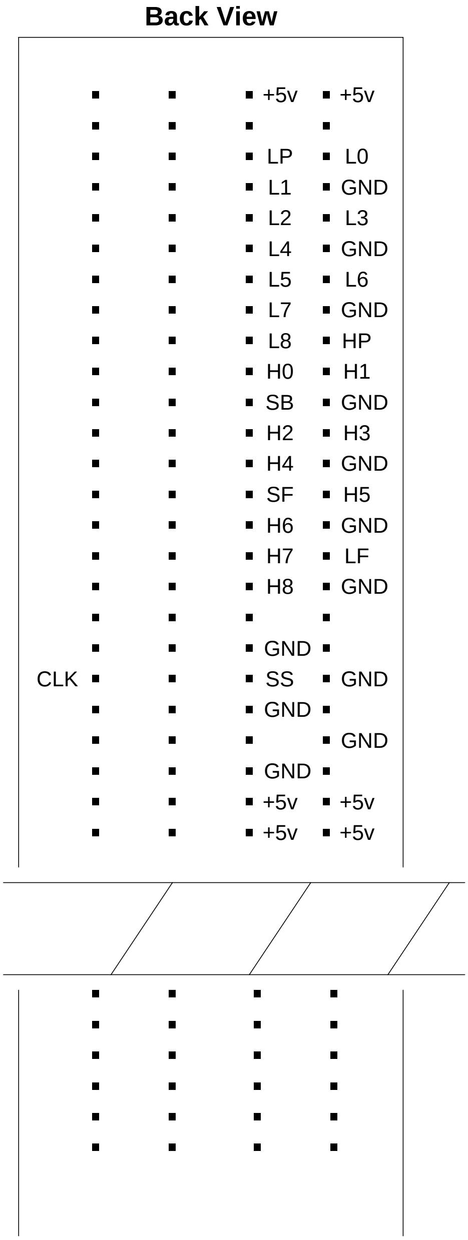

Figure 5-44. Packet Bus Leads on the Backplane

Special Precaution Concerning the TN771D

A TN771D Maintenance/Test circuit pack must be taken to the customer site if:

- The Maintenance/Test packet bus port indicates that a Packet Bus fault is present by logging a Major or Minor alarm against PKT-BUS. A Major alarm is indicated in the error log by Error Type 513; a Minor alarm is indicated by Error Type 2049.
- Test #572 of the PKT-BUS test sequence is the only test that fails.

This precaution is taken because certain failures of the Maintenance/Test circuit pack can appear as packet bus failures. To ensure that the problem is indeed with the packet bus, proceed through the following steps:

1. If the TN771D Maintenance/Test circuit pack is replaced during this process, enter the **test pkt P long** command to determine if the packet bus faults have been resolved. If there are still packet bus problems, correct them by using the procedures in the sections that follow.
2. If the Maintenance/Test circuit pack was *not* replaced, enter **test pkt P**. Record the results (PASS/FAIL/ABORT) and error codes for Test #572.
3. Enter **status port-network P**. Record the information listed for PKT-BUS.
4. Busyout the Maintenance/Test circuit pack with **busyout board UUCSS**.
5. Replace the Maintenance/Test circuit pack with the new circuit pack.
6. Release the Maintenance/Test circuit pack with **release board UUCSS**.
7. Enter the **test pkt P** and **status port-network P** commands as described in Steps 2 and 3.
8. If the data matches the previously recorded data, a packet bus problem exists, and the original TN771D Maintenance/Test circuit pack is not defective. Reinsert the original TN771D, and correct the packet bus problem by using the procedures in the sections that follow.
9. If the data does *not* match the previously recorded data, the original TN771D circuit pack is defective. If there are still indications of packet bus problems, correct them by using the procedures in the following sections.

Packet Bus Fault Isolation Flowchart

The flowchart below shows the steps to be taken for isolating and resolving packet bus problems. The order in which the maintenance objects should be examined can be determined by assessing how wide-spread the failure is. For example, since all ISDN-BRI devices communicate with the TN1655 Packet Interface circuit pack, this MO should be examined early in the sequence. On the other hand, a failure of a TN570 circuit pack in an EPN may cause ISDN-BRI failure in the EPN, but not in the PPN.

Whenever the flowchart refers to MO documentation, keep in mind that the repair procedure for that MO may in turn refer to another MO's repair procedure. The flowchart tries to coordinate these procedures so that a logical flow is maintained if the packet bus problems are not resolved via the first set of repair procedures. However, a packet bus failure can lead to a somewhat haphazard referencing of various MO procedures that may result in taking steps that are repetitive or unnecessary. If this occurs, return to the flowchart at the step that follows the reference to Chapter 9, "Maintenance Object Repair Procedures", and continue from there. The following **status** commands can also help diagnose packet bus problems, especially when logged in remotely.

status port-network P	**status packet-interface**
status pnc	**status bri-port**
status station	**status data-module**
status link	**status pms-link**
status sp-link	**status cdr-link**
status journal-link	

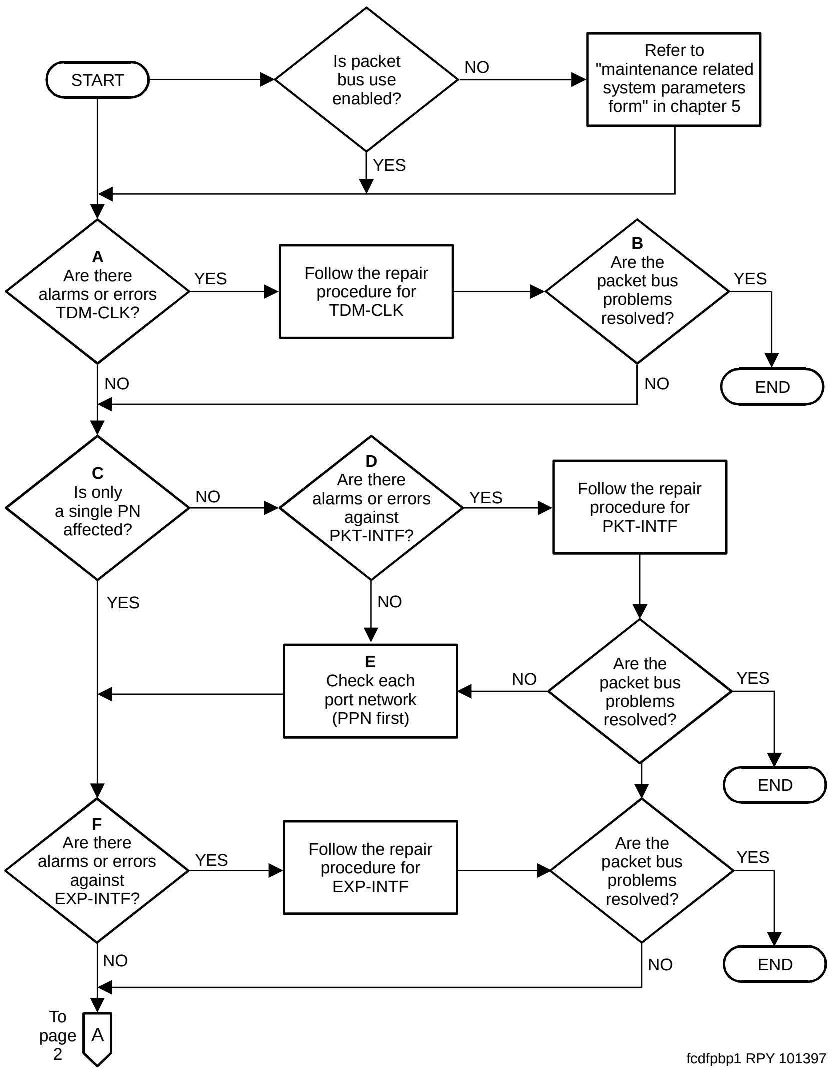

Figure 5-45. Troubleshooting Packet Bus Problems (Page 1 of 2)

Boldface letters in the flowchart refer to paragraphs in the explanatory section that follows.

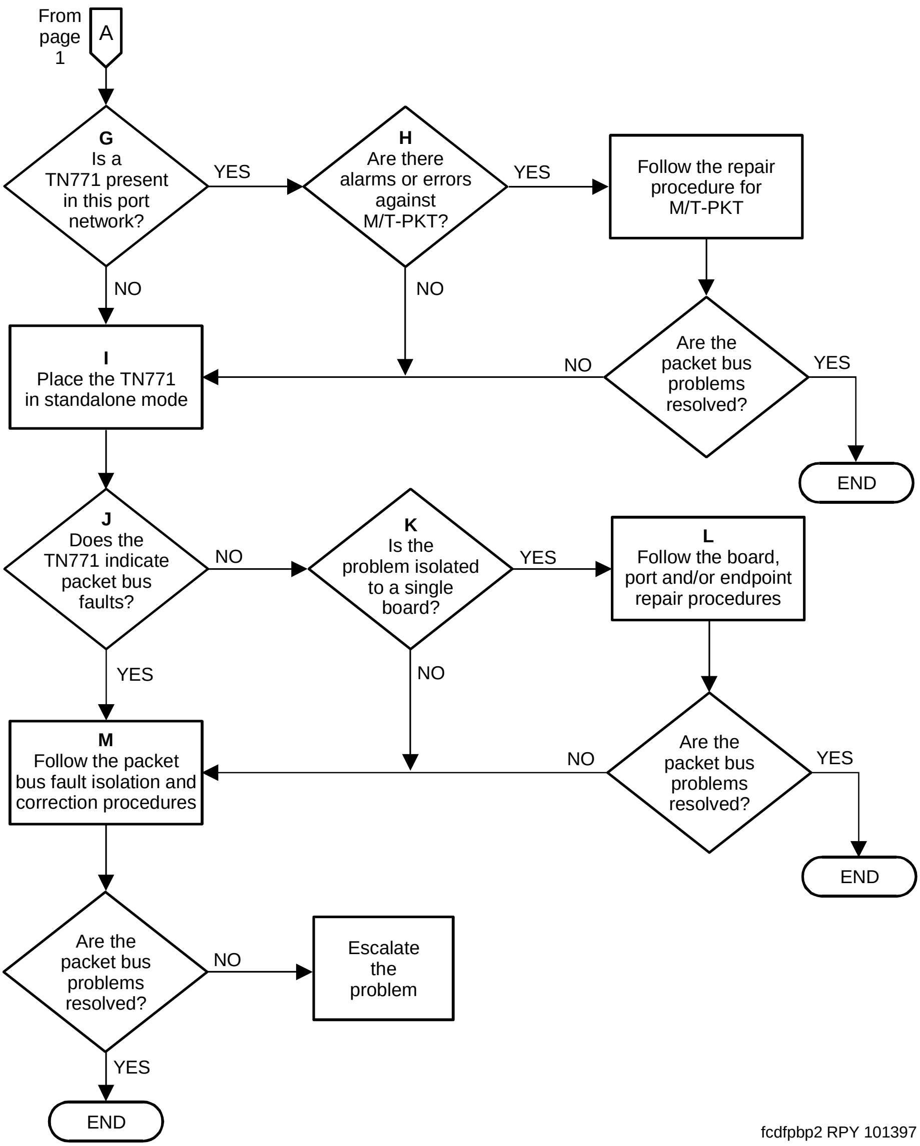

Figure 5-46. Troubleshooting Packet Bus Problems (Page 2 of 2)

Boldface letters in the flowchart refer to paragraphs in the explanatory section that follows.

Flowchart Notes

The following paragraphs refer by letter to corresponding entries in the preceding flowchart. Individual errors and alarms are not detailed in the flowchart. When referring to explanations of these in Chapter 9, ''Maintenance Object Repair Procedures'', any that do not refer explicitly to the TDM bus (except TDM-CLK) should be considered a possible cause of packet bus problems.

a. Problems with the system clock (TDM-CLK) can cause service disruptions on the packet bus. All alarms active against TDM-CLK should be resolved first, even if the explanation refers only to TDM bus. A packet bus problem cannot cause a TDM-CLK problem, but a TDM-CLK problem can cause a packet bus problem.

b. Throughout the flowchart, the question, ''Are the packet bus problems resolved?,'' refers to the problems that led you to this chart, and can involve several checks, such as:

- Are all packet bus alarms resolved?
- Are all packet circuit pack port and endpoint alarms resolved?
- Are all ISDN-BRI stations/data modules, ASAI adjuncts, System Port supported adjuncts, Packet Gateway supported adjuncts, and ISDN-PRI D-channel links in service?
- Does the Maintenance/Test packet bus port (in normal or standalone mode) still indicate a packet bus fault?

c. If only a single PN is affected, the Packet Interface is probably not the source of the problem. Nonetheless, if all of the ISDN-BRI, Packet Gateway, Packet Data, and Universal DS1 circuit packs are located in a single EPN, assume that the answer to this question is ''No,'' and check the Packet Interface.

d. A packet problem that affects more than one port network is probably caused by either a Packet Interface failure or a PPN packet bus failure. The Packet Interface is checked before the packet bus.

e. Because the packet bus in each port network is physically separate, each affected port network must be checked individually. The PPN should be checked first since any EPN packet problems are usually resolved once a PPN packet problem is resolved. After resolving the problem in one port network, make sure that problems in other port networks have also been resolved.

f. This step applies only when attempting to resolve an EPN packet bus problem. When checking the Expansion Interfaces in an EPN, be sure to check the corresponding one(s) in the PPN. (G3r supports only the TN570 Expansion Interface, not the earlier TN776 Port Network Interface).

g. If a TN771D is not present, one must be installed to accommodate the standalone mode. See the above section on standalone mode.

h. If a TN771D is present, it can fail in such a way that it eventually disrupts the packet bus or misinterprets a packet bus problem.

i. If work is being done on-site, follow the procedures described earlier in this discussion on standalone mode. If work is not being done on-site, go to the next step.

j. The answer is yes if any of the following apply:

   - The TN771D in standalone mode indicates any faulty leads.
   - Test #572 in the PKT-BUS test sequence fails.
   - The **status port-network P** display indicates that faulty leads are present and the TN771D in the port network is known to be functioning correctly.

k. If the non-functional endpoints are isolated to a single circuit pack, that circuit pack is probably the cause of the problem.

l. Investigate errors and alarms in the following order:

   1. Circuit pack-level
   2. Ports
   3. Endpoints

m. Follow the ''Troubleshooting Procedures'' outlined later in this discussion. If the packet bus problem cannot be resolved with these procedures, follow normal escalation procedures.

Correcting Packet Bus Faults

The Status Port-Network Command

Status port-network P displays include the service state, alarm status, and, if the Maintenance/Test packet bus port is present, the number of faulty and open leads for the packet bus in the specified port-network. This information can be used to determine the urgency of the repair. In general, a service state of "out" indicates extreme urgency, while a service state of "reconfig" indicates moderate urgency.

NOTE:
Ultimately, the urgency of a repair is determined by the customer's requirements. A customer who uses ISDN-BRI for station sets, or who relies heavily on packet bus supported system adjunct features like DCS, Audix, or CDR, probably considers a packet bus failure critical. On the other hand, a customer with little ISDN-BRI service and no adjunct features may consider even an uncorrectable packet bus fault unimportant, and may prefer to delay repairs due to their disruptive nature.

If background maintenance is running on the packet bus when the **status port-network** command is issued, the data reported for the packet bus may be inconsistent due to updating by the tests. If the data seems inconsistent, enter the command again.

If test results or the results of the **status port-network** command indicate that there are 24 faults on the packet bus, the problem is probably caused by faulty cables between carriers, or by defective or missing bus terminators. However, before proceeding, make sure that the Maintenance/Test packet bus port is not generating a false report by looking for an M/T-PKT error in the error log. Then test the Maintenance/Test packet bus port with **test port UUCSSpp**. See "Special Precaution Concerning the TN771D" above if any problems are suspected.

NOTE:
If the carrier into which a TN771D Maintenance/Test circuit pack is inserted does not have a -5V power supply, the Maintenance/Test packet bus port reports 24 open leads in response to **status port-network**, or Test #572 of the PKT-BUS test sequence. Refer to CARR-POW maintenance in Chapter 9 to ensure that a -5 volt power supply is available.

Considerations for Duplicated Systems

Some packet bus-related components are duplicated in systems with one of the duplication options:

- In High Reliability systems (duplicated SPE, simplex PNC), Packet Interface circuit packs are duplicated with the SPEs, a Maintenance/Test circuit pack is required in the PPN, and Maintenance/Test packet bus reconfiguration is not enabled.
- In Critical Reliability Systems (duplicated SPE and PNC), the Packet Interface circuit packs are duplicated, Maintenance/Test circuit packs are required in all port networks, and packet bus reconfiguration by the Maintenance/Test circuit packs is enabled.

If a packet bus problem is caused by a duplicated component, switching to the standby component may alleviate the problem and isolate the faulty circuit pack. Start by executing the commands in the following list when they apply.

- **reset system interchange**: If this command resolves the packet bus problem, the problem is with the Packet Interface in the SPE which was just switched to standby. Refer to "PKT-INT (Packet Interface Circuit Pack)" in Chapter 9, "Maintenance Object Repair Procedures".
- **reset pnc interchange**: If this command resolves the packet bus problem, the problem is with the EIs or the link on the PNC (a or b) that just became the standby. Refer to "EXP-INTF (Expansion Interface Circuit Pack)" in Chapter 9, "Maintenance Object Repair Procedures".

- **set tone-clock**: If this command resolves the packet bus problem, the problem is with the Tone/Clock that just became the standby. Refer to ''TDM-CLK (TDM Bus Clock)'' in Chapter 9, ''Maintenance Object Repair Procedures'' of this document.

Continue with the procedures in the next section.

Troubleshooting Procedures

Packet bus faults are usually caused by a defective circuit pack connected to the backplane, by bent pins on the backplane, or by defective cables or terminators that make up the packet bus. The first two faults cause shorts, while the third fault causes either shorts or opens.

There are four procedures for correcting packet bus faults. Which are used depends on the nature of the fault. For example:

- If the Maintenance/Test packet bus port is activated, and if there is an indication of open leads on the packet bus from **status port-network** or Test #572, go directly to Procedure 4. Procedures 1 through 3 try to locate faulty circuit packs or bent pins and these do not cause open faults.
- If there are both shorts and opens, start with Procedure 4, and return to Procedure 1 if shorts persist after the open leads are fixed.

CAUTION:
Packet bus fault isolation procedures involve removing circuit packs and possibly disconnecting entire carriers These procedures are destructive. Whenever possible, implement these procedures during hours of minimum system use.

CAUTION:
To replace the following circuit packs, follow instructions in the appropriate sections: Tone-Clock (''TONE-BD (Tone-Clock Circuit Pack)''), Expansion Interface (''EXP-INTF (Expansion Interface Circuit Pack)''), Packet Interface (''Replacing SPE Circuit Packs'').

When the procedure asks whether the packet bus problem has been resolved, the following conditions should all be met:

- All faulty leads reported by the TN771D standalone mode should no longer be reported.
- All alarms against the packet bus and packet circuit packs have been resolved.
- All ISDN-BRI stations and data modules and all relevant ASAI, System Port, and Packet Gateway supported adjuncts are in service.

Procedure 1

Procedure 1 determines whether any circuit packs that use the packet bus have faults. For each circuit pack type in Table 5-8 proceed through the steps below. Check the circuit pack in the order presented by the flowchart which appears earlier in this discussion unless newly inserted circuit packs are involved. Newly added boards are the most likely cause of a problem.

1. **Display errors** and **display alarms** for the circuit pack.
2. For any errors or alarms, follow the repair actions recommended in Chapter 9, "Maintenance Object Repair Procedures".
3. After following the recommended repair actions, *whether they succeed or fail*, determine if the packet bus fault is resolved. If so, you are finished.
4. If the packet bus fault is still present, apply this procedure to the next circuit pack.
5. If there are no more circuit packs in the list, go to Procedure 2.

Table 5-8. Packet Circuit Packs

Circuit Pack Name	Circuit Pack Code	Associated Maintenance Objects
ISDN-BRI	TN556	BRI-BD, BRI-PORT, ABRI-PORT, BRI-SET, BRI-DAT, ASAI-ADJ
Maintenance/Test	TN771D	M/T-BD, M/T-PKT
Packet Gateway	TN577	PGATE-BD, PGATE-PT
Packet Data	TN553	PDATA-BD, PDATA-PT
Universal DS1	TN464F	UDS1-BD, ISDN-LNK
Packet Interface	TN1655	PKT-INTF
Expansion Interface	TN570	EXP-INTF

Procedure 2

Procedure 2 removes and reinserts *port* circuit packs (purple slots), and the Expansion Interface one or several at a time. Use Procedure 2 for each port circuit pack in the port network until the problem is resolved *or* all port circuit packs have been tried.

NOTE:
The Expansion Interface circuit pack should be the last one checked since removing it disconnects the EPN. To check an active Expansion Interface in a system with duplicated PNC, use **reset pnc interchange** to make it the standby. (Always check the status of the standby before executing an interchange.)

NOTE:
The Tone/Clock circuit pack should be the next-to-last one checked. (The TN771D must be reseated after the Tone/Clock is reinstalled.) Refer to Procedure 3 for the TN768 or TN780 Tone/Clock circuit pack in a PPN with duplicated SPEs.

If the packet bus problem is present when the circuit pack is inserted, but is resolved when the circuit pack is removed, either the circuit pack or the backplane pins in that slot caused the problem. If the backplane pins are intact, replace the circuit pack. Keep in mind that there may be more than one failure cause.

In Procedure 2, you may try one circuit pack at a time, or multiple circuit packs simultaneously. The allowable level of service disruption should guide this choice. If the entire port network can be disrupted, trying large groups of circuit packs will save time. If traffic is heavy, trying 1 circuit pack at a time is slow but will minimize outages.

If the TN771D Standalone mode does *not* indicate packet bus faults, perform Procedure 2 for *only the port* circuit packs (purple slots) listed in Table 5-8 in Procedure 1. In this case, you need not check for problems with the backplane pins. It is sufficient to determine whether the problem is resolved by removing circuit packs.

If you decide to remove multiple circuit packs, consider working with an entire carrier at a time to more quickly and reliably determine which circuit packs are *not* the source of trouble. Any circuit packs, (packet or non-packet), that have been recently inserted should be checked first. Packet circuit packs should be checked before non-packet circuit packs.

1. Remove one or several circuit packs.
2. Determine if the packet bus fault is still present. If not, go to step 4.
3. If the packet bus fault is still present:
   a. Determine if the backplane pins in the removed circuit pack's slot are bent using the output from the Maintenance/Test standalone mode and the backplane illustrations which appear earlier in this discussion.
   b. If the backplane pins are bent:

      Power down the carrier (see "Replacing a BIU or Rectifier"), straighten or replace the pins, reinsert the circuit pack and restore power. Repeat Step 2 for the same circuit pack.
   c. If the backplane pins are not bent:

      Reinsert the circuit pack(s), and repeat this procedure for the next set of circuit packs.

4. If the packet bus fault is not present:
   a. Reinsert circuit packs one at a time and repeat the following substeps until all circuit packs have been reinserted.
   b. Determine if the packet bus fault has returned.
   c. If the packet bus fault has returned, the reinserted circuit pack is defective. Replace the circuit pack and then continue.
   d. If the packet bus fault does not return when all of the circuit packs have been reinserted, you are finished.

Continue with Procedure 3 if all the port circuit packs have been checked, but the packet bus fault is still not resolved.

Procedure 3

Procedure 3 removes and reinserts SPE and EPN control circuit packs one at a time. In the PPN, the following SPE circuit packs either use the packet bus or are connected to it in the backplane wiring:

- TN1655 Packet Interface
- TN768/TN780 Tone/Clock
- UN332 MSSNET

In the EPN, the following control circuit packs either use the packet bus for communication or are connected to it in the backplane wiring:

- TN775 EPN Maintenance Board
- TN768/TN780 Tone/Clock

These are the only SPE and EPN control circuit packs that are likely to cause a packet bus problem in a stable system. Perform this procedure on only these circuit packs.

If the TN771D Standalone mode does *not* indicate packet bus faults, perform Procedure 3 for *only* the Packet Interface and Tone/Clock circuit packs and do not check for problems with the backplane pins. Determining if the problem is resolved by removing circuit packs is sufficient.

For a system with simplex SPE:

1. Power down the control carrier. Refer to ''Replacing SPE Circuit Packs''.
2. Remove the suspect circuit pack.
3. Determine if the backplane pins in the removed circuit pack's slot are bent.

4. If the backplane pins are bent:

   a. Straighten or replace the pins.

   b. Insert the same circuit pack.

5. If the backplane pins are not bent:

   a. Replace the circuit pack (reinsert the old one if a replacement is not available).

6. Turn the power back and allow the system to reboot. This may take up to 12 minutes. Log in at the terminal.

7. Determine if the packet bus fault is still present. If not, you are finished.

If the problem is still present,

a. If the old circuit pack was reinserted in Step 5, replace the circuit pack, and repeat Procedure 3.

b. If the circuit pack was replaced in Step 5, repeat Procedure 3 for the next SPE circuit pack.

If Procedure 3 fails to identify the cause of the problem, go to Procedure 4.

For a system with duplicated SPEs:

1. For SPE circuit packs, follow the "Replacing Circuit Packs on a Duplicated SPE: Lock-and-Power-Down" procedure within the "Replacing SPE Circuit Packs" section to remove and replace the circuit pack.

2. To remove an EPN Tone/Clock circuit pack, use **set tone-clock** if necessary to make the suspect circuit pack the standby. (Always check the status of the standby Tone/Clock with **status port network** before executing an interchange.)

3. Determine if the backplane pins in the removed circuit pack's slot are bent.

4. If the pins are bent:

   a. Power down the carrier if it is not already.

   b. Straighten or replace the pins.

   c. Insert the same circuit pack.

   d. Restore power to the carrier.

5. If the backplane pins are not bent:

   Insert or replace the circuit pack.

6. Determine if the packet bus fault is still present. If not you are finished.

7. If the packet bus fault is still present, do the following:
   a. If the old circuit pack was reinserted in Step 5, replace the circuit pack and repeat Procedure 3 starting at Step 2.
   b. If the circuit pack was replaced with a new one, proceed with the next step.
8. Repeat this procedure for the other SPE or Tone/Clock. If both have already been checked, go to the next step.
9. If all SPE and/or EPN control circuit packs have been checked and the problem is not resolved, continue with Procedure 4.

Procedure 4

Procedure 4 is used when the preceding procedures fail or when open leads are present. It is helpful in identifying multiple circuit pack faults and carrier hardware faults. It attempts to isolate the failure to a particular set of carriers and checks only the circuit packs in those carriers.

In Procedure 4, the TDM/LAN Cable Assemblies and TDM/LAN termination resistor packs are replaced. If this action does not resolve the packet bus fault, the carriers are reconfigured by moving the termination resistor packs on the carrier backplanes in such a manner that certain carriers are disconnected from the bus. To terminate the packet bus at the end of a particular carrier, unplug the cable that connects the carrier to the next carrier and replace the cable with a TDM/LAN terminator resistor pack (see Figure 5-47). When the length of the packet bus is modified with this procedure, circuit packs that are essential to system operation (and the TN771D Maintenance/Test in standalone mode) must still be connected to the new ‘shortened’ packet and TDM busses.

DANGER:
Power must be removed from the entire port network before any cables or terminators are removed. Failure to do so can cause damage to circuit packs and power supplies, and can be hazardous to the technician.

DANGER:
Circuit packs in carriers that are not part of the shortened bus are not inserted. As a result, these circuit packs are not alarmed Ignore alarm status for these circuit packs for now All alarms should be resolved when the cabinet is restored to its original configuration.

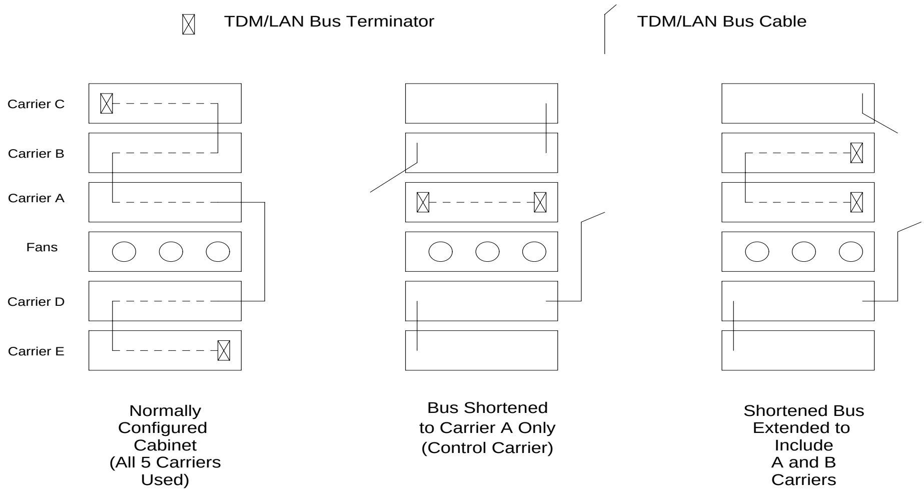

Figure 5-47. Carrier Rewiring Example—Rear View of Multicarrier Cabinet

Procedure 4 consists of two parts. Part 1 attempts to clear the packet bus fault by replacing all the bus cabling and terminators within a port-network. Part 2 attempts to isolate the fault to a particular carrier by extending the packet bus from the control carrier to additional carriers one at a time.

Part 1:

1. Power down the port network.
2. Replace all of the TDM/LAN Cable Assemblies and both TDM/LAN Terminators.
3. Restore power to the port network.
4. Determine if the packet bus fault is still present.
5. If the packet bus fault is resolved, the procedure is completed. Otherwise, go to Part 2.

Processor Port Network:

1. Power down the cabinet and terminate the packet bus so that it extends only from the carrier that contains the active SPE (A or B) to the carrier that contains the Maintenance/Test circuit pack.
2. Power up the cabinet, allow the system to reboot, and determine if the packet bus fault is still present. If not, proceed to the next step.

   If there are shorts on the packet bus, perform Procedures 2 and/or 3 for the circuit packs in the active SPE and carriers connected to it on the shortened bus. (Procedure 2 is performed for port circuit packs, and Procedure 3 is performed for SPE circuit packs.)
3. If the packet bus fault is not present, extend the packet bus to another carrier, and repeat the procedure in the previous step. When the addition of a carrier causes the fault to recur, and if there are shorts, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.
4. If the packet bus fault recurs when the packet bus is extended, and if there are no shorts, or Procedures 2 and 3 do not resolve the problem, the added carrier(s) that caused the problem to recur are defective and must be replaced.

Expansion Port Networks:

1. Place the Maintenance/Test circuit pack into a carrier that contains the active Expansion Interface circuit pack to permit isolation of the failure to the smallest possible number of carriers.
2. Power down the cabinet and terminate the packet bus on the carrier with the M/T and active EI.
3. Determine if the packet bus fault is still present If so, and if there are shorts on the packet bus, perform Procedure 2 and/or Procedure 3 for only the circuit packs in carriers connected to the “shortened” packet bus.
4. If the packet bus fault is not present, extend the packet bus to another carrier, and repeat the procedure in the previous step. When a carrier that causes the fault to recur is added, and if there are shorts, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.
5. If the packet bus fault recurs as the packet bus is extended, and if there are no shorts, or Procedures 2 and 3) do not resolve the problem, the added carrier(s) that caused the problem to recur are defective and must be replaced.

Additional Maintenance Procedures

6

Software updates

A software update is the complete replacement of the software load running on a switch with a new version of software. Updates are used to provide new features and improved services, and to repair bugs discovered in the field. Note that the process is called a software update; the command used is **upgrade software**. A description of this command appears in Chapter 8, ''Maintenance Commands''.

Software *field updates* are partial replacements of a software load normally used for emergency bug fixes. Usually, a field update is transmitted electronically to the system from a remote site, but a technician must be on site to apply the update to backup cartridges and insure that the system returns to normal operation. This procedure should be guided by the remote facility applying the update.

Refer to *DEFINITY Enterprise Communications Server Upgrades and Additions for R8r* for specific upgrade information.

Software Version Number

Each software load is identified by a version number. The following are typical software version numbers displayed when **list configuration software-version** is entered:

```
SOFTWARE VERSION: DG3r01.06.1.00.0
```

```
SOFTWARE VERSION: G3r5.01.2.0.078
```

This identifier is also called the release number or the vintage number. Version numbers are interpreted as follows:

Release 8r loads:

G3r5	m	01	2	0	078
Product ID	Boot Image	Major Release	Minor Release	Unscheduled Release	Load Number

The `Boot Image` field contains “m” (mips) for Release 8r systems.

The system expects any software upgrade to be going from a lower, or older version number, to a higher, or newer version number. To install an older version (for example, when backing out a failed upgrade), follow normal escalation procedures to avoid putting the system into a corrupted state.

Each software version also has a compatibility index of the form:

8	1
Major Field	Minor Field

Differences between old and new version numbers and compatibility indexes can be used to determine what service effects can be expected from the update. See the “Service effects of a software update” section that follows.

Service effects of a software update

Simplex SPE

The **upgrade software** command executes a system reboot similar to a **reset system 4**. Emergency transfer is invoked and all calls drop. The MT login is terminated and error logs are cleared. The service outage lasts for a period of up to 15 minutes. Results of each step in the upgrade process and initialization diagnostics are displayed on the terminal screen. Screen output is described in *Maintenance Commands*, **upgrade software**. Failure of initialization will produce an SPE-down mode, described in *Initialization and Recovery*. Translations are reloaded from the primary storage device and reformatted for the new software if necessary.

Duplicated SPE

On a system with a duplicated SPE, a software update may be either *call-preserving* or *call-dropping*. The compatibility of the old and new versions determines which type of update is performed. If the major fields of the compatibility indexes of the two versions are equal, then a call-preserving update is possible. The documentation accompanying the update removable media cartridges (Engineering Design Information, or EDI, and the Release Letter) should confirm this. With rare exceptions, this is the case when the Feature Version and Product ID numbers match.

If these conditions are not met, The **upgrade software call-override** option must be used, and the update will result in a system reset level 2 (cold-2 restart). An additional option, **preserve-calls**, can be added to force the system to attempt to preserve calls, but this must be used with care. If the incompatibility is great enough, this option may cause the system to escalate to a reboot (**reset system 4**). It is recommended that you escalate any such software update.

Call-Preserving Update

During a call-preserving update, calls in which two or more parties are connected and talking are preserved. The following types of calls are dropped: wideband calls, held calls, dialing calls, and calls that are connected to announcements, speech synthesizers, or tones. Administered connections are dropped and automatically restored. Feature activation attempts are ignored. No new calls are processed for a brief period. This period usually lasts less than 5 seconds but can last up to 1 minute depending on traffic load during the SPE interchange. Conference calls that attempt a new connection are either ignored or dropped.

Call-Dropping Update

During a call-dropping update, the effect will be similar to a cold-2 restart (**reset system 2**). All calls and system links drop, and the MT login is terminated. The service outage lasts up to 4 minutes.

Preparing for a Software Update

1. Notify users of anticipated service effects described in the preceding section and arrange to do the update at a suitable time. Also advise appropriate users of the following feature interactions:

   - Administered connections are temporarily dropped.
   - Leave Word Calling messages stored in the SPE are lost. Those stored in a Message Server Adjunct or AUDIX system are saved.
   - Some feature settings will be lost and must be restored afterward. The effect is the same as a cold-2 restart. Features affected include night service, trunk/hunt group control, and manual/clock-manual override status on time of day routing. For example, hunt groups and attendant are put into night service after the update.
   - ACD queues will be lost. There is no mechanism to drain the queues. CMS or BCMS can be used to monitor the queue lengths. If it is important to empty all queues before the update, you must coordinate with the customer to redirect traffic away from ACD splits before the update. Changing vectors to temporarily route calls to a disconnect announcement is one way to accomplish this. ACD agents will need to log in again after the update and their status lamps may be incorrect for about an hour (until periodic background maintenance completes one cycle).
   - CMS links are dropped and restored, resulting in a loss of incoming data during the upgrade. Data loss can be minimized by performing the update soon after the end of a CMS measurement interval.
   - Wideband calls are dropped.

2. Some information which is stored in system memory will be lost and must be manually recorded and then re-entered after the update:

   - Record all busied out maintenance objects. Enter **display errors print**, and select error type 18 on the menu. All busyouts will be lost during the update and must be reentered afterward. Disabled maintenance objects will likewise be re-enabled by the update.
   - All measurement data stored in memory, including BCMS, is lost. Print any desired reports before the update.
   - Enter **list report-scheduler**. Reports that are currently printing or queued will be lost. Wait until reports are finished printing or notify the customer. Reports are printing if the Link State field displays up on the **status sp-link** screen.
   - Enter **list wakeup print** and **list do-not-disturb stations print**. These feature settings will be lost and must be re-entered afterwards.

3. Make sure that the system's health and activity can support a successful update:
   - Enter **status spe** and verify that the state of health of the SPE is *functional*. This must hold true for active and standby SPEs when duplicated.
   - Enter **display alarms** and **display errors**. Resolve any active alarms or errors against SPE components or the PPN Tone-Clock.
   - Enter **status logins** and make sure that no other logins except yours are active.
   - Enter **status health** and look at the amount of load on the system. If call processing is greater than 50 percent, an update is not recommended due to increased customer impact.
   - Disable TTI changes by the **change system-parameters features**.
   - Enter **change system-parameters maintenance** and make sure that scheduled daily maintenance will not be running during the update. The Start Time field should be set to a time well after the session will end. If scheduled daily maintenance is running and needs to be shut off, set the Stop Time field to one minute after the current time. Be sure to restore the original settings when finished.

Restoring the System after an Update

During software updates, including call-preserving updates, several feature settings are lost. These must be manually restored afterward.

- Re-enter all Maintenance Object busyouts.
- Re-enter wakeup calls and do-not-disturb stations.
- Restore attendant feature settings.
- Notify Administration and ACD users that the update is complete.
- Re-enable TTI changes by the **change system-parameters features**.
- On the **change system-parameters maintenance** form, restore Alarm Origination, Save Translations, CPE Alarm Level and SPE Interchange fields and Scheduled Daily Maintenance times to their original settings.
- Manually reset any speakerphones which derive power from the switch by pressing the button on the voice terminal.

Backing Out of a Software Update

If fatal hardware errors or memory faults prevent the update from completing, the system must be recovered and the update backed out. If the update command has already been entered, follow normal escalation procedures. Backing out after this point is hazardous and may leave the system in a corrupted state.

Software Update Procedure — Simplex SPE

After making the preparations described above, execute the following sequence of steps, entering the commands shown in bold type. This part of the procedure normally takes about 3 1/2 hours. Screen output for each command is described in Chapter 8, "Maintenance Commands". If errors are encountered after entering the *update software* command, follow normal escalation procedures. Avoid touching the keyboard while the save or upgrade commands are running since doing so may cause diagnostic messages to be lost.

Table 6-1. Software Update—Simplex SPE

Step	Time (min)	Remarks
change sys-par maint	2	Note the current settings of the Save Translation and Alarm Origination Activated fields and then set them to **n**. Set CPE Alarm Activation Level to none. Make sure scheduled daily maintenance is not set to run during the update.
save announcements	40	These steps create a backup removable media cartridge in case the update fails and a backout is necessary. Saving announcements may be skipped if **display announcements** shows no administered announcements.
save translation	2	
backup disk	10	
Remove the backup removable media cartridge Clean the tape drive – TN1656 ONLY	5	The procedure to clean a TN1656 tape drive is described under "R-MEDIA" in Chapter 9, "Maintenance Object Repair Procedures".
Insert the removable media cartridge with the new software	2	Wait for the removable media cartidge to reposition itself.
list config software-version	5	Make sure the removable media cartridge has the expected version number.
restore disk install	10	This copies files from the new removable media cartridge to disk. If you are updating *from* a load earlier than 6.0, substitute for this step the following sequence: **copy announce removable-media**, **save translation removable-media**, then **restore disk full**.

Continued on next page

Table 6-1. Software Update—Simplex SPE — *Continued*

Step	Time (min)	Remarks
The following step will result in the service effects described above.		
upgrade software to-version	10	Use the new software version number described above. The system will reboot and then reload translations. Results of each step in the upgrade process and initialization diagnostics will be displayed on the terminal. A full description of screen output appears in **upgrade software** in Chapter 8, ''Maintenance Commands''. **NOTE:** Be careful not to touch the G3-MT keyboard while waiting for the command to execute, or the result messages may be lost.
Login on the G3-MT.		
change sys-par maint	2	Set the Save Translation, Alarm Origination Activated, CPE Alarm Level, and Daily Scheduled Maintenance times to the values that were in effect before starting this procedure.
save translation	2	This step stores the upgraded translations on disk.
backup disk	20	This step makes a backup copy of the new files. If a coredump from before the upgrade is on disk, this can take up to 50 minutes.
test stored-data	10	This step verifies that all MSS files are consistent. The next run of scheduled maintenance will also do this.
list config soft long	5	Verify that all files are correct.
backup disk	20	Make extra backup copies of the new files as needed. The next run of scheduled maintenance will also do this.
set vector 8	1	Sets the coredump vector to take a coredump when the system reboots.
Restore the system as described above.		

Software Update Procedure — Duplicated SPE

After making the preparations described above, execute the following sequence of steps, entering the commands shown in bold type. This part of the procedure normally takes about 3-1/2 hours. Screen output for each command is described in Chapter 8, ''Maintenance Commands''. If errors are encountered after entering the **update software** command, follow normal escalation procedures. Avoid touching the keyboard while the save or upgrade commands are running since doing so may cause diagnostic messages to be lost.

Table 6-2. Software Update—Duplicated SPE

Step	Time (min)	Remarks
change sys-par maint	2	Note the current settings of the Save Translation, SPE Interchange, and Alarm Origination Activated fields and then set them to n. Set CPE Alarm Activation Level to none. Make sure scheduled daily maintenance is not set to run during the update.
save announcements	40	These steps create a backup removable media cartridge in case the update fails and a backout is necessary. Saving announcements may be skipped if **display announcements** shows no administered announcements.
save translation	2	
backup disk	10	
Remove removable media cartridges. Clean TN1656 tape drives, if present.	5	Thie procedure to clean a TN1656 tape drive is described under “R-MEDIA” in Chapter 9, “Maintenance Object Repair Procedures”.
Insert the removable media cartridges containing the new software	2	Wait for the removable media cartridge to reposition itself.
list config software-version long	5	Make sure the removable media cartridges have the expected version number.
restore disk install both	10	Copies new removable media cartridge files to disk. If updating *from* a load earlier than 6.0, substitute for this step the following sequence: **copy announce removable media cartridge**, **save translation removable media cartridgeremovable media cartridge**, then **restore disk full both**.

Continued on next page

Table 6-2. Software Update—Duplicated SPE — *Continued*

Step	Time (min)	Remarks
The following step will result in the service effects described above. **upgrade software** to-version	10	Use the new software version number described above. The system will reboot the standby SPE, reload translations, and then execute an SPE interchange. Results of each step in the upgrade process and initialization diagnostics will be displayed on the terminal. **NOTE:** Be careful not to touch the G3-MT keyboard while waiting for the command to execute, or the result messages may be lost.
Log in on the G3-MT.		
status spe	5	Repeat this command until the states of health of both SPEs are *functional*.
reset spe-standby 4	5	This step initiates a reboot of the standby SPE with the new software load.
status spe	15	Repeat this command until the states of health of both SPEs are *functional*.
change sys-par maint	2	Set the Save Translation, Alarm Origination Activated, CPE Alarm Level, SPE Interchange fields and Daily Scheduled Maintenance times to the values that were in effect before starting this procedure.
save translation both	2	This step stores the upgraded translations on both disks.
backup disk	20	This step makes a backup copy of the new files. The next run of scheduled maintenance will also do this. If a coredump from before the upgrade is on disk, this can take up to 50 minutes.
test stored-data	10	This step verifies that all MSS files are consistent. The next run of scheduled maintenance will also do this.
list config soft long	5	Verify that all files are correct.

Continued on next page

Table 6-2. Software Update—Duplicated SPE — *Continued*

Step	Time (min)	Remarks
backup disk	20	Make extra backup copies of the new files as needed.
set vector f spe-maint	1	Sets the coredump vector to take a coredump when the system reboots.
Restore the system as described above.		

DS1 CPE Loopback Jack (T1 Only)

Using the DS1 CPE Loopback Jack (apparatus code 700A, comcode 107988867), a technician can test the DS1 span between the system and the network interface point. The loopback jack is required when DC power appears at the interface to the ICSU. *The loopback jack isolates the ICSU from the DC power and properly loops the DC span power*.

NOTE:
The loopback jack operates with any vintage of TN767E (or later) or TN464F (or later) DS1 circuit packs and with G3V3 EDI Release 3 (or later) software. The loopback jack operates with the 120A2 (or later) Integrated Channel Service Unit (ICSU) only; *not* the 31xx series of Channel Service Units or other external CSUs or earlier ICSUs.

Loopback Jack Installation

Configurations Using a Smart Jack

The preferred location of the loopback jack is at the interface to the Smart Jack. This provides maximum coverage of CPE wiring when remote tests are run using the loopback jack. If the Smart Jack is not accessible, install the loopback jack at the extended demarcation point.

1. If there is no extended demarcation point, install the loopback jack directly at the network interface point as shown in Figure 6-1.
2. If there is an extended demarcation point and the Smart Jack is not accessible, install the loopback jack as shown in Figure 6-2.
3. If there is an extended demarcation point, but the Smart Jack is accessible, install the loopback jack as shown in Figure 6-3.

Configurations without a Smart Jack

1. Install the loopback jack at the point where the cabling from the ICSU plugs into the “dumb” block. If there is more than one “dumb” block, choose the one that is closest to the Interface Termination feed or the fiber MUX. This provides maximum coverage for loopback jack tests. Refer to Figure 6-4 and Figure 6-5.

Installation

1. To install the loopback jack, simply disconnect the RJ-48 (8-wide) connector (typically an H600-383 cable) at the appropriate interface point and connect the loopback jack in series with the DS1 span. See Figure 6-1 through Figure 6-5.
2. Plug the H600-383 cable from the ICSU into the female connector on the loopback jack.
3. Plug the male connector on the loopback jack cable into the network interface point.

   NOTE:
   Do not remove the loopback jack after installation. This is not a test tool and should always be available to remotely test a DS1 span.

Administration

1. At the management terminal, enter **change ds1** ***location*** (the DS1 interface circuit pack for which the loopback jack was installed).
2. Be sure the `near-end CSU type` is set to **integrated**.
3. On page 2 of the form, change the `supply CPE loopback jack power` field to **y**.

   NOTE:
   Setting this field to **y** informs the technician that a loopback jack is present on the facility. This allows a technician to determine that the facility is available for remote testing.

4. Enter **save translation** to save the new information.

DS1 Span Test

This test should only be performed after the DS1 circuit pack and the 120A2 (or later) ICSU have been successfully tested using appropriate maintenance procedures. The DS1 span test consists of 2 sequential parts. Each part provides a result indicating if there is a problem in the CPE wiring. CPE wiring may be considered problem-free only if the results of both parts are successful.

The first part of the span test powers-up the loopback jack and attempts to send a simple code from the DS1 board, through the wiring and loopback jack, and back to the DS1 board. Maintenance software waits about 10 seconds for the loopback jack to loop, sends the indication of the test results to the management terminal, and proceeds to the second part of the test.

The second part of the test sends the standard DS1 3-in-24 stress testing pattern from the DS1 board, through the loopback jack, and back to a bit error detector and counter on the DS1 board. The bit error rate counter may be examined at will via the management terminal, and provides the results of the second part of the test. The test remains in this state until it is terminated so that the CPE wiring may be bit error rate tested for as long as desired.

1. Busy out the DS1 circuit pack by entering **busyout board UUCSS**.
2. At the management terminal, enter **change ds1 *location*** and verify the `near-end csu type` is set to **integrated**.
3. Change to page 2 of the DS1 administration form and confirm that the TX LBO field is **0** (dB). If not, record the current value and change it to 0 dB for testing. Press Enter to implement the changes or press Cancel to change nothing.
4. Enter **test ds1-loop *location* cpe-loopback-jack**. This turns on simplex power to the loopback jack and waits about 20 seconds for any active DS1 facility alarms to clear. A "PASS" or "FAIL" displays on the terminal. This is the first of the 2 results. A "FAIL" indicates a fault is present in the wiring between the ICSU and the loopback jack. The loopback jack may also be faulty. A "PASS" only indicates that the loopback jack looped successfully, not that the test data contains no errors. If a "PASS" is obtained, continue with the following steps.

   NOTE:
   The loss of signal (LOS) alarm (demand test #138) is not processed during this test while the 3-in-24 pattern is active.

5. Enter **clear meas ds1 loop <location>** to clear the bit error count.
6. Enter **clear meas ds1 log <location>** to clear the performance measurement counts.
7. Enter **clear meas ds1 esf <location>** to clear the ESF error count.
8. Enter **list meas ds1 sum <location>** to display the bit error count. Refer to Table 6-3 for troubleshooting information.

Table 6-3. DS1 Span Troubleshooting

Displayed Field	Function	Indication
Test: cpe-loopback-jack	Pattern 3-in-24	The loopback jack test is active.
Synchronized	Y or N	If “y” displays, the DS1 circuit pack has synchronized to the looped 3-in-24 pattern and is accumulating a count of the bit errors detected in the pattern until the test has ended. If “n” displays, retry the test 5 times by ending the test per Step 11 and re-starting the test per Step 4. If the circuit pack never synchronizes, substantial bit errors in the 3-in-24 pattern are likely. This could be intermittent connections or a broken wire in a receive or transmit pair in the CPE wiring.
Bit Error Count	Cumulative count of detected errors	If there are no wiring problems, the counter remains at 0. A count that pegs at 65535 or continues to increment by several hundred to several thousand on each **list meas** command execution indicates intermittent or corroded connections, severe crosstalk, or impedance imbalances between the two conductors of the receive pair or the transmit pair. Wiring may need replacement. Note that “ESF error events” counter and the ESF performance counter summaries (“errored seconds”, “bursty errored seconds”, and so forth) will also increment. These counters are not used with the loopback jack tests. However, they will increment if errors are occurring. Counters should be cleared following the test.

9. Repeat Steps 5 through 8 as desired to observe bit error rate characteristics. Also, wait 1 to 10 minutes between Steps 5 through 7. One minute without errors translates to better than a 1 in 10 to the eighth error rate. Ten minutes without errors translates to better than a 1 in 10 to the ninth error rate.
10. If the test runs for 1 minute with an error count of 0, confirm that the 3-in-24 pattern error detector is operating properly by entering **test ds1-loop <location> inject-single-bit-error**. This causes the 3-in-24 pattern generator on the DS1 circuit pack to inject a single-bit error into the transmit pattern. A subsequent **list meas ds1 summary <location>** command displays the bit error count. If a count greater than 1 is displayed, replace the ICSU and retest. If the problem continues, replace the DS1 circuit pack.

11. Terminate the test by entering **test ds1-loop <location> end cpe-loopback-jack-test**. Wait about 30 seconds for the DS1 to re-frame on the incoming signal and clear DS1 facility alarms.

    Loopback termination fails under the following conditions:

    a. The span is still looped somewhere. This could be at the loopback jack, at the ICSU, or somewhere in the network. This state is indicated by a fail code of 1313. If the red LED on the loopback jack is on, replace the ICSU. Re-run the test and verify that the loopback test terminates properly. If not, replace the DS1 circuit pack and repeat the test.

    b. The DS1 cannot frame on the incoming span's signal after the loopback jack is powered down. This means that there is something wrong with the receive signal into the loopback jack from the "dumb" block or the Smart Jack. If the service provider successfully looped and tested the span, up to the Smart Jack, this condition isolates the problem to the wiring between the loopback jack and the Smart Jack. Refer to "Loopback Jack Fault Isolation Procedures" for information on how to proceed in this case. The test cannot be successfully terminated until a good signal is received. To properly terminate the test before a good receive signal is available, enter **reset board <location>**.

12. Restore the "TX LBO" field to the original value recorded in Step 2.

13. Release the DS1 circuit pack using the **release board UUCCSSpp** command.

14. Leave the loopback jack connected to the DS1 span.

Loopback Jack Fault Isolation Procedures

This section describes the possible DS1 configurations in which the loopback jack may be used. These configurations are: when the DS1 provider includes a Smart Jack, when no Smart Jack is provided at all, and when sites use fiber multiplexers. These configurations are separated into "Configurations Using a Smart Jack" and "Configurations Without a Smart Jack."

Configurations Using a Smart Jack

The addition of the loopback jack and the presence of a Smart Jack divides the DS1 span into 3 separate sections for fault isolation. These sections are shown in Figure 6-1 through Figure 6-3 for the different span configurations. They are:

Section 1: Between the 120A2 (or later) ICSU and the loopback jack.
Section 2: Between the loopback jack and the Smart Jack (network interface point).
Section 3: From the Smart Jack to the CO. It is necessary to contact the DS1 provider to run this test.

A problem can exist in 1 or more of the 3 sections. The field technician is responsible for finding and correcting problems in the first 2 sections. The DS1 service provider is responsible for finding and correcting problems in the third section. Testing is divided into 3 steps.

- Test customer premises wiring (section 1 in the following 3 figures) from the ICSU to the loopback jack as described in “DS1 Span Test.”
- Test the CO-to-network interface wiring (section 3 in Figure 6-1) using the Smart Jack loopback (CO responsibility). Coordinate this test with the DS1 provider.
- Test the short length of customer premises wiring (section 2 in the following 3 figures) between the loopback jack and the Smart Jack. This can be done using a loopback that “overlaps” section 2 of the cable. Any of the following loopbacks can do this:

  a. The local ICSUs line loopback, which is typically activated, tested, and then deactivated by the DS1 service provider at the CO end.

  b. The local DS1 interface’s payload loopback, activated and tested by the DS1 service provider at the CO end.

  c. The far-end ICSU’s line loopback. This test is activated at the management terminal by entering **test ds1-loop <location> far-csu-loopback-test-begin**. The test is terminated by entering **test ds1-loop <location> end-loopback/span-test**. Bit error counts are examined as described in “DS1 Span Test.” This test method is the least preferable because it covers wiring that is not in the local portion of the span. This test only isolates problems to section 2 wiring if there are no problems in the wiring between the far-end CO and the far-end ICSU. Coordinate this test with the DS1 service provider.

  If any of the above tests (a, b, or c) fail, a problem is indicated in section 2 as long as the tests for section 1 and section 3 pass. Since section 2 includes the network interface point, it is necessary to work with the service provider to isolate the fault to the loopback jack cable, the “dumb” block, or the Smart Jack.

4. RJ-48 to Network Interface (Up to 1000 Feet) (305 m)
5. Loopback Jack
6. “Dumb” Block (Demarcation Point)
7. Repeater
8. Fiber MUX
9. Central Office

Figure 6-5. Network Interface at “Dumb” Block with Repeater Line to Fiber MUX

Section 2 includes the short cable from the loopback jack to the “dumb” block demarcation point (part of the loopback jack). This is the only portion o f section 2 that is part of customer premises wiring but is not covered in the loopback jack’s loopback path.

A problem can exist in 1 or both of the 2 sections. The field technician is responsible for finding and correcting problems in section 1 and the loopback cable portion of section 2. The DS1 service provider is responsible for finding and correcting problems in the majority of section 2. Testing is divided into 2 steps.

1. Test customer premises wiring (section 1 in Figure 6-4) from the ICSU to the loopback jack as described in the “DS1 Span Test” section.

2. Test the loopback jack-to-"dumb" block and "dumb" block-to-CO wiring (section 2 in Figure 6-4). This can be done using a loopback that "overlaps" the section of the span. Any of the following loopbacks can do this:

   a. The local ICSUs line loopback, which is typically activated, tested, and then deactivated by the DS1 service provider at the CO end.

   b. The local DS1 interface's payload loopback, activated and tested by the DS1 service provider at the CO end.

   c. The far-end ICSU's line loopback. This test is activated at the management terminal by entering **test ds1-loop <location> far-csu-loopback-test-begin**. The test is terminated by entering **test ds1-loop <location> end-loopback/span-test**. Bit error counts are examined as described in the "DS1 Span Test" section. This test only isolates problems to section 2 wiring if there are no problems in the wiring between the far-end CO and the far-end ICSU. Coordinate this test with the DS1 service provider.

   If any of the above tests (a, b, or c) fail, a problem is indicated in section 2. This could mean bad loopback jack -to-"dumb" block cabling, but is more likely to indicate a problem somewhere between the "dumb" block and the CO. This is the responsibility of the DS1 service provider. If the DS1 Span Test confirms that there are no problems in section 1, the technician should proceed as follows to avoid unnecessary dispatch.

   - Identify and contact the DS1 service provider
   - Inform the DS1 provider that loopback tests of the CPE wiring to the "dumb" block (section 1) showed no problems
   - If the far-end ICSU line loopback test failed, inform the DS1 provider
   - Request that the DS1 provider perform a loopback test of their portion of the section 2 wiring by sending someone out to loop section 2 back to the CO at the "dumb" block.

     If this test fails, the problem is in the service provider's wiring.

     If the test passes, the problem is in the cable between the loopback jack and the "dumb" block. Replace the loopback jack.

Configurations Using Fiber Multiplexers

Use the loopback jack when customer premises DS1 wiring connects to an on-site fiber multiplexer (MUX) and allows wiring to the network interface point on the MUX to be remotely tested. This requires that ICSUs be used on DS1 wiring to the MUX.

Fiber MUXes can take the place of Interface termination feeds as shown in Figure 6-1 , Figure 6-2, Figure 6-3, and Figure 6-4. Test these spans using the same procedures as metallic spans. Note the following points:

1. Fiber MUXes may have loopback capabilities that can be activated by the service provider from the CO end. These may loop the signal back to the CO or back to the DS1 board. If the MUX provides the equivalent of a line loopback on the "problem" DS1 facility, this may be activated following a successful loopback jack test and used to isolate problems to the wiring between the loopback jack and the MUX.
2. Be aware that there are installations that use repeatered metallic lines between the MUX and the "dumb" block. These lines require DC power for the repeaters and this DC power is present at the "dumb" block interface to the CPE equipment. *A loopback jack is required in this configuration to properly isolate and terminate the DC power*.

To check for the presence of DC, make the following 4 measurements at the network interface jack:

1. From Transmit Tip (T, Pin 5) to Receive Tip (T1, Pin 2)
2. From Transmit Ring (R, Pin 4) to Receive Ring (R1, Pin 4)
3. From Transmit Tip (T, Pin 5) to Transmit Ring (R, Pin 4)
4. From Receive Tip (T1, Pin 2) to Receive Ring (R1, Pin 4)

All measurements should read 0 (zero) volts DC. For pin numbers and pin designations, refer to *Integrated Channel Service Unit (ICSU) Installation and Operation*, 555-230-193.

Operating Charasteristics

If a TN464F or TN767E and a 120A2 were installed in a system running pre-G3V3 software and the software is later upgraded to G3V3 Release 3 or later, reseat the DS1 circuit pack so that the ICSU administration fields will appear on the DS1 administration form.

Facility test calls

The Facility Test Calls feature allows you to use a voice terminal to make test calls to specific trunks, time slots, tones, and tone receivers within the system. The test call verifies that the accessed component is functioning properly. To use this feature, it must be enabled on the Class of Restriction form, and you must know the Facility Test Call Access Code. The code can be retrieved by entering **display feature-access-codes**. It appears on page one of the screen output.

NOTE:
For the ISDN-PRI Test Call feature see ''Troubleshooting ISDN-PRI Test Call Problems'' in Chapter 5, ''Alarms, Errors, and Troubleshooting''.

NOTE:
The following test call descriptions are for voice terminal users:

Trunk test call

The trunk test call accesses specific Tie or CO trunks, including DS1 trunks. If the trunk is busied out by maintenance, it will be temporarily released for the test call and returned to busyout afterwards. Before making the test call, use **list configuration** to determine the location of the trunk ports that you which to test. DID trunks cannot be accessed.

NOTE:
Do not use this trunk test call procedure to test ISDN-PRI or ATM-CES trunks. For more information on testing ISDN-PRI or ATM CES trunks see ATM-BCH, Test #258.

To place a trunk test call:

1. Dial the FAC described above and listen for dial tone.
2. Dial the 7-digit port location UUCSSpp, where:

   UU= Cabinet number (01 for PPN, 02 -- 44 for EPNs)

   C = Carrier number (A=1, B=2, C=3, D=4, E=5)

   SS = Slot number (01--20)

   pp = Port circuit number (01--24)

   The channels on a DS1 trunk are addressed by using the channel number for the port number.
3. Listen for one of the following tones:

Dial tone or Silence	The trunk is connected. Go to step 4.
Busy Tone	The trunk is either busy processing a call or is out of service. Check **status trunk**.
Reorder tone	The trunk requested is in a different port network from your station, and inter-PN resources are not available to access it.
Intercept Tone	The port addressed is not a trunk, or it is a DID trunk, or the trunk is not administered.
Confirmation Tone	The port is a tone receiver. See the "DTMR Test Call" section.

4. Place a call. If the call does not go through (no ringing is heard) check to see if the circuit has been removed or if the trunk is a rotary trunk.

The dial tone heard is coming from the far-end. If the far end has been disabled, you will not hear dial tone. However, depending on far-end administration, you may still be able to dial digits. All digits dialed after the port number are transmitted using end-to-end DTMF signaling. If the trunk being tested is a rotary trunk, it is not possible to break dial tone.

DSO Loop-Around Test Call

The DS0 Loop Around feature provides a loop around connection for incoming Non-ISDN DS1 trunk data calls. This feature is similar to the far end loop around connection provided for the ISDN Test Call feature. This DS0 loop around is provided primarily to allow a network service provider to perform facility testing at the DS0 level before video teleconferencing terminals are installed at the PBX.

The feature is activated on a call-by-call basis by dialing a test call extension specified on the second page of the System Parameters Maintenance form. No special hardware is required. When the test call extension is received by the PBX, a non inverting 64 kbps connection is set up on the PBX's Time Division Multiplexed bus. More than one loop around call can be active at the same time.

For calls routed over the public network using the ACCUNET Switched Digital Service (SDS) or Software Defined Data Network (SDDN), the data transmission rate is 56 Kbps since robbed bit signaling is used. For calls established over a private network using common channel signaling, the full 64 kbps data rate is available.

When the incoming trunk group is used only for data calls (SDS), the Communications Type on the associated Trunk Group form should be set to “data”. When the incoming trunk group is used for robbed bit alternate voice and/or data (SDN/SDDN), the Communications Type on the Trunk Group form should be set to “rbavd” (robbed bit alternate voice data). For private network trunks using common channel signaling, the Communications Type on the associated Trunk Group form can be set to “avd”.

DTMR Test Call

This call accesses and tests the dual tone multifrequency receivers (DTMR-PTs) located on TN420 and TN748 Tone Detector circuit packs. These tone receivers are also known as touch tone receivers (TTRs). Before making the test call, use **list configuration** to determine the location of the TN420 or TN748 that you which to test.

To place a tone receiver test call:

1. Dial the FAC described in the introduction to this section and listen for dial tone.
2. Dial the seven-digit port location UUCSSpp of one of the four DTMR ports located on a Tone Detector circuit pack:

   C = Carrier number (A=1, B=2, C=3, D=4, E=5)

   SS = Slot number (00-20)

   pp = Port circuit number (DTMR ports are numbered 01, 02, 05, and 06.
3. Listen for one of the following tones:

Confirmation tone	The DTMR is connected. Go to step 4.
Intercept tone	The port entered is not a TTR, (if a trunk, see above), or the board is not inserted.
Reorder tone	The DTMR is in use, (call processing), the board is busied out, or inter-PN resources are unavailable for the call.
Dial tone	The port is a trunk. See the preceding section.

4. Dial the sequence **1234567890*#**.

   If the sequence is entered and received correctly, dial tone is returned and another test call can be made. If the test fails, intercept tone is returned. A failure may indicate a faulty DTMR port or circuit pack, a faulty voice terminal, or an error in the entry of the sequence.
5. To test another DTMR, repeat steps 2 through 4.
6. To terminate the test call, hang up the station set used for testing.

TDM Bus Time Slot Test Call

The time slot test call connects the voice terminal to a specified time slot on the A or B TDM Bus of a specified port network. To connect to any out-of-service time slots, refer to the ''Out-of-Service Time Slot Test Call'' section.

To test a specific time slot on the TDM bus of a specific port network:

1. Dial the FAC described in the introduction to this section and listen for dial tone.
2. Dial the 2-digit port network number followed by # and the 3-digit time slot number listed in the following table.
3. Listen for one of the following tones:

Reorder tone	The time slot is in use, the time slot is not addressable, or inter-PN resources are not available to make the call.
Confirmation tone	The time slot is idle or out-of-service. The time slot may be on the TDM bus (A or B) that is not currently carrying tones, or it may be busied out. The call is connected to the time slot so that any noise may be heard.
System tone	The time slot is carrying a system tone as listed in the following table.

TDM Bus Time Slots

When you address a tone-carrying time slot on the TDM bus (A or B) that is currently carrying tones, you will be connected to that time slot and will hear the tone.

Time slots 005-021 and 261-277 are reserved to carry the system's dedicated tones. Time slots 000-004 and 256-260 carry control information and are not addressable. Time slots 254 and 510 are not addressable due to a hardware constraint. At any given time, only one of the TDM busses (A or B) carries the dedicated tones, with B being the default. Entering **status port-network** will display which TDM bus is currently carrying the dedicated tones. The corresponding time slots on the other bus are normally inactive and are used for call service only as a last resort when all other non-control channel time slots on both busses are busy. Bus A's tone time slots are numbered 005-021; bus B's tone time slots are numbered 261-277.

Table 6-4. TDM Bus Time Slot Numbers

TDM Bus A time slot	TDM Bus B time slot	Tone Heard
000	256	Reorder
001	257	Reorder
002	258	Reorder
003	259	Reorder
004	260	Reorder
005	261	Touch Tone 1 - 697Hz
006	262	Touch Tone 2 - 770 Hz
007	263	Touch Tone 3 - 852Hz
008	264	Touch Tone 4 - 941 Hz
009	265	Touch Tone 5 - 1209 Hz
010	266	Touch Tone 6 - 1336Hz
011	267	Touch Tone 7 - 1447 Hz
012	268	Touch Tone 8 - 1633 Hz
013	269	Dial Tone
014	270	Reorder Tone
015	271	Alert Tone
016	272	Busy Tone
017	273	Ringback Tone
018	274	Special Ringback Tone
019	275	2225 Hz Tone
020	276	Music
021	277	Tone on Hold
022-253	278-509	Confirmation (used for calls)
254	510	Reorder
255	511	Confirmation

Out-of-Service Time Slot Test Call

This call can be used to determine if there are any out-of-service time slots on the TDM bus of a specified port network. If there are, you will be connected to one. By listening to noise on the time slot and selectively removing circuit packs, you may be able to isolate the source of interference.

To place the call:

1. Dial the FAC described above and listen for dial tone.
2. Dial the port network number followed by **** and listen for one of the following tones:

Reorder tone	There are no out-of-service time slots on the specified port network.
Confirmation tone	Connection is made to an out-of-service time slot.

3. Repeated test calls will alternate between out-of-service time slots on TDM bus A and TDM bus B.

System Tone Test Call

This test connects the voice terminal to a specific system tone.

To place the call:

1. Dial the FAC described above.
2. Dial the port network number followed by * and the two-digit tone identification number from the following table.
3. Listen for one of the following tones:

Intercept tone	The number entered is not a valid tone number.
Reorder tone	Inter-PN resources are not available.
System tone	The specified tone will be heard if it is functioning.

NOTE:
For a definition of Call Progress Tones see *DEFINITY Communications System Generic 3 System Descriptions and Specifications, 555-230-206,* Chapter 11.

Table 6-5. System Tone Identification Numbers

Number	Description
00	Null tone

68	Conference/bridging tone

Preventive Maintenance

The following preventive maintenance procedures should be followed when visiting customer sites. The chart that follows shows a sample of the Preventive Maintenance Log. Whenever you complete a preventive maintenance procedure, be sure to fill in the information on the log form before you leave the customer's premises.

Air Filters

Air filters should be inspected annually. If a filter is dirty or clogged, first tap it on the ground. If the filter is still dirty or clogged, then wash it with warm water and a mild detergent. A vacuum cleaner can be used if one is available. If there is no facility for washing or vacuuming the air filter, then replace the filter. Refer to ''CABINET (Cabinet Sensors)'' maintenance documentation for information on air filters and fans.

TN1656 Tape Drive

Note: This procedure applies ONLY to the TN1656 Tape Drive. DO NOT attempt to clean a TN2211 Optical Disk Drive, as this will damage the optical disk drive. The TN2211 Optical Disk Drive does NOT require cleaning.

The head and capstan on the tape drive of the SPE should be cleaned every three months. Abrasive particles from worn tape and environmental debris can cause loss of information and services. The procedure for cleaning the removable media drive is described in the section on R-MEDIA in Chapter 9.

Batteries

The backup batteries in the power distribution unit in the bottom of the cabinet should be replaced every four years or whenever a POWER alarm that indicts the condition of the batteries is logged. Systems with an uninterruptible power supply (UPS) may not be equipped with backup batteries.

PREVENTIVE MAINTENANCE LOG

3 Replace every 4 years

Post this form with the equipment.

Analog Tie Trunk Back-to-Back Testing

The TN760 circuit pack can be configured for back-to-back testing (also known as connectivity testing) by making translation and cross-connect changes. This testing configuration allows for the connection of Tie Trunks back-to-back in the same switch to verify the operation of Tie Trunk ports. The tests can be performed in either the E&M or simplex modes. (Refer to *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test,* 555-230-104, for instructions on how to make connections at the cross-connect field).

E&M Mode Test Procedure

1. At the administration terminal, enter **list configuration trunks** to determine which ports are assigned on the Tie Trunk circuit pack.
2. Enter **display dialplan** command to determine the Trunk Access Code (TAC) format.
3. Enter **display port** xxx for all ports defined in Step 1. This displays the trunk groups of which the ports are members. See Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’ for details of how to remove and replace port circuit packs.
4. Insert the circuit pack back into the slot.
5. Enter **display trunk** xxx **p** for each trunk group identified in Step 3. This command displays the specified trunk group on the administration terminal screen and prints a hard copy on the printer. Save this data for later use.
6. Remove all members defined by these ports from the trunk group(s) using the **change trunk** xxx command.
7. Remove the Tie Trunk circuit pack from the carrier slot.
8. Set the dip (option) switches for each of the two ports to be tested on the Tie Trunk circuit pack to “E&M mode” and “unprotected.”
9. Enter **add trunk n** to add a new (test) trunk group. Then enter information for the following fields:

Group Type	tie
TAC	Use trunk access code obtained from dial plan
Trunk Type (in/out)	wink/wink
Port	Assign two of the ports from the tie trunk.
Mode	E&M for both ports
Type	Specify one port as **t1 standard** and other port as **t1 compatible**.

10. Locate the Tie Trunk port terminal connections at the cross-connect field. Consult the appropriate table below for either 110-type or 66-type hardware.
11. At the cross-connect field, disconnect outside trunk facilities from the Tie Trunk ports and mark the disconnected wires for reconnecting the Tie Trunk ports to their normal configuration later. The D Impact Tool (AT-8762) is required to perform this step.
12. Use jumper wires (DT 24M-Y/BL/R/G and DT 24P-W/BRN) and the D Impact Tool to connect wiring between the two ports assigned in Step 9 at the cross-connect field. For example, if the two ports on the Analog Tie Trunk circuit pack are port 1 and 2, connect the wirings as shown below:

Port 1 (t1 stan) (E & M)		Port 2 (t1 comp) (E & M)
T1	connected to	T12
R1	“	R12
T11	“	T2
R11	“	R2
E1	“	M2
M1	“	E2

13. Check all wirings to verify good connections between the two test ports.
14. Place a call from one voice terminal to another voice terminal using the Tie Trunk ports assigned. Dial TAC and extension. For example, if TAC of Tie Trunk group is 110 and station number is 5012, then dial 110 5012. If the call cannot be made, either one of these ports could be defective. There are four ports on the TN760. Try different combinations to determine defective ports.
15. If there is a defective port on the circuit pack, try to switch to an unused port. If all ports are normally used, then replace the circuit pack.
16. Disconnect the jumpers between two ports. Then use administration terminal and trunk printouts to restore all trunk group changes to normal values.

Simplex Mode Test Procedure

1. Repeat Steps 1 through 7 of the E&M Mode Test Procedure.
2. Set the dip (option) switches for each of the two ports to be tested on the Tie Trunk circuit pack to simplex mode.
3. Enter **add trunk n** to add a new (test) trunk group. Then enter information for the following fields:

Group Type	tie
TAC	Use trunk access code obtained from dial plan.
Trunk Type (in/out)	wink/wink
Port	Assign two of the ports from the tie trunk.
Mode	simplex
Type	type 5

4. Locate the Tie Trunk port terminal connections at the cross-connect field. Consult the appropriate table above for either 110-type or 66-type hardware.
5. At the cross-connect field, disconnect outside trunk facilities from the Analog Tie Trunk ports and mark the disconnected wires for later when the Tie Trunk ports are placed back into normal operation. The D Impact Tool (AT-8762) is required to perform this step.
6. Use jumper wires (DT 24M-Y/BL/R/G) and the D Impact Tool to connect wiring between the two ports assigned in Step 4 at the cross-connect field. For example, if the two ports on the Analog Tie Trunk circuit pack are ports 1 and 2, connect the wirings as shown below:

Port 1	connected to	Port 2
(type 5)		(type 5)
(simplex)		(simplex)
T1	connected to	T12
R1	“	R12
T11	“	T2
R11	“	R2

7. Repeat Steps 13 through 16 of the E & M Mode Test Procedure.

Terminating Trunk Transmission Testing

The Terminating Trunk Transmission (TTT) (non-interactive) feature provides for extension number access to three tone sequences that can be used for trunk transmission testing from the far end of the trunks.

The three test types should have extension numbers assigned on the Maintenance-Related System Parameters Form.

```
Test Type 100:___   Test Type 102:___   Test Type 105:___
```

Test Type 100 provides:

- 5.5 seconds of 1004 Hz tone at 0dB
- Quiet until disconnect; disconnect is forced after one minute

Test Type 102 provides:

- 9 seconds of 1004 Hz tone at 0dB
- 1 second of quiet
- This cycle is repeated until disconnect; disconnect is forced after 24 hours.

Test Type 105 provides:

- 9 seconds of 1004 Hz at -16dB
- 1 second of quiet
- 9 seconds of 404 Hz at -16dB
- 1 second of quiet
- 9 seconds of 2804 Hz at -16dB
- 30 seconds of quiet
- 1/2 second of Test Progress Tone (2225 Hz)
- Approximately five seconds of quiet
- Forced disconnect

Removing and Restoring Power

CAUTION:
*Error Log information is lost when the PPN cabinet is powered down. If this information is to be saved, enter the **reset system 4** command. The command will take several minutes to complete, and will result in saving of the Error Log to the MSS.*

CAUTION:
Before powering down a cabinet or carrier that contains DEFINITY AUDIX circuit packs (TN566 and TN2169), you must first power down the AUDIX unit to avoid damage to the AUDIX software Instructions for powering down this unit appear on the circuit pack and in DEFINITY AUDIX documentation.

CAUTION:
If there is an alarm or problem suspected on the Removable Media or Disk Circuit packs do not save translations or announcements to the affected device. If there is an alarm or problem suspected with the Host Adapter circuit, do not save data to either MSS device. Saving data under these circumstances can destroy good copies of the file. If necessary, obtain a spare removable media cartridge to save data.

To remove power to the cabinet:

1. If the cabinet is the PPN, execute **save translation** and **save announcement** unless a removable media drive problem is active.
2. Set the Emergency Transfer switch(es) in the affected cabinet to ON. In the PPN these are located on the SYSAM circuit pack(s). Set both in a system with duplicated SPE. In an EPN the switch is located on the EPN Maintenance circuit pack. This locks the system in the emergency transfer mode until the trouble is cleared.
3. Depending on which type of cabinet you are powering down, do one of the following:
   - In an AC-Powered multi-carrier cabinet, set the circuit breaker to OFF at the Power Distribution Unit.
   - In a DC-Powered multi-carrier cabinet, turn off the DC Power supply.
   - In an AC-Powered single-carrier cabinet stack, turn off the power in each affected carrier individually. The ON/OFF switch is located at the back of the carrier behind the WP-91153 Power Unit.
   - In a DC-Powered single-carrier cabinet stack, turn off the power in each affected carrier individually. The ON/OFF switch is located at the back of the carrier behind the 676B Power Unit.
4. Power is restored by reversing the action taken above.

   When restoring power to a PPN, the system will reboot. When restoring power to an EPN, the EPN will under go a restart. This process is described under EXP-PN in Chapter 9, ''ABRI-PORT (ASAI ISDN-BRI Port)''.

   If a powered down carrier contains a 676B Power Unit, the 676B must have been powered down for at least 10 seconds for the unit to restart.

Automatic Transmission Measurement System (ATMS)

The ATMS performs transmission tests on analog trunks to determine whether they are performing satisfactorily. The switch automatically originates test calls from an Originating Test Line (OTL), over the trunks to be tested, to a Terminating Trunk Line (TTL) on the switch at the far end of the trunk. Several different measurements of noise and attenuation are made and compared to administered thresholds. Test measurements can be viewed in the form of detailed or summary reports which are described below.

ATMS test calls can be initiated on demand from the management terminal, or automatically by ATMS Trunk Test Schedules. For complete details on how to set up ATMS Trunk Test Schedules, see Chapter 4 of *Generic 3 V2 Implementation, 555-230-653*. Demand tests are run with the **test analog-testcall** command which is described below.

Trunk groups can be administered to respond in different ways when a trunk fails to perform within the administered thresholds. Alarms and errors may be logged, and the trunk can be automatically busied out. When a trunk fails an unacceptable threshold twice, the system will busy it out if the trunk group is so administered and doing so will not exceed an administered limit (25, 50, 75, or 100% of the members in the group). This limit is not applied to later busyouts caused by other factors. Trunks can be manually returned to service by changing the thresholds and running a demand test or by using the release command.

ATMS Requirements

ATMS tests utilize the analog port (port number 01) on a TN771 Maintenance/Test circuit pack. Each PPN contains one TN771. Depending on system configuration, each EPN may also contain one TN771. Multiple TN771s allow up to 3 concurrent test calls.

AMTS tests are designed to operate on the types of trunks found in the US, and the TN771 analog port is Mu-law companding only. The tests will not be useful in all environments.

For ATMS tests to run, several administrative prerequisites must be met. The following list shows the field entries necessary to enable testing.

Table 6-7. ATMS Administration

Form	Field	Entry/Remarks
System-parameters customer options	ATMS?	**y** (You must logoff/login in order for changes on this form to take effect.)
Station	Extension	At least one TN711 analog port must be assigned.
	Port Number	**UUCSS01** where UUCSS is the location of any TN771
	Port Type COR	**105TL** The number of a COR that has testing enabled (see next form)
Class of Restriction	Facility Access Trunk Test	**y**
Trunk Group	Maintenance Tests? ATMS Thresholds (page 4 of form)	**y** This page is used to specify performance thresholds, the type and access number of the far-end TTL, and system response to test failures.
Hunt Group		(Optional, for incoming test calls) If the system has several TN771s, you can use this form to make up a hunt group of TTLs so that one extension can be used for the whole pool.
ATMS Trunk Test Schedule		(Optional) To set up a test schedule, see Chapter 4 of *Generic 3 V2 Implementation,* 555-230-653.

Running ATMS Tests (Test Analog-Testcall Command)

ATMS test calls can be originated either on demand or according to the ATMS Test Schedule. Test schedules are set up with **test-schedule** commands which are described in *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*.

Demand test calls are originated by the **test analog-testcall** command. You can specify testing of an entire trunk group, an individual trunk, or all trunks on a single circuit pack. Trunks can be addressed by either group/member numbers or circuit pack/port locations. The type of test call, the number of the testing line on the far-end switch and various other parameters must be administered on the trunk group form before the command can execute.

Normally you should invoke only the full or supervision tests. The other options are provided mainly for use in setting up an ATMS schedule. Which tests are run depend on the type of TTL at the far end to which the test call is made. The following table shows which tests are run for each type of TTL. Command syntax is as follows:

test analog-testcal

> **trunkgroup#/| member#| port UUCSSpp | boardUUCSS [full | supervision | no-selftest | no-return-loss | no-st-or-rl] [repeat#][schedule]**

Input Parameters

trunk addresses	You can specify a single trunk or several trunks by using **trunk**, **port**, or **board** addresses. These parameters are described in the introduction to Chapter 8, ''Maintenance Commands''. If you enter a trunk group number without a member number, all members of the group are tested.
full	This executes the most comprehensive test call available using the administered test set type. "Full"is the default.
supervision	This test takes about 10 seconds and simply confirms the presence of testing capability at the far end.
no-selftest	This executes the full test, but skips self test sequences. This saves about 20 seconds on the type 105 transmission test and has no effect on type 100 and 102 transmission tests.
no-return-loss	This executes the full test, but skips return loss sequences. This saves about 20 seconds on the type 105 transmission test and has no effect on type 100 or 102 transmission tests.
no-st-or-rl	This executes the full test, but skips the self test and the return loss sequences. This saves about 40 seconds on the type 105 transmission test and has no effect on type 100 or 102 transmission tests.
repeat #	This specifies repeating the tests up to 99 times. The default is a single run of the tests.
schedule	This qualifier brings up a form for scheduling execution of the test at a later time. This is not the same as setting up an ATMS Test Schedule, which is described above.

Different TTLs have different measurement capabilities and you will need the following information about specific TTL types. This table does not include the self-test nor does it distinguish between measurements for different test tone levels.

Table 6-8. Measurement Capability by TTL Type

Test	Terminating Test Line Type: 105 Type with Return Loss	105 Type without Return Loss	High-level/ Low-level Tone Source	100 Type	102 Type
1004 Hz Loss Far-End to Near-End	x	x	x	x	x
1004 Hz Loss Near-End to Far-End	x	x			
404 Hz Loss Far-End to Near-End	x	x	x		
404 Hz Loss Near-End to Far-End	x	x			
2804 Hz Loss Far-End to Near-End	x	x	x		
2804 Hz Loss Near-End to Far-End	x	x			
C-Message Noise Near-End	x	x	x	x	
C-Message Noise Far-End	x	x			
C-Notched Noise Near-End	x	x			
C-Notched Noise Far-End	x	x			
Return Loss[1] Near-End	x	x	x	x	
Return Loss Far-End					

1 Return Loss includes Singing Return Loss High Frequency, Singing Return Loss Low Frequency, and Echo Return Loss.

Test Call Results

If the test call successfully completes, and all trunks test within administered thresholds for marginal and unacceptable performance, then a PASS result is returned. If the test aborts or fails, an error code indicating the cause is returned. The error codes are explained in the CO-TRK and TIE-TRK sections of Chapter 9, ''ABRI-PORT (ASAI ISDN-BRI Port)''. When the trunk is being used for call processing, the test aborts. When the trunk is already being tested by maintenance software, the test is queued and run when the maintenance activity finishes.

Measurement data gathered by analog testcalls can be retrieved with the **list testcalls** command which is described below. Which measurements are made and recorded depends on which type of test is specified and the capabilities of the far-end TTL.

Screen 6-1 shows a typical result for **test analog-testcall trunk 60**

```
test analog-testcall trunk 60                                  SPE B

                                  TEST RESULTS

 Port      Maintenance Name  Alt. Name  Test No. Result   Error Code

 02B1901   TIE-TRK           060/001     845      PASS
 02B1902   TIE-TRK           060/002     845      PASS
 02B1903   TIE-TRK           060/003     845      PASS
 02B1904   TIE-TRK           060/004     845      ABORT      1004
 02B1905   TIE-TRK           060/005     845      PASS
 02B1906   TIE-TRK           060/006     845      ABORT      1004
```

Screen 6-1. Test Results for test analog-testcall trunk 60

Output Fields

`Port`	The physical location of the port supporting the trunk being tested. The format is UUCSSpp where UU is the cabinet number, C is the carrier letter, SS is the circuit pack slot, and pp is the port circuit number.
`Maintenance Name`	The name of the maintenance object tested, TIE-TRK or CO-TRK.
`Alt. Name`	The trunk group number and member number of the trunk being tested.
`Test Number`	ATMS tests are numbered 844 through 848.
`Result`	If the test call successfully completes, and all trunks test within administered thresholds for marginal and unacceptable performance, then a PASS result is returned. If measurements fall outside the thresholds, the test fails. The trunks group can be administered to log errors and alarms, and to busy out the failed trunk. If the test call cannot be completed, an ABORT is returned.
`Error Code`	This numerical code indicates the reason for a failure or abort. The codes are explained in the CO-TRK and TIE-TRK sections of Chapter 9, ''ABRI-PORT (ASAI ISDN-BRI Port)''.

ATMS Reports (List Testcall Command)

The **list testcalls** command produces detailed and summary reports of measurements made by the Automatic Transmission Measurement System (ATMS). Measurement reports contain data on trunk signal loss, noise, singing return loss, and echo return loss, and are used to determine the quality of trunk lines. The system maintains a database with the results of the last test for each trunk. System resets clear all transmission test data, and ATMS measurements are not backed up by the Mass Storage System.

ATMS parameters are administered on page 4 of the trunk group form. These include thresholds for marginal and unacceptable performance. On the screen display, measurements that exceed the marginal threshold are highlighted. Measurements that are exceed the unacceptable level appear flashing, indicating unusable trunks. Trunk groups can be administered to log errors and alarms, and busyout the failed trunk in response to such results.

The detailed report lists measurements for each trunk group member. The summary reports lists trunk groups as a whole. Which measurements are displayed depends on what type of test, if any, was last run on the trunk, and the capabilities of the TTL on the switch at the far end of the trunk. See the preceding description of the **test analog-testcall** command. A blank line indicates that no test data is available for that trunk or group.

The number of pages of each report is dependent upon the selection criteria and the number of outgoing trunks in the system. About 10 measurements can be listed on a page on the administration terminal, or about 50 measurements can be listed on a printer. By default, reports list all measurements. Filtering can be used to limit the output. For example, the report can be set up to print only failed measurements.

The syntax of the command is as follows:

list testcalls detail | summary

[port UUCSSpp]
[grp group#] [to-grpgroup#]
[mem member#] [to-memmember#]
[resultresultID> | not-resultresultID]
[count#] [print | schedule]

Input Parameters - List Testcall Command

detail	This qualifier specifies a detailed report that shows each measurement made for each trunk.
summary	This qualifier specifies a report that shows totaled results of ATMS tests for trunk groups as a whole.
grp #	This qualifier specifies a report showing measurements for a specific trunk group. When used with **to-grp**, this option specifies the starting trunk group in a range.
to-grp	This qualifier specifies a report showing measurements for all trunk groups from 1 up to the trunk group number entered. When used with **grp**, this is the ending trunk group in a range.
mem	Used with **grp**, this qualifier specifies a report showing measurements for a specific trunk group member. When used with **to-mem**, this is starting trunk group member in a range.
to-mem	Used with **grp**, this qualifier specifies display of measurements for all trunk group members from 1 up to the specified trunk group member entered. When used with **mem**, this is the ending trunk group member in a range.
port	This qualifier specifies display of measurements for the trunk assigned to a specific port circuit.

result	Only measurements that match the specified result are displayed. Result IDs include **pass**, **marg**, **fail**, and numerical abort codes.
not-result	Only measurement results that do not match the specified result are displayed.
count number	This qualifier limits the total number of records displayed.
print	With this qualifier, the command executes immediately (if resources are available) and sends output both to the screen and to a printer connected to the terminal where the command was entered.
schedule	With this qualifier, a scheduling form is displayed which allows you to specify a start time for the command. The command is placed in the queue and, when executed, sends the output to the system printer.

ATMS Summary Reports

The ATMS Summary Report summarizes, on a trunk group basis, the collective results of the latest ATMS tests performed on each trunk group. By interacting with the trunk group form, it highlights out-of-tolerance measurements. Marginal trunks are highlighted, and unusable trunks blink, allowing you to quickly identify out-of-tolerance or unusable trunks. Screen 6-2 shows a typical summary report.

```

```

Screen 6-2. Summary Report Screen

Output Fields - ATMS Summary Report

`Trk Grp Num`	Results for each trunk group are listed by trunk group number. Trunk group number Only outgoing or two-way analog trunks are listed.
`Num Of Trks`	The number of members in the trunk group.
`Last Test Date`	The date of the oldest measurement in the trunk group.
`Last Test Time`	The time of the oldest measurement in the trunk group.
`Trunks Passed Transm Test`	The number of trunks that have passed the trunk transmission tests.
`Trunks Failed Marginal Threshld`	The number of trunks that performed outside the marginal threshold, but not the unacceptable threshold, as defined on the trunk group form.
`Trunks Failed Unaccept Threshld`	The number of trunks that performed outside the unacceptable threshold, as defined on the trunk group form.
`Trks In-Use`	The number of trunks that were in use at the time of testing. Abort codes for trunk-in-use are 1000 and 1004.
`Trks Not Test`	The number of trunks that were not tested due to error conditions other than trunk-in-use. Abort codes are given in the detailed report.
`Busied Out Trunks`	The number of trunks that were busied out in response to test failures. These may be caused by hardware problems, incorrect threshold values, and so on.

ATMS Detail Report

This report is divided into two sections. The upper section lists the trunk group, trunk type, trunk vendor, TTL type, and the user-defined threshold values administered on page 4 of the trunk group form. The lower section lists the most recent set of measurements for each member of the trunk group selected for the report. Measurements that exceed the marginal threshold, but not the unacceptable threshold, are highlighted. Measurements that exceed the unacceptable threshold blink, identifying unusable trunks. When a marginal or unacceptable measurement is located, scan the top section to find out how far the measurement deviates from its defined threshold.

Output Fields - ATMS Detail Report

Measurements are made in both directions, near to far end, and far to near end. For each measurement, there are 2 columns on the lower part of the report, “NE” for near end, and “FE” for far end. These refer to the destination end for that measurement.

`Group`	The trunk group number selected.
`Type`	The trunk group type.
`Vendor`	The vendor of this trunk group.
`TTL Type`	The type of terminating test line on the switch at the far end of the trunk to which the test call was made.
`Threshold Values`	The list of marginal and unacceptable threshold values for each type of measurement. These are defined on the trunk group form.
`Trk Mem`	The trunk member number.
`Test Date`	The month and day this trunk was last tested.
`Test Time`	The time of day this trunk was last tested.

`Tst Rslt`	The results of the trunk transmission test as follows: pass The test call completed successfully and trunk performance was satisfactory marg Trunk measurements exceeded the marginal threshold, but not the unacceptable. fail Trunk measurements exceeded the unacceptable threshold. xxxx A numerical error code indicates the reason for an aborted test call. The codes are explained in the CO-TRK and TIE-TRK sections of Chapter 9, "ABRI-PORT (ASAI ISDN-BRI Port)". blank A blank line indicates that no measurements have been made on this trunk since the database was last initialized.
`1004Hz-loss Min`	Far-to-near and near-to-far measurements of 1004-Hz loss from low-level tone.
`1004Hz-loss Max`	Far-to-near and near-to-far measurements of 1004-Hz loss at 0 dBm.
`Loss dev at 404Hz`	These low-frequency transmission tests measure maximum positive and negative deviation of +9 and -9 dB from the 1004-Hz loss measurements.
`Loss dev at 2804Hz`	These high frequency transmission tests measure maximum positive and negative deviation of +9 and -9 dB from the 1004-Hz loss measurements.
`C-msg Noise`	Maximum noise interference noise) terminating on a voice terminal within the voice-band frequency range (500 to 2500 Hz). The measurement ranges from 15 to 55 dBrnC (decibels above reference noise).
`C-ntch Noise`	Maximum signal-dependent noise interference on a line between 34 and 74 dBrnC.
`SRL-LO`	Singing return loss from 0 to 40 dB between the sum of the circuit (repeater) gains and the sum of the circuit losses. SRL-LO occurs most often in the frequency range of 200 to 500 Hz.
`SRL-HI`	Singing return loss from 0 to 40 dB between the sum of the circuit (repeater) gains on a circuit and the sum of the circuit losses. SRL-HI occurs most often in the frequency range of 2500 to 3200 Hz.
`ERL`	Echo return loss from 0 to 40 dB between the level of signal strength transmitted and the level of signal strength reflected. ERL occurs most often in the frequency range of 500 to 2500 Hz

ATMS Measurement Analysis

ATMS compares the results of the test measurements with threshold values to identify trunks that are out of tolerance or unusable. Once a defective circuit has been pinpointed, a proper analysis must be made to determine the appropriate action to take on the facility failures. Although there is no “right” procedure for every situation, the following items will help in troubleshooting problems:

- If a circuit fails an ATMS transmission test, it does not necessarily mean the trouble is in the facility itself. The problem could be caused by a faulty test line, bad switch path, or a variety of other reasons.
- If a circuit fails a transmission test but successfully passes a supervision test, some of the items mentioned above are probably not at fault, since proper call routing and circuit continuity are required for successful of a supervision test.
- If several circuits in the same group are failing, this could indicate the failure of some common equipment (such as a carrier system, test line, or cable) or erroneous information in the threshold tables.
- When a test call can be successfully made, but not completed, either the OTL or TTL is probably defective. For this failure type, further ATMS testing might be seriously impaired, but the system is not otherwise affected.
- If a test call cannot be successfully made, the wrong number might have been dialed, the far-end device might be busy, the far-end device is defective, or there is a serious trunk failure obstructing the call.

LED Interpretation

7

If a maintenance object in the system begins to fail some of the periodic tests, the system automatically generates an alarm. This alarm indicates to maintenance personnel that action is required to restore the system to a normal condition. The system identifies three levels of alarms:

- Major Alarms — Failures that cause critical degradation of service and require immediate attention.
- Minor Alarms — Failures that cause some degradation of service, but do not render a crucial portion of the system inoperable. This condition requires action, but its consequences are not immediate. Problems might be impairing service to a few trunks or stations or interfering with one feature across the entire system.
- Warning Alarms — Failures that cause no significant degradation of service or failures in equipment external to the system. Warning alarms are not reported to the attendant console or INADS.

Alarms are communicated to the system users and technicians by entries in the Alarm Log and the lighting of LEDs located on the attendant console, on all circuit packs in the switch cabinets, and, optionally, on customer-designated voice terminals.

Terminal Alarm Notification

Terminal Alarm Notification is an optional feature which displays several types of alarms on voice terminals with administered feature buttons or the attendant console. A maximum of ten digital and/or hybrid voice terminals may be used.

When an alarm occurs, the green status LED associated with the assigned button will be in a steady state. The lamp may be turned off by pressing the button associated with the lighted alarm lamp. If the lamp is turned off, and the alarm has not been resolved by the time maintenance reschedules testing, the green status LED will resume its steady state. The following alarms are displayed:

ac-alarm	Administered Connection Alarm: a locally administered connection (ADM-CONN) has a Major, Minor, or Warning alarm active.
pr-awu-alm	Auto Wakeup Journal Printer Alarm: the automatic wakeup journal printer has a Major, Minor, or Warning alarm active.
off-bd-alarm	DS1 or ATM Facility Alarm: an off-board Major, Minor, or Warning alarm is active on a DS1-BD, UDS1-BD, or ATM-TRK board.
trk-ac-alm	Facility Access Alarm: The facility access trunk test feature is activated.
major-alrm	Major Alarm: The system has logged a Major Alarm.
mj/mn-alrm	Major/Minor Alarm: The system has logged a Major or Minor Alarm.
pr-pms-alm	PMS Printer: The Property Management System printer has a Major, Minor, or Warning alarm active.
rs-alert	Reset-Alert: **reset system 2** or **3** has been performed.
cdr1-alrm	Call Detail Recording Alarm: The Primary CDR Link has a Major, Minor, or Warning alarm active.
cdr2-alrm	Call Detail Recording Alarm: The Secondary Link has a Major, Minor, or Warning alarm active.
pr-sys-alm	System Printer Alarm: The System Printer (SYS-PRNT) has a Major, Minor, or Warning alarm active.
pms-alarm	The Property Management System has a Major, Minor or Warning alarm active.

Attendant Console LEDs

The console has two red LEDs, labeled “ALM” and “ACK.” The ALM LED lights steadily when there is a Major or Minor alarm at the switch cabinet. The ACK LED lights steadily if the alarm has been successfully reported to INADS. If the system is unable to report the alarm to INADS, the LED flashes; this signals the attendant to call INADS and report the alarm.

Circuit Pack LEDs

Each circuit pack typically has three LEDs on the front panel visible at the front of the carrier, there are some exceptions to this (for example DS1CONV circuit pack) that are covered later in this section. On most circuit packs, the LEDs indicate the following when lit. Exceptions to these indications are explained in subsequent sections.

Red	Alarm	The system has detected a fault in this circuit pack. The Alarm Log should contain an on-board alarm for this circuit pack or one of the maintenance objects associated with it. The red LED is also lit briefly when a circuit pack is inserted or reset. If the circuit pack passes its initialization tests, the LED is extinguished. If a fault is detected, it remains lit.
Green	Testing	The system is currently running tests on this circuit pack as part of background maintenance or demand testing. This LED is also lit briefly during initialization tests when a circuit pack is inserted or reset.
Yellow	Busy	The circuit pack is currently in use by the system.

LED Alarms without Alarm Log Entry or with Error Type 1

Whenever the system or a part of the system is reset, all affected circuit packs will briefly light their red and green LEDs as they are initialized. Upon power-up of a newly installed system, several alarm indicators may remain lit until the circuit packs are administered. These alarms should be ignored until administration is completed.

During routine or demand testing of Mass Storage System components, the red, green and yellow LEDs on the MSSNET, R-MEDIA, and DISK circuit packs all light temporarily. This is normal and does not indicate a problem.

After a circuit pack has been initialized, a lit red LED should be accompanied by an alarm in the Alarm Log. A single fault can sometimes light alarm LEDs on several circuit packs, as in the following examples.

- A TDM bus problem may cause several port circuit packs to display red LEDS.
- An EPN Maintenance circuit pack can prevent an Expansion Interface circuit pack from initializing.
- Extensive interactions in the Center Stage Switch can cause multiple alarms from single faults in DS1C, SNI and SNC circuit packs and fiber links.
- Tone/clock problems may cause other circuit packs to report alarms.

- Misconnected optical fiber cables may cause several circuit packs to alarm.
- Packet bus faults can cause several port circuit packs to display red LEDs.

If a circuit pack has had at least five minutes to be initialized, and the red LED is lit without an associated alarm in the Alarm Log, the circuit pack may not be in communication with the system. This may also be the case when a circuit pack is properly administered and present in its slot, but there is an error type 1 logged against it. To determine if this is so, proceed as follows:

- Issue the **list configuration board** UUCSS command. If the system does not detect the circuit pack, this command will return

  `identifier not assigned`

  or

  `no board`.

  If the documentation for the associated maintenance object gives no special instructions for this situation, go to the next step.
- Check the Hardware Error Log for TONE-BD or TDM-BUS errors. Use the **test tdm** and **test tone-clock** commands and use the appropriate maintenance procedures to resolve any identified faults. If this does not resolve the problem, go to the next step
- Reseat the suspect circuit pack.

  CAUTION:
  This procedure can cause a partial or total service outage. Consult thoroughly the documentation for the associated maintenance object before proceeding. Observe the precautions and procedures described above.

- Inspect the backplane connectors for bent pins.
- If the system seems to be functioning correctly, but the circuit pack in question will not communicate with the system, replace the circuit pack.

Expansion Interface Circuit Pack LEDs

The Expansion Interface (EI) TN570 circuit pack has the standard red, green and yellow LEDs. The red and green LEDs have the traditional meaning, where red indicates an alarm condition, and green indicates testing in progress.

The yellow LED displays various flashing patterns to provide status information useful in isolating faults in the fiber link and other components connected to the fiber link. Table 7-1 illustrates the EI yellow LED states.

Table 7-1. Expansion Interface Yellow Led Flashing Codes

LED on	LED off	Condition
0.1 sec	0.1 sec	Fiber Out-of-Frame. This state indicates a failure of test #989. This may be caused by absence of the opposite end EI or Switch Node Interface, a broken or missing fiber, or a missing lightwave transceiver on either endpoint.
0.5 sec	0.5 sec	In Frame — No Neighbor. This state corresponds to a failure of test # 237, usually due to a failure of this EI or of the EI or SNI at the other end of the fiber.
2 sec	0.2 sec	Expansion Interface Active. This is the normal state of an active EI that is an archangel of an Expansion Port Network.
solid on		Expansion Interface Active. This is the normal state for an active EI that is not an EPN archangel. These include EPN EIs connected to other EPN EIs in Direct Connect Configurations, and EIs located in the Processor Port Network.
	solid off	Expansion Interface Standby. This is the normal state for a standby EI in systems with a duplication option.

SYSAM and Maintenance Circuit Pack LEDs

TN1648 System Access-Maintenance (SYSAM) and TN775 EPN Maintenance circuit packs have seven LEDs on their front panels. The top three LEDs are the standard group of red, green and yellow, and indicate the status of the circuit pack. The green LED on TN775s blinks faintly once per second, indicating continual self-testing.

The second group of three LEDs, labeled “ALARMS”, reflect maintenance conditions throughout the system, and indicate alarms reported against other components, as shown in Table 7-2.

NOTE:
On systems with duplicated SPEs, disregard the Major, Minor, and Warning alarm LEDs on the standby SYSAM circuit pack. Only those on the active SYSAM (see yellow LED, third from the top) are updated with the current system status.

Table 7-2. SYSAM and Maintenance circuit pack LED interpretation

LED color	State	Level/Function	Interpretation
Red	flashing	MAJOR	Major alarm against a component in the same cabinet, (PPN for SYSAM, and EPN for MAINT).
	solid	MAJOR	Major alarm against a component in another cabinet.
	flashing	MINOR	Minor alarm against a component in the same cabinet.
Red	solid	MINOR	Minor alarm against a component in another cabinet.
Yellow	flashing	WARNING	Warning alarm against a component in the same cabinet.
	solid	WARNING	Warning alarm against a component in another cabinet.
Green	on	ACK	Acknowledged; alarm has been reported to INADS.
Red	on	EMERGENCY TRANSFER	Emergency transfer has been invoked. This occurs upon power-up as well as during disabling failures.

These LEDS are illustrated Figure 7-1.

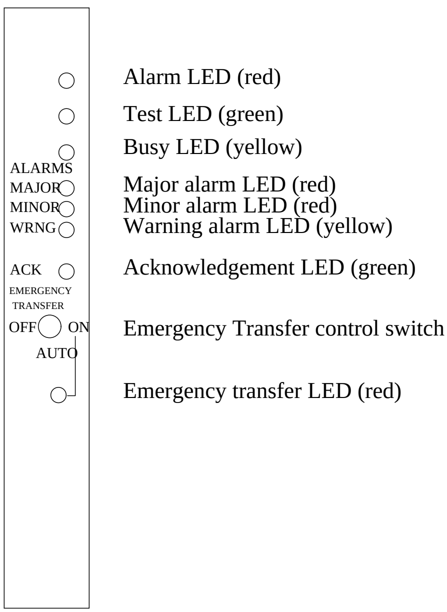

Figure 7-1. SYSAM and EPN Maintenance Circuit Pack LEDs

Duplication Interface Circuit Pack LEDs

In systems with duplicated SPEs, (High Reliability and Critical Reliability), there are two Duplication Interface UN330B circuit packs. One is located in carrier A and one in carrier B of the PPN. Each circuit pack has four LEDs. The top three have the traditional function of indicating the status of the pack.

The LED located at the bottom of the faceplate directly beneath the SPE Select switch is labeled OVERRIDE. Under normal operating conditions, the SPE Select switch is in the AUTO (center) position, and the OVERRIDE LED remains unlit. This means that the system controls which SPE is active. System selection of the active SPE can be manually overridden by moving the SPE Select switches from the AUTO position to either the “A” position or the “B” position on both Duplication Interface circuit packs. At this time, the red OVERRIDE LEDs on both Duplication Interface circuit packs will light steadily to indicate that one SPE is locked Active and the system is not duplicated. If both SPE Select switches are not in the same position, the system software retains control of Active SPE selection, and the OVERRIDE LED remains unlit. When control of the SPE selection is returned to the system by returning the SPE Select switches on both Duplication Interface circuit packs to the AUTO position, the OVERRIDE LED will go dark. Forced SPE selection should be undertaken only after consulting the appropriate sections in Chapter 9, “Maintenance Object Repair Procedures”.

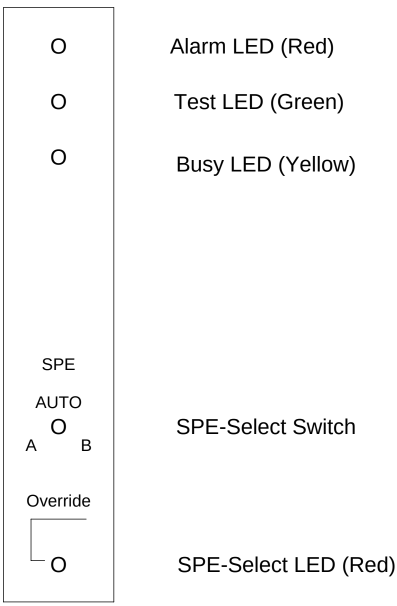

Figure 7-2. Duplication Interface Circuit Pack LEDs

Switch Node Interface LEDs

The Switch Node Interface (SNI) TN573 circuit pack has the standard red, green, and yellow LEDs. The red and green LEDs have the traditional meaning, where red indicates an alarm condition, and green indicates testing in progress.

The yellow LED displays various flashing patterns to provide status information useful in isolating faults in the fiber link and other components connected to the fiber link. Table 7-3 illustrates the SNI yellow LED states.

Table 7-3. Switch Node Interface Yellow Led Flashing States

LED on	LED off	Condition
0.1 sec	0.1 sec	Fiber Out-of-Frame. This state indicates a failure of test #238, which may be caused by absence of the opposite end EI or Switch Node Interface, a broken or missing fiber, or a missing lightwave transceiver on either endpoint.
0.5 sec	0.5 sec	In Frame — No Neighbor. This state corresponds to a failure of test # 237, usually due to a failure of this SNI, or the EI or SNI at the opposite of the fiber. This condition may also be due to a faulty Switch Node Clock.
solid on		SNI Active. This is the normal state for an active SNI.
	solid off	SNI Standby. This is the normal state for a standby SNI in systems with a duplication option.

DS1 CONV (TN574/TN1654) Circuit Pack LEDs

The TN574 and the TN1654 LEDs provide an indication of the state of the DS1 Converter and facilities, and are covered in the following sections of this document.

TN574 Circuit Pack LEDs

Seven LEDs provide an indication of the state of the DS1 Converter (DS1 CONV) TN574 circuit pack and the DS1 facilities. The top group has the standard red, green and yellow LEDs. The red and green LEDs have the traditional meaning, where red indicates an alarm condition, and green indicates testing in progress. The four green LEDs on the bottom indicate the status of the DS1 facilities (see following section).

The yellow LED is used to indicate the state of the Fiber Interface, the Fiber Channel, and the DS1 channel in the following manner and order of priority.

Table 7-4. DS1C Yellow Led Flashing States

LED on	LED off	Condition
0.1 sec	0.1 sec	Fiber Out-of-Frame or Fiber Loss of Signal
0.5 sec	0.5 sec	In Frame, fiber channel down. The fiber channel communicating between the DS1C and the other fiber endpoint (EI or SNI) is down.
1 sec	1 sec	In Frame, DS1 channel down. The channel between the two DS1Cs in the DS1C complex is down.
2 sec	0.2 sec	No response from SPE. The SPE is not acknowledging messages from the DS1C or the communications link to the SPR is down.
solid on		DS1C active. This is the normal state for an active DS1C.
	solid off	DS1C standby. This is the normal state for a standby DS1C in Critical Reliability Systems (duplicated PNC).

DS1 Facility LEDs

Below the three standard LEDs on the DS1C circuit pack are four green LEDs used to indicate whether a receive signal is present for each of the four DS1 facilities. Figure 7-3 shows which facility (A, B, C, or D) corresponds to each LED. If a green LED is off, there is a Loss of Signal condition on the DS1 facility associated with that LED. The presence of a signal does not guarantee that the signal is using the correct framing format or line coding; an Alarm Indication Signal indicating that the opposite end of the DS1C complex is out of service may be present.

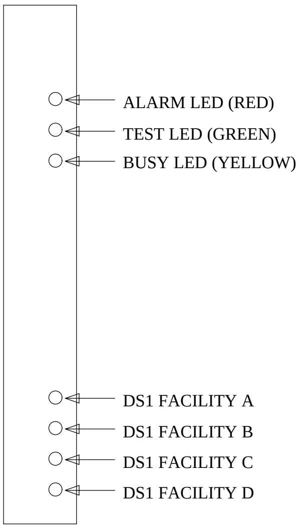

Figure 7-3. TN574 DS1C Circuit Pack LEDs

TN1654 Circuit Pack LEDs

The TN1654 DS1CONV board has 11 LEDs on its faceplate. The top 3 system standard LEDs indicate the state of the DS1CONV board. These LEDs are under firmware control until the board has established a link to the SPE via the EI or SNI. Once the link is established, software controls the 3 LEDs. If the link breaks, the LEDs are again under firmware control.

The red and green LEDs have the traditional use: red means an alarm condition, and green indicates that maintenance testing is in progress. The red and green LEDs are also turned on during circuit pack initialization by firmware. When the control link to the circuit pack is lost, firmware controls the red LED to indicate an alarm condition.

The yellow LED under firmware control is used to indicate the state of the physical Fiber Interface, the Fiber Channel (link to EI or SNI), the DS1 Control Channel (link to opposite DS1CONV board), and the SPE communications link in the following manner and order of priority. (The yellow LED remains on for longer periods of time as the DS1CONV Complex becomes closer to being fully operational.)

1. If the Fiber is Out of Frame or if a Fiber Loss of Signal condition exists, the yellow LED will flicker at a 5 Hz rate (on for 100 mS, off for 100 mS).
2. If the Fiber Channel is down (DS1 Converter circuit pack/fiber endpoint communications), the yellow LED will flash at a 1 Hz rate (on for 500 ms, off for 500 ms).
3. If the DS1 Control Channel is down between the two DS1CONVs in the DS1CONV Complex, the yellow LED will pulse at a 0.5 Hz rate (on for 1 second, off for 1 second).
4. If the SPE communications link is down, the yellow LED will wink off every 2 seconds for 200 ms (2 seconds on, 200 ms off).
5. If all is well with the Fiber Interface and all communications channels, the yellow LED will remain on continuously in a Standard Reliability and High Reliability System configuration. In Critical Reliability systems (duplicated PNC), an active DS1CONV circuit pack will have its yellow LED on continuously, and a standby DS1CONV circuit pack will have its yellow LED off. The LED will then be under software control.

The bottom four green LEDs on the TN574 DS1CONV board are under hardware control. The four green LEDs indicate, for each DS1CONV facility, whether a receive signal is present for the DS1 facility

The next four LEDs on the TN1654 DS1CONV board are labeled STATUS LEDs and are for future use. These LEDs will not be lit.

The bottom four LEDs on the TN1654 board are labeled SPAN LEDs. These LEDs are under firmware control. If the facility is not administered, then the LED is not lit. The LED is lit amber if the facility is running alarm free. If the facility is detecting either a red alarm (loss-of-signal or loss-of-frame), a yellow alarm (remote frame alarm) or a blue alarm (AIS signal) then the LED is lit red. The SPAN SELECT Switch on the TN1654 faceplate is for future use. Pushing the switch will have no effect on the board. See Figure 7-4 for a view of the face plate on the TN1654 DS1CONV circuit pack.

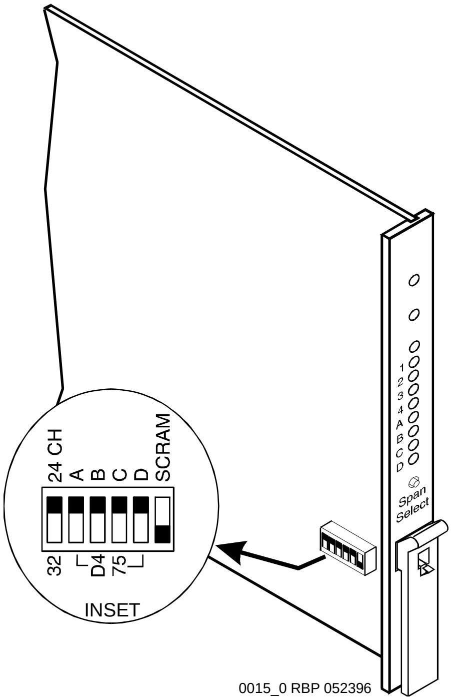

Figure 7-4. TN1654 DS1CONV Circuit Pack

Tone-Clock Circuit Pack LEDs

The Tone-Clock circuit packs have the standard red, green and yellow LEDs. The red LED has the traditional meaning. The yellow and green LEDs flash in specific patterns to indicate the status of the circuit pack. The standby status applies only to systems with a duplication option.

Maintenance/Test Circuit Pack LEDs

The TN771D Maintenance/Test circuit pack has the standard red, green, and yellow LEDs. The red and green LEDs have the traditional meaning, where red indicates an alarm condition, and green indicates testing in progress.

The yellow LED can be off or on continuously or flashing, depending on the mode of operation of the TN771D and whether or not it has detected errors. The yellow LED is on steady when the TN771D's analog test port or digital test ports are being used to test trunks or line circuits. The yellow LED is also used to indicate Packet Bus status. Table 7-5 illustrates the Maintenance/Test yellow LED states as they apply to Packet Bus activity.

Table 7-5. TN771D Maintenance/Test Yellow LED States

LED State*	TN771D Mode	Condition
Solid off	Normal	The Maintenance/Test circuit pack detects no Packet Bus faults.
Solid on†	Normal	The Maintenance/Test Packet Bus port has successfully reconfigured the Packet Bus around a fault.
Flashing (1 Hz)	Normal	The Maintenance/Test Packet Bus port is unable to reconfigure the Packet Bus around a fault.
Solid off	Standalone‡	The Maintenance/Test detects no Packet Bus faults.
Solid on	Standalone	This condition cannot normally occur. The LED is always either off or blinking in standalone mode.
Flashing (1 Hz)	Standalone	The Maintenance/Test Packet Bus port detects a Packet Bus fault.

*. It takes 5 to 10 seconds for the yellow LED to respond to a change in the state of the Packet Bus.

†. Because the yellow LED on the Maintenance/Test circuit pack can also be on steady when the digital and analog test ports on the circuit pack are in use, exact interpretation of the yellow LED may require that the technician busy out the analog and digital test ports or examine the error and Alarm Logs for PKT-BUS errors and alarms.

‡. "Standalone" refers to the TN771D's capability to operate autonomously as a troubleshooting aid. A detailed description of the TN771D standalone mode is provided in the ''Packet Bus Fault Isolation and Repair'' section of Chapter 5, "Alarms, Errors, and Troubleshooting".

LEDs on Standby Components

In high reliability and critical reliability option systems, duplicated components that are on standby will usually have their yellow LEDs unlit, with the following exceptions.

- The Major, Minor and Warning alarm LEDs on the SYSAM circuit pack on the standby SPE do not give reliable indications. Pay attention only to those LEDs that are on the active SYSAM circuit pack.
- The yellow LED will blink on and off when the standby Processor circuit pack is up and standby maintenance is running.
- In high reliability systems with a Center Stage Switch, (duplicated SPE, simplex PNC), the standby Switch Node Clock's yellow LED is off. In critical reliability systems, the standby SNC is located on a separate carrier and normally remains lit.
- Yellow LEDs on Power Units on standby carriers normally remain lit.

When LED indications are not clear, use the **status pnc, status spe** and **status pn** commands to determine which components are active.

Maintenance Commands

8

This chapter contains descriptions of commands available to the craft login. Introductory sections explain the meaning of common input parameters, or command line arguments, common output fields, and error codes for busyout, release and reset commands.

CAUTION:
This document is intended for Release 5 and later systems only. For previous DEFINITY systems (G3V4 and earlier), refer to DEFINITY Enterprise Communications Server Release 5 Maintenance for R5r, 555-230-105.

Command Line Syntax

Each command consists of an action word, an object upon which the action is performed, and optional qualifiers that modify the execution of the command. In some cases the choice of a qualifier may be required. The syntax of the command appears under the heading at the beginning of each command description. The syntax is interpreted as follows:

Command	Object	Optional Qualifiers
test station	***extension***	[**short|long**] [**repeat** number | **clear**] [**schedule**]
bold	bold italic if a variable, bold if entered literally	bracketed; either/or choices are separated by a vertical slash (|); bold italic if a variable, bold if entered literally

Command words can be abbreviated. A partially spelled word is recognized as long as enough letters are entered to distinguish it from other valid entries. Otherwise, the screen displays a selection of command words that match the abbreviation. For example, **test alarms step short clear** can be entered as **t al st sh c**. Drop leading zeroes from numerical entries. For example, cabinet number 03 can be entered as 3.

Pressing the HELP key displays all available commands. If an incomplete command is entered, pressing HELP displays all valid qualifiers for the command.

NOTE:
When the successful execution of a command is prevented, an error message that is usually self-explanatory displays. If the following message appears, the software is most likely corrupt:

```
Error encountered; can't complete request
```

In this case, follow normal escalation procedures.

Common Input Parameters

Characters in bold type are entered literally on the command line. Characters in italic bold type are variables. See Table 8-1 for common test command parameters and their explanations and for explanations of less common parameters.

Table 8-1. Common Test Command Parameters

Parameter	Range	Meaning
UU	1-22	One or two-digit cabinet number For many commands this defaults to cabinet 1, the PPN
C	A-E	Letter designation of a carrier. For many commands relating to SPE or EPN control circuit packs, this defaults to A, the control carrier. For PPNs with duplicated SPEs, A or B is usually specified for SPE MOs.
SS	1-21	One or two-digit number identifying a circuit pack slot on a carrier For many commands relating to SPE or EPN control circuit packs, this usually defaults to the only possible slot number.
pp	1-24	One or two-digit number identifying an individual port circuit on circuit pack The range of this variable differs depending on the type of circuit pack.

For example, **display cabinet** requires only the entry of *UU*: **display cabinet 12**. **Test port** requires a location of the form *UUCSSpp*: **test port 05c1506** to test port circuit 6 on the circuit pack in cabinet 5, carrier C, slot 6. The **list** and **display** commands are useful in relating MO locations to information such as PN number, extension, link numbers, and so forth. Table 8-2 contains information about the less-common command parameters.

Table 8-2. Less-Common Test Command Parameters

Parameter	Range	Default	Meaning
PN#			One or two-digit port network number. EPN cabinets may contain one or two port networks. Use **list cabinet** to find which port networks are in each cabinet.
print			This command executes immediately (if resources are available) and sends output both to the screen and to a printer connected to the terminal where the command was entered. This option is available for **display**, **list** and **status** commands.
schedule			A scheduling form is displayed which allows you to specify a start time for the command. The command is placed in the queue and, when executed, sends the output to the system printer. The **schedule** option is available for **display**, **list** and **test** commands. When used with **display alarms** or **errors**, a full report is generated. The usual selection form for error and alarm reports is suppressed so that it will not interfere with the command’s execution when it is issued from the queue. You can see what commands are currently queued with the **list command-queue** command. A queued command can be canceled with **remove command-queue** job#. This option requires that the system printer be administered on page 4 of the Feature-Related System Parameters form.
group#	1-666		One to three-digit trunk group number; used to address trunk maintenance objects.
group#/ member#	1-255		Group number followed by a slash and the one to three-digit member number of an individual trunk; used to address trunk maintenance objects.

Continued on next page

Table 8-2. Less-Common Test Command Parameters — *Continued*

Parameter	Range	Default	Meaning
extension			The extension number assigned to the port or other maintenance object. The number of digits in an extension is determined by the system dial plan. The **list** and **display** commands are useful in relating extension numbers, maintenance objects, and other components.
repeat #	1-100	1	Used with test commands, the number of times a test sequence is to be repeated. The word **repeat**, or simply the letter **r**, followed by the number.
short **long**			Used with **test** commands, these qualifiers determine either the long or short test sequence run for this maintenance object. The test sequence run varies for each maintenance object. **CAUTION:** *For some maintenance objects, the long sequence is destructive, that is, disruptive to call service.* The short sequence is always non-destructive.
clear			Used with **test** commands, this specifies that the test sequence is to be repeated until any active alarms against the maintenance object is cleared by the passing of tests or until any test in the sequence fails. If no such alarms are active, the sequence is run once. The **long clear** combination effects a clearing of all alarms against the maintenance object if no errors are encountered. The **short clear** combination clears only alarms pertinent to the tests in the short sequence. **CAUTION:** *If all tests pass, the **long clear** combination clears all error counters. If firmware counters are cleared while actual problem exists, customer service may degrade due to calls being routed over faulty components.*

Common Output Fields

- An indication that the command successfully completed or a self-explanatory message giving a reason for a failure or abort.
- An input form for entering additional information required to complete the command. These are described under each command that presents an input form.
- A form listing one or more lines of results with error codes that indicate the reason for a FAIL or ABORT result.

Many commands that use the last form display the fields listed in the table below. Some return one line of output. Other commands that run either one test on several objects or several different tests on one or more objects return several lines of output. In this case, each line represents one test result.

Variable	Range	Meaning
UU	1-22	One or two-digit cabinet number
C	A-E	Letter designation of a circuit pack carrier
SS	1-21	One or two-digit number identifying a circuit pack slot on a carrier
pp	1-24	One or two-digit number identifying an individual port circuit on circuit pack
Port		The address or physical location of the MO. Usually this is **UUCSSpp**.

The length of this variable differs for the various types of commands. A port circuit requires a full length address such as 11C1502, which indicates circuit number 2 on the circuit pack in cabinet 11, carrier C, slot 15. A control carrier component such as a SYSAM circuit pack is designated simply as **01B**, indicating the SYSAM in carrier B of cabinet 1, the PPN cabinet.

Some MOs such as TDM-BUS are addressed by PN number. In this case, the number is usually preceded by PN. For example, TDM bus A in port network 5 is designated as **PN 05A**.

In critical reliability systems, Port Network Connectivity is duplicated as two independent sets of PNC components. These are designated as A-PNC and B-PNC.

Maintenance Name	The name of the MO as it appears in the alarm and error logs.
Alt. Name	The output screens of many commands list an alternate name for certain MOs in addition to their port address (physical location). The meaning of the name depends upon the type of the object, as shown in the following table.

Maintenance Object	Alternate Name	Example
Station	extension	84140
Trunk	trunk group # / member # (001-666) / (001-255)	45/3
Personal CO line	P/ personal CO line group # (001-200)	P/23

Test No. The number of the test run on the MO as part of a test command. Descriptions of each test and its related error codes appear under the relevant MO. Other commands such as **clear firmware-counters** and **reset** also report a test number.

Result One of the following results:

PASS: The command successfully completed. For a test command this indicates that no errors were detected by the test.

ABORT: The command was prevented from completing. See Error Code below.

FAIL: Indicates that a serious error was detected by the test. See Error Code below.

NO BOARD: The system does not detect a circuit pack in the location specified on the command line.

CONFLICT: Another user was testing this maintenance object.

EPN-DOWN: The EPN holding the MO is inaccessible. The Expansion Archangel Link may be down.

DISABLED: The MO or test has been disabled by the Tier 3 disable command.

NOT ASSIGNED: The location specified does not have a circuit pack administered to it.

EXTRA BOARD: This result can appear for the Maintenance/Test, Call Classifier, Tone Detector, Announcement, and Speech Synthesis circuit packs. Each of these circuit packs has restrictions on how many can be in the system or a port network:

Maintenance/Test circuit pack: 1 per port network

Tone Detector circuit pack: up to 50 per system

Call Classifier circuit pack: up to 25 per system

Speech Synthesis circuit pack: 40 per system

Announcement circuit pack: 1 per system

Remove the extra circuit pack(s).

Error Code A number indicating the reason for a FAIL or ABORT result. For test commands and other commands that return a test result, consult the tables of test error codes under the relevant MO. For **busyout**, **release** and **reset** commands, see ‘‘Common Abort and Fail Codes’’ and Test Commands.

Contention Between Simultaneous Commands

The following limits apply to simultaneous maintenance and administration activities:

- Up to 8 users can be logged into the system at the same time.
- Up to 5 maintenance commands can run concurrently.
- Up to 3 maintenance commands issued from system access port (SAP) or EPN Maintenance circuit pack logins can run concurrently. The other 2 are reserved for the SYSAM and INADS ports.
- Up to 5 administration commands can run concurrently.
- In general, a maintenance object or other system entity can be acted upon by only one command at a time. This restriction applies to such action commands as:
  — busyout
  — change
  — clear
  — recycle
  — release
  — set
  — test
- In general, only 1 SPE component can be acted upon at one time by commands such as those just mentioned.
- When an action command is acting on a circuit pack, that circuit pack and all maintenance objects located on it are unavailable for other commands.
- Display-only commands such as the following generally do not conflict with any other commands.
  — display
  — status
  — get
  — monitor

- Certain system-wide actions such as **reset system** and **upgrade software** cannot run concurrently with any other command.
- Most commands require the use of shared system resources in order to execute. When required resources are already in use, the command will abort. For example, **save**, **restore**, **backup**, and **test disk** commands all require the use of the Mass Storage System (MSS). Only one such command can run at one time.

Busyout and Release Commands

The **busyout** command places the object of the command in a maintenance busy state. In this state, the object is removed from active service and is not available for use by call processing. Services dependent on the busied out component are dropped. If the component supports a link, the link is dropped. No scheduled or periodic background tests are run on the object while it is busied out. Demand maintenance tests can be run on the object, though some tests require that the object be released to complete. A WARNING alarm with error type 18 is logged against each busied out object. All busied out MOs can be displayed by entering error type 18 in the Error Type field on the Hardware Errors Report Form (see **display errors**). The matching release command returns the maintenance object to service, providing the object is not otherwise incapacitated.

On systems with duplicated SPE, busyouts are preserved across planned SPE interchanges and level 1 system resets (Warm). System resets of level 2 or higher release the busied out objects.

A variety of self-explanatory error messages may be displayed if the command cannot be executed as entered. In addition to these there are a number of numerical error codes which may be displayed in the Error Code field if the command ABORTS or FAILS as indicated in the Result field. These are explained in the *Common Abort and Fail Codes* section of this chapter.

The following screen display shows a typical result for **busyout board 1c03** (analog line circuit pack in cabinet 1, carrier c, slot 7 with three administered ports):

```
busyout board 01C03

                               Command Results

 Port           Maintenance Name   Alt. Name     Result     Error Code

01C03             ANL-BD                          PASS
01C0301           ANL-16-L          5409          PASS
01C0302           ANL-16-L          5416          PASS
01C0303           ANL-16-L          5421          PASS
01C0304           ANL-16-L          5422          PASS
01C0305           ANL-16-L          5411          PASS

Command successfully completed
```

The following display shows a typical result for most maintenance objects. See "Common Output Fields" above for an explanation of the fields displayed.

```
busyout disk b

                               COMMAND RESULTS

  01B         DISK                              PASS

Command successfully completed
```

Common Abort and Fail Codes

Table 8-3 lists common error codes associated with abort and fail results for busyout, release, test, and reset commands. In addition to these, many maintenance objects have other unique error codes.

Table 8-3. Common Error Codes for Busyout, Release, Test, and Reset Commands

Error Code	Command Result	Description/Recommendation
	ABORT	System resources are unavailable to run command. 1. Try the command again at 1-minute intervals up to 5 times.
0	ABORT	Internal system error. 1. Retry the command at 1-minute intervals up to 5 times.
1005	ABORT	A DS1 interface circuit pack could not be reset because it is currently supplying the on-line synchronization reference. 1. Use the **set sync** command to designate a new DS1 interface circuit pack as the on-line reference, then try the reset again.
1010	ABORT	Attempt was made to busyout an object that was already busied out.
1011	ABORT	Attempt was made to release an object that was not first busied out.
1015	ABORT	A reset of this circuit pack requires that all maintenance objects on it be in the out-of-service state. 1. Use the **busyout board** command to place all objects on the circuit pack in the out-of-service state, and try the reset again.
1026	ABORT	The specified TDM bus cannot be busied out because the control channel or system tones are being carried on it. You can use the **set tdm PC** command to switch the control channel and system tones to the other TDM bus.
1030	ABORT	This command is not allowed on a circuit pack on the standby SPE.

Continued on next page

Table 8-3. Common Error Codes for Busyout, Release, Test, and Reset Commands — *Continued*

Error Code	Command Result	Description/Recommendation
1338	ABORT	The system could not execute the command on a component on the Standby SPE because an interchange was pending. 1. Refer to "STBY-SPE (Standby SPE Maintenance)" in Chapter 9. 2. Try the command again after the SPE interchange occurs.
1339	ABORT	The system could not execute the command on a component on the Standby SPE because an handshake communication was down. 1. Refer to "STBY-SPE (Standby SPE Maintenance)" in Chapter 9, "Maintenance Object Repair Procedures". 2. Try the command again after the standby SPE is restored to service. Use **status spe** to determine state of standby SPE.
1347	ABORT	The system could not execute the command on a component on the Standby SPE because memory refresh was not complete. 1. Refer to "STBY-SPE (Standby SPE Maintenance)" in Chapter 9. 2. Try the command again after the standby SPE is restored to service. Use **status spe** to determine state of standby SPE.
1350	ABORT	The system could not execute the command on a component on the Standby SPE because memory shadowing was not enabled. 1. Refer to "STBY-SPE (Standby SPE Maintenance)" in Chapter 9. 2. Try the command again after the standby SPE is restored to service. Use **status spe** to determine state of standby SPE.
2012 2500	ABORT	Internal system error.
2100	ABORT	System resources to run this command were unavailable. 1. Try the command again at 1-minute intervals up to 5 times.

Continued on next page

Table 8-3. Common Error Codes for Busyout, Release, Test, and Reset Commands — *Continued*

Error Code	Command Result	Description/Recommendation
62524 62525 62526	ABORT	Maintenance is currently active on the maximum number of maintenance objects that the system can support. This condition is commonly caused by the fact that the system contains a large number of stations or trunks that have been administered, and whose circuit packs are installed, but which are not physically connected. 1. Resolve as many alarms as possible on the station and trunk MOs, or busyout these MOs to prevent maintenance activity on them. Then try the command again.
	NO BOARD	The circuit pack is not physically installed.
	EXTRA BD	This result can appear for Maintenance/Test, Call Classifier, Tone Detector, Announcement and Speech Synthesis circuit packs. Each of these circuit packs has restrictions on how many can be installed in the system or in a port network. The restrictions are as follows: TN771D Maintenance/Test: 1 /port network TN748 Tone Detector: 50 /system TN744 Call Classifier: 25 /system Speech Synthesizer: 40 /system TN750 Announcement: 1 /system Remove any extra circuit packs.
1	FAIL	For reset commands, the circuit pack was not successfully halted.
2	FAIL	For reset commands, the circuit pack was not successfully restarted after being halted. For both results, replace the circuit pack.
	FAIL	Refer to the applicable maintenance object in Chapter 9.
	PASS	The requested action successfully completed. If the command was a reset, the circuit pack is now running and should be tested.

Alarm and Error Categories

The **display alarms** and **display errors** commands allow you to generate reports for certain groups of maintenance objects. By entering a category from the Table 8-4 into the `Category` field of the input form, you can restrict the report to only those maintenance objects included in that category. The report can be further narrowed down by using the other fields on the form.

Table 8-4 is a list of the categories showing which MOs are included. Table 8-5 is sorted by MO and shows the categories containing each MO.

add atm pnc

This command adds a new atm pnc to the system configuration.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
add atm pnc	***number***	Number to assign to new atm pnc	init inads craft	none	none
	next	Next number automatically assigned to new atm pnc. Examples: **add atm pnc 23** **add atm pnc next**			

Output

The following example shows the output for the **add atm pnc next** command.

```
add atm pnc next                                          Page   1 of   1   SPE A
                                    ATM PNC
                             Connection Number: 17
      Location:
          Name:
Address Format: E.164 ATM Private
           AFI: 39
         E.164:
        HO-DSP:
           ESI:
           SEL:

Command Successfully Completed
```

Field descriptions

`Location`	5-character board number **UUCSS**; cabinet (1-44) carrier (A-E) slot (0-20)
`Name`	16-character alpha-numeric characters for identification
`Address Format`	`DCC ATM`, `E.164 ATM Private`, or `ICD ATM`
`E.164`	Up to 15 decimal digits (0-9)
`HO-DSP`	8 hexidecimal digits (0-9, a-f, A-F)
`ESI`	12 hexidecimal digits (0-9, a-f, A-F)
`SEL`	2 hexidecimal digits (0-9, a-f, A-F); currently “00”

backup disk

backup disk [spe-a | spe-b | active | standby | both | either] [incremental | full]

This command copies all information from the disk drive in the specified processor carrier(s) to the removable media system in the same carrier. This can take up to 40 minutes to complete.

On a simplex SPE, the default is to perform an incremental backup of SPE-A. On a duplex SPE, the default is to perform an incremental backup on both SPE-A and SPE-B.

NOTE:
The backup command can take up to 10 minutes to complete. Avoid pressing the ENTER key on the keyboard during this time, since doing so will cause the result messages to be lost.

Parameters

spe-a	Specifies a backup from the A processor carrier hard disk to the A SPE Removable Media Cartridge (RMC).
spe-b	This specifies a backup from the B processor carrier hard disk to the B SPE RMC.
active	This specifies a backup of the active processor.
standby	This specifies a backup of the standby processor.
both	This specifies a backup of both processor carriers.
either	Specifies a backup of both SPE carriers. If the standby is not accessible, the command performs a backup of the active SPE.
incremental	Causes all data marked “good” that has been changed since the last backup to removable media to be copied to the RMC. That is, all files that have a date newer than the date on the RMC file.
full	This causes all data to be copied from disk to removable media regardless of the dates and the state of the data (“good” or “bad”).

Examples

backup disk
backup disk spe-b
backup disk active incremental

Output

`Processor`	Identifies the processor carrier that was backed up (SPE-A, or SPE-B).
`Command Completion Status`	Results of the command, and the reason for any failure are displayed.

For the following output example, assume that the command, **backup disk** is entered on a duplex system.

```
backup disk
                                  BACKUP DISK

Processor Command Completion Status

SPE-A      Success
SPE-B      Success

Command Successfully Completed
```

busyout cdr-link

busyout cdr-link [primary | secondary]

The busyout cdr-link command puts a specified call detail recording link in a maintenance busy state. When busied out, the link is dropped and must be reestablished later when returned to service. See the description of **status link** for more information on links.

Parameters

[primary | secondary]	This qualifier is used to specify one of the two possible links to CDR output devices. Primary is the default.

Examples

busyout cdr-link
busy cdr secondary

For more information see the following sections at the beginning of this chapter: Busyout and Release Commands, Common Input Parameters, and Common Output Fields.

busyout data-module

busyout data-module extension

This command puts the specified data module in a maintenance busy state, whether or not it is installed. No call processing may be executed on the data modules or over the data channels. A list of all data-modules administered on the system can be displayed with **list data-module**. This form gives the extension, port, type and other data for each data-module. The following table gives the maintenance object name for each type of data-module listed in the "Type" field on the list data-module form.

Type	Maintenance Object
adm-t	BRI-SET
announcement	DAT-LINE
dtdm	DIG-LINE
pdm	PDMODULE
system-port	DAT-LINE
x.25	PGATE-PT

busyout disk

busyout disk C

This command puts the hard disk drive of the Mass Storage System (MSS) into a maintenance busy state. Placing the disk in a busyout state prevents read and write access to the disk except when performed by demand maintenance testing. This command and the release command abort if any other MSS operation has already begun.

When the **release** command is issued, all alarms against the disk are automatically resolved. If the host-adapter is busied out, it must be released before the disk can be released. When the host-adapter becomes out-of-service due to test or reset failures and becomes uninstalled, the disk also becomes uninstalled, and all access by system software and maintenance tests and commands is blocked.

The cabinet is always **1** and need not be entered. The carrier, **a** or **b**, must be entered only on systems with duplicated SPEs.

busyout ds1-facility

busyout ds1-facility UUCSSf [override]

This command puts a specified DS1 facility of a DS1C Complex into a maintenance busy state. Each DS1C complex uses from 1 to 4 DS1 facilities. One of the facilities, called the packet facility, carries the control channel for all facilities in the complex, all packet traffic, and some circuit connections. The other facilities carry circuit connections only. Whenever the circuit pack resets, the packet facility is set on the “a” facility. If system software detects a problem with this facility, it switches the packet and control traffic to another facility. The **busyout** command is not allowed on the packet facility unless the override qualifier is used. When the override is used, all packet and circuit traffic on the packet facility is switched to one of the other 3 facilities; all traffic that was on the destination facility before the switch is dropped. There is no way to tell which facility is carrying the packet and control traffic without attempting to busy it out. If there is only 1 facility left in service on the circuit pack, it cannot be busied out. In this case, the circuit pack must be busied.

CAUTION:
Busying out a non-packet facility disrupts all traffic carried on that facility. Use of the override command to busy the packet facility disrupts all traffic on the facility to which the packet and control traffic is moved. Which facility this is cannot be determined in advance.

On critical reliability systems (duplicated PNC) a facility on the active PNC cannot be busied out. To busyout a facility on the standby PNC, the standby PNC must first be busied out by **busyout pnc**.

busyout fiber-link

busyout fiber-link fiber# [a-pnc | b-pnc]

The **busyout fiber-link** command puts a specified fiber link into a maintenance busy state. (See **Busyout** and **Release** Commands at the beginning of this chapter). A fiber link is a connection carrying all circuit and packet traffic between two port networks, two switch nodes, or a port network and a switch node. A fiber link may contain a DS1 CONV complex used to provide connectivity to a remote EPN.

CAUTION:
*On systems with simplex PNC, the **busyout** command is destructive. All calls and application links carried on the busied out fiber link will be torn down, and new calls will not be established over the link.*

On systems with duplicated PNC, the command is allowed only on a fiber link on the standby PNC, does not impact service, and requires that the standby PNC be busied first.

For more information on fiber links, see FIBER-LNK in Chapter 9.

Parameters

fiber#	The administered number assigned to the fiber link. (In a system with duplicated PNC, this represents a fiber link pair.) **List fiber-link** displays a list of all fiber links with their numbers, endpoints, and other useful information.
a-pnc	If PNC is duplicated, this identifier is used to distinguish between the two fibers of a duplicated pair. For non duplicated PNC “a-pnc” is the only valid qualifier.
b-pnc	On a system with duplicated PNC, this identifier distinguishes between the two fibers of a duplicated fiber pair. This identifier is invalid on a system with simplex PNC.

If neither PNC is specified, the command defaults to **a-pnc**.

Examples

Duplex PNC: **busyout fiber-link 01 b-pnc busyout fiber-link 03** (defaults to a-pnc)

busyout host-adapter

busyout host-adapter C

The **busyout host-adapter** command puts the host-adapter circuit on the MSSNET circuit pack into a maintenance busy state. When the host-adapter is busied out, the removable media and disk devices on the same carrier are also busied out, and warning alarms with error type 526 are raised against DISK and R-MEDIA. The removable media and disk do remain available for maintenance testing. This command will abort if any other MSS operation has already begun.

When the host-adapter is out of service due to test failures, or uninstalled due to a reset failure, the related removable media and disk devices are also placed in the uninstalled state. All access by system software, maintenance tests, and commands, including reset, are blocked from execution.

Parameters

C The cabinet is always **1** and need not be entered. On systems with duplicated SPEs only, carrier **a** or **b** must be entered.

Examples

Simplex:	**busyout host-adapter**
Duplicated:	**busyout host-adapter b**

For more information see the following sections at the beginning of this chapter: **Busyout** and **Release** Commands, Common Input Parameters, and Common Output Fields.

busyout journal-printer

busyout journal-printer pms-log | wakeup-log

The **busyout journal-printer** command puts the link to the Property Management System log or wakeup log printers in a maintenance busy state. (See Busyout and Release Commands at the beginning of this chapter). When busied out, the link is dropped and no data transfer can take place over it.

This command can be used to prevent unwanted interference between different maintenance processes. Maintenance software may put a component that is part of a link in a busy state, causing link set-up to fail, and resulting in attempts by the system to reestablish the link. If a maintenance test requires that the component be idle, frequent attempts at re-setup may delay the recovery of a faulty component. Busying out the link will prevent re-setup attempts.

Parameters

pms-log	Busies out the link to the Property Management System printer
wakeup-log	Busies out the link to the Wakeup Log printer

Examples

busyout journal-printer pms-log
busyout journal-printer wakeup-log

For more information see the following sections at the beginning of this chapter: **Busyout** and **Release** Commands, Common Input Parameters, and Common Output Fields.

busyout link

busyout link link#

The **busyout link** command puts a specified Packet Gateway link in a maintenance busy state. (See **Busyout** and **Release** Commands at the beginning of this chapter). A link may also be busied out with **busyout port** using the address of the PGATE port that supports the link.

CAUTION:
*Busyout of a link drops all calls and packet traffic dependent on that link. The application, adjunct, or switch connected to the link will be inaccessible and the link will have to be reestablished later when returned to service. See **status link** for more details on links.*

Parameters

Link#	A number (1-16) assigned to the link on the Communication-Interface Links form.

For more information see the following sections at the beginning of this chapter: **Busyout** and **Release** Commands, Common Input Parameters, and Common Output Fields.

busyout removable media

busyout removable media C

The **busyout removable media** command puts the removable media into a maintenance busy state. Placing the removable media in a busyout state prevents read and write access of the removable media except for that requested by demand maintenance testing. This command aborts if the host adapter on the same carrier is already busied out.

When the host-adapter is busied out, only the demand maintenance busyout and test commands are permitted on the attached removable media in the same carrier. Reset, release, scheduled and periodic testing and other system software access are blocked. In this case, the host-adapter must first be released before the removable media can be released.

When the host-adapter is taken out-of-service due to maintenance test or reset failures, the removable media is also placed in the uninstalled state and all access by system software, maintenance tests and commands, including reset, are blocked.

Parameters

C The cabinet is always **1** and need not be entered. On systems with duplicated SPEs only, the carrier, **a** or **b**, must be entered.

Examples

Simplex: **busyout removable media**

Duplicated: **busyout removable media a**

For more information, refer to the following sections: **Busyout** and **Release** Commands, Common Input Parameters, and Common Output Fields. This command will abort if any other MSS operation has already begun.

busyout spe-standby

busyout spe-standby

The **busyout spe-standby** command lowers the Software State Of Health of the standby Switch Processing Element (SPE) kept by the standby Duplication Interface (DUPINT) board to the lowest possible level above non-functional. This diminishes the chance that an interchange will occur, but does not guarantee that an interchange will not occur. This command also turns off memory shadowing. Periodic and scheduled testing *are not* turned off on busied out objects, but warning alarms with error 18 are generated.

Busyout of the standby SPE is allowed if communication to the standby is down (handshake failure), but the state of health may not be lowered. Use **status spe** to determine the condition of the SPE after the busyout has been entered.

When a busyout of the standby SPE is performed, the software state of health of the standby SPE is set to the lowest possible level and memory shadowing is turned off. This is done to lessen the probability that the system will switch to the standby SPE. However, in some cases a “spontaneous” (hard) interchange of the SPEs may still occur.

This command can be used as a mechanism to turn off memory shadowing of the standby SPE.

The busyout *will* execute even if the standby SPE state of health is less than “functional”, memory shadowing is already off, or handshake communication with the standby is down.

For more information see the following sections at the beginning of this chapter: Busyout and Release Commands, Common Input Parameters, and Common Output Fields.

busyout sp-link

busyout sp-link

The **busyout sp-link** command puts the system printer link into a maintenance busy state. Placing the system printer link in a busyout state prevents access to the system printer.

The system printer link is a link from the switch to an external printer. This link is created by administering the system printer extension and setting up a call to the system printer.

For more information, refer to the following sections: **Busyout** and **Release** Commands, Common Input Parameters, and Common Output Fields.

busyout trunk

busyout trunk group# [/member#]

The **busyout trunk** command puts an entire trunk group or a single trunk group member in a maintenance busy state whether it is installed or not. Entering only the group number busies out all members in the group. (Although not recommended, entering a group number and a slash (/) without a member number busies out the member with the lowest-numbered port location.)

Examples

busyout trunk 78
busyout trunk 78/1

For more information see the following sections at the beginning of this chapter: **Busyout** and **Release** Commands, Common Input Parameters, and Common Output Fields.

cancel hardware-group

cancel hardware-group

In the course of executing **test hardware-group**, you may find it necessary to halt the test temporarily or permanently. This can be accomplished with **cancel hardware-group**. The canceled **test hardware-group** command may be restarted where it left off with **resume hardware-group**, or another test hardware-group test may be started. In addition to the cancel hardware-group command, pressing CANCEL will cancel a hardware-group test executing in the foreground.

The status of a canceled test hardware-group command will show up as "canceled" on the "status hardware-group" screen.

When a hardware-group test is executing in the foreground with the "continuously" option and CANCEL is pressed or the cancel hardware-group is entered, then the hardware-group test is canceled and for security reasons, the MT running the hardware-group test will be logged off. However, after logging back on the system, you can still restart the canceled hardware-group test command with resume hardware-group command.

Scheduled and Periodic Maintenance

When a **test hardware-group** is entered, all activity related to scheduled background maintenance, periodic background maintenance, and data audits is suspended for the duration of the execution of the **test hardware-group** command. All activity related to scheduled background maintenance, periodic background maintenance, and data audits will restart if the "test hardware-group" command is canceled.

Status Hardware-Group

The state of a canceled **test hardware-group** command is displayed by the **test hardware-group** command and the state shows up as canceled.

All Ports Option

When **test hardware-group all-ports** is canceled, the internally generated port translations for ports that are otherwise untranslated are removed. If **resume hardware-group** is then entered, only customer-administered ports will subsequently be tested. **resume** does *not* reinstate the port translations that were removed by the **cancel**.

Output

If a **test hardware-group** command started in the background is successfully canceled with **cancel hardware-group**, this response is displayed:

```
Hardware-group command successfully canceled
```

If a **test hardware-group** command executing in the foreground is successfully canceled with a **cancel hardware-group** command from another terminal, the following response will be displayed on the terminal where the **hardware-group** command was executing:

```
Hardware-group command aborted with cancel
command entered from another terminal
```

change atm pnc

This command only allows you to change the name of the ATM switch.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
change atm pnc	***number***	Number assigned to the atm pnc Example: **change atm pnc 23**	init inads craft	none	none

Output

The following example shows the output for the **change atm pnc 2** command.

```
change atm pnc 2                                         Page    1 of    1    SPE A
                                    ATM PNC
                             Connection Number: 2
      Location: 01D01
          Name: dup atm pnc
Address Format: ICD ATM
           AFI: 47
           ICD: 0005
        HO-DSP: 80FFE1000000F21C31D4

           SEL: 00
```

Field descriptions

Name	16-character alpha-numeric characters for identification

change circuit packs

change circuit-packs UU

This command allows the user to administratively add, change or remove circuit packs that are to be inserted into port, expansion control, and switch node carriers. It is used to configure the system when the circuit packs have not yet been physically inserted. This command does *not* support displaying or modifying the boards in the PPN control carrier.

Parameters

UU The number of the cabinet containing the circuit packs to be modified. Default is 1.

Output

An input form is displayed containing the following fields:

`Cabinet`	The administered number of the cabinet (1-22).
`Cabinet Layout`	Type of cabinet.
`Carrier`	Each page of this form reports the information for 1 carrier. This field indicates the letter designation of the carrier displayed on the current page.
`Carrier Type`	The function of the carrier: (port, processor, switch-node, dup-switch-node, or not-used).
`Slot`	The carrier slot numbers (00 - 21).
`Code`	The TN or UN part number of the circuit pack. This number identifies the circuit pack type to system software.
`Sfx`	The letter suffix of the circuit pack, if applicable.
`Name`	The name of the circuit pack. This field aids in entering the circuit pack codes.

The following display shows a typical result when **change circuit-packs 1** is entered on a system with simplex SPE and a Center Stage Switch (cabinet 1 is always 5-carrier).

```
change circuit-packs 1                                  Page   1 of   5

change fiber-link

change fiber-link fiber#

The **change fiber-link** command changes the translation data associated with an existing fiber link. On critical reliability systems (duplicated PNC), each fiber link is duplicated and exists as a pair. When PNC duplication is enabled, only the fields on pages 2 and 3 (the DS1 CONV complex attributes) can be changed.

Translation data is not changed until the Enter key is pressed. Pressing CANCEL any time before pressing Enter to enter the changes returns you to the command line without changing any translation data.

When you enter a command that changes translation data, two checks are made:

- You must have permission to administer the feature.
- No other user may be executing a **change, add**, or **remove fiber-link** command.

On a simplex PNC or fully operational duplex PNC, you must remove a fiber and add it again to change the endpoint board locations.

Parameters

number	The administered number (1-27) associated with a fiber link or, on a duplicated PNC, with a fiber link pair.

Examples

change fiber-link 21

Output

`Fiber Link #`	This display-only field shows the identifying number of the fiber link entered on the command line.
`Board Location`	The physical address (cabinet-carrier-slot) of the circuit packs comprising the two endpoints (ENDPOINT-1 and ENDPOINT-2) of the fiber link.
`Board Type`	This display-only field shows the type of circuit pack administered at each endpoint (“ei” or “sni”).
`DS1 Converter?`	**y** indicates that a DS1C Converter Complex is used on this link to remotely locate a port network. If this is the case, a second page displays for administration of the DS1C Complex attributes.

The following fields appear on Page 2 when a DS1 CONV complex is administered on the fiber link. Only the DS1 CONV complex *attributes* are administered here. The circuit pack itself is administered by **change circuit pack**. Entries on Page 2 represent the A-PNC. If the PNC is duplicated, these fields are repeated on Page 3 for the B-PNC. Page 3 fields are display-only, and can be changed only by changing their counterpoints on Page 2.

`Board Location`	This field under the heading DS1C-1 is used to define the physical location of the converter board connected to ENDPOINT-1. It is a data entry field consisting of the board's physical address by cabinet-carrier-slot. When the location is entered, validation is performed to ensure that the board has been administered and is of the correct type (DS1 CONV).
`DS1 Converter Facilities`	The fields under this heading define attributes of the four DS1 facilities (A, B, C, D) that can be connected to the DS1 CONV.
`Facility Installed?`	This specifies (**y** or **n**) whether the indicated facility has been provided and installed. Facility A is required for the DS1 CONV Complex.
`Passes Far-end Clock?`	This specifies whether the DS1 CONV can use the timing of the received signal as a clock source (as when passing timing from a master PN to a slave PN. If the DS1 signal does not come directly from the far-end DS1 CONV board or the network, **n** should be entered. (For example, when using a 'combined' facility in which the signal is converted from digital to analog and back to digital.)
`Digital Data Compatible?`	This specifies whether the facility is suitable for transmission of digital data. Facility A must be so and this field cannot be changed. If Customer Premises Equipment that alters digital data exists on this facility (for example, a channel expansion multiplexer or a combined DS1 facility), **n** should be entered. (Thus, a multiplexer cannot be installed on facility A).
`DS1C-1 Line Compensation`	This specifies the type of line compensation or line equalization for each facility of the DS1 CONV connected to ENDPOINT-1. Valid entries are **1** to **5**. Meanings of these entries are shown in Table 8-6.

Table 8-6. DS1 Line Equalization Settings

Equalizer Setting	Distance to DSX-1 Interface (feet)	
	22 AWG ABAM and 24 AWG PDS	26 AWG PDS
1	1 to 133	0 to 90
2	133 to 266	90 to 180
3	266 to 399	180 to 270
4	399 to 533	270 to 360
5	533 to 655	360 to 450

The line equalization setting defaults to the median value of 3. This setting remains in effect until changed by administration. Incorrect equalizer settings may cause a higher error rate on the DS1 facility.

`DS1 CONV-2 Line Compensation:` Same as the above for ENDPOINT-2 of the DS1 CONV Complex.

`Zero Code Suppression:` Specifies the line coding format for each facility. Valid entries are: **zcs** and **b8zs**. There are 2 line coding options supported by the DS1 Interfaces to meet ones-density requirements in the data stream. Zero Code Suppression (ZCS) line coding is the default and is in place following an initialization until changed by administration. Note that either line coding option may be used on the DS1 Interface that carries the packet time slots.

`Framing Mode:` Specifies the data framing format (**esf** or **d4**) used on the facility. It is initialized to ESF. In this mode, an automatic selection process is executed until either the DS1 Interface is brought into frame, or an Options CCMS message is received by the framing options master. Once options are set by administration, they remain fixed on the framing option master until the board is again initialized, reset, or sent new options. The framing option on the framing option slave Converter Board can change to track the framing option master's option.

The following display shows a typical result when **change fiber-link 1** is entered on a system with simplex PNC and Center Stage Switch.

```

Screen 8-1. Customer Options form (page 2 of 5)

change system-parameters maintenance

This command specifies and displays scheduled maintenance operations and maintenance support functions. It also activates and deactivates INADS alarm origination during repairs. To deactivate alarm origination:

1. Make a note of the current entries in the Alarm Origination and CPE Alarm fields so you can restore them later.
2. Change the `Alarm Origination to OSS Numbers` field to **neither**.
3. Change the `CPE Alarm Activation Level` field to **none**.
4. If daily scheduled maintenance must remain idle during a maintenance procedure, set the `Start Time` field to a time after the session ends. If daily Scheduled Maintenance is running and needs to be deactivated, set the `Stop Time` field to one minute after the current time.
5. Press Enter and verify that the screen displays the message:

   `Command successfully completed`

NOTE:
For earlier releases of system software, disable Cleared Alarm Notification and Restart Notification before submitting the form.

NOTE:
When finished working on the switch be sure to return all fields to their original settings.

```

Field Descriptions (Page One)

Operations Support Parameters

`Product Identification`	Identifies switch to an Operations Support System (OSS): 10-digit number starting with 1.
`First OSS Telephone Number`	Switch reports alarms first to the First OSS telephone number (for example, INADS or Trouble Tracker). The number must be obtained from the National Customer Support Center (NCSC) or the TSC. (# and ***** are not allowed in the telephone number.)
`Abbrev Alarm Report`	Enables the Abbreviated Alarm Report feature for the first OSS. (**yes**)
`Second OSS Telephone Number`	The switch reports alarms secondly to the second OSS telephone number. For example, INADS or DEFINITY SNMP. The number must be obtained from the National Customer Support Center (NCSC) or the TSC. (# and ***** are not allowed in the telephone number.)
`Abbrev Alarm Report`	Enables the Abbreviated Alarm Report feature for the second OSS. (**no**)

`Alarm Origination to OSS Numbers`	Indicates one of four options for alarm origination (**neither**): `both` = Major and Minor alarms result in an automatic call to both administered OSS telephone numbers. `first-only` = Major and Minor alarms result in an automatic call to the first administered OSS number. `neither` = alarm origination does not occur; reports are not sent to either number. `second no-backup` = Major and Minor alarms result in an automatic call to the first administered OSS telephone number. If calling the first OSS telephone number fails four times, the switch calls the second administered OSS telephone number until calling the first OSS telephone number is successful. If Alarm Origination is deactivated, Cleared Alarm Notification and Restart Notification deactivate, even though they may still be activate in the administration.
`Cleared Alarm Notification`	The switch originates calls to the OSS and sends an alarm resolution message once all previously-reported Major and Minor alarms are resolved. Activate Alarm Origination to enable Cleared Alarm Notification. (**no**)
`Restart Notification`	Enables the switch to originate calls to the OSS and report any system restarts caused by switch problems. Activate Alarm Origination to enable Restart Notification.
`Suspension Threshold`	Some problems cause alarms to be generated and resolved repeatedly. To detect these problems, the switch suspends Cleared Alarm Notification when it has reported the specified number of Cleared Alarm notifications in a 24 hour period. A suspended Cleared Alarm Notification reactivates with a successfully-completed “logoff” command, a system reset, or when the threshold is changed. This field is irrelevant if `Cleared Alarm Notification` or `Alarm Origination` are disabled. (1–15)
`Test Remote Access Port`	Indicates if remote access testing on the SYSAM circuit pack is active. This field should be set to **yes** when an INADS line is connected to the switch and a maintenance contract is in effect to maintain alarm origination capability. If no equipment is connected to the remote access port, or if a trunk for remote access and alarm origination is not provided, running tests on the remote access port on the SYSAM results in test failures. This causes unnecessary maintenance alarms and allows potentially destructive tests to be run. To prevent this, set this field to **no**.

`CPE Alarm Activation Level`	Indicates the minimum level (Major, Minor or Warning) to activate Customer-Provided Equipment (CPE) alarm. If the level is **none**, the CPE does not activate for any alarm. **NOTE:** When the switch goes into Emergency Transfer, the CPE alarm activates regardless of the CPE Alarm Activation Level setting.
`Packet Bus Activated`	If this field is set to **yes**, maintenance software assumes that a Packet Control circuit pack is installed. If packet endpoints (for example, ASAI, and/or BRI) are administered, and maintenance testing runs on both the Packet Control circuit pack and Packet Bus, set this field to **yes** after a packet control circuit pack is installed. If a Packet Control circuit pack is not installed in the system, a major alarm is raised against the PKT-CTRL MO. Change this field to **no** if no packet endpoints are administered, to ensure that no packet endpoints can be administered if the packet bus deactivated. If a Packet Control circuit pack is not installed, then this field should be set to **no** (the only exception is system translations that do not have all required hardware).
`Customer Access to INADS Port`	To prevent customer login ID access to system administration and maintenance interface control, set this field to **no**. Lucent Technologies services has sole access to this field.
`Repeat Dial Interval (MMS)`	Number of minutes that the system must wait before attempting another call origination to an OSS. Lack of a far-end acknowledgment triggers the timer.

Scheduled Maintenance

`Start Time`	Hour and minute (24-hour notation) when daily scheduled maintenance starts
`Stop Time`	The hour and minute when scheduled daily maintenance ceases. If any daily maintenance operations are not completed by this time, the system notes its stopped sequence location and includes those operations during the next scheduled daily maintenance.
`Daily Maintenance`	This display-only field lists the standard test series run by maintenance software during daily maintenance.
`Save Translation`	Indicates days that translation data in memory automatically saves to the Mass Storage System disk and/or tape devices during scheduled maintenance. The operation saves to disk, then completes a backup to tape. Translation data saves to both SPEs, if systems have duplicated SPEs. (daily, days of the week, or no - prevents automatic saves)

`Control Channel Interchange`	Each port network has a pair of TDM busses (A and B). Each has a set of time slots dedicated to the control channel. One bus at a time carries the control channel in each PN. (daily, days of the week, or no - prevents interchanges). (**no**)
`System Clocks Interchange`	For High and Critical Reliability systems, this option initiates a Tone-Clock interchange in each port network possessing duplicated Tone-Clock circuit packs. Each port network interchanges into the standby Tone-Clock for 20 seconds and then back to the originally-active Tone-Clock. This field indicates the days that interchanges occur. (daily, days of the week, or no). “No” prevents interchanges. (**no**) The system performs a Tone-Clock interchange, activating the stand by Tone-Clock. After the newly-active Tone-Clock circuit pack is tested, it provides system clocks for its native port network. Then the system interchanges to the originally active Tone-Clock circuit pack.
`SPE Interchange`	This field indicates the days SPE interchanges execute during scheduled maintenance, for duplicated SPE systems. (daily, days of the week, or no). **No** prevents scheduled interchanges. (**no**)
`EXP-LINK Interchange`	This field indicates if expansion links between port-networks interchange as part of scheduled maintenance. The value **daily** means that EXP-LINK interchanges automatically occur everyday. The value **no** means that EXP-LINK interchanges do not automatically occur as part of scheduled maintenance. Values represented by the days of the week mean that EXP-LINK interchanges automatically occur automatically on specified days. Since EXP-LINK interchanges apply to duplicated systems, simplex systems do not display this field. (**no**)

Output (Page Two)

```

Field Descriptions (Page Two)

Minimum Maintenance Thresholds (Before Notification)

`TTRs`	When the number of touch tone receivers (TTRs) in service falls below this number (4 to 200), a WARNING alarm is raised against TTR-LEV. These are also known as dual-tone multifrequency receivers (DTMRs). There are 4 TTRs on each TN748, TN718, TN420, or TN756; TN2182 and TN744 (suffix C or later) each have 8 TTRs. To alarm the first occurrence of a TTR being taken out of service, set this field to the total number of TTRs in the switch.
`CPTRs`	When the number of call progress tone receivers in service falls below this number (2 to 100), a WARNING alarm is raised against TTR-LEV. These are also known as general purpose tone detectors (GPTDs). There are 2 CPTRs on each TN748, TN718, TN420, or TN756; TN2182 and TN744 (suffix C or later) each have 8 CPTRs. To alarm the first occurrence of a CPTR being taken out of service, set this field to the total number of CPTRs in the switch.

`Call Classifier Ports`	When the number of call classifier ports (CLSFY-PTs) in service falls below this number, a WARNING alarm is raised against TTR-LEV. Valid entries are 1 to 200. There are 8 ports on each TN744 or TN2182 circuit pack. To alarm the first occurrence of a CLSFY-PT being taken out of service, set this field to the total number of CLSFY-PTs. If there are no TN744 or TN2182 circuit packs in the system, leave this field blank.
`MMIs`	The MMIs field contains the minimum number of MMI ports needed for the Multimedia Call Handling (MMCH) feature to run efficiently. The MMCH feature must be enabled on the System-Parameters Customer-Options form before the MMIs field can be changed to a number greater than zero. If the number of in-service Multimedia Interface (MMI) ports falls below the minimum port capacity (valid entries between 0-128), a MMI-LEV error is logged. Each MMI circuit pack contains a maximum of 32 ports. To alarm the first occurrence of an MMI being taken out of service, set this field to the total number of MMI ports. If this outage continues for 15 minutes, a MAJOR alarm is raised.
`VCs`	The VCs field contains the minimum number of VC ports needed for the Multimedia Call Handling (MMCH) feature. The MMCH feature must be enabled on the System-Parameters Customer-Options form before the VCs field can be changed to a number greater than 0. Each VC circuit pack contains 16 physical ports: 8 ports are reserved for VC-DSPPT ports, and the remaining 8 ports are designated as VC-SUMPT ports. The 8 DSP ports are made up of 4 encoder and 4 decoder resources that encode and decode audio formats. Thus, *one VC circuit pack is required for every 8 ports of MMCH port capacity*. If the number of in-service VC ports falls below the MMCH port capacity (valid entries between 0 and 128), a VEC-LEV error is logged. To alarm the first occurrence of a VC port being taken out of service, set this field to the total number of VC ports. If this outage continues for 15 minutes a MAJOR alarm is raised.

Terminating Trunk Transmission Test (Extension)

`Test Type 100`

This field specifies extensions assigned to receive tie-trunk calls from other switches that have test line origination capability. The system responds by sending a sequence of test tones. Test Type 100 tests far end to near end loss and C-message by sending:

- 5.5 seconds of 1004 Hz tone at 0 dB
- Quiet until disconnect; disconnect is forced after one minute

`Test Type 102`	Test Type 102 tests far end to near end loss by sending: ■ 9 seconds of 1004 Hz tone at 0 dB ■ 1 second of quiet ■ This cycle is repeated until disconnect; disconnect is forced after 24 hours.
`Test Type 105`	Test Type 105 tests 2-way loss, gain slope, and C-message and C-notch noise by sending: ■ nine seconds of 1004 Hz at -16 dB ■ one second of quiet ■ nine seconds of 404 Hz at -16 dB ■ one second of quiet ■ nine seconds of 2804 Hz at -16 dB ■ 30 seconds of quiet ■ one-half second of Test Progress Tone (2225 Hz) ■ approximately five seconds of quiet ■ forced disconnect

ISDN Maintenance

`ISDN-PRI Test Call Extension`	This field indicates the extension used by far-end ISDN nodes to place calls to the system, for testing ISDN-PRI trunks between the far-end and the system.
`ISDN-BRI Service SPID`	This field shows if the link associates with the Service SPID. If the link is associated with the Service SPID. This number is the test SPID (0 – 99999) (under BRI-SET MO). Otherwise, this field is blank. Service SPID is a feature used by the system technician to check building wiring between the switch and the BRI endpoint.

DS1 Maintenance

`DSO Loop-Around Test Call Extension`	The extension used to set up a DSO loop around connection for testing non-ISDN DS1 trunks. The DSO Loop-Around Test Call feature is used primarily for testing DSO channels associated with non ISDN-PRI trunks. The loop-around is activated by dialing the test extension number; multiple DSO Loop-Around connections can be established by placing multiple calls to the loop-around extension. For more information see ''Facility test calls'' in Chapter 6, "Additional Maintenance Procedures".

SPE Optional Boards

`Packet Intf1?`	These fields indicate if a Disk circuit pack is present, and identify administered Packet Interface slots. If a Packet Interface circuit pack is present, the corresponding Packet Interface field is set to **y** when the system boots. No change to that field is allowed. If the system is equipped with duplicated SPEs, the `Packet Interface` field is set to **y** if either SPE carrier contains a Packet Interface circuit pack in the corresponding position. If a Packet Interface circuit pack is not present, the value for the `Packet Interface` field is read from translation data, and stored on disk or tape. If the field is set to **n**, a Packet Interface circuit pack may be administered by changing the corresponding `Packet Interface` field to **y**. This field identifies the presence of `Packet Interface 1` (always set to **y** for csi and si models).
`Packet Intf2?`	This field identifies the presence of `Packet Interface 2` (always set to **y** for the si model). It is changeable for the csi model. If set to **y** for the csi model, the `Bus Bridge` and `Inter-Board Link Timeslots` fields display. Default is **n**.
`Packet Intf3?`	This field identifies the presence of `Packet Interface 3` (Unavailable in the si and csi models). It is changeable in the r model. Default is **n**.
`Bus Bridge`	(If `Packet Intf2` set to **y**) This field gives the location of the C-LAN circuit pack performing the bus bridge functionality when the packet bus is activated. Enter the 5-character circuit pack number (CCcss, where CC = cabinet number 1-3, c = carrier A-E, ss = slot number 0-20). Default is blank.
`Inter-Board Link Timeslot Pt0`	The number of timeslots to be used for port 0 on the Inter-Board Link. Displays only if the switch model type is csi and the `Packet Intf2` field is **y**. Enter the number of timeslots (**1-9**) to be used by this Inter-Board Link port. Default is **6**.
`Inter-Board Link Timeslot Pt1`	The number of timeslots to be used for port 1 on the Inter-Board Link. Displays only if switch model type is csi and the `Packet Intf2` field is **y**. Enter the number of timeslots (**1-3**) to be used by this Inter-Board Link port. Default is **1**.
`Inter-Board Link Timeslot Pt2`	The number of timeslots to be used for port 2 on the Inter-Board Link. Displays only if switch model type is csi and the `Packet Intf2` field is **y**. Enter the number of timeslots (**1-3**) to be used by this Inter-Board Link port. Default is **1**.

Output (Page Three)

The following example shows the output from *page 3* of the **change system-parameters maintenance** command.

```

```

Field descriptions (Page Three)

Modem Connection

On page 3 of the example forms, 11 fields disappear when the `Modem Connection?` field is set to **internal**. In this example the `Modem Connection` field is set to **external**, revealing the 11 fields.

The first 2 fields on page 3 establish the data format for transmitting serial data from the switch to the modem. The two valid combinations for these 2 fields are:

- Data Bits = 8, Parity = None
- Data Bits = 7, Parity = (odd, even, mark, or space)

`Modem Connection`	Valid entries are `internal` (default) or `external`.
`Modem Name`	This field is 20 characters long and will permit alpha-numeric characters to provide a unique qualifier for a given modem. ( )
`RTS/CTS Enabled`	This field will inform the modem that communication with the data source UART will be driven with RTS/CTS flow control. This field is 6 characters long and is case in-sensitive. (\Q3)

`Asynchronous Data Mode`	This field will configure the modem as an asynchronous communications device. This field is 8 characters long and is case in-sensitive. (&M0&Q0)
`DTE Auto-Data Speed`	This option will adjust the speed of the data source (DTE) UART to the outgoing (modem-to-modem) data rate. So, at maximum this speed would be 9600 baud. This field is 6 characters long and is case in-sensitive. Note that this field sets the link speed between the switch and the modem. It does not set the speed of the modem. It is not desirable to have the serial data fill the modem buffer faster than the outgoing data rate especially because data compression is disabled. ( )
`Disable Data Compression`	This field will turn off the default data compression algorithms that are in use by most consumer modems. This field is 6 characters long and is case in-sensitive. ( )
`Enable Error Control`	This field will turn on the V.42 LAPM and MNP error control protocols, if available on the modem. This field is 6 characters long and is case in-sensitive. This V.42/MNP/Buffer mode first attempts to negotiate V.42 error control with the remote modem. If this fails, then the modem transitions to MNP, and if this fails then no error control is used. ( )
`Misc. Init. Param`	This field supports any initialization parameters that are not already specified. The AT commands specified in this free-form field will be always the last initialization parameters to be sent to the external modem. This field is 20 characters long and is case in-sensitive. ( )
`Auto-Answer Ring Count`	This field controls the number of rings required before the modem automatically answers an incoming call, if and only if the switch doesn't answer first. (If the switch is healthy, it answers an incoming within the first few rings.) This field is 6 characters long and is case insensitive. Typically, the maximum permissible value for this register is 255. The values 1-255 denote the number of incoming ring cycles. (S0=10) **NOTE:** The number of rings is optimally set above 5, and if at all possible, keep the default of S0=10.
`Dial Type`	This field controls the type of inter-register signaling to be used between the modem and the Central Office. Use "T" for tone dialing and "P" for pulse dialing. The field length is be 3 characters long and is case in-sensitive. This field will be concatenated with the dial string. (T)

`Adjustable Make/Break Ratio`	This field can be of particular importance when using a modem that may be transferable from country to country. The intent of this field is to control the make/break ratios of pulses and DTMF dialing. The Intel product information has support for the different make/break options for pulse dialing only. Intel uses the option “&P0” to select a ratio of 39% make and 61% break for communication within the U.S. and Canada. The option “&P1” sets a ration of 33% make and 67% break for the U.K. and Hong Kong. This field is 5 characters long and is case in-sensitive. ( )
`Dial Command`	This field simply denotes the dialing command of the modem. This is a fairly standard command. (D)
`No Answer Time-Out`	Most off-the-shelf external modems provide a timer that abandons any outbound data call after a predetermined interval. Some modems provide for this timer to be disabled, thus allowing an outbound call to ring indefinitely. AT&T Paradyne does not provide this capability with their modem line, because it is generally undesirable to have an outbound call attempt ring indefinitely. The internal modem must have this parameter disabled or set to at least 255 seconds. This is a non-administrable parameter. For the external modem connection, this parameter will be the first initialization string to be transmitted to the external modem. This field will be visible on the administration form in display mode only. This hardcoded constant can be overriden for type approval applications, specifically in the U.K and other Western European nations, by the use of the “Misc. Init. Param:” field. (S7=255)

clear errors

clear errors

The **clear errors** command moves all errors and resolved alarms to the cleared errors list, thereby making room for new incoming error messages which might otherwise be dropped. This command does not clear active alarms from the alarm log. Cleared error entries are the first entries overwritten when additional room is needed to log new entries. To retrieve cleared errors, use **display errors clear**.

NOTE:
Use this command with care. Cleared data will be lost if the logs fill up.

clear firmware-counters

clear firmware-counters UUCSS | a-pnc | b-pnc

This command clears the firmware error counters on the specified circuit packs(s). This command is valid only for SNI, SNC, and DS1C board locations. When a- or b-pnc is specified, all such circuit packs in a single PNC can be cleared at once. On a Critical Reliability systems (duplicated PNC), only circuit packs on a standby PNC that is busied out can be cleared.

This command is useful for quickly clearing lingering alarms after a hardware problem has been fixed. (**Test clear** commands do not clear alarms on SNI, SNC, and DS1C circuit packs.)

WARNING:
This command can mask actual hardware problems since firmware is cleared and appears as if no problems were ever encountered.

Parameters

UUCSS	The specified location must be occupied by an SNI, SNC or DS1C circuit pack. All circuit packs on the standby PNC can be cleared at once by specifying a- or b-pnc. To do so, the standby PNC must first be busied out.

For more information see Common Output Fields at the beginning of this chapter.

clear link n

This command clears the counters associated with a numbered PPP C-LAN link. The clear clan-port command accomplishes the same thing. The statistical counters cannot be cleared for an Ethernet C-LAN link.

clear pgate-port

clear pgate-port UUCSSpp

The **clear pgate-port** command clears the hardware error counters associated with the specified packet gateway port by performing a reset. If the number of the link assigned to the port is known, **clear link** accomplishes the same thing.

For more information see Common Input Parameters and Common Output Fields at the beginning of this chapter.

disable suspend-alm-orig

This command disables one or more active Suspend Alarm Origination entries.

Synopsis

disable suspend-alm-orig (board location).

Examples

disable suspend-alm-orig 1C03
disable suspend-alm-orig 1E07

Description

This command disables one or more active Suspend Alarm Origination entries from the Suspend Alarm Origination table. This command disables all entries (boards and ports) matching the specified physical board location.

NOTE:
A port entry cannot be disabled with this command. Allowing for different ways to disable one or more entries greatly increases the complexity of updating and displaying the Suspend Alarm Origination table.

Defaults

None.

Parameter

board location	This parameter specifies the physical board location of the hardware component that has been replaced or corrected. A port location is not supported because of it complexities.

Help Messages

N is the maximum number of cabinets in the switch:

```
Enter board location:[cabinet(1-N)];
          carrier(A-E);slot(0-20)
```

Output

The command returns one of the following messages:

1. If the board specifier is not valid:

   `Board invalid`

2. If no entries can be disabled in the Suspend Alarm Origination table:

   `Entry not found; no entries disabled`

Feature Interactions

None.

display alarms

This command will display an options form which allows the technician to choose which alarms are to be displayed.

Synopsis

display alarms *[print | schedule]*

Permissions

The following default logins may execute this command: system technician, inads, cust, rcust, bcms, init, browse.

Examples

display alarms display alarms print display alarms schedule

Description

The **display alarms** command brings up a hardware alarm report. This screen allows the technician various different options to select which alarms will be displayed on the alarm report. There are no parameters entered on the command line, parameters are selected on the hardware alarm report form instead.

An alarm can occur for any hardware object when it has been determined by the maintenance subsystem that a problem definitely exists. The impact of the problem is indicated by the alarm type:

Warning alarm—A problem which has been deemed important enough to log, or may be external to the system, but not severe enough to cause a noticeable degradation of service.

Minor alarm—A problem which could disable a local area of the system and so noticeably degrade the system.

Major alarm—A problem which widely degrades the system and seriously impairs service. This would cause a call to be placed to INADS.

A resolved alarm is a problem which has been corrected, and the alarmed component of the system is functioning correctly again. The alarm will be stamped with a resolved date and time, indicating that it is no longer a concern (any errors associated with the alarms will also be considered resolved).

Defaults

All alarms will be displayed.

Parameters

print	This will cause the report to be printed if a printer is linked to the SAT.
schedule	When the “schedule” option is specified, the command is validated and then a scheduling form is displayed to allow the technician to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. Refer to the Report Scheduler and System Printer feature specification [4] for more details.
	There are no parameters entered on the command line, parameters are selected on the hardware alarm report form instead.

Help Messages

If the technician presses HELP after entering “display alarms” the following message will be displayed:

```
['print' or'schedule']
```

Error Messages

If during the execution of a command a resource problem occurs that requires the user to restart the command, then the following message will be displayed:

```
Command resources busy; Press CANCEL to clear, and then resubmit
```

If all of the available maintenance resources are currently in use, then the following message will be displayed:

```
All maintenance resources busy; try again later
```

From Input

After entering the command **display alarms**, the system technician will be presented with an options form.

`Alarm Types`	The type of alarm to be displayed is specified by placing a "y" or "n" in the alarm type fields. The technician can choose a combination of active alarms, major, minor, warning, or resolved alarms.
`Interval`	Display alarm records for the last (m)onth, last (h)our, last (d)ay, last (w)eek, or (a)ll. The default is all.
`From`	Display alarm records from the time specified by mm/dd/hh/mm, where mm is the month, dd is the day, hh is the hour and mm is the minute. If no "from" date is entered, then no checking is done. This will give the user all the alarms active since a month prior to the current time.
`To`	Display alarm record to the time specified by mm/dd/hh/mm, where mm is the month, dd is the day, hh is the hour and mm is the minute. If no "to" date is entered, any alarm which is active after the from date will be selected.

`Equipment Type` The technician can choose between seven different equipment types. If there is no input to any of these fields, the system will default to all the equipment. The user can select one of the following fields:

- Cabinet: This allows the technician to display all alarms associated with a particular cabinet. Alarms for a cabinet are referenced by a number ranging from 1 to 3 which is assigned during cabinet administration.
- Port Network: This allows the technician to display all alarms associated with a particular port network. Alarms for a port network are referenced by a number ranging from 1 to 3.
- Board Number: This allows the technician to choose all alarms associated with a particular circuit pack for display. Alarms for a (cabinet-carrier-slot). If the cabinet number is omitted, the system will default to 1.
- Port: This allows the technician to choose all alarms associated with a particular port on a circuit pack for display. Alarms for a port circuit are referenced by port location (cabinet-carrier-slot-circuit). If the cabinet number is omitted, the system will default to 1.
- Category: Alarms for a particular equipment category.
- Extension: Alarms associated with an extension number.
- Trunk (group/member): The technician can choose to view all alarms associated with a particular trunk group or trunk group member. The group identifier should be entered to view all alarms associated with a trunk group XXX/___. The group identifier and member identifier should both be entered to view all alarms associated with a specific trunk group member XXX/XXX.

```
display alarms                                                   Page 1 of 1
                                 ALARM REPORTS

        The following options control which alarms will be displayed.
        ALARM TYPES
                   Active? y_      Resolved? n_
                    Major? y_         Minor? y_      Warning? y_
        REPORT PERIOD
                 Interval: m_    From: __/__/__:__  To: __/__/__:__
        EQUIPMENT TYPE ( Choose only one, if any, of the following )
                                   Cabinet: ____
                              Port Network: __
                              Board Number: _______
                                      Port: ________
                                  Category: ________
                                 Extension: _____
                    Trunk ( group/member ): ___/___
```

Field Help

Following are the help messages that the system technician will see upon tabbing to the specified field and pressing the HELP key.

Active?	n(o) y(es)
Resolved?	n(o) y(es)
Major?	n(o) y(es)
Minor?	n(o) y(es)
Warning?	n(o) y(es)
Interval:	The interval field help is a list of objects. This list includes: m(onth), h(our), d(ay), w(eek), a(ll). From (month) “Enter month between 1-12
From (day)	Enter day between 0-31
From (hour)	Enter hour between 0-23
From (minute)	Enter minute between 0-59
To (month)	Enter month between 1-12
To (day)	Enter day between 0-31
To (hour)	Enter hour between 0-23
To (minute)	Enter minute between 0-59
Cabinet:	Enter cabinet number (1-3)
Port Network:	Enter port network number (1-3)
Board Number:	Enter 5 character board number; cabinet(01-3):carrier(A-E):slot(00-20)
Port:	Enter port number; [cabinet(1-3)]: carrier(A-E): slot(0-20): circuit(01-31)
Category:	The category field help is a list of objects. This list includes the following: adm-conn, announce, bri/asai, card-mem, cdr, data-mod, detector, dup-spe, environ, exp-intf, ext-dev, generatr, inads-link, infc, maint, mbus, memory, misc, mnt-test, modem, netcon, pkt, pkt-ctrl pms/jrnl, procr,removable-media, quick-st, s-syn, stabd, stacrk, stations, sys-prnt, tdm, tone, trkbd, trkcrk, trunk, wideband. For a table describing the category entries in greater detail, see the **display errors** command.

Extension:	Enter assigned extension
Trunk (group)	Enter group number between 1-99
Trunk (member)	Enter group member between 1-99, or blank

Field Error Messages

Following are the error messages that display on the screen. The messages display when the system technician tabs out of a field and the validation routines are executed. In the following messages, an “x” represents the character that was entered by the user.

Body	
Active?	“x” is an invalid entry; please press HELP
Resolved?	“x” is an invalid entry; please press HELP
Major?	“x” is an invalid entry; please press HELP
Minor?	“x” is an invalid entry; please press HELP
Warning?	“x” is an invalid entry; please press HELP
Interval:	“x” is an invalid entry; please press HELP
From (month)	Entry must be all digits
From (day)	Entry must be all digits
From (hour)	Entry must be all digits
From (minute)	Entry must be all digits
To (month)	Entry must be all digits
To (day)	Entry must be all digits
To (hour)	Entry must be all digits
To (minute)	Entry must be all digits
Cabinet:	Entry invalid
Port Network:	Entry invalid
Board Number:	Board invalid
Port:	Port invalid
Category:	“xxxxxxxx” is an invalid entry; please press HELP
Extension:	Entry must be all digits
Trunk (group)	Entry must be all digits
Trunk (member)	Entry must be all digits

Output

After valid options are entered by the technician, an alarm report is displayed. The data displayed on this form will be:

`Port`	The location of the alarmed object. For installed circuit packs, the location is displayed as **cabinet-carrier-[slot]-[circuit]**. For Port Network-related objects, the location is displayed as **PN UUB**, where “UU” is the Port Network number and B is the bus (A or B). For Fiber Link-related objects, the location is displayed as **x a-PNC** where “x” is the Fiber Link number and “a” is the PNC side (A or B). This is the same identifier as used by the alarm log.
`Maintenance Name`	The logical name of the MO which has been alarmed.
`On Brd`	Whether the fault detected is on the associated circuit pack, or an off board element connected to the circuit pack.
`Alt Name`	The alternate means of identifying the MO. This field contains the extension when the object is a station, and it contains xxx/yyy when the object is a trunk, where xxx is the trunk group number and yyy is the member number. It contains P/xxx when the object is a private CO line, where xxx is the private CO line group number.
`Alarm Type`	MAJOR, MINOR, or WARNING. This is an indicator to the seriousness of the alarm raised.
`Service State`	RDY (ready for service), OUT (out of service), or IN (in service). This is the current service state of the station and trunk ports shown. If a blank is displayed in this field it means that no service state is associated with the MO.
`Ack?`	The columns under the “1” and “2” headings denote if the alarm has been acknowledged by the first and second OSS telephone numbers, respectively. A “y” in this field means that the alarm has been acknowledged. An “n” means that the alarm has not been acknowledged. A “c” means that the alarm resolved and cleared and the alarm notification was acknowledged. A blank means that there will be no attempt to report the alarm.
`Date Alarmed`	Day, hour, and minute of alarm.
`Date Resolved`	Day, hour, and minute of resolution. For active alarms this field is zero (0).

For the following example, the ENTER key was pressed immediately after entering the **display alarms print** command.

```

Command successfully completed
```

Feature Interactions

If the alarm origination is disabled by “change system-parameters maintenance,” the `Ack?` field displays blanks no matter what the true acknowledge state is for the alarm.

If “second-as-backup” is administered in the `Alarm Origination to OSS Numbers` field, the column under the “2” heading will be blank for the alarms that the switch has not attempted to send to the second OSS telephone number. For the alarms that the switch has attempted to send to the second OSS telephone number, the column will be “y,” “n,” or “c,” depending on the acknowledgment status of the alarm. After calling the first OSS telephone number becomes successful, for the alarms that the switch has attempted to send to OSSN2, the column will be consistent with the column under the “1” heading.

display atm pnc

This command displays specific atm pnc data.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display atm pnc	***number***	The administered number of the atm pnc	init inads craft	none	none
	print				
	schedule				

Output

The following example shows the output for the **display atm pnc 2** command.

```
display atm pnc 2                                                    SPE A
                                    ATM PNC
                             Connection Number: 2
      Location: 01D01
          Name: dup atm pnc
Address Format: ICD ATM
           AFI: 47
           ICD: 0005
        HO-DSP: 80FFE1000000F21C31D4

           SEL: 00
```

display capacity

This form describes how you have administered your system and provides a "snapshot" status of the switch resources.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display capacity	***print***	Report sent to printer	init inads craft cust rcust	none	none
	schedule	Command validated first, then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed is sent to the system printer instead of the screen.[1]			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

The screen below shows the output from the **display capacity** command.

NOTE:
The capacities listed may not coincide with your system. The figures that follow are included to help explain the command and the field values, not to provide capacity information.

```

Figure 8-1. System Capacity form (page 2 of 9)

Field descriptions (page 2)

Attendant Service

`Attendant Positions`	The number of administered attendants.
`Queue Length`	A *real-time* snapshot of the number of calls waiting for all attendants.
`Authorization Codes`	The number of authorization codes used for security purposes. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.

Basic Call Management System (BCMS)

`Measured Agents Per System`	The number of agents the Basic Call Management System (BCMS) is measuring.
`Measured Splits/Skills`	The number of hunt groups BCMS is measuring.
`VDNs`	The number of vector directory numbers BCMS is measuring.

```

              CALL COVERAGE
                      Coverage Answer Groups:          0       750       750
                              Coverage Paths:          7      9992      9999

                          Call Pickup Groups:          0      5000      5000

                                Call Records:          -         -      7712

     CALL VECTORING/CALL PROMPTING
                    Vector Directory Numbers:          2     19998     20000
                          Vectors Per System:          3       509       512
   BSR Application-Location Pairs Per System:          0      1000      1000
```

Figure 8-2. System Capacity form (page 3 of 9)

Field descriptions (page 3)

Call Coverage

`Coverage Answer Groups`	The number of Coverage Answer Groups. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.
`Coverage Paths`	Coverage Paths — The number of coverage paths which is a path taken when a call goes to coverage. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.
`Call Pickup Groups`	The number of call pickup groups have been administered. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.
`Call Records`	The maximum number of active calls at a given time. This field does not display real-time data, just the system limit and is not administerable.

Call Vectoring/Call Prompting

`Vector Directory Numbers`	The number of system VDNs. For further information, see *DEFINITY Call Vectoring/Expert Agent Selection*.
`Vectors Per System`	The number of vectors per system. For further information, see *DEFINITY Call Vectoring/Expert Agent Selection*.
`BSR Application - Location Pairs Per System`	The number of mappings administered in a multisite network. The maximum number of application-location pairs per system is 1000. For example, for a network of 10 locations, you can assign100 applications; with 50 locations, you can assign 20 applications. For further information, see *DEFINITY Call Vectoring/Expert Agent Selection*.

```

Figure 8-3. System Capacity form (page 4 of 9)

Field descriptions (page 4)

Data Parameters

Administered Connections	The number of connections between two access or data endpoints. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.
Alphanumeric Dialing Entries	For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.

Dial Plan

Extensions	This includes stations, data endpoints, hunt groups, announcements, TEGs, VDNs, common shared extensions, and code calling IDs.
Miscellaneous Extensions	Anything that is not a station, trunk, data module, or attendant. This includes, but is not limited to, PCOL groups, common shared extensions, access endpoints, administered TSCs, code calling IDs, VDNs, LDNs, hunt groups, announcements, and TEGs.
UDP Extension Records	The number of 4- or 5-digit extension numbers that allow a user to call from one PBX to another using that number.

`Digital Data Endpoints` The number of digital serial communication devices that permit the asychronous transfer of data. This also includes the number of analog adjuncts.

`Expansion Port Networks` The number of port networks connected to the TDM bus and packet bus of a process port network.

`Facility Busy Indicators` The number of visual indicators of the busy/idle status of any particular trunk group, hunt group member, or station user. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.

HUNT GROUPS, SPLITS, OR SKILLS
                        Groups/Splits/Skills:      9       591       600
                        Logged-In ACD Agents:      0      5200      5200
                    Group Members Per System:     17      9983     10000
                    CMS Measured ACD Members:      0     10000     10000
                      Queue Slots Per System:      2     14998     15000
                        Queue Status Buttons:      0      2000      2000

                  Intercom Groups Per System:      0       256       256

                 Modem Pool Groups Per System:     0        63        63

        Personal CO Line (PCOL) Trunk Groups:      0       200       200
```

Figure 8-4. System Capacity form (page 5 of 9)

Field descriptions (page 5)

Hunt Groups, Splits, or Skills

`Groups/Splits/Skills` The number of ACD hunt groups.

`Logged-In ACD Agents` A *real-time* field displaying the number of agents actually logged in. For example, if an agent is logged into 4 skills (and there are no other agents), then the `Logged-In ACD Agents` field is 1 and the `Group Members Per System` field is 4.

`Group Members Per System` The number of agent/group pairs.

`CMS Measured ACD Members`	The number of agent pairs being measured by CMS.
`Queue Slots Per System`	The number of hunt group queue positions.
`Queue Status Buttons`	The number of hunt group queue status buttons administered on stations. There are four types of queue status buttons; attendants use the last two queue status buttons: ■ q-calls (Queue Calls) ■ q-time (Queue Time) ■ atd-qcalls (ATD - Queue Calls) ■ atd-qtime (ATD - Queue Time)
`Intercom Groups Per System`	The number of intercom groups set up within your organization.
`Modem Pool Groups Per System`	The number of modem pool groups. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.
`Personal CO Line (PCOL) Trunk Groups`	The number of PCOL trunk groups. For further information, see *DEFINITY Enterprise Communications Server Administration and Feature Description*.

```

Figure 8-5. System Capacity form (page 6 of 9)

Field descriptions (page 6)

`Recorded Announcement Analog Queue Slots`	The number of calls in queue for the system's analog announcements.

Temporary Signaling Connections (TSC)

`Administered TSCs`	The number of allowed Temporary Signaling Connections (TSCs).
`NCA-TSC Calls`	The number of allowed Non-Call Associated TSCs.

Trunks

`DS1 Circuit Packs`	The number of allowed DS1 circuit packs.
`ICHT For ISDN Trunks`	The number of Incoming Call Handling Table (ICHT) entries administered for trunk groups.
`ISDN CBC Service Selection Trunks`	The number of call-by-call trunk groups.
`Trunk Groups`	The number of trunk groups administered.
`Trunk Ports`	The number of trunk ports administered.

                       Stations Without Port:     0       -          -
                             Other Stations:     6       -          -
                                  TTI Ports:     0       -          -

           TOTAL SUBSCRIBED PORTS
                             ISDN BRI Ports:     3     6997       7000
                     Station and Trunk Ports:   119    13881      14000
```

Figure 8-6. System Capacity form (page 7 of 9)

Field descriptions (page 7)

Voice Terminals

`Station Button Memory (units)`	The percentage of memory being consumed by all administered buttons.
`Station Records`	The number of resources being used by regular stations, announcements, and music on hold.
`Stations`	The number of voice terminals.
`Stations With Port`	The number of connected voice terminals (stations with specific administered ports).
`Stations Without Port`	The number of voice terminals not having an administered port, such as AWOH.
`Other Stations`	The number of ports used as conversion resources, agent login ID, MASI, and analog announcements.
`TTI Ports`	The number of ports assigned by TTI features.

Total Subscribed Ports

`ISDN BRI Ports`	The number of ISDN-BRI ports.
`Station and Trunk Ports`	The number of stations with ports and assigned trunk ports.

```
                                                                Page 8 of 9
                              SYSTEM CAPACITY

CURRENT SYSTEM INFORMATION

          Software Load: G3V6r.03.0.211.0
   Memory Configuration: G3rV6
         Offer Category: A

LAST TRANSLATION LOADED INFORMATION:

          Software Load: G3V4r.06.0.075.0
   Memory Configuration: G3r (large)
         Offer Category: unknown
```

Figure 8-7. System Capacity form (page 8 of 9)

Field descriptions (page 8)

Current System Information

`Software Load`	The current software load on which the system is running.
`Memory Configuration`	The system platform.
`Offer Category`	The system's offer category.

Last Translation Loaded Information

`Software Load`	The software load translations saved before upgrade or reboot. Can also be `unknown/no trans` if no flash card is present. Also, if load translations were upgraded from one prior to G3V4 load 71 or early G3V5 loads, `unknown/no trans` displays.
`Memory Configuration`	The platform on which the translations were saved. Can also be `unknown` if no flash card is present or translations made on old load. This is important because platforms are not always compatible.
`Offer Category`	The offer category that was set when the last save translation was done before upgrade or reboot. Can also be `unknown` if no flash card is present or translations made on old load.

```

 11: n      n
 12: n      n
 13: n      n
 14: n      n
 15: n      n
 16: n      n
 17: n      n
```

Screen 8-2. Interface links screen

Field descriptions

`Link`	Number of the administered link (data module form).

`Enable`	Yes (y) or no (n) depending upon data module administration (Processor Interface, X.25, Ethernet, and PPP).
`Est. Conn.`	Establish Connection data from the data module forms (Processor Interface, X.25, and PPP).
`Ext`	Extension number of the local data module for this link.
`Type`	Protocol for this link: ■ `bx.25` (Processor Interface and X.25) ■ `ppp` ■ `ethernet`
`Destination Number`	Destination of the link as administered on the data module forms (Processor Interface, X.25 and PPP).
`DTE/DCE`	Processor Interface administration from data module form (Processor Interface only).
`Conn. Mod.`	Connected Data Module administration from data module form (Processor Interface and X.25 only)
`Name`	Administered name from the data module forms (Processor Interface, X.25, Ethernet, and PPP)

display errors

display errors [high-resolution] [print | schedule]

The **display errors** command brings up an input form that allows you to select which errors will be displayed on the hardware error report.

Errors can result from in-line firmware errors, periodic tests, failures detected while executing a test command, software inconsistency, or a data audit discrepancy. The Error Log is restricted in size. A new entry overwrites the oldest unalarmed entry. The overwritten entry must be at least six minutes old, or the new entry is dropped.

Help Messages

The following help message will be displayed when the first page of a multiple page list of alarms/errors or after the Prev Page key is pressed:

`Press CANCEL to abort or NEXT PAGE for next page`

The following help message will be displayed after the Next Page key is pressed and there are more pages of alarms/errors to be displayed:

`Press CANCEL to abort, NEXT PAGE for next page, PREV PAGE for previous page`

The following help message will be displayed after the Next Page key is pressed and there are no more alarms/errors to be displayed:

`Press CANCEL to abort, NEXT PAGE to complete, PREV PAGE for previous page`

Actions

The following command will display the next page of alarms/errors or echo “Command successfully completed” and exit if there a no more pages of alarms/errors to display:

`Next Page`

The following command will display the previous page of alarms/errors and the “press CANCEL to abort or NEXT PAGE for next page” help message:

`Prev Page`

The following display command will be cancelled and echo “Command aborted” and exit.

`Cancel`

System Reboots and the Error and Alarm Logs

The system attempts to save the error and alarm logs to the disk on the *active* SPE when any of the following events take place:

— The **save translation** command is executed.

— Translations are saved as part of scheduled maintenance (as administered on the maintenance-related system parameters form).

— A demand or software-escalated system reboot takes place.

— The PPN is about to lose all power after having been on battery backup.

Conditions such as unavailability of the MSS can prevent this attempt from succeeding.

Whenever the system reboots, the error log is restored from the disk on the SPE that becomes active with the reboot. Since the logs are saved to the disk on the SPE that was active before the reboot, the versions restored at reboot time may not be current. This occurs when either:

— The attempt to save at reboot did not succeed.

— The SPE that is active coming out of the reboot is not the same one to which the logs were last saved.

In such a case, the logs will not show the errors and alarms that have been logged since the last time a save was made to the SPE that became active with the reboot. When looking at errors that precede the last reboot, look for indications preceding the reboot to determine whether the logs restored at reboot are complete.

System resets less severe than a reboot rarely affect the error and alarm logs.

NOTE:
If there are SYSTEM errors in the Error Log, use **display initcauses** to obtain additional information. Information that could not be logged during a system reset may be found here.

Parameters

high-resolution	This option specifies an error report with high resolution time stamps for the first occurrence and last occurrence of the error. The high resolution time stamp includes seconds and a sequence count within a second. The sequence count starts over for each second.

For more information see "Common Input Parameters" at the beginning of this chapter.

Input Form

This form specifies which errors display on the report. When all selections have been made, press ENTER. If no selections are made, or if the schedule option is specified, all errors from the last day that are associated with active alarms display (or print).

`Error Type` The report can be restricted to specific error codes. This field defaults to all errors.

`Error List` The report can be restricted to errors from one of three lists described below: active-alarms, errors, or cleared-errors. Default is active-alarms.

`Interval` Specifies error records for the last month, hour, day, week, or all errors (m, h, d, w, a). The default is all.

`From` Specifies error records starting from the time specified by mm/dd/hh/mm (month/day/hour/minute). If no "from" date is entered, errors from the earliest record in the log are displayed.

`To` Specifies all error records up to the time specified by mm/dd/hh/mm. If no "to" date is entered, all errors up to the current date are displayed.

`Equipment Type` To limit the report to a specific group of components, enter the location of a type of equipment in one of the following fields. If no entry is made, errors for the entire system are displayed.

- Cabinet: Enter the cabinet number (1-22).
- Port Network Number: 1-22
- Board Number: Enter the cabinet-carrier-slot address of the circuit pack (for example, 11c04). If the cabinet number i omitted, it defaults to 1.
- Port: Enter the cabinet-carrier-slot-circuit address of the port (for example, 11c0408). If the cabinet number is omitted, the system will default to 1.
- Category: errors for a particular equipment category. See the list of alarm and error categories at the beginning of this chapter. The HELP key displays a list of categories.
- Extension: Enter the extension number of a port.
- Trunk (group/member): Enter a trunk group number, or a trunk group and member number separated by a slash (for example, 78 or 78/1).

```

Error Log Report Standard Resolution

`Port`	The physical location of the alarmed object. For circuit pack based MOs, the location is cabinet-carrier-[slot]-[circuit]. For PN-based objects, such as TDM-BUS, the location displays as `3PN xx`, where xx is the PN number. For Fiber Link-based objects, the location displays as `x a,b-PNC` where x is the Fiber Link number and a- or b-pnc indicates one of the PNC pair. (Always a-pnc on systems with simplex PNC.)
`Maintenance Name`	The abbreviated name of the MO that encountered the error.
`Alt Name`	An alternate means of identifying the MO.
`Error Type`	Numerical error code that identifies the type of problem. The meanings of these codes are explained under the name of the MO in Chapter 9.
`Aux Data`	Additional numerical information about the error type. Only the most recent auxiliary data for each error type is displayed.
`First Occur`	Month, day, hour, and minute (and second if the high-resolution command line option is used) that the error was first recorded.
`Seq Cnt`	Sequence Count. These numbers give the order in which the errors were logged. Each sequence covers a period of one second. Sequence numbers are assigned to the first and last occurrences of a given error within the one second period given in the time stamp. There may be gaps in the sequence numbers within a given second because the last occurrence of an error may replace an existing entry and because sequence numbers are also assigned to software events not shown in the hardware error log. This information is displayed only if the high-resolution option is specified on the command line.
`Last Occur`	The month, day, hour, and minute (and second if the high-resolution command line option is used) of the most recent error. If the system is unable to retrieve the time of day when the error occurred, a “dummy” date will be stamped in the log so as to distinguish it from reliable data. It appears as “00/00/01:07”
`Err Cnt`	The total number of times that the error type has occurred. The maximum entry displayed is 999.
`Err Rt`	Average hourly rate at which the error has occurred from the first occurrence to the present. The maximum entry displayed is 999.
`Rt/Hr`	An approximation of the rate at which this error occurred in the last hour. The maximum entry displayed is 999.

`Al St` Alarm Status - A character indicating the status of this MO in the error and alarm logs. The allowed values are:

- a — Active alarm entry
- r — Resolved alarm entry
- c — Resolved alarm entry as a result of the long "clear" option of the test command.
- s — Resolved alarm entry as a result of a software requested (non-demand) system restart.
- t — Resolved alarm entry as a result of a technician requested system restart.
- n — Not alarmed.

Ac A flag (yes or no) indicating whether or not the maintenance object is still under active consideration by the maintenance subsystem.

The following display shows a typical result when **disp errors** is entered with the default input settings.

```

display events

display events [print]

A vector event is the occurrence of something unexpected during a vector-routed call due to resource exhaustion or faulty vector programming. (For example, route-step failures are typically due to the programming of an invalid extension.) These types of failures are not due to faulty hardware or system software error and do not constitute incorrect feature operation. This command allows you to diagnose and correct vectoring problems due to the above-mentioned causes. See *DEFINITY Communications System Generic 3 Call Vectoring and Expert Agent Selection (EAS) Guide*, 555-230-520, for information on how to interpret this report.

Input Form

The following entry form is displayed to allow limiting the report to events of a certain type or from a certain time period. Enter the desired parameters and press ENTER.

`Category`	"Vector" specifies the type of event report to display and is the only valid entry.
`Report Period`	The fields in this section allow you to view only those vector events that occurred within a specific time period. If these are left blank, all vector events recorded are displayed.
`Interval:`	This field specifies a display of all events within the last time period of the type Enter the first letter of one of the following selections: *a*ll, *m*onth, *d*ay, *h*our, *m*inute.
`Start/Stop Time`	The starting and ending times, in 24-hour notation, of the interval to be reported.
`Vector Number`	The number of the vector (1-256) for which events will be reported. If this field is left blank, events for all vectors will be reported.
`Event Type`	Specific types of vector events are associated with numbers from 50000 to 50999. Entering one of these numbers will limit the report to events of this type. If this field is left blank, events for all types of vectors will be reported.

Output

See *DEFINITY Communications System Generic 3 Call Vectoring and Expert Agent Selection (EAS) Guide*, 555-230-520, for more information on how to interpret this report. In particular, the Event Data 2 field will be associated with possible causes and repair strategies for the event.

`Event Type`	A number from 50000 to 50999 that identifies what type of vector event occurred.
`Event Description`	A text string describing the event.
`Event Data 1`	If in the format *number*/*number* such as "200/10", this indicates the vector number and step number associated with the event. If in the format "Split *number*" such as "Split 2", this indicates the split number.
`Event Data 2`	Additional data concerning the event encoded as a hex number.
`First Occur`	The date and time when the vector event first occurred.
`Last Occur`	The date and time when the vector event last occurred.
`Evnt Cnt`	The total number of times, up to 255, that vector events of this type have occurred.

The following example shows the input form for **display events**:

```
display events                                Page  1 of  1   SPE B

display fiber-link

display fiber-link fiber# [print | schedule]

The **display fiber-link** command displays the translation data associated with an existing fiber link.

The output for this command is the same as that for **change fiber-link**.

Parameters

fiber# The administered number (**1** to **27**) associated with a fiber link (or fiber link pair in a duplicated PNC).

display initcauses

display initcauses [print | schedule]

The **display initcauses** command displays a history of recovery steps taken by the system. *This command displays information for restarts of the active processor only*. Whenever the processor resets and the system is restarted, whether initiated by a technician command or by system software, information about the recovery is stored. If the reset is escalated, only the reset that successfully completes is recorded. Information about the reset may also be found in the Error Log. When a reset 4 (reboot) occurs, the Error Log is saved on the Mass Storage System.

Records of the last 16 restarts are retained in the initcauses log in chronological order. A power failure results in loss of all records in the initcauses log.

Output

The entire initcauses log, consisting of 16 resets, fills one screen.

`Cause` This gives the reason for the system reset, as follows:

Agent Request: The restart was requested through the Agent/GEMINI debugger interface (not available to craft login).

Craft Request: The reset was initiated using **reset system**. This includes restarts requested through the SPE-Down interface.

Initialized: This represents a power-up, and is always the first entry in the log unless more than 15 restarts have occurred since the last power up.

Interchange: A spontaneous interchange was executed by the system usually in response to a major hardware fault on the active SPE.

Maintenance Reset: The SPE was reset by maintenance software on the SYSAM circuit pack. This includes periodic resets initiated by the SYSAM during SPE-Down mode.

`Cause` **mon:** A restart was initiated from the system monitor (not available to craft login).

Sanity Timer Reset: The sanity timer on the processor timed out and reset the system. This usually indicates corrupted software.

Scheduled Interchange: An interchange was performed as part of scheduled daily maintenance.

Software Request: System software detected problems and executed a restart to recover.

SPE-Select Lead Change: On systems with duplicated SPEs, the SPE select lead changed and reset the processor.

SPE-Select Switch: The SPE select switches on the DUPINT circuit packs were manually set to lock the standby SPE active, causing a spontaneous interchange. This is **not** a recommended procedure.

Unknown: The restart could not be classified. The Error Log may contain more information about the restart.

Upgrade Software: The indicated SPE was reset as part of the execution of the upgrade software command. If this precedes a Software Requested level 2 reset, both are probably associated and indicate a non-call preserving upgrade took place.

`Action`	The level of recovery performed by the system. 1 Reset system 1 (Warm) 2 Reset system 2 (Cold-2) 3 Reset system 3 (Cold-1) 4 Reset system 4 (Reboot) 5 Reset system 5 (Extended Reboot) Planned SPE Interchange (requested by **reset system** command or scheduled maintenance)
`Escalated`	Whether the restart was escalated to a higher level than originally attempted. The system's software escalation strategy can perform a higher level restart than the one initiated if problems prevent or conditions interfere with normal execution.
`Carrier`	The carrier (always A in a simplex system) on which the restart took place. If an interchange took place, this indicates the carrier of the newly active SPE that was switched into.
`Time`	The month, day and time of the restart.

The following display shows a typical result when **dis init** is entered.

```
display initcauses

                         INITIALIZATION CAUSES

Cause                  Action   Escalated   Carrier     Time

display system-parameters duplication

This command displays the status (enabled or disabled) of Switch Processing Element (SPE) and Port Network Connectivity (PNC) duplication. The following must be duplicated:

- Each switch node record and every switch node with its duplicate (cabinet administration is a prerequisite)
- Every fiber link containing either an expansion interface circuit pack as an endpoint, or a DS1-C (fiber link administration is a prerequisite; circuit pack administration then follows duplication administration)

All nonduplicated switch node interfaces (SNI) to SNI fiber links are automatically duplicated.

NOTE:
You must enable (y) the `PNC Duplication` field on the customer options form (**change system-parameters customer-options**) before you can do any duplication administration.

PNC Duplication cannot be enabled until all pnc-a and pnc-b boards are released from the “busyout” state.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display system-parameters	**duplication**	SPE or PNC duplication Examples: **display system-parameters duplication**	init inads craft	none	none

Output

The following example shows the output from the **display system-parameters duplication** command.

```
                                                          Page 1 of 1
                     DUPLICATION-RELATED SYSTEM PARAMETERS
          Enable Operation of SPE Duplication? y
          Enable Operation of PNC Duplication? y
```

Screen 8-3. Duplication-Related System Parameters form (page 1 of 1)

Field descriptions

`Enable Operation of SPE Duplication?`	Status of SPE duplication: **y** is enabled; **n** (default) is disabled
`Enable Operation of PNC Duplication?`	Status of PNC duplication: **y** is enabled; **n** (default) id disabled. This field appears only if `PNC Duplication` has been enabled on the System-Parameters Customer-Options form.

display node-names

This command displays a list of the administered node names.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display node-names	***print schedule***	Example: **display node-names**	init inads craft	none	none

Output

The following example shows the output from the **display node-names** command.

Field descriptions (page 2)

`Name`	Non-specific node name (up to 15 characters each) for CMS nodes, DCS nodes, and so forth. Valid entries are alpha-numeric and/or special characters for identification.
`IP Address`	IP address for the adjunct or switch. Enter **0 - 255** or leave blank (default).

display system-parameters maintenance

This command displays existing maintenance-related system parameters.

Synopsis

display system-parameters maintenance [high-resolution] [print | schedule]

Permissions

Logins with the following service levels may execute this command: craft, inads, init, super-user, or logins with Maintain Switch Circuit Packs permissions enabled.

Examples

display system-parameters maintenance
display system-parameters maintenance print
display system-parameters maintenance schedule

Description

The **display system-parameters maintenance** command displays the translation data for maintenance related system parameters.

Parameters

Print	This option causes the report to be printed if a printer is linked to the SAT.
Schedule	When the schedule option is specified, the command is validated and a schedule form is displayed to allow the technician to schedule execution of the command at a specified time. The information displayed by the command will be sent to the system printer instead of the screen.

For more information see ‘‘Common Input Parameters’’ at the beginning of this chapter.

Help Messages

The following help message will be displayed when the system technician presses the help key after entering the **display system-parameters maintenance** command:

```
[‘Print’ or ‘schedule’]
```

Output

An input form is displayed with the following fields. Defaults for data entry fields are listed in parentheses.

The following display shows a typical result when **display system-parameters maintenance** is entered.

```
display system-parameters maintenance                          Page   1 of 3

Help/Error Message Line
```

`Product Identification`	This is a 10-digit number starting with 1 that identifies the switch to an Operations Support System (OSS), for example, INADS.
`First OSS Telephone Number`	The first telephone number that the switch uses to report alarms to, for example, INADS or Trouble Tracker. The number must be obtained from the National Customer Support Center (NCSC) or the TSC. **#** and ***** are not allowed in the telephone number.
`Abbrev Alarm Report`	Enables the Abbreviated Alarm Report feature for the first OSS. (yes)
`Second OSS Telephone Number`	The second telephone number that the switch uses to report alarms to, for example, INADS or DEFINITY SNMP. The number must be obtained from the National Customer Support Center (NCSC) or the TSC. **#** and ***** are not allowed in the telephone number.
`Abbrev Alarm Report`	Enables the Abbreviated Alarm Report feature for the second OSS. (no)

`Alarm Origination to OSS Numbers`	Indicates one of four options for alarm origination (neither): ■ If "both," all Major and Minor alarms result in an automatic call to both OSS telephone numbers. Both OSS telephone numbers must be administered. ■ If "first-only," all Major and Minor alarms result in an automatic call to the first OSS number only. The switch does not call the second OSS telephone number even if the number is administered. The first OSS telephone number must be administered ■ If "neither," alarm origination does not take place. Warning alarms are not reported to either numbers. ■ If "second-as-backup," all Major and Minor alarms result in an automatic call to the first OSS telephone number. If calling the first OSS telephone number fails four attempts, the switch starts to call the second OSS telephone number as a backup until calling the first OSS telephone number becomes successful. Both OSS telephone numbers must be administered. Before Release 5, the name of this field is "Alarm Origination Activated." If Alarm Origination is deactivated, both Cleared Alarm Notification and Restart Notification are disabled, even though they may still be activated in the administration.
`Cleared Alarm Notification`	Enables the switch to originate a call to the OSS and send an alarm resolution message whenever all previously reported Major and Minor alarms are resolved. Alarm Origination must be activated in order for Cleared Alarm Notification to work. (no)
`Restart Notification`	Enables the switch to originate a call to the OSS and report any system restarts caused by problems with the switch.
`Suspension Threshold`	The threshold for suspending Cleared Alarm Notification. Some problems may cause alarms to be generated and then resolved repeatedly. To detect these problems (by not sending additional Cleared Alarm notifications to indicate a problem- free system), the switch suspends Cleared Alarm Notification when it has reported this administrable number of Cleared Alarm notifications in a 24 hour period. A suspended Cleared Alarm Notification is only enabled again with a successfully completed "logoff" command, a system reset, or when the threshold is changed. This field is irrelevant if Cleared Alarm Notification or Alarm Origination is disabled. The possible range of threshold values is between 1 and 15.
`Test Remote Access Port`	Specifies whether testing of the remote access port on the SYSAM circuit pack is enabled. This field should be set to "yes" whenever there is an INADS line connected to the switch and there is a maintenance contract in effect so that alarm origination capability is maintained.

`CPE Alarm Activation Level`	Indicates the minimum level (Major, Minor or Warning) at which the Customer-Provided Equipment (CPE) alarm is activated. If the level is “none,” the CPE does is not activated for any alarm. (none)

NOTE:
The CPE alarm is always activated when the switch goes into Emergency Transfer, regardless of the CPE Alarm Activation Level setting.

Scheduled Maintenance

A series of maintenance tests and operations runs automatically every day according to the schedule and settings specified in the following fields.

`Start Time`	The hour and minute in 24-hour notation at which daily scheduled maintenance will begin running. (22:00)
`Stop Time`	The hour and minute when scheduled daily maintenance will stop running. If any daily maintenance operations are not completed by this time, the system will note where in the sequence it stopped and perform those operations during the next scheduled daily maintenance.
`Daily Maintenance`	This display-only field simply represents the series of tests that are always run by maintenance software as part of daily maintenance.
`Save Translation`	This field indicates on which days translation data in memory will automatically be saved to the Mass Storage System disk and/or removable media devices during scheduled maintenance. The save operation is first made to disk, followed by a disk backup to removable media. On systems with duplicated SPEs, translation data is saved on both SPEs. Valid entries are **daily**, days of the week, or **no**. “No” specifies that no automatic saves are to be executed. (daily)
`Control Channel Interchange`	Each port network has a pair of TDM busses called A and B, each of which has a set of time slots dedicated to use by the control channel. At any one time, the control channel in each PN is carried on only one of the two busses. This field indicates on which days the control channel in each port network will be switched from one of the paired TDM busses to the other. Valid entries are **daily**, days of the week, or **no**. “No” specifies that no interchange be executed. (no)

`System Clocks Interchange`	On High and Critical Reliability systems, this option causes a Tone-Clock interchange in each port network with duplicated Tone-Clock circuit packs. Each port network interchanges into the standby Tone-Clock for 20 seconds and then back to the Tone-Clock that was originally active. This field indicates on which days the interchanges are to take place. Valid entries are **daily**, days of the week, or **no**.”No” specifies that interchanges be executed. (no)
`SPE Interchange`	On systems with duplicated SPEs, this field indicates on which days an SPE interchange will be executed during scheduled maintenance. Valid entries are **daily**, days of the week, or **no**.”No” specifies no scheduled interchanges. (no)
`Minimum Threshold for TTRs`	When the number of touch tone receivers (TTRs) in service falls below this number (4 to 200), a WARNING alarm is raised against TTR-LEV. These are also known as dual-tone multifrequency receivers (DTMRs). There are 4 TTRs on each TN748, TN718, TN420, or TN756; TN2182 and TN744 (suffix C or later) each have 8 TTRs. To alarm the first occurrence of a TTR being taken out of service, set this field to the total number of TTRs in the switch.
`Minimum Threshold for CPTRs`	When the number of call progress tone receivers in service falls below this number (2 to 100), a WARNING alarm is raised against TTR-LEV. These are also known as general purpose tone detectors (GPTDs). There are 2 CPTRs on each TN748, TN718, TN420, or TN756; TN2182 and TN744 (suffix C or later) each have 8 CPTRs. To alarm the first occurrence of a CPTR being taken out of service, set this field to the total number of CPTRs in the switch.
`Minimum Threshold for Call Classifier Ports`	When the number of call classifier ports (CLSFY-PTs) in service falls below this number, a WARNING alarm is raised against TTR-LEV. Valid entries are 1 to 200. There are 8 ports on each TN744 or TN2182 circuit pack. To alarm the first occurrence of a CLSFY-PT being taken out of service, set this field to the total number of CLSFY-PTs. If there are no TN744 or TN2182 circuit packs in the system, leave this field blank.
`Test Type 100, Test Type 102, Test Type 105`	An extension assigned to receive tie-trunk calls from other switches with test line origination capability. The system responds by sending a sequence of test tones. Test Type 100 tests far-end to near-end loss and C-message by sending: ■ 5.5 seconds of 1004 Hz tone at 0dB ■ Quiet until disconnect; disconnect is forced after 1 minute
`ISDN-PRI Test Call Extension`	The extension used by a far-end ISDN node to place a call to the system to test the ISDN-PRI trunks between the far-end and the system.

`ISDN-BRI Service SPID`	This field shows whether or not the link is associated with the Service SPID. If the link is associated with the Service SPID, this field contains a “yes” and the extension field is blank; otherwise, this field is blank. Service SPID is a feature used by the system technician to check building wiring between the switch and the BRI endpoint.
`DSO Loop-Around Test Call Extension`	This field contains the extension number for the test call extension number. This test extension number will be used to establish a loop-around connection on the selected trunk. The DSO Loop-Around Test Call feature is used primarily for testing DSO channels associated with non-ISDN-PRI trunks. The loop-around is activated by dialing the test extension number. Multiple DSO Loop-Around connections can be set up by placing multiple calls to the loop-around extension.
`DSO Loop-Around Test Call Extension`	The DS0 Loop Around feature provides a loop around connection for incoming non-ISDN DS1 trunk data calls. This feature is similar to the far-end loop around connection provided for the ISDN Test Call feature. This DS0 loop around is provided primarily to allow a network service provider to perform facility testing at the DS0 level before video teleconferencing terminals are installed at the PBX. The feature is activated on a call-by-call basis by dialing a test call extension specified on the second page of the System Parameters Maintenance form. No special hardware is required. When the test call extension is received by the PBX, a non-inverting, 64 kbps connection is set up on the PBX's Time Division Multiplexed bus. More than one loop around call can be active at the same time. *More information follows.*
`DSO Loop-Around Test Call Extension` *(cont’d.)*	For calls routed over the public network using the ACCUNET Switched Digital Service (SDS) or Software Defined Data Network (SDDN), the data transmission rate is 56 kbps, since robbed bit signaling is used. For calls established over a private network using common channel signaling, the full 64 kbps data rate is available. When the incoming trunk group is used only for data calls (SDS), the Communications Type on the associated Trunk Group form should be set to “data.” When the incoming trunk group is used for robbed bit alternate voice and/or data (SDN/SDDN), the Communications Type on the Trunk Group form should be set to “rbavd” (robbed bit alternate voice data). For private network trunks using common channel signaling, the Communications Type on the associated Trunk Group form can be set to “avd.”

`Loss Plan` Use only when extra loss is required to maintain quality of transmission on conference calls. Leave this field blank if no extra loss is required. If extra loss is required, enter digits as shown below.

No. Of Parties To Be Conferenced	Enter Digit
3	2
4	3
5	4
6	5
7	6

`SPE Optional Boards:` These fields indicate whether a Disk circuit pack is present in the system, and which Packet Interface slots are administered. If a Packet Interface circuit pack is physically present, the corresponding Packet Interface field is set to y when the system boots, and no change to that field is allowed. If the system is equipped with duplicated SPEs, a Packet Interface field is set to y when either SPE carrier contains a Packet Interface circuit pack in the corresponding position. If a Packet Interface circuit pack is not present, then the value for the Packet Interface field is read from translation data stored on disk or removable media. If the field is set to n, a Packet Interface circuit pack may be administered by changing the corresponding Packet Interface field to y.

Modem Connection

On page 3 of the example forms shown below, there are 11 fields that are hidden when the `Modem Connection?` field is set to **internal**. In this example the `Modem Connection` field is set to **external**, and these additional 11 fields are visible.

The first 2 fields on page 3 help setup the data format for the serial data from the switch to the modem.There are only two valid combinations for these 2 fields:

- Data Bits = 8, Parity = None
- Data Bits = 7, Parity = (odd, even, mark, or space)

The remaining fields are listed below:

`Modem Connection` Internal or external (internal)

`Modem Name` This field is 20 characters long and will permit alpha-numeric characters to provide a unique qualifier for a given modem. ( )

`RTS/CTS Enabled`	This field will inform the modem that communication with the data source UART will be driven with RTS/CTS flow control. This field is 6 characters long and is case in-sensitive. (&H1)
`Asynchronous Data Mode`	This field will configure the modem as an asynchronous communications device. This field is 8 characters long and is case in-sensitive. ( )
`DTE Auto-Data Speed`	This option will adjust the speed of the data source (DTE) UART to the outgoing (modem-to-modem) data rate. So, at maximum this speed would be 9600 baud. This field is 6 characters long and is case in-sensitive. Note that this field sets the link speed between the switch and the modem. It does not set the speed of the modem. It is not desirable to have the serial data fill the modem buffer faster than the outgoing data rate especially because data compression is disabled. ( )
`Disable Data Compression`	This field will turn off the default data compression algorithms that are in use by most consumer modems. This field is 6 characters long and is case in-sensitive. (&K0)
`Enable Error Control`	This field will turn on the V.42 LAPM and MNP error control protocols, if available on the modem. This field is 6 characters long and is case in-sensitive. This V.42/MNP/Buffer mode first attempts to negotiate V.42 error control with the remote modem. If this fails, then the modem transitions to MNP, and if this fails then no error control is used. ( )
`Misc. Init. Param`	This field supports any initialization parameters that are not already specified. The AT commands specified in this free-form field will be always the last initialization parameters to be sent to the external modem. This field is 20 characters long and is case in-sensitive. ( )
`Auto-Answer Ring Count`	This field controls the number of rings required before the modem automatically answers an incoming call, if and only if the switch doesn’t answer first. (If the switch is healthy, it answers an incoming within the first few rings.) This field is 6 characters long and is case insensitive. Typically, the maximum permissible value for this register is 255. The values 1-255 denote the number of incoming ring cycles. (S0=10) **NOTE:** The number of rings is optimally set above 5, and if at all possible, keep the default of S0=10.
`Dial Type`	This field controls the type of inter-register signaling to be used between the modem and the Central Office. Use “T” for tone dialing and “P” for pulse dialing. The field length is be 3 characters long and is case in-sensitive. This field will be concatenated with the dial string. (T)

`Adjustable Make/Break Ratio`	This field can be of particular importance when using a modem that may be transferable from country to country. The intent of this field is to control the make/break ratios of pulses and DTMF dialing. The Intel product information has support for the different make/break options for pulse dialing only. Intel uses the option “&P0” to select a ratio of 39% make and 61% break for communication within the U.S. and Canada. The option “&P1” sets a ration of 33% make and 67% break for the U.K. and Hong Kong. This field is 5 characters long and is case in-sensitive. ( )
`Dial Command`	This field simply denotes the dialing command of the modem. This is a fairly standard command. (D)
`No Answer Time-Out`	Most off-the-shelf external modems provide a timer that abandons any outbound data call after a predetermined interval. Some modems provide for this timer to be disabled, thus allowing an outbound call to ring indefinitely. AT&T Paradyne does not provide this capability with their modem line, because it is generally undesirable to have an outbound call attempt ring indefinitely. The internal modem must have this parameter disabled or set to at least 255 seconds. This is a non-administrable parameter. For the external modem connection, this parameter will be the first initialization string to be transmitted to the external modem. This field will be visible on the administration form in display mode only. This hardcoded constant can be overriden for type approval applications, specifically in the U.K and other Western European nations, by the use of the “Misc. Init. Param:” field. (S7=255)

display test-schedule

Automatic Transmission Measurement System (ATMS) provides advanced maintenance procedures for monitoring system trunk facilities. This system performs transmission tests on system trunks to determine if trunks are performing satisfactorily. These tests can be initiated in two ways:

demand	user enters command at the System Administration Terminal (SAT) to initiate a test immediately
scheduled	schedules tests through a schedule form to automatically initiate tests at a predetermined time

Output

The following is the output from the **display test-schedule *n*** command.

```
                                                                  Page 1 of 1

Field descriptions

`Schedule`	The current schedule number.
`Schedule Time`	The hour and minute that the test begins (24-hour time, with "00:00" being midnight). This time must be greater than the current time.
`Schedule Date`	Month (**1** to **12**), day (**1** to **31**), and year on which testing begins (default is the system date). This date must be equal to or greater than the current date.

`Schedule Test Days`	A **y** next to the days of the week indicates which days of the week this test runs.
`Interval`	The length of this schedule in weeks. If this field is **0** (default), the schedule runs on the specified days only once.
`OTL Throttle`	The number of concurrent tests run within a schedule. This guarantees that all trunk members within a schedule are tested serially or if multiple trunk members are tested from the same schedule.
`Test Type`	One of the following types of test to be performed on the trunk group/members in this schedule: ■ **full** (default) runs the most comprehensive test and collects all associated measurements for each TTL type. ■ **supv** performs a supervision test and only confirms the presence of the test set at the far end. No measurements are taken for this test. ■ **no-st** runs the "full" test, but skips any self-test sequences. This saves about 20 seconds on the type 105 test and does not have any effect on type 100 or 102 tests. ■ **no-rl** runs the "full" test, but skips any return loss sequences. This saves about 20 seconds on the type 105 test and does not have any effect on type 100 or 102 tests. ■ **no-st/rl** runs the "full" test, but skips all self-test and return loss sequences. This saves about 40 seconds on the type 105 test and does not have any effect on type 100 or 102 tests.
`Duration`	The maximum number of hours (**1** to **24**) a schedule can remain active. Schedules continue to run until all trunk group/members for that particular schedule are tested or until the schedule duration is reached. If the duration is reached before all trunk groups/members can be tested, the schedule stops.
`Trk Trp`	The trunk group numbers to be tested when this schedule runs. There is no limit to the number of times that a trunk group can appear on any particular schedule, or to the number of different schedules in which a trunk group can appear. Default is blank.
`Bgn Mbr`	The beginning member number of the trunk group to be tested; default is **1**.
`End Mbr`	The ending member number of the trunk group to be tested. This value must be greater than or equal to the value of the beginning member field.

display time

display time [print | schedule]

This command displays the system date and time that is used by software processes for scheduling and so on.

Output

```
display time
                                 DATE AND TIME

       DATE

           Day of the Week: Sunday                 Month: January
          Day of the Month: 1                       Year: 1992

       TIME
                      Hour: 6                     Second: 20
                    Minute: 8
```

enable administered-connection

enable administered-connection [adm-conn# | all

This command re-enables scheduled and periodic testing and in-line error processing on a specified administered connection (AC) or all ACs. It is used after previously disabling maintenance via the **disable administered-connection** command. These commands can be useful in isolating results of certain maintenance processes by preventing interference from others.

Parameters

`adm-conn#`	The number (1-128) of the administered connection as assigned during administration.
`all`	This qualifier causes all ACs in the system to be enabled.

enable suspend-alm-orig

This command suspends Alarm Origination for alarms generated from a specified hardware component over a time-out duration.

Synopsis

enable suspend-alm-orig (board or port location) [off-board-only] expires-in-hrs(1-72).

Examples

enable suspend-alm-orig 1C03 expires-in-hrs 3
enable suspend-alm-orig 1E0701 expires-in-hrs 72
enable suspend-alm-orig 1E07 off-board-only expires-in-hrs 24

Description

This command enables Suspend Alarm Origination for a board (which also includes all ports and endpoints on the board) or for a port (which includes all endpoints on the port), and either for both on- and off-board alarms or for off-board alarms only. Many control circuit packs do not have a board location, so this command cannot support all circuit packs.

On the command line, specify a time-out duration between one and 72 hours. The “off-board-only” keyword is optional; if the keyword is not specified, the entry suspends Alarm Origination for both on-and off-board alarms. Each enable command becomes a new entry or replaces an existing entry in the Suspend Alarm Origination table. A new entry that matches both the physical location and off-only/on- and off-board specifications of an active entry replaces the active entry in the Suspend Alarm Origination table.

This command may be useful for improving control over situations such as the following:

- Improved control over customer requests. For example, to suspend off-board DS1 alarms temporarily for customers that periodically disconnect DS1 trunks for testing or other business related purposes.
- Improved control over external (non-Lucent) problems. For example, to suspend off-board DS1 alarms before a customer resolves facility problems (such as working with the vendor of a T1 trunk that has developed an off-board condition).
- Improved control over internal (Lucent) problems that cannot be resolved right away. For example, to suspend Alarm Origination for a bad circuit pack detected late Friday night and personnel cannot be dispatched until Monday.

NOTE:
Also see other Suspend Alarm Origination related commands, including “disable suspend-alm-orig” and “list suspend-alm-orig”.

Defaults

This command enables Suspend Alarm Origination for both on- and off-board alarms if the “off-board-only” keyword is not specified.

Parameter

`board or port location`	This parameter specifies the physical location of the hardware component for suspending Alarm Origination.
`off-board-only`	This option enables Suspend Alarm Origination for off-board alarms only.
`expires-in-hrs`	This parameter specifies the time-out duration for a Suspend Alarm Origination entry. Expired entries are removed automatically.

Help Messages

```
Enter board or port location,
[‘off-board-only’], expires-in-hrs(1-72)
```

Output

The command returns one of the following messages:

1. If the time-out duration is not between one and 72:

   `XX is an invalid identifier; please press HELP`

2. If the port or board specifier is not valid:

   `Port/Board invalid`

3. If the Suspend Alarm Origination table is full:

   `Table full; cannot enable a new entry`

Feature Interactions

None.

enable synchronization-switch

enable synchronization-switch

This command returns control of the selection of synchronization source to the maintenance subsystem and tone-clock after being previously turned off by the **disable synch** command. See "SYNCH" in Chapter 9 for details.

enable test-number

enable test-number test#

Examples

enable test-number 102

This command will re-enable a specified test that was previously turned off with the **disable test** command. (The **disable test** command is not available to the craft login.) While disabled a test cannot be run by background or demand maintenance. Before enabling a test, ascertain why it was disabled, and inform INADS that it has been turned back on.

Parameters

`test#` The number of the test to be re-enabled

Descriptions of each test appear under the relevant MO in Chapter 9. See the Index for a numerical list of all demand maintenance tests.

format card-mem

This command formats the active and standby processor Flash Read-Only Memory.

Synopsis

format card-mem [translation] [announcements] [coredump]

Permissions

The following default logins may execute this command: browse, system technician, cust, inads, init.

Examples

format card-mem translation
format card-mem announcements
format card-mem coredump

Description

The maintenance command, "format card-mem translation" will erase and format the memory card for translations only. The maintenance command **format card-mem announcement** will erase and format the memory card for translations and announcements. The maintenance command **format card-mem coredump** will erase and format the memory card for translations, announcements and coredump.

Defaults

No defaults.

Parameters

print	This parameter causes the information displayed by this command to be sent to the printer attached to the terminal as well as to the screen.
schedule	When the "schedule" option is specified, the command is validated and then a scheduling form is displayed to allow the technician to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. Refer to the Report Scheduler and System Printer feature specification [1] for more details.

Help Messages

If the system technician presses help after entering **displaymemory-configuration** the following message will be displayed:

Error Messages

If the format memory [translation] [announcements] [coredump] maintenance command is executed and errors occur, one of the following error messages will be displayed:

- `flash card to small for operation requested`
- `card is bad (reformat failed)`
- `card is write protected`
- `command cannot be executed due to command contention`
- `NETCON 12V programming power failure`

Output

For the following output example the command **format card-mem** was entered.

```
Enter 'translation' or 'announcements' or 'coredump' or 'firmware'
  'translation' option includes translation only
'announcements' option includes translation and announcments
       'core-dump' option includes translation, announcments, and code-dump
        'firmware' option includes translation, announcements, and firmware
Or press CANCEL to cancel the command

-------------------------------------------------------------------------------
Identifier command word(s) omitted; please press HELP PREV-FIELD to edit

Feature Interactions

None

get vector

get vector [long] [print]

This command displays the triggering conditions and the SPE associated with a core dump of memory to the removable media or disk device. The vector is a set of system reset levels which will cause the contents of memory to be saved on removable media. When the core dump occurs, the vector settings are cleared. The vector is set with the **set vector** command (not available to craft logins). If no core dump has taken place since the vector was set, the settings are displayed. If a core dump has taken place, the time and location of the core dump files is displayed.

NOTE:
When a system reset of a level that is set to trigger a core dump takes place, the vector is cleared regardless of whether the core dump is successful.

Parameters

`long` Specifies display of the timestamps for the core dump. If SPEs are duplicated, timestamps are printed for both SPEs (or a message stating why the timestamp cannot be printed is displayed).

`Core Dump Vector` The conditions which are enabled to initiate a core dump to removable media or disk, as represented by a hexadecimal value. The hexadecimal value represents a combination of four system reset levels: warm restart (reset level 1), cold 2 restart (2), cold 1 restart (3), and reboot (4). The table below shows which reset levels will initiate a core dump for each value of the vector.

Vector Value	Reset Levels	Vector Value	Reset Levels
0	none	8	4
1	1	9	1, 4
2	2	a	2, 4
3	1, 2	b	1, 2, 4
4	3	c	3, 4
5	1, 3	d	1, 3, 4
6	2, 3	e	2, 3, 4
7	1, 2, 3	f	1, 2, 3, 4

`Set Vector Command Option`	This indicates from which SPE the core dump is to be taken as specified with the **set vector command**. This is always spe-active for simplex systems. Additional options for systems with duplicated SPEs are spe-standby and spe-smm. If the vector has been cleared or not set, blanks are displayed.
`Core Dump Time`	For each SPE, the date and time at which the core dump took place, or on of the following: Blank: No core dump has been stored. Cannot access: The system cannot currently access the core dump file. (For example, a standby SPE may not be refreshed). Non-duplicated SPE: This SPE does not exist (as in a simplex system). Device busy: the MSS device on which the core dump is stored is busy with another operation.

The following display shows a typical result when **get vic is** entered and no core dump has taken place.

```
get vector

                      GET RESULTS

  Core Dump Vector           Set Vector Command Option

list cabinet

list cabinet [print | schedule]

The list cabinet command displays the type, layout, room, floor, building, operational carriers and port network number for each cabinet in the system. This command is useful when the port network number is needed for another command entry and only the cabinet number is known.

Output

`Number`	The administered number of the cabinet.
`Type`	The type of cabinet (`PPN` or `EPN`).
`Layout`	The layout of the cabinet .
`Room`	Room where cabinet is located, if administered on the cabinet form.
`Floor`	Floor where cabinet is located, if administered on the cabinet form.
`Building`	Building where cabinet is located, if administered on the cabinet form.
`A B C D E`	The letter designation of each carrier. For each carrier the port network number is given (`PN #`). If the carrier is a switch node this number is preceded by `SN`.

The following display shows a typical result when **list cabinet** is entered on a system with four port networks. In this example there are two port networks in cabinet 2.

```
list cabinet                                          Page   1   SPE A

Screen 8-4. Processor Channel Assignment

Field descriptions

`Proc Chan`	Displays the BX.25 virtual channed number or the TCP/IP listen port channel to carry this processor (virtual) channel.
`Enable`	Type **y** to enable a processor channel. Type **n** (default) to disable a processor channel.

`Appl.`	Identifies the switch application used over this link. The application gateway is used for conversion between ISDN and either TCP/IP or BX.25. Use the **gtwy-tcp** entry for conversion between BX.25 and TCP/IP. Valid entries are: audix, dcs, fp-mwi, gateway, gtwy-tcp, mis, msaamwl, msaclk, msahlwc, msallwc, msamcs, qs-mwi, blank (default)
`Gtwy To`	Identifies which processor channel the given processor channel is serving as a gateway to. Valid entries are a number between 1-(maximum number of processor channels), or blank (default).
`Mode`	Identifies whether the IP session is passive (client) or active (server). This field must be blank if the type of interface link is **x.25** (r model) or **procr-intf** (si model). This field cannot be blank if the type of interface link is **ehternet** or **ppp**. Valid entries are **client**, **server**, or blank (default).
`Interface Link`	Identifies the physical link carrying this processor (virtual) channel. Links numbered 1 through (4 times the number of PI circuit packs) for the si model can be either **x.25** or **tcp/ip**. The rest of the links (up to 25) must be **tcp/ip**.
`Interface Chan`	Identifies the BX.25 virtual channel number or the TCP/IP listen port channel to carry this processor (virtual) channel. The channel number 0 means any port can be used. Valid entries for link type x.25 are **1-64**; for Ethernet or ppp, **0**, **5000-64500**.
`Destination Node`	Identifies the switch or adjunct at the far end of this link. Enter an adjunct name, switch name, far end IP address, node ID, or leave blank (default) for services local to this switch.
`Destination Port`	Identifies the port number of the destination. The number 0 means any port can be used. Valid entries are **0** (default), **5000-64500**.
`Session Local`	Field ported forward from R6.
`Session Remote`	Field ported forward from R6.
`Mach ID`	Field ported forward from R6.

list configuration

list configuration hardware-group [print | schedule]

NOTE:
The **list configuration software-version** command is discussed separately under its own heading.

Hardware configuration reports list, for each circuit pack in the group specified, the type, code, suffix, and vintage of the requested circuit packs as installed in the switch, and all ports assigned to the circuit pack.

Parameters

Enter one of the following hardware groups.

- **all—**Specifies the display of all circuit packs administered and/or physically inserted in port, switch node and control carriers on the entire system.
- **board *UUCSS***—Specifies the display of all assigned ports on the circuit pack specified by cabinet, carrier and slot.
- **carrier *c***—Specifies the display of all circuit packs and assigned ports on a specified carrier.
- **control—**Specifies the display of all circuit packs located in the control complex.
- **ds1**—Specifies the display of all the DS1 (TN722, TN767 and TN464) circuit packs administered and/or physically inserted in port carriers on the entire system.
- **port-network pn#**—Specifies the display of all circuit packs located in a specified port network. **List cabinet** gives the port network number(s) associated with a particular cabinet. Circuit packs on switch node carriers are not displayed when the port-network qualifier is entered. To display SN circuit packs, use the **all**, **carrier** or **board** qualifiers.
- **stations**—Specifies the display of all circuit packs that can be assigned stations (including DS1 circuit packs for remote stations). All assigned ports are displayed.
- **trunks**—Specifies the display of all circuit packs that can be used for administering trunks. All assigned ports are displayed.

Examples

list configuration carrier 2c schedule
list configuration port-network 5
list configuration stations print

Output

Assigned Ports:

- **Board Number**—The functional name of the circuit pack
- **Code**—The TN or UN code and suffix of the circuit packs are displayed.
- **Vintage 00000000-065535 KKKKKK**—The vintage number of the circuit pack.
- **no board**—The circuit pack is administered but not physically installed.
- **conflict**—The circuit pack administered to the slot differs from the circuit pack that is physically installed.

- **no link**—The T1 link is down to a DS1 circuit pack.

Field definitions:

- **Signaling**—This field is displayed only when ”list configuration ds1” option is selected. The contents of the field are the same as the signaling mode administered for the ds1 circuit pack (via add/change ds1 command) or ”none” if the circuit pack is not administered.
- **Name**—This field is displayed only when “list configuration ds1” option is selected. The contents of the field are the same as the name administered for the ds1 circuit pack (by the **add/change ds1 command**) or “blank” if the circuit pack is not administered.
- **CSU MOD**—This field is displayed only when “list configuration ds1” option is selected. The field contains the identification number of the Integrated CSU module present on the ds1 circuit pack (TN767E or later / TN464F or later) or “none”. If the circuit pack is a TN464E or TN767D, “unknown” will be displayed. If the circuit pack is a TN464D or TN767C or earlier suffix DS1 board, then “n/a” will be displayed.

Assigned Ports

Each port on the circuit pack is represented by a position corresponding to its circuit number in ascending order from left to right. The assigned ports are not displayed for **list configuration ds1**. Two rows are required for circuit packs with more then 8 ports. The position displays one of the following values depending on its administered status:

- **01-16**—The circuit number of an assigned port.
- **u**—The port corresponding to this position exists but is unassigned.
- **t**—The port is not currently assigned and is supported by the Terminal Translation Initialization feature. Ports in this state can be activated by the TTI association sequence.
- **mj**—The port corresponding to this position is currently assigned as an external device (mj) alarm port.
- **mn**—The port corresponding to this position is currently assigned as an external device (mn) alarm port.

Each port on a TN556 ISDN-BRI circuit pack can have two BRI endpoints. BRI ports are displayed once when assigned only one endpoint and twice when fully configured with two endpoints.

The following display shows a typical result when **list configuration all** is entered.

```
   list configuration all                                          Page   1

Field descriptions

`Signaling` This field is displayed only when **list configuration ds1** is entered. The contents of the field are the same as the signaling mode administered for the ds1 circuit pack or none if the circuit pack is not administered.

`Name` This field is displayed only when **list configuration ds1** is entered. The contents of the field are the same as the signaling mode administered for the ds1 circuit pack or none if the circuit pack is not administered.

`CSU MOD` This field is displayed only when **list configuration ds1** option is selected. The field contains the identification number of the Integrated CSU module present on the DS1 circuit pack (TN767E or later / TN464F or later) or none. If the circuit pack is a TN464E or TN767D, `unknown` displays. If the circuit pack is a TN464D or TN767C or earlier suffix DS1 board, then `n/a` displays.

list configuration software-version

list configuration software-version [memory-resident | long] [print | schedule]

This command displays

- Software version numbers and compatibility indexes of the software load modules stored in system memory (RAM) and on the Mass Storage System devices (removable media and disk).
- The dates and times when translation and announcement data were last saved to the MSS.
- Information about any software update files that have been applied to the system. See "Software updates" in Chapter 6, "Additional Maintenance Procedures" for an explanation of software versions and compatibility indexes.

Parameters

`long`	Specifies display of data for both SPEs in a high or critical reliability If not used, only data for the active SPE is shown.
`memory-resident`	Specifies display of RAM-resident files only. Fields for removable media and disk data will contain `n/a`

Output

If the removable media contains a core dump file, fields for removable media data display `coredump`. When a core dump is present, all other files on the device are marked invalid. If the removable media or disk files cannot be read at the time the command is entered, the relevant fields display `no r-media` or `no disk`. (This does not indicate that the system does not recognize the presence of the device.)

Fields in the SPE-B column are blank for standard reliability systems. On high and critical reliability systems, only fields for the active SPE are displayed unless the **long** option is specified.

Removable Media and Disk Second Copy Fields

Many of the files on disk and removable media are duplicated: a second copy of the file is stored on the same device. The Second Copy fields indicate whether the two copies are consistent using the following entries:

`Good`	The second copy is considered usable. The time stamp and/or vintage of the second copy matches the first, and its status bits mark it as a good file.

`Inconsistent`	The time stamp or vintage of the file is inconsistent with the first copy, or the status bits mark it as a bad file. Follow normal escalation procedures.
`Inaccessible`	The second copy of the file could not be accessed. Media failure is the most probable cause.

Update File Section

The top half of page 1 of the form displays information pertaining to software field-update files (“patches”).

`Creation (GMT) R-Media and (GMT) Disk`	When the update file was originally created, in Greenwich Mean Time (GMT). Note that this is *not* the time at which the update file was written to the MSS device.
`Old-Version R-Media and Disk`	The software version for which the update was created.
`Old-Identifier R-Media and Disk`	Which previous update file this update file expected to find stored in the MSS when it was applied.
`New-Identifier R-Media and Disk`	Uniquely identifies the current update file.

Software Verson Section

This section at the bottom of page 1 of the output form displays information related to the current software-load module stored in memory and in the MSS.

`Memory Resident`	Version number of the RAM-resident load module.
`R-Media Resident`	Version number of the removable media-resident load module.
`R-Media Second Copy`	See Second Copy remarks above.
`Disk Resident`	Version number of the disk-resident load module.
`Disk Second Copy`	See Second Copy remarks above.
`Update-identifier`	This uniquely identifies the update file, if any, that has been applied to memory.

`Update-state`	The status of the software field-update (“patch”) file: none in memory No software update has been applied to memory. immediate partially applied A software update failed in the process of being applied. Check the validity of the update file that was sent. Check also the hardware error log for removable media errors, and follow standard maintenance procedures. all immediate applied deferred pending A valid update file was received by the switch, and all update files marked for immediate application were applied. This message indicates that there are additional files in the update file whose application has been deferred until a system reset of a required level takes place. deferred partially applied Application of the deferred files of a software update was attempted and failed. Check the validity of the update file that was sent. Check also the hardware error log for removable media errors, and follow standard maintenance procedures. entirely applied to memory All files in a software update have been successfully applied.

Translation Date Section

This section at the top of page 2 displays information related to the translation files as stored in memory and the MSS.

`Memory Resident`	Date and time marked on the removable media or disk when translation data was last read from the MSS into memory. This is stored in SPE memory and is not modified by changes to translation data. A save translation will update this date. If “Date invalid” is displayed, the timestamp does not contain the expected information.
`R-Media Resident`	The last date and time that translation data was saved to removable media. This date is read from removable media and appears blank if the removable media is not installed.
`R-Media Second Copy`	See Second Copy remarks above.

`Disk Resident`	The last date and time that translation data was saved to disk. This date is read from disk and appears blank if the disk is not installed.
`Disk Second Copy`	See Second Copy remarks above.

System Configuration Section

This section of page 2 pertains to size of the memory configuration. All fields should display large except when the removable media indicates the presence of a `coredump`.

Announcement Date Section

This section at the bottom of page 2 displays data pertaining to the recorded announcement files.

`R-Media Resident`	The last date and time that announcement data was saved to removable media. This date is read from the removable media.
`R-Media Second Copy`	The last date and time that announcement data was saved to removable media. This date is read from the second copy of the file on the removable media.
`Disk Resident`	The last date and time that announcement data was saved to disk. This date is read from disk and appears blank if the disk is not installed.
`Disk Second Copy`	The last date and time that announcement data was saved to disk. This date is read from the second copy of the file on the disk.

Compatibility Index Section

This section on page 3 displays data pertaining to the compatibility index, which is used to determine what types of software updates can be applied to a system running this software load.

`Memory Resident`	The compatibility index of the software version in memory.
`R-Media Resident`	The compatibility index of the software version on removable media.
`Disk Resident`	The compatibility index of the software version on disk.

The following display shows a typical result when **list configuration software-version** is entered on a simplex system. On a duplicated system the fields under SPE-B should display the same entries as the SPE-A fields if all files are consistent.

list disabled-MOs

list disabled-MOs [print | schedule]

This command displays a list of the maintenance objects that have been disabled with the **disable MO**, **disable all**, or **disable MO-all** command (not available to craft logins). as well as whether or not the command has been run. Use **display disabled-tests** for numbers of tests that have been disabled.

Output

`Maintenance Name`	Type of maintenance object(s) disabled. “ALL” is displayed if all MOs are either enabled or disabled.
`Location`	The physical location (cabinet-carrier-[slot-circuit]) of the maintenance objects. Blank when “ALL” is displayed under Maintenance Name.
`Status`	Whether the MOs displayed are enabled or disabled.

The following display shows a typical result when **list disabled-MOs** is entered and no MOs are currently disabled.

```
list disabled-MOs

                    DISABLED MAINTENANCE OBJECT INFORMATION

               Maintenance Name     Location      Status

```

list fiber-link

list fiber-link [print | schedule]

This command displays a list of all fiber links in the system. The list is a summary of data entered on the fiber link form (**add, display, change**, or **remove fiber-link**).

Output

`FIBER LINK #`	The administered number used to identify the fiber link (1 to 27).
`TYPE`	The types of circuit packs that constitute endpoint 1 and endpoint 2 of the fiber link. (ei or sni).
`A-PNC LOC`	The physical locations (cabinet-carrier-slot number) of the circuit packs that constitute the endpoints.
`B-PNC LOC`	In a system with duplicated PNC, the physical location (cabinet-carrier-slot number) of the circuit packs that constitute the endpoints of the link in the B-PNC.
`DS1 CONV`	Whether or not an endpoint of the link is remotely located by means of a DS1C Converter Complex.

The following display shows a typical result when **list fiber** is entered on a system with duplicated PNC and 5 EPNs, one of which is DS1C remoted.

```

Command Successfully Completed
```

list history

list history [print | schedule]

The **list history** command generates a log listing of the most recent data-affecting administration and maintenance commands successfully completed.

Administration data commands change translation data. Maintenance data commands change state information. For example, **change station** would be classed as a data command, whereas **display station** would not.

All information in the transaction log is saved on removable media as translation data when the **save translation** command is performed (LIFO order). A system reset of level 3 or higher (COLD 1 and reboots) saved translations and the transaction log are read from removable media. In this way, the translation data and the data in the transaction log will remain compatible.

The translation log is written to removable media as translation data when the save translation command is executed.

Translation data is time stamped when saved on removable media. This time stamp is noted when translation is loaded from removable media and included in all recent change history reports.

When a user requests a recent change history report, there could be other users concurrently issuing data commands and altering the contents of the transaction log. Therefore, if the user pages the entire way through the report, the oldest entries in the transaction log may have been overwritten by data commands issued by these other users. Should this occur, the final entries of the report will show the data commands which have been issued by these other users since the recent change history report was originally requested.

Use of the maintenance command “set time” to alter the system clock could make it look as if the recent change history report is not in true LIFO order.

A maximum of 250 commands are stored in the transaction log.

Output

NOTE:
The date listed in the header, refers to the last date on which a reset level 3 (COLD-1 restart) or greater took place. *This date is not updated* when translation is saved manually by command, or automatically by scheduled daily maintenance. Thus, it is usually *not* the date of the current translations.

```
Date of Loaded Translation:
```

`Date` The date the command was issued. Format “mm/dd” where “mm” is the month and “dd” is the day.

`Time` The time the command was issued. Format “hh:mm” where “hh” is the hour and “mm” is the minute.

`Port` The port field indicates the port type to which the user was connected when the command was issued.

Port Type	List History Display
EPN Maintenance Board Port	MAINT
System Access Port	SYS-PORT
Maintenance Board Port	SYSAM-LCL
Remote Maintenance Board Port	SYSAM-RMT

`Login` The login of the user performing the data command; for example “craft.”

`Actn` The first word (verb) of the command, specifying the operation to be performed. This field is truncated after four characters to allow enough space for objects and qualifiers. Four characters is enough to uniquely identify each action.

`Object` The second phrase of the command specifying the particular thing being acted upon by the command.

NOTE:
Where the object is multiple words in length, only the first word will be displayed in the object field. All succeeding words will be treated as qualifiers. This field is truncated after twelve characters to allow enough space for qualifiers. 12 characters is enough to uniquely identify each object.

`Qualifier` One or more qualifiers which specify the characteristics of the action/object pair. This field is truncated after 31 characters to keep information for a command on a single line.

The following display shows a typical result when **list history** is entered.

```
 list history                                      Page 1      SPE A

list ip-route

This command displays a list of the IP routes from DEFINITY ECS out to the LAN. You may enter the “board” parameter and specify which C-LAN circuit pack for which to show the IP routes (for example, **list ip-route board UUCss**).

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list ip-route	***board UUCss***	Board Location Example: **list ip-route board 01A03**	init inads craft	none	none

Output

The following example shows the output from the **list ip-route** command.

```
list ip-route
IP ROUTING

 Route    Destination                        C-LAN           Route   Accepted
 Number      Node            Gateway         Port    Metric  Type    by C-LAN

 xxx      xxxxxxxxxxxxxxx  xxxxxxxxxxxxxxx  xxxxx   x       xxxx    xxxxxx
 xxx      xxxxxxxxxxxxxxx  xxxxxxxxxxxxxxx  xxxxx   x       xxxx    xxxxxx
 xxx      xxxxxxxxxxxxxxx  xxxxxxxxxxxxxxx  xxxxx   x       xxxx    xxxxxx
```

Field descriptions

`Route Number`	IP-route number
`Destination Node`	Destination of the route. The destination is a name administered on the **Node Name** form that can include the keyword `Default` indicating the default route.
`Gateway`	The node name of the Gateway through which the destination is to be reached. The Gateway is a name administered on the **Node Name** form.
`C-LAN Port`	Indicates the C-LAN port location that provides the interface for the route.
`Metric`	Specifies the desirability of the IP route in terms of the efficiency of data transmission over the route. Valid entries are `0` (a simple route) and `1` (a complex route). A metric value of `1` is used only when the switch has more than one C-LAN board installed. A metric-1 route diverts usage of the route to a metric - 0 route, if available.
`Route Type`	A non-administrable field that specifies whether this is a **network** or **host** route. A **network** route is a route to all nodes on the (sub)network specified in the `Destination Node` field. A **host** route is a route to the single node specified in the `Destination Node` field.
`Accepted by CLAN`	Indicates whether a C-LAN circuit pack has accepted the administered IP-route. Routes for a link are downloaded to the C-LAN circuit pack when the link comes into service. Possibilities include: ■ `accepted` – the route has been accepted by the C-LAN circuit pack ■ `rejected` – the route has been rejected by the C-LAN circuit pack. The Gateway may not be on the attached ethernet subnet or may not be the IP address of the far end of the PPP link. ■ `pending` – the route has not been sent to the C-LAN circuit pack, or it has been sent but no reply has been received. Typically, this status changes to `accepted` or `rejected` when some condition changes, such as a link coming up. ■ `obsolete` – the route is no longer needed (some host routes were needed in R7 but are no longer needed in subsequent releases, or are duplicates of existing routes)

list isdn-testcall

list isdn-testcall [print | schedule]

The **list isdn-testcall** command displays the ISDN-PRI trunks that are currently in use for outgoing ISDN test calls.

Output

`B-Channel`	The trunk group number and member number of the trunk in use.
`Start Time`	Day of the month, hour and minute when the test call began.
`Duration`	Expected duration, in minutes, of the test call.
`M/T Port`	Cabinet, carrier, slot and circuit number of the port on the Maintenance/Test circuit pack in use for the outgoing test call.

The following display shows a typical result when **list isdn-testcall** is entered.

```
list isdn-testcall

                            ISDN-PRI TESTCALLS

      B-Channel    Start Time     Duration    M/T Port

      078/001      25/14:36       120         1B1102

Command successfully completed
```

list marked-ports

list marked-ports [print | schedule]

The list marked-ports command displays all of the ports that have been marked unusable with the mark port command.

Output

`Port`	The physical location (cabinet-carrier-slot-port circuit) of the marked port.
`Board-Type`	The type of circuit pack with the marked port.

```
list marked-ports

                   MARKED-PORT INFORMATION

        Port       Board-Type

        1C0101     DIG-BD
        1C0102     DIG-BD

Command successfully completed
```

list measurements clan ethernet

This command provides a 24-hour history of important packet-level statistics from which you can infer some LAN performance characteristics. For example,

- high collision counts could indicate high traffic on the LAN segment (congestion on the bus).
- high Cyclic Redundancy Check (CRC—detects and corrects errors on every frame) errors could suggest that
  - — the LAN connection may be “noisy”
  - — a wire connection is loose
  - — a wire is frayed or broken.

The 24-hour history gives the ability to look back at these measures if the trouble cleared.

The data is collected at 15-minute intervals over 24 hours for the Cyclic Redundancy Check (CRC) and collisions for ethernet connections. If the data cannot be retrieved for the 15-minute interval, N/A displays in the field. The delta (the change from the last inquiry) and the total are provided for each error count. After the occurrence of “N/A” (not available), the delta equals the total.

The primary use of this command is to quickly and unambiguously determine if the fault lies within the Lucent-provided equipment or if the fault is with the LAN or LAN administration to which the DEFINITY ECS switch is connected.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list measurements	***clan ethernet***	Designates ethernet connection	init inads craft customer		
	UUCss	Cabinet-carrier-slot address of the C-LAN circuit pack			
	print	Report sent to printer			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen.[1]			
		Examples: **list measurements clan ethernet 1A05** **list measurements clan ethernet 1A05 print**			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output from the **list measurements ethernet** command.

```
list measurements clan ethernet 1C1017                                   Page 1 of x

Switch Name: sierra                                   Date:4:07pm MON AUG 01,1999

               C-LAN ETHERNET PERFORMANCE MEASUREMENT DETAILED REPORT

Date      Time            CRC Check                 Collision Count
                          total        delta        total           delta
08/01     0308              650           50          650             250
08/01     0253              600          600          400             400

08/01     0208       1000000550  10000000550 10000000550     10000000550
```

Field descriptions

`Date`	The date that the data was collected.
`Time`	The current 15-minute interval in which the action was performed
`CRC Check`	The error count for CRC errors
`Total`	The total value of the counter on the board

NOTE:
The counter value can be up to 11 digits long because of the 32-bit counter on the board. After the occurrence of an "N/A," the delta equals the total. Busyout or release of a board or a port, the **reset board** command, and reseating the board all clear the firmware counters.

`Delta`	The difference between the current and the previous sample
`Collision Count`	The error count for collisions on the ethernet

list measurements clan ppp

This command provides a 24-hour history of important packet-level statistics from which you can infer some LAN performance characteristics. For example,

- Invalid frames—the number of frames that are misaligned
- CHAP failures—Challenge Handshake Authentication Protocol—the number of attempts for ppp authentication that failed
- High Cyclic Redundancy Check (CRC)—detects and corrects errors on every frame) errors could suggest that the connection may be "noisy"

The 24-hour history gives the ability to look back at these measures if the trouble cleared.

Data is retrieved for 15-minute intervals for 24 hours for CRC, Invalid Frame and Chap Failures for PPP connections. If the data cannot be retrieved for the 15 minute interval, `N/A` displays in the field. The delta (the change from the last inquiry) and the total are provided for each error count. After the occurrence of an "N/A," the delta equals the total.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list measurements	***clan ppp***	Link identifier (primary or secondary)	init inads craft customer	Primary	
	UUCCSS pp	Port Address			
	print	Report sent to printer			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen.[1]			
		Examples: **list measurements clan ppp** **list measurements**			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output from the **list measurements clan ppp** command.

```
list measurements clan ppp 1C1001                                 Page 1 of x

`Total`	Total value of the board counter.

NOTE:
The counter value can be up to 7 digits long because the 16-bit counter on the board. After the occurrence of an “N/A” the delta equals the total. Busyout or release of a board or a port, the **reset board** command, and reseating the board all clear the firmware counters.

`Delta`	The difference between the current and the previous sample
`Invalid Frame`	The number of invalid frames detected. Invalid frames are the frames that are misaligned.
`CHAP Failures`	The number of failed attempts for ppp authentication

list measurements ds1

list measurements ds1 UUCSS [print | schedule]
list measurements ds1-log UUCSS [print | schedule]
list measurements ds1-fac UUCSSf [log | summary] [print | schedule]

The **list measurements** ds1 and **list measurements ds1-log** commands provide performance measurements on a DS-1 link. The **ds1** option provides a summary report while the **ds1-log** option provides a detailed report.

The performance measurements of a DS-1 link indicate the quality of the DS-1 physical interface between the system and a far-end system.

The **list measurements ds1-fac** command provides link performance measurements on a DS1 Converter facility.

The DS1 Converter Complex consists of two DS1Cs connected by one to four DS1 facilities. This complex allows the distance between two port networks to extend up to 100 miles, thereby extending the range of the optical fiber link within limited bandwidth (96 channels). A DS1C Complex can be used in a direct connectivity configuration or a Center Stage Switch configuration. The DS1 converters may be connected to an Expansion Interface(EI) or a Switch Node Interface(SNI) via a metallic connection.

Parameters

UUCSS	The location of a DS1 circuit pack.
UUCSS	The location of a DS1 converter facility where *UUCSS* is the location of the circuit pack and *f* is a letter (a-d) designating one of the four DS1 facilities.

Examples

list measurements ds1 2a18
list measurements ds1-log 2e01a
list measurements ds1-facility summary 2e01d schedule

Output

The following field descriptions pertain to the summary reports accessed by **list measurements ds1** and **list measurements ds1-facility summary**.

`Counted Since:`	The start time and date when the associated measurement counters were cleared, or when the DS1C circuit pack or facility was administered.

`Number of Seconds Elapsed Into Current 15-min Interval:`	The number of seconds from the beginning of the current 15-minute interval. This field has a value from 0 to 900.
`Total of Valid 15-min Intervals in Past 24-hr Period:`	The total number of 15-minute intervals in the past 24-hour period that contain valid data. This field has a value from 0 to 96.
`Category`	The following four fields report data form the error counters.
`Errored Seconds`	The value of the errored seconds counter for the specified 15-minute interval. This field has a value from 0 to 900 or N/A if the data for the 15-minute interval is invalid.
`Bursty Err Secs`	The value of the bursty errored seconds counter for the specified 15-minute interval. This field has a value from 0 to 900 or N/A if the data for the 15-minute interval is invalid.
`Severely Err Secs`	The value of the severely errored seconds counter for the specified 15-minute interval. This field has a value from 0 to 900 or N/A if the data for the 15-minute interval is invalid.
`Failed Seconds`	The value of the failed seconds counter for the specified 15-minute interval. This field has a value from 0 to 900 or N/A if the data for the 15-minute interval is invalid.
`Worst 15-Min Interval`	The date(Date), end time(Time), and error count (Count; from 0 to 900 in increments of four) of the 15-minute interval in the previous 24-hour period that contains the maximum value for each of the four error categories (errored seconds, bursty errored seconds, severely errored seconds, and failed seconds).
`Total of 24-Hour Count`	The sum of all valid 15-minute counts for the previous 24-hour period for each of the four error categories. This field has a value from 0 to 65535.
`Current 15-Minute Interval`	The error count for the current (incomplete) 15-minute interval for each of the four error categories. This field has a value from 0 to 899 or N/A if the data for the current 15-minute interval is invalid.

The following field descriptions pertain to the detailed reports accessed by the **list measurements ds1-log** and **list measurements ds1-facility log** commands.

`Counted Since:`	The start time and date when the associated measurement counters were cleared or the DS1C circuit pack was administered.
`Date`	The date of the 15-minute interval.
`Time`	The time of the 15-minute interval.

`Errored seconds` The value of the errored seconds counter for the specified 15-minute interval. This field has a value from 0 to 900 or N/A if the data for the 15-minute interval is invalid.

`Bursty err secs` The value of the bursty errored seconds counter for the specified 15-minute interval. This field has a value from 0 to 900 or N/A if the data for the 15-minute interval is invalid.

`Valid interval` This field indicates whether the data for the specified 15-minute interval is valid. Data is considered valid when a count for that 15-minute interval. If the field has a value of ‘‘y’’, the data for the four error categories is valid; otherwise, the data is invalid. Data is considered valid when a count for that 15-minute interval is retrieved and none of the following invalid conditions occur. Data is invalid if a system warm start or a system cold start occurred during the interval, if the DS1C circuit pack was not inserted during the interval, if the system time was changed during the interval, or if the system was too busy to respond to a poll request for the interval.

The following output examples show all of the four different DS1 reports.

```

list pms-down

list pms-down [start-time][stop-time][print]

This command lists all events that have meaning to the Property Management System (PMS) that have occurred while the link between the switch and the PMS was down. For example, any room status codes entered by hotel housekeeping staff during a time of PMS outage would be shown in this report.

Parameters

`start-time`	The starting time in 24-hour notation from which events are to be listed.
`stop-time`	The time in 24-hour notation up to which events are to be listed.

Output

`Extension`	The extension associated with the reported event.
`Event`	The PMS event that was reported to the switch, but which could not be sent to the PMS.
`Reason`	The reason that the event could not be reported by the switch to the PMS.
`Time`	The time at which the event was reported.

The following example shows a typical result when **list pms-down** is entered.

```
list pms-down

                  PROPERTY MANAGEMENT SYSTEM ACTIVITY

Extension    Event                 Reason                     Time

 402     from room, code 1    PMS link out of service    7:00am
 405     from stn, code 1     PMS link out of service     9:00am
 411     check in, complete   PMS link out of service     9:30am
 411     PBX enabled MWL      PMS link out of service    12:00am
 450     from room, code 1    PMS reject                 12:05am
```

list suspend-alm-orig

This command lists entries in the Suspend Alarm Origination table.

Synopsis

list suspend-alm-orig [print | schedule]

Examples

list suspend-alm-orig
list suspend-alm-orig print
list suspend-alm-orig schedule

Description

This command lists active entries in the Suspend Alarm Origination table. Even though this command only lists active entries, an entry that expires during the list process still appears in the output. If the Suspend Alarm Origination table is empty, the output would only contain the title and field headings.

Parameters

Print This option causes the report to be printed if a printer is linked to the SAT.

Schedule When the schedule option is specified, the command validates and a schedule form displays to allow the technician to schedule execution of the command at a specified time. The information displayed by the command is sent to the system printer instead of the screen.

Help Messages

```
['print' or 'help']
```

Output

```
list suspend-alm-orig

                      Suspend Alarm Origination Entries

                     Physical   Board        Expires At

Feature Interactions

None.

list sys-link

list sys-link [print | schedule]

The list sys-link displays all of the system links. The location, link type and channel number, link state, current path status, faulted path status, and last recorded fault, if any, are displayed for each system link. See SYS-LINK in Chapter 9, ''Maintenance Object Repair Procedures'' for details.

Output

`Location`	The physical location of the far endpoint associated with the system link (cabinet-carrier-slot-circuit).
`Link Type/Channel`	The type of system-link and the processor channel number of the link (if there is one). System links include the following (see MO SYS-LINK): Expansion Archangel Links (EAL), Indirect Neighbor Links (INL), Processor Gate Control links (PGC), PRI signaling links (PRI), System Port links (SAP), Remote Neighbor links (RNL), Local Neighbor links (LNL), X25 adjunct links. Processor channel numbers range from 1 to 128.
`State`	Whether the system link is "up" or "down."
`Current Path`	This field specifies the status of the current path. This field displays "none" if the link is down or "present" if the current path is functional.
`Faulted Path`	This field shows whether the link has experienced a fault and been switched to another path. "Present" indicates that the link has been faulted at least once. "None" is displayed if the link has not gone down. "Default" is displayed if the default faulted path is being used.
`Last Fault Recorded`	The date and time that the most recent fault on the link took place.

The following display shows a typical result when **list sys-link** is entered on a system with 5 PNs and PNC duplication.

```
list sys-link                                             Page   1   SPE A

                          SYSTEM LINKS INFORMATION

```

mark port

mark port UUCSSpp

The **mark port** command will identify a port as unusable by normal call processing. The port will be able to be tested, etc. but calls will not be attempted through the port. The marking of a port is saved as part of translation. The port can be restored to service by using the clear port command.

For more information see ''Common Input Parameters'' and ''Common Output Fields'' at the beginning of this chapter.

monitor bcms

monitor bcms split split# | system system# | skill skill#

The **monitor bcms** command displays output for agents and splits summarizing the Basic Call Management System (BCMS) condition. This on-line status report is automatically updated every 30 seconds or on demand by pressing UPDATE. The command is canceled by pressing CANCEL which results in termination of the login. Three display options are available: split, system and skill.

Parameters

split This specifies display of status information for one particular split (ACD hunt group). The qualifier is followed by an ACD hunt group number (split number) that identifies the split to the switch.

system This specifies display of split queue status as well as cumulative split information for all splits measured by BCMS. The qualifier is followed by ACD hunt group numbers (split numbers) separated by spaces and/or split number ranges separated by a hyphen ("-").

skill This specifies display of status information for one particular skill group. The qualifier is followed by a skill number that identifies the group.

Examples

monitor bcms split 1
monitor bcms system 1 5 7 8 9
monitor bcms system 1-15

Output for the System Option

`Date`	The current date and time which is updated every 30 seconds or when the UPDATE key is pressed.
`SPLIT`	The name of the split being reported, if no name is administered then the split extension is displayed in the form “EXTxxxxx”. Splits are displayed in split number order. This field is translation data.
`CALLS WAIT`	The number of calls currently waiting in this split’s queue. If any of these calls are Direct Agent Calls, the field will be preceded by an asterisk. This field is real-time status data.
`OLDEST CALL`	The amount of time that the oldest call has waited in queue. This field is real-time status data.
`AVG ANSW SPEED`	The average time required for an answer in this split during the current period, including time in queue and time ringing at the agent’s voice terminal. Intraflow calls (those that overflow from one ACD split to another split) will not have queue time from previous splits included in the average. The calculation is Total Answer Time/Total Automatic Call Distribution (ACD) Calls. This is measurement data and includes only those calls that have completed.
`AVAIL AGENT`	The number of agents in this split currently available to receive an Automatic Call Distribution (ACD) call from this split. This field is real-time status data.
`# ABAND`	The number of calls that have abandoned during the current period. This field is measurement data.
`AVG ABAND TIME`	The average time abandoned calls waited in queue before abandoning during the current period. The calculation is Total Abandon Time/Total Calls Abandoned. This field is measurement data and includes only those calls that have completed (terminated).
`# ACD`	The number of Automatic Call Distribution (ACD) calls handled by this split during the current period. This includes calls that intraflow into the split. This field is measurement data.
`AVG TALK`	The average talk time for Automatic Call Distribution (ACD) calls handled by this split during the current period. This does not include ring time at the agents’ voice terminal. The calculation is Total ACD Talk Time/Number of ACD Calls. This field is measurement data and includes only those calls that have completed (terminated).
`AVG AFTER CALL`	The average After Call Work (ACW) time for Automatic Call Distribution (ACD) calls handled by this split during the current period. ACD calls with no ACW time are included in the average. Time spent on direct incoming or outgoing calls while in ACW will not be included in the average. The calculation is (Total ACW Time - Total ACW Incoming Time - Total ACW Outgoing Time)/Total ACD Calls. This field is measurement data and includes only those calls that have completed (terminated).

The following display shows a typical result when **monitor bcms system** is entered.

```
monitor bcms system                                        Page   1 of   1
                              BCMS SYSTEM STATUS

                       Date:   14:02 THU OCT 17 1991

                               AVG                    AVG                  AVG
        CALLS   OLDEST   ANSW   AVAIL    #     ABAND    #     AVG     AFTER
SPLIT   WAIT     CALL   SPEED   AGENT   ABAND   TIME    ACD    TALK    CALL

Service   3      1:03    :45      0       3      :30    20    2:30    1:25
Sales     5       :33    :15      0      11      :45    36    1:32     :35
```

Output for the Split Option

`Split:` The number of the split requested. This field is translation data.

`Split Name:` The name of the split requested. If no name exists the split extension is displayed in the form “EXT xxxxx”. This field is translation data.

`Date:` The current date and time which is updated every 30 seconds or when the UPDATE key is pressed.

`Calls Waiting:` The number of calls currently waiting in this split’s queue. If any of these calls are Direct Agent Calls, the field will be preceded by an asterisk. This field is real-time status data.

`Oldest Call:` The time in minutes:seconds that the current oldest call has waited in this split’s queue. This field is real-time status data.

`Staffed:` The number of agents currently logged into this split. This field is real-time status data.

`Avail` The number of agents currently available to receive an Automatic Call Distribution (ACD) call in this split. Agents are in either the Auto-in or Manual-in work modes and are not currently on a call. If the agent is on another split’s call or in After Call Work (ACW) for another split, this agent is not considered available and will not be recorded here. This field is real-time status data.

`ACD` The number of agents in this split currently on an Automatic Call Distribution (ACD) call for this split. This includes ACD calls that are being handled by this split that arrive as coverage from another split. This field also includes outbound calls (Outgoing Call Manager) that are distributed through the ACD. Note that if an agent puts an ACD call on hold, but does not enter another state (for example, the agent does not enter the AVAIL state), the agent will still be seen as in the ACD state. This field is real-time status data.

`ACW`	The number of agents in this split currently in After Call Work (ACW) split. This field is real-time status data.
`AUX`	The number of agents in this split currently in AUX work for this split. If an agent is on another split's call or in After Call Work (ACW) for another split, this agent is not considered in AUX work and will not be recorded here. This field is real-time status data.
`Extn`	The number of agents in this split currently on non-ACD (Automatic Call Distribution) calls, either incoming or outgoing directly to/from their extensions. If the agents are also in After Call Work (ACW) or AUX they will be recorded as Extn rather than ACW or AUX. This field is real-time status data.
`OtherSplit`	The number of agents in this split on another split's call or in After Call Work (ACW) for another split. Only used if agents belong to multiple splits. This field is real-time status data.
`AGENT`	The name of the agent associated with the extension. If no name exists this field will be left blank. This field is translation data.
`EXT`	The agent's extension. This field is translation data.
`STATE`	The current state of the agent for this split. This possible states are Avail, ACD, ACW, AUX, Extn In, Extn Out, OtherSplit, and Unstaff. If an agent is staffed, the agent must also be in one of the above states. This field is real-time status data.
`TIME`	The clock time at which the agent entered the current state. This field is real-time status data.
`ACD CALLS`	The number of Automatic Call Distribution (ACD) calls (inbound and outbound), that the agent has completed for this split during the current period (half hour or hour). The maximum number of calls is 255, and if this maximum is exceeded, 255 is displayed. This field is measurement data.
`EXTN IN CALLS`	The number of non-ACD incoming calls that the agent has received and completed during the current period. The maximum number of calls displayed is 255. This field is measurement data.
`EXTN OUT CALLS`	The number of outgoing non-ACD (Automatic Call Distribution) calls that the agent has completed during the current period. The maximum number displayed is 255. This field is measurement data.

The following display shows a typical result when **mon bcms spl 1** is entered.

```
monitor bcms split 1                                     Page   1 of   1   SPE A

```

monitor health

monitor health

The **monitor health** command displays the same information as the **status health** command and updates the display automatically every minute. The command is terminated by pressing Cancel. When the command is canceled, the management terminal login is dropped. See **status health** for a description of the fields displayed.

monitor security violations

monitor security-violations [print]

The **monitor security-violations** command displays the following information about failed attempts to access the system: the time of the violation, the login entered, and the port accessed during the failed login attempt. For remote access violations, the trunk group number, member, and extension are also shown. A total of 16 entries are maintained for each type of access. The report is automatically updated every 30 seconds until the command is canceled by pressing CANCEL. Unlike some other monitor commands, canceling does not cause the terminal to be logged off.

Output

`Date`	The date of the security violation given as MM/DD.
`Time`	The time of the logged security violation given as HH:MM.
`Login`	The login ID that was entered as part of the violation attempt.

System Management Violations

`Port Type`	The type of port through which the login violation was attempted: SYS-PORT A dial-in connection to a system port. MAINT A physical connection to the G3-MT terminal connector on an EPN maintenance circuit pack. SYSAM-LCL A physical connection to the ACTIVE terminal connector on the SYSAM circuit pack in a PPN control carrier. SYSAM-RMT A connection to the Remote Access Port (RAP) on the SYSAM circuit pack. This port is usually accessed by dialing in and is reserved for use by INADS.
`Ext`	The extension assigned to the data module that was used to attempt the failed login. If a data module was not used (as in the case of dedicated EIA connections, for example) the field is blank.

Remote Access Violations

`TG No.`	The trunk group that carried the incoming remote access attempt (remote access violations only).
`Mbr`	The trunk group member number associated with the trunk from which the remote access attempt terminated (remote access violations only).
`Ext`	The extension used to access the RAP (remote access violations only).

monitor system

This command with the **view1** or **view2** option displays one screen page of output summarizing the overall condition of the system. With the **connection** option, the command displays the real-time status for time slots and buses. Additionally, there are other miscellaneous parameters displayed that show call rates, intervals, etc.

Synopsis

monitor system [view1 | view2 | conn [pnn *pnn number 1 pnn number 2 pnn number 3*]]

Permissions

The following default logins may execute this command: system technician, inads, cust, init, nms, browse.

Examples

monitor system view1
monitor system view2
monitor system conn
monitor system conn pnn 1 5 7

Description

The **monitor system view1** and **view2** commands display a page of output summarizing the condition of the system. This on-line status report is automatically updated until the command is canceled by pressing the CANCEL key. Two display options are available: view1 and view2.

The current overall system status is available with either of the view options. "View1" displays attendant, maintenance, and traffic status. Attendant and maintenance status are updated every minute and traffic status is updated on an hourly basis. When the command is canceled, the technician will be automatically logged off for security reasons. The "view2" report contains everything the "view1" report does, except the hunt group measurements are omitted from the traffic status portion of the "view2" report. These forms contain simplified high-level information from which a basic picture of the system's health can be drawn. The monitor system conn command displays output that shows the status of connections in the connection manager process. Data is collected frequently in the connection manager for certain key information items. It is from this database that this report is drawn. This on-line status report is automatically updated every minute (or by pressing the UPDATE key) until the command is canceled by pressing the CANCEL key. Pressing the CANCEL keys forces a logout of the current login id.

There is one option to the command line entry, monitor system conn. That parameter is *pnn*. On the *gaz target*, there are only 3 possible pnns. On the *mips target*, however, up to 22 pnn can be administered. The command line parameter *pnn* is used to indicate which 3 pnns the user wishes to see.

Defaults

No defaults.

Parameters

view1	This specifies a form that will include the attendant status, the maintenance status, the last hour's measurement of trunk groups, hunt groups, and the attendant group, and finally, the time of day.
view2	This specifies a form that will display a subset of the view1 form entries. This form will include all of the view1 form except the last hour's hunt group measurements.
conn	This option will bring up the connection monitor output for key information.
entering no options	Omitting the "pnn # # #" argument on the command line will cause the default configuration of Pnn's 1, 2 and 3 to be displayed.
pnn # # #	Entering "pnn # # #", where "#" is replaced by a pnn number from 1 to 3, will cause data for the specified pnns to be displayed.

Help Messages

If the system technician presses HELP after entering "monitor system", the following object command word choices will be displayed:

```
conn          view1          view2
                scr
```

If the system technician presses HELP after entering "monitor system conn" the following message will be displayed:

```
Enter 3 port network numbers (xx-xx) ['pnn' x x x]
```

Error Messages

If the pnn number entered is non numeric, not administered, or invalid in any other way, one of following messages will be displayed:

```
Object command word omitted; please press HELP
"xx" is an invalid identifier; press RETURN to execute modified command
```

If during the execution of a command a resource problem occurs that requires the user to restart the command, then the following message will be displayed:

```
Command resources busy; Press CANCEL to clear, and then resubmit
```

If all of the available maintenance resources are currently in use, then the following message will be displayed:

```
All maintenance resources busy; try again later
```

Output

The following output fields are for the **monitor system view1** and **monitor system view2** commands.

`Console #`	A list of console numbers that are either activated or deactivated.
`Activated:`	The attendant console is in service. An attendant console is considered activated if its handset/headset is plugged in, it is not busied out, and the system is in day service and the console is a day or day/night or principle console, or the system is in night service and the console is a night or day/night console.
`Deactivated:`	The attendant console is not in service. The attendant console is considered deactivated if it does not meet the previous activated conditions.
`# of alarms for trunks`	The total number of existing minor and major alarms on trunk ports.
`# of alarms for other resources`	The total number of existing minor and major alarms on all maintainable objects in the system except trunks and stations.
`First OSS number has been informed?`	Has all the alarm been reported and acknowledged by the first OSS telephone number. If the "Alarm Origination" is not enable or there are no active alarm, the field will be "n".
`MeasurementHour`	The starting time of the period for which the measurement was taken. For example, if the measurement hour is shown as 1800, it means the traffic status data displayed is for the time period from 6 PM to 7 PM (The measurement is taken on an hourly basis).
`Grp no`	A number between 1 and the maximum trunk group number or maximum hunt group number in the system.
`Grp dir`	Group direction: incoming, outgoing or two way.
`Calls qued`	Total calls that arrived and were placed in the queue for trunk groups.
`Calls aban`	Total calls that were abandoned by the caller.
`%Out blkg:`	The ratio of outgoing calls that are not carried (due to overload conditions) on a trunk group to the outgoing calls offered.
`% Time ATB:`	The percentage of time within the polling interval that all trunks in the trunk group were unavailable for use.
`Time of day`	The current time of day acquired from the system.

For the following output example, the command monitor system view1 was entered.

```
monitor system view1
                 ATTENDANT STATUS                  MAINTENANCE STATUS

                   Console no.                        # of alarms for trunks: 4
  Activated: 1 2 3 4 5 6                            # of alarms for stations: 2
                                                   # of alarms for other res: 1
Deactivated: 7 8                       First OSS number has been informed? n

                               TRAFFIC STATUS
                             Measurement Hour: 1800

                                                     16:08 WED MAR 6 1996
                 - press CANCEL to quit -
```

Output

The following output fields are for the **monitor system conn** command.

`Time Slot Status`	There are 4 numbers associated with the time slot status for each specified pnn; for each of the two buses (0 and 1) there is a maintenance and a normal state. The first row is the pnn, the second specifies the bus while the third specifies the bus's state while the last column represents the number of idle counts. These fields represent real-time status data.
`Bus Status`	For the bus status fields, there are two numbers associated with each of the two buses for each pnn. Shown are the pnn number; the bus associated with it, i.e., 0 or 1; and the state of the bus, i.e., "avail" or "unavail". These fields represent real-time status data.
`Callrate`	The callrate field represents the call rate being experienced currently on the switch. This is a counter which is bumped each time a call attempt is made. This field represents real-time status data.
`Interval`	This field is related to the above field in that it represents the interval being applied with which the call rate is applicable. It is normally set to a 36 second time period. This field represents a constant status data.
`Max_callrate`	This field represents the maximum call rate which has been hit during the time since the last hour has passed. If, for example, at 20 minutes past 12:00 this command is executed, this field will represent the maximum call rate obtained during the past 20 minutes. This field represents real-time status data.
`Next_hour`	This field will contain a value of 0 or 1 depending upon if the measurements being taken are for this hour or the next. It is related to the previous field in that the maximum call rate is reflected for this hour. When this flag is set, then statistics begin to accumulate for the next hour and shortly thereafter, the maximum call rate will become zero and accumulations will begin anew.
`tot_ts_req`	This field holds the total time slots in use during the time period elapsed since the top of the last hour. Data is internally collected every 100 seconds. When the timer fires and the data collection occurs, a check is made as to how many time slots are currently in use. That's where the total comes from. There are three numbers displayed for this field on the form; one for each of the pnns requested. This field represents real-time status data.
`ts_denied`	This field holds the total time slots requests that were denied during the time period elapsed since the top of the last hour. Data is internally collected every 100 seconds. There are three numbers displayed for this field on the form; one for each of the pnns requested. This field represents real-time status data.

`tot_fts_req`	This field represents the total fiber time slots that have been requested. This field is incremented each time a fiber time slots that have been allocated since the last top of the hour measurements polling. There are three values shown on the form; one for each of the requested pnns. This field represents real-time status data.
`ts_count`	This field indicates how many time slots are in use during the last 100 second poling period. An internal timer causing polling to occur every 100 seconds. The value in this field represents the requests for time slots during that 100 second interim. There are three numbers displayed for this field on the form; one for each of the pnns requested. This field represents real-time status data.
`ts_total`	This field gets it's value from the time slots count field discussed above every 100 seconds. It represents the total number of time slots requested since the top of the last hour and is real-time status data.
`fts_count`	This field indicates how many fiber time slots are in use during the last 100 second poling period. An internal timer causing polling to occur every 100 seconds. The value in this field represents the requests for fiber time slots during that 100 second interim. There are three numbers displayed for this field on the form; one for each of the pnns requested. This field represents real-time status data.
`fts_total`	This field indicates the total number of fiber time slots. This field gets it's value from the fiber time slots count field discussed above every 100 seconds. It represents the total number of fiber time slots requested since the top of the last hour and is real-time status data.
`Requests-TN748 TTRs`	The total number of touch tone receivers requested is reflected in this field. It is a running count of currently active requests. It is decremented when a tone receiver is freed and incremented when they are requested. Note that this field applies strictly to the TN748 board. This field represents real-time status data.
`Requests-TN748 CPTRs`	The total number of call progress tone receivers requested is reflected in this field. It is a running count of currently active requests. It is decremented when a call progress tone receiver is freed and incremented when they are requested. Note that this field applies strictly to the TN748 board. This field represents real-time status data.
`Requests-TN744 CPTRs`	The total number of call progress tone receivers requested is reflected in this field. It is a running count of currently active requests. It is decremented when a call progress tone receiver is freed and incremented when they are requested. Note that this field applies strictly to the TN744 board. This field represents real-time status data.

`Requests-TN744 TTRs`	The total number of touch tone receivers requested is reflected in this field. It is a running count of currently active requests. It is decremented when a tone receiver is freed and incremented when they are requested. Note that this field applies strictly to the TN744 board. This field represents real-time status data.
`Requests-TN744 MFC`	The total number of multi-frequency receivers requested is reflected in this field. It is a running count of currently active requests. It is decremented when a multi-frequency receiver is freed and incremented when they are requested. Note that this field applies strictly to the TN744 board. This field represents real-time status data.

The following display was produced by entering **monitor system conn**.

```
       Time Slot Status                 Bus Status
Pnn      Bus   State  *Idle Count   Pnn  Bus  State

```

Feature Interactions

None.

monitor traffic

monitor traffic trunk-groups [group#]
monitor traffic hunt-groups

The monitor traffic command shows the current load on specified trunk and hunt groups and the length of time that the oldest call in the group has been waiting.

Parameters

trunk-groups The trunk group report displays the number of calls in the queue waiting to be serviced for each trunk group. The total number of members in the group and the number of members active on calls are displayed for comparative analysis. Only administered trunk groups up to a maximum of 60 are displayed.

You can specify the starting trunk group. For example, if you enter 5, trunk groups from group 5 up are displayed.

hunt-groups The hunt-group report is similar to the trunk-group report. In addition to the information contained in the trunk-group report, this report displays how long the oldest call in each group's queue has been waiting. The display is updated every minute. refreshed. Fields are blank for unadministered hunt groups.

Output

`#` Group number for the trunk or hunt group.

`S` The size (number of members administered) of each trunk or hunt group.

`A` The number of members in a group that are active on a call. This does not include members which have been busied out.

`Q` The length of the queue administered for a group.

`W` The number of calls waiting in the group queue to be serviced.

`LCIQ` The longest call in queue (LCIQ) indicates the time in seconds the oldest call in the hunt group queue has been waiting to be serviced.

The following display shows a typical result when **mon tr hu** is entered.

```
monitor traffic hunt-groups

                             HUNT GROUP STATUS     22:49 G3-MT DEC 31 1988

```

monitor trunk

monitor trunk group# / member#

This command displays the same information as the **status trunk** command and updates the data automatically every minute or on demand. To manually update the display, press UPDATE (f6 on most terminals). Press CANCEL to cancel the command. Unlike some monitor commands, the terminal login is not dropped when you cancel the command.

netstat ip-route

This command displays the routing tables that are resident in the C-LAN circuit pack. With the “board” option, the command **netstat ip-route board UUCss** displays the routing tables that are resident on the specified C-LAN circuit pack.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
netstat ip-route	***board UUCss***	Example: **netstat ip-route board 01A03**	init inads craft	none	none

Output

The following example shows the output from the **netstat ip-route** command.

```
netstat ip-route                                   page 1 of xxx
                    IP ROUTING - C-LAN

  Destination     Gateway                C-LAN Bd/Pt      Interface
1:___.___.___.___  ___.___.___.___       01C0514          ppp13
2:___.___.___.___  ___.___.___.___       01C0517          cmp0
3:___.___.___.___  ___.___.___.___       01C0518          lo03
```

Field descriptions

`Destination`	Fixed field giving the destination of the route. The destination is a name administered on the Node Name form which can include the keyword “Default,” indicating the default route.
`Gateway`	The node name of the Gateway by which the Destination can be reached. The Gateway must be a name administered on the Node Name form.
`C-LAN Board/Pt`	The circuit pack location for the circuit pack that provides the interface for the route.

`Interface`

- pppn represents one of the PPP interfaces on the C-LAN, which is administered as port n+1.
- `cpm0` represents the ethernet interface on the C-LAN which is administered as port 17.
- `lo0` represents the loopback interface on the C-LAN which does not need to be administered.

ping

When debugging connectivity problems, a ping only indicates low-level connectivity. If an external ping works but higher-level applications such as DCS, CMS, or INTUITY do not, then you can only assume that there is connectivity to the board. Interrogate the switch for other clues as to why the higher-level application is not working.

Action/ Object	Qualifier	Qualifier Description	Permissions[1]	Defaults	Feature Interactions
ping	**ip-address**	The IP address of the device to ping in the following format: www.xxx.yyy.zzz	init inads craft customer	packet length = 64 bytes	
	node-name	Administered node name (use **display node-names**)			
	board	The location of the C-LAN circuit pack (**UUCSS**)			
	packet-length	Range: 64-1,500 bytes			
	repeat	1-100 Examples: **ping ip-address 192.68.3.26** **ping ip-address 192.68.3.26 board 1C05** **ping ip address 168.24.3.66 packet-length 1500**			

1. You can place additional restrictions on the command by selecting the object "ip-address" on the Restricted Object List:

   Type **change permissions *loginid*** (an administered login such as inads), and press Enter.

   Set the `Additional Restrictions` field to **y** in the Administration Commands section of the form.

   Go to the second or third page of the form.

   Enter **ip-address** in the list of Restricted Objects and press Enter.

The ping command has 4 qualifiers:

- "ping ip-address"
- "ping node-name"
- "ping board"
- "ping packet-length"

ping ip-address

This command "pings" the given IP address of the destination to ping. The command returns

- the port used to perform the test
- the pass/fail results of the test
- the round-trip delay time for successful tests
- the error code on tests that failed.

ping node-name

This command pings an administered node. Look the "**node-name**" up with the **display node-names** command).

ping board

The **board** qualifier specifies which C-LAN circuit pack from which to ping. By adding the ***board UUCSS*** qualifier to the command, you can also specify which C-LAN circuit pack (in the case of multiple C-LAN circuit packs). If only one C-LAN circuit pack is present, the **board** qualifier is optional.

ping packet-length

The **packet-length** qualifier specifies the packet length of the ping packet. Packet lengths of from 64 to 1500 bytes can be specified. The **packet-length** qualifier is optional, and if not used, the default packet length is 64 bytes. Specifying a longer packet length in the command line can show

- if a router or host has a problem fragmenting or reassembling transferred packets
- a more complete indication of the link status

If the packet length is not specified, the default is 64 bytes. You can add the **packet-length** qualifier and the packet size (64-1500 bytes) to the other ping commands. Some examples include:

- **ping node-name packet-length 800**
- **ping ip-address 24.103.5.7 packet-length 100**
- **ping board UUCSS packet-length 1000**

Output

The following example shows the output from the **ping ip-address packet-length** command.

```
ping ip-address 192.68.3.26 packet-length 1500

TEST RESULTS
  End-pt IP        Port        Port Type  Result   Time(ms)  Error Code
  192.68.3.26      01C0202     PPP-PT     PASS     221       XXXX
```

Screen 8-5. ping ip-address report

Field descriptions

`End-pt IP`	The TCP/IP destination address of the ping command.
`Port`	Location of the C-LAN circuit pack (**UUCSS**).
`Port Type`	Can be either `PPP-PT` for PPP ports (ports 1-16) or `ETH-PT` for the Ethernet port (port 17).
`Result`	PASS or FAIL
`Time (ms)`	The round-trip time (in milliseconds) of the ping.
`Error Code`	Identifies problems associated with the circuitry in the data path for a peer-to-peer IP layer connection

Error messages

The system returns error messages listed in Table 8-7.

Table 8-7. Ping command error messages

Message	Interpretation
`www.xxx.yyy.zzz Internet address not assigned`	The system cannot find the IP address.
`Internet address not reachable from this board`	The IP address is not in the route table of the specified board.
`More than one default route exists, specify board`	The IP address is not in the route table, and more than 1 C-LAN circuit pack has a default route.
`Invalid internet address`	Invalid Internet address parameter
`“CCcss” is an invalid identifier; please press HELP`	Invalid board location (when using the “board” option).
`Error encountered, could not complete request`	The internal error of not being able to find the port through which the IP address is reached.
`Out of range`	The packet size is greater than 1500 or less than 64 bytes in length or if there are invalid or unrecognized parameters
`WARNING Default packet length of 64 bytes used for TN799`	Indicates that the default packet length of 64 bytes is used for a TN799 board

recycle carrier

recycle carrier UUC

The recycle carrier command turns power off, then back on, on a specific carrier. When a power unit is replaced in a carrier, this command must be entered to restart the power on that carrier. The following carriers cannot be recycled:

- PPN Control Carrier (active or standby)
- Switch Node Carrier
- EPN Control Carrier
- Any carrier holding an active Tone-Clock or an active Expansion Interface circuit pack

CAUTION:
When a port carrier is recycled, all ports and adjuncts supported by circuit packs on that carrier undergo a service outage.

CAUTION:
Never recycle power to a carrier containing DEFINITY AUDIX TN566/TN2169 circuit packs without first shutting down the AUDIX system. Doing so can damage AUDIX software. Follow instructions on the TN566/TN2169 faceplate (these also appear under ADXDP-PT in Chapter 9, "Maintenance Object Repair Procedures"*). On G3r V1 systems, the TN566/TN2169 may appear as a TN746 with a vintage greater than 50.*

For more information see Common Input Parameters and Common Output Fields at the beginning of this chapter.

release commands

release board UUCSS
release maintenance-name [address]

Release commands release specified maintenance objects from the maintenance busyout state and puts them back into service, assuming the health of the component(s) permits. Hardware tests specific to the maintenance object are performed to verify that it is functioning.

For each maintenance object, the release command is entered in the same fashion as the associated busyout command, except that the word **release** is entered instead of **busyout**. See the description of the related busyout command for details of command syntax.

If a release command is entered for an object that is not busied out, the command will abort. Some release commands trigger recovery actions by the system, such as the refresh of a standby PNC or SPE. See the description of the related busyout command for details of command execution and interactions.

Parameters

Input parameters consist of specifying the location, if required, of the given maintenance object. Use the same format as that used for the related busyout command.

Examples

release board 01c11
release data-module 310
release tone-clock 2a
release ds1-fac 02e01a
release fiber-link 13
release standby-spe

Output

The identity of the maintenance object and the result of command execution is displayed on a screen form similar to the related busyout screen. When the command aborts or fails, an error code indicating the reason is displayed. See Common Abort and Fail Codes at the beginning of this chapter.

The following display shows a typical result when **release board 01c07** is entered.

```
release board 01C07

                             COMMAND RESULTS

Port        Maintenance Name  Alt. Name    Result   Error Code

01C07       ANL-BD                         PASS
01C0701     ANL-LINE          5409         PASS
01C0702     ANL-LINE          5416         PASS
01C0703     ANL-LINE          5421         PASS

Command successfully completed
```

reset board

reset board UUCSS [repeat #]

CAUTION:
This command can be service disrupting and may cause extraneous alarms. Effects of a reset vary depending upon the type of object being reset and upon whether the component is duplicated. Consult the section in Chapter 9, "Maintenance Object Repair Procedures" *on the relevant maintenance object for details.*

When a port circuit pack is specified, the reset board command performs a software reset of every administered port on the circuit pack. All ports must be busied out before the port circuit pack is reset.

On Critical Reliability systems (duplicated PNC), reset of an Expansion Interface, Switch Node Interface, Switch Node Clock, or DS1 Converter circuit pack on the active PNC is not permitted. Standby components must first be busied out before entering the reset.

Cabinet number and repeat both default to 1. For more information see Common Input Parameters and Common Output Fields at the beginning of this chapter.

reset disk

reset disk [C]

This command resets the disk device, queries the device for ID, size and other information, and initiates self-testing by the device. Upon successful completion, all alarms on that disk are cleared and the device is returned to service.

The cabinet is always **1** and need not be entered. On systems with duplicated SPEs only, carrier **a** or **b** must be entered.

Failure of the reset command places the disk in the uninstalled state. All system access to the disk, including demand testing, is prevented except for demand resets.

When the host-adapter is busied out, only the demand busyout and test commands are permitted on the attached disk. Reset, release, scheduled and periodic testing and other system software access are blocked. In this case, the host-adapter must first be released before the disk can be released.

When the host-adapter is taken out of service due to test or reset failures, and becomes uninstalled, the disk is also placed in the uninstalled state and all access by system software, including resets, is blocked.

reset fiber-link

reset fiber-link fiber# [a-pnc | b-pnc]

CAUTION:
The reset fiber-link command is destructive on standard and high reliability systems (simplex PNC), and may cause an entire port network to be removed from service.

This command resets the Expansion Interface and/or Switch Node Interface circuit packs that are endpoints of a specified fiber link, dropping the link in the process.

A fiber link must be busied out before being reset. To busyout a fiber on critical reliability systems, the fiber must be on the standby PNC and the standby PNC must first be busied out. See **busyout fiber-link** for associated interactions.

The **list fiber-link** command displays a list of fiber links and their locations.

Parameters

fiber#	The administered number of the fiber link (1-27). On critical reliability systems (duplicated PNC), this number designates a fiber link pair; the following qualifier specifies which fiber in the pair is to be reset.
a-pnc, b-pnc	On critical reliability systems (duplicated PNC), this distinguishes between the two fibers in a duplicated pair. On systems with simplex PNC this is always a-pnc and need not be specified.

Examples

Simplex PNC: reset fiber-link 1
Duplex PNC: reset fiber-link 1

reset host-adapter

reset host-adapter C

This command resets and initializes the host-adapter circuit on the MSSNET circuit pack. Upon successful completion, the host-adapter is put into service and all alarms active for that host-adapter circuit are cleared.

The cabinet is always 1 and need not be specified. Carrier a or b must be specified only on systems with duplicated SPEs.

This command will abort if any other MSS operation has already begun.

Failure of this command will place the host-adapter in the uninstalled state, preventing all maintenance testing, including demand testing, of the failed host-adapter. The reset must pass to put the host-adapter back into service.

When the host-adapter is taken out of service due to failures of its tests, or fails a reset and becomes uninstalled, the attached removable media and disk are also placed in the uninstalled state and all access by system software, maintenance tests and commands including reset are blocked from execution.

reset maintenance

reset maintenance UUC

This command performs a reset on a specified maintenance circuit pack. Specifying cabinet 1 resets the PPN SYSAM circuit pack on the selected carrier, dropping any remote or local logins. Specifying cabinets 2 through 22 resets the EPN maintenance circuit pack in the 'a' carrier of the specified cabinet, dropping any local login to that circuit pack.

The cabinet number defaults to 1. The carrier must be specified only for PPNs with duplicated SPEs.

reset packet-interface

reset packet-interface C [S]

CAUTION:
Resetting a packet interface is disruptive under the following conditions:

- On all standard reliability systems (simplex SPE)
- When SPEs in a duplicated system are locked, or handshake is down, and the active packet interface is reset.
- When the standby SPE in a duplicated system has a state of health lower than the active, and the active packet interface is reset.

CAUTION:
In the above cases, call service throughout the system is disrupted, the terminal is logged off and all EPNs are unavailable during the reset interval. A minor alarm is logged against the circuit pack to be reset. This lowers the state of health of the associated SPE and may cause a spontaneous SPE interchange in duplicated systems.

This command resets and initializes the packet interface circuit pack hardware and firmware. The actual sequence of operation depends on the type and status of the SPEs.

When an active packet interface is reset, its links are dropped and reassigned to the remaining in-service packet interface circuit packs. These links are not migrated back to the packet interface after the reset. A level 2 (Cold-2) or greater system restart is required to redistribute the links equally among all active packet interfaces, including the one that was reset.

Simplex SPE

For standard reliability systems the specified packet interface circuit pack is simply reset. Failure of the reset can lead to the circuit pack being placed in the out-of-service state. When a packet interface is out of service, scheduled, periodic, error and demand testing of the circuit pack is prevented and it is not used for links. The circuit pack returns to the in-service state upon passing the reset. A level 2 (Cold-2) or greater system restart is then performed to distribute the links equally among the available packet interface circuit packs.

Duplicated SPE Standby Packet Interface

Reset of a packet interface on the standby SPE does not disrupt service and results in a reset of all packet interfaces on the standby SPE. The following conditions are necessary:

- Handshake communication is up.
- The SPE carriers are not locked with the SPE-Select switches.

The following sequence occurs:

1. Memory shadowing is turned off.
2. All standby packet interfaces are reset.
3. If the reset succeeds, shadowing is turned on, memory refresh initiated, and the packet is put into the standby state.
4. If the reset fails, the circuit pack is put into the out-of-service state, lowering the standby SPE's state-of-health.

Duplicated SPE Active Packet Interface

Standby SPE available

When a packet interface on the active SPE of a duplicated system is specified, a spontaneous SPE interchange is first performed by the system, assuming that:

- The SPE carriers are not locked with the SPE-Select switches.
- Handshake communication is up.
- The state of health of the standby SPE is not lower than that of the active.

If these conditions are met, the interchange places the active SPE into the standby state, and then all standby packet interfaces are reset as in the above case. Links are not disrupted, but due to the interchange transient calls are dropped and the terminal is logged off.

Standby SPE Not Available

If any of the three conditions listed above are not met, an SPE interchange is prevented and the active packet interface is reset, resulting in disruption of all links associated with the circuit pack (see the Caution above). When the interchange is prevented by lower state of health of the standby, the standby packet interfaces are also reset according to the sequence listed above.

Parameters

C, CS	The cabinet is always 1 and need not be specified. Carrier a or b must be specified only for duplicated SPEs. The slot number (1-3) designates one of the dedicated PKT-INTFC slots on the PPN control carrier and defaults to the lowest-numbered slot with a packet interface installed in it.

reset interchange

reset pnc interchange [override-and-lock]

NOTE:
This command does not work like other reset commands. Instead of resetting or initializing hardware, a PNC interchange is executed. Before entering this command, look at the states of health of the two PNCs with **status pnc**.

This command executes a PNC interchange on a Critical Reliability system (duplicated PNC). The standby PNC becomes active and assumes control of active call processing, and the active goes to standby. If the health of the standby PNC is the same as or better than that of the active, no service disruption takes place; all stable calls and links are preserved. Some unstable calls may drop.

Both demand and spontaneous PNC interchanges are prevented by the following conditions:

- The standby PNC is busied out.
- The PNCs are locked by means of the **set pnc lock** or **reset PNC override-and-lock** commands.
- For 5 minutes after a spontaneous PNC interchange, or for 30 seconds after a demand interchange, an anti-thrashing mechanism prevents subsequent interchanges unless the override-and-lock option is used.

- If the state of health of the standby PNC is worse than that of the active, the command will abort unless the override-and-lock option is used.
- If the standby PNC has not completed a global refresh since it was last initialized or released, the reset will abort unless the override-and -lock option is used.

Note the following caution regarding the use of the **override-and-lock** option.

See **status pnc** for details of how to obtain and interpret the states of health and other current information about the PNCs. For a more complete explanation of PNC duplication and interchanges, see PNC-DUP in Chapter 9.

Parameters

interchange ”interchange” (without a preceding hyphen) must be specified on the command line.

override-and-lock This option is also used to override the anti-thrashing mechanism. Subsequent PNC interchanges are prevented, regardless of changes in the states health of the PNCs. Double call setup still takes place; each call is set up on both PNCs. To unlock the PNCs, use **set pnc unlock**.

CAUTION:
This option forces execution of the interchange regardless of the state of health of the standby, possibly disrupting service.

Output

One of the following messages is displayed:

```
Command successfully completed
```

If the reset pnc interchange command is unsuccessful due to the state of health of the standby Port Network Connectivity, operation of anti-thrashing, or the following message will be displayed:

```
Interchange of pnc failed;
try again using the ’override-and-lock’ identifier
```

See the preceding caution regarding use of the override-and-lock option. If the reset pnc interchange command is unsuccessful due to a busyout of the standby PNC, the following message will be displayed:

```
Must release port network connectivity first
```

reset pnc interchange [override-and-lock]

NOTE:
This command does not work like other reset commands. Instead of resetting or initializing hardware, a PNC interchange is executed. Before entering this command, look at the states of health of the two PNCs with **status pnc**.

This command executes a PNC interchange on a Critical Reliability system (duplicated PNC). The standby PNC becomes active and assumes control of active call processing, and the active goes to standby. If the health of the standby PNC is the same as or better than that of the active, no service disruption takes place; all stable calls and links are preserved. Some unstable calls may drop.

Both demand and spontaneous PNC interchanges are prevented by the following conditions:

- The standby PNC is busied out.
- The PNCs are locked by means of the **set pnc lock** or **reset PNC override-and-lock** commands.
- For five minutes after a spontaneous PNC interchange, or for 30 seconds after a demand interchange, an anti-thrashing mechanism prevents subsequent interchanges unless the override-and-lock option is used.
- If the state of health of the standby PNC is worse than that of the active, the command will abort unless the override-and-lock option is used.
- If the standby PNC has not completed a global refresh since it was last initialized or released, the reset will abort unless the override-and -lock option is used.

Note the following caution regarding the use of the override-and-lock option.

See **status pnc** for details of how to obtain and interpret the states of health and other current information about the PNCs. For a more complete explanation of PNC duplication and interchanges, see PNC-DUP in Chapter 9.

Parameters

interchange ”interchange” (without a preceding hyphen) must be specified on the command line.

override-and-lock This option is also used to override the anti-thrashing mechanism. Subsequent PNC interchanges are prevented, regardless of changes in the states health of the PNCs. Double call setup still takes place; each call is set up on both PNCs. To unlock the PNCs, use **set pnc unlock**.

CAUTION:
This option forces execution of the interchange regardless of the state of health of the standby, possibly disrupting service.

Output

One of the following messages is displayed:

```
Command successfully completed
```

If the reset pnc interchange command is unsuccessful due to the state of health of the standby Port Network Connectivity, operation of anti-thrashing, or the following message will be displayed:

```
Interchange of pnc failed;
try again using the ’override-and-lock’ identifier
```

See the preceding caution regarding use of the override-and-lock option. If the reset pnc interchange command is unsuccessful due to a busyout of the standby PNC, the following message will be displayed:

```
Must release port network connectivity first
```

reset port-network

reset port-network PN# level [1 | 2]

CAUTION:
A reset of level 2 is destructive, causing all calls and application links on the specified EPN to drop. EPN resets are described under EXP-PN in *Chapter 9*.

This command resets a specified port network to a specified level. This does not cause an interchange on a system with duplicated PNC. The command will not execute on the PPN, or on an EPN whose fiber link to the PPN or CSS is down.

Parameters

PN# Port network number

Use **list cabinet** to find the PN number(s) associated with a given cabinet.

level 1 | 2 Reset level 1 (WARM restart) is used to restart an EPN that is still fully or partially in service. All stable calls are preserved, and full service is restored within 35 seconds.

Reset level 2 (COLD restart) results in reset, removal, and reinsertion of all EPN circuit packs. It is used to recover an EPN that has been taken out of service. Level 2 restarts should take less than 2 minutes. All calls and application links with an endpoint in the EPN are dropped. If two level 2 resets within an hour fail to return the EPN to service, EPN Emergency Transfer is invoked. (EPN Emergency Transfer will already be in effect if the link to the EPN has been down for more than 1 minute).

Examples

reset port-network 10 level 2

Output

`Port` The PN number of the reset EPN.

For more information, see "Common Output Fields" and "Common Abort and Fail Codes" at the beginning of this chapter. The following display shows a typical result when **reset port-network 4 lev 1** is entered.

```
reset port-network 4 level 1

                                 TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result  Error Code

04        EXP-PN                       956       PASS

Command Successfully Completed
```

reset spe-standby

reset spe-standby level# [removable media]

This resets the standby SPE on a system with duplicated SPEs to a specified level. The command is increasingly destructive as the reset level increases. On a system with disk and removable media devices, the reset is executed using the boot image stored on disk unless a reset of level 4 (reboot) with the "removable media" qualifier is requested. During the reset, the standby SPE is taken out of service for several minutes. Reset status can be monitored with the **status spe** command.

During a reset of any level, memory shadowing is turned off. After the reset completes, memory shadowing is automatically restored and a memory refresh of the standby takes place. The standby is not fully in service until the refresh is complete. **Reset spe-standby** invokes initialization of the standby in the same fashion as low level maintenance. The reset level requested will not be escalated by software. The level requested will always be the level that is performed.

Any reset of the standby SPE turns off shadowing, leaving the standby SPE unrefreshed. It may take several minutes before the standby is available for service.

Parameters

level# This specifies the level of reset to be executed, from 1 to 5:

Removable Media	Recovery
1	Warm Restart
2	Cold-2
3	Cold-1
4	Reboot
5	Extended Reboot

Removable Media Valid only for a reset of level 4, this specifies a reboot using the boot image stored on removable media instead of disk.

Output

The message: `Command successfully completed` indicates that the reset has been initiated. Execution and recovery can take several minutes.

reset system

reset system [level# | interchange] [disk | removable media] [contention-override]

CAUTION:
All system resets (except planned interchanges) are service affecting, with higher levels being increasingly destructive. Some resets may take up to one half hour to complete. Certain conditions may result in a higher reset level than the one requested. Unless you are experienced with resetting a system, follow normal escalation procedures.

NOTE:
reset system interchange, used to switch control of the system from an active SPE to the standby, is discussed separately under its own heading.

This command resets a Switch Processing Element (SPE) at a specified level that is increasingly disruptive as the reset level increases. *All system resets (except reset system interchange) are disruptive and terminate the G3-MT login.*

When the command is entered, the MSS devices are checked to see if they are currently in use. If any command or maintenance process that accesses the MSS is in progress, the reset is denied and a message is displayed. In this case, the **contention-override** option is required to force the reset. This check prevents aborting of a **save translation** or other MSS process.

If the vector bit is set to trigger a core dump for the specified reset level, a copy of system memory is first written to the primary MSS device. The system then clears the vector and proceeds with the request. If the vector is set for an active SPE core dump for reset level 1 a reset level 2 will be performed to recover the Packet Interface links. See the **get vector** command.

System software will generally not escalate a demand system reset to a higher level. There are certain conditions that result in a higher level reset than that requested. These include the following:

- The vector is set to trigger a core dump on the active SPE in the event of a level 1 reset.
- A PNC interchange is already in progress.
- A change in translation administration is in progress.

Reset levels greater than 1 turn off shadowing in a duplicated system, and leave the standby SPE in an unrefreshed condition for several minutes.

Parameters

Level Reset levels are numbered as shown in Table 8-8. The execution times listed are approximations.

Table 8-8. Approximate Recovery Time for System Resets (min:sec)

Level	Recovery	2,400 lines		5,000 lines		15,000 lines	
		R-Media	Disk	R-Media	Disk	R-Media	Disk
1	Warm Restart	:10	:10	:10	:10	:10	:10
2	Cold-2	1:00	1:00	2:00	2:00	4:00	4:00
3	Cold-1	3:00	2:00	5:00	3:00	11:00	7:00
4	Reboot	12:00	4:00	15:00	6:30	23:00	11:00
5	Extended Reboot	15:00	7:00	18:00	10:00	25:00	15:00

Interchange	See **reset system interchange**
Health-override	See **reset system interchange**
Disk	Valid only for reset level 4, this specifies use of the boot image stored on disk for the reboot. Disk is the default device.
R-Media	Valid only for reset level 4, this specifies use of the boot image stored on removable media for the reboot.
Contention-override	Contention control aborts the reset system command if any other command is currently running. The **contention-override** option forces other processes to abort, allowing the reset to proceed.

Examples

reset system 1
reset system 4 removable media contention-override

Output

Once this command is entered, it may not be canceled. The screen will display the results of various initialization tests. If the reset command is successful the user will be logged off (except for **reset system interchange**). Several conditions may prevent a requested reset. If the reset fails and the message displayed is not self-explanatory, use **status spe** to determine what caused the failure.

reset system interchange

reset system interchange [health-override][contention-override]

CAUTION:
Although this command is normally not disruptive, certain conditions may escalate the interchange to a higher reset level.

This command is used to switch control from the currently active SPE to the standby. This type of interchange is called a planned, soft, demand or requested interchange. Interchanges caused by hardware faults or the SPE-Select hardware switches are called spontaneous or hard interchanges. Planned interchanges are discussed under:

— SPE Duplication in Chapter 1, ‘‘Maintenance Architecture’’

— Executing a Planned Interchange in Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’

— STBY-SPE in Chapter 9

This operation is not disruptive if the state of health of the standby SPE is “functional.” If this condition is not met, system software will normally abort a requested interchange. When this is the case, the **health-override** option can be specified to try to force a *spontaneous* (hard) interchange.

CAUTION:
Use of health-override may cause serious service disruption.

Once a planned interchange has been initiated, it cannot be aborted with the CANCEL key. A **reset system interchange** command will abort for the following reasons:

- If the standby SPE is down
- If the SPEs are locked by means of the SPE-Select switches
- If communication to the standby SPE is not possible (handshake is down)
- If shadowing to the standby SPE is not turned on
- If the standby SPE is not fully refreshed

- If the State-of-Health of the standby is not “functional”
- There is an SCD dual-port RAM failure
- If there is any Mass Storage System activity
- If Packet Interface link migration fails
- If a minor or major alarm is logged against the standby SPE’s SYSAM or Packet Interface circuit packs
- If the standby SPE is busied out

The destructiveness of an interchange that fails depends on how far the interchange proceeds before it fails. A non-destructive recovery should occur if an interchange is aborted before link migration has started. If the interchange fails after link migration has started, the system will perform a WARM restart to recover.

The SPE-Select switches located on the Duplication Interface circuit packs override any demand maintenance activities. If the SPEs are locked by means of these hardware switches, an interchange cannot take place until the switches are unlocked.

If a planned interchange aborts or fails, an error will be logged against SYSTEM, signaling that the expected interchange has not occurred. In this case, the reset may be escalated by software. This condition is described in Failure of Planned Interchange in Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’.

If **reset system interchange override** is specified while a PNC interchange is occurring, a spontaneous (hard) SPE interchange will occur which results in a Cold restart. After the restart, the active PNC will be the one that was being switched into before the restart.

If a requested SPE interchange fails, an error conveying additional information about the failure will be logged against the SYSTEM maintenance object.

Parameters

health-override If a planned (demand) interchange fails for any of the previously listed reasons, this option can be specified to try to force a switch to occur. This option causes the active SPE’s state of health to be downgraded as much as possible in order to allow a spontaneous (hard) switch to occur. However, if the standby SPE’s state of health is still not better than that of the active, or if the SPEs are locked, the interchange will still not occur.

contention-override Due to contention control, **reset system interchange** aborts if any other command is currently running. Use of this option overrides contention control and forces the command to execute regardless of whether other commands are currently running.

Output

Once this command is entered, it may not be canceled. The screen will display the results of various initialization tests. Several conditions can prevent a requested interchange. If the interchange fails and the message displayed is not self-explanatory, use **status spe** to determine what caused the failure. Executing a Planned SPE Interchange in Chapter 5, "Alarms, Errors, and Troubleshooting" and STBY-SPE in Chapter 9 contain useful information for troubleshooting interchange failures, The following display shows a typical result when **reset sys int** is entered while a save operation is currently running.

```
reset system interchange                                SPE A

              Unable to interchange due to MSS activity.
```

reset removable media

reset removable media [C]

This command resets the removable media circuit pack, queries the device for ID, size and other information, initiates self testing of the device, and rewinds the removable media cartridge. If successful, all alarms active for the removable media device are cleared and the device is put back in service.

This command will abort if any other MSS operation has already begun.

Failure of the reset command will place the removable media in the uninstalled state, preventing all maintenance testing including demand testing of the failed removable media, as well as all system access to the failed removable media except for this reset command.

When the host-adapter is busied out, only the busyout and test commands are permitted on the removable media in that carrier. Reset, release, scheduled and periodic testing and other system software access are blocked. The host-adapter must be released before the removable media can be released.

When the host-adapter is taken out-of-service due to test failures, or fails a reset and becomes uninstalled, the removable media on the same carrier is also placed in the uninstalled state. All access to that removable media by system software, including maintenance tests, resets and other commands are blocked from execution.

Parameters

C The cabinet is always 1 and need not be entered. Carrier a or b must be specified only for systems with duplicated SPE.

Examples

Simplex SPE:	**reset removable-media**
Duplicated SPE:	**reset removable-media a**

For more information see "Common Output Fields" at the beginning of this chapter.

restore announcements

restore announcements [disk | removable-media]

This command copies stored announcement data from the specified MSS device to the announcement board. On a duplicated system, data is always copied from the device on the active SPE.

NOTE:
The restore command can take up to 40 minutes to complete. Avoid pressing the ENTER key on the keyboard during this time, since doing so will cause the result messages to be lost.

The command is not executed if any of the following conditions is present:

- An announcement data module and a system port data module have not been administered.
- The announcement data module port is out of service or already in use (for example, performing an announcement playback).
- An integrated announcements session is in progress or the circuit pack is currently being uploaded or downloaded. Announcements cannot be save or restored after the restore announcements command has started. Removable Media is specified and a removable media cartridge is not in the removable media drive.
- A system port is not available.
- The MSS is in use by either another user or by maintenance.
- An announcement file does not exist on the specified device, or is corrupted.

In case of a failure of the restore command, you must make sure the announcement file is completely copied to the announcement circuit pack. The system will continually attempt to download the circuit pack at 10 minute intervals until either a download is successful, announcements are recorded, or a download is initiated from the terminal. In case of a hardware or firmware error, an error will be logged, pointing to the source of trouble. Maintenance software will invoke tests to diagnose and attempt to correct the problem. If maintenance software fails to correct the problem, an alarm is raised.

If a system crash or spontaneous SPE interchange takes place, the restore operation will fail, leaving the announcement circuit pack without a valid announcement file. To remedy this, repeat the restore command on the newly active SPE.

NOTE:
Until announcements are completely copied to the announcement circuit pack, calls will not be connected to any announcements on the announcement circuit pack.

When the announcement circuit pack is inserted or reset, an automatic download of the announcement file is performed.

Parameters

disk	This specifies copying the announcement data stored on the disk device. Disk is the default device.
removable media	This specifies copying the announcement data stored on the removable media device.

Output

`Processor`	The SPE from whose MSS device the announcement data was copied.
`Command Completion Status`	This field indicates the results of the command execution an gives a self-explanatory reason for any failures.
`Error Code`	A number indicating whether the announcement file was successfully restored to the announcement board: 0 = The restore was successful. 1 = The restore failed.

The following display shows a typical result when **restore announcements** is entered.

```
restore announcements                          Page   1 of   1   SPE A

                       RESTORE ANNOUNCEMENTS

 Processor  Command Completion Status                Error Code

 SPE-A      Success                                      0
```

restore disk

restore disk **[active | standby] [spe-a | spe-b] [both | either] [incremental | full]**

This command copies all information from the removable media device in the specified SPE to the disk device on the same carrier. Defaults are a full restore and, if the SPE is duplicated, both SPEs.

NOTE:
The restore command can take up to 1 hour to complete. Avoid pressing the ENTER key on the keyboard during this time, since doing so will cause the result messages to be lost.

Parameters

spe-a This specifies a restore from the A carrier removable media device to the A carrier disk device.

spe-b This specifies a restore from the B carrier removable media device to the B carrier disk device.

active This specifies a restore on the active SPE.

standby This specifies a restore on the standby SPE.

both This specifies a restore on both SPEs. If the MSS on either SPE is inaccessible, the restore will abort on both SPEs.

either This specifies a restore on both SPEs. If the standby SPE is inaccessible, the active SPE only will be restored.

incremental	This specifies that all data on removable media marked “good” that has a date newer than the date on the disk be copied to the disk from the removable media.
full	This specifies that all data be copied to the disk regardless of the dates and the status of the data (e.g., “good” or “bad”).

Examples

restore disk
restore disk active incremental

Output

The outcomes are displayed for each SPE.

`Processor`	This identifies the processor carrier that was backed up (SPE-A or SPE-B).
`Command Completion Status`	This field displays one of various self-explanatory messages indicating the success or failure of the command.

The following display shows a typical result when **restore disk** is entered.

```
restore disk

                    RESTORE DISK

Processor     Command Completion Status

SPE-A         Success
SPE-B         Success

Command Successfully Completed
```

resume hardware-group

resume hardware-group

In the course of execution of a **test hardware-group** command, it may be desirable to halt the test temporarily or permanently. This is accomplished by either the **cancel hardware-group** command for a background test, or by pressing Cancel for a foreground test. **Resume hardware-group** enables you to restart the hardware group test at the point where it was canceled. This capability is not available if another hardware group test has been started. The status of a hardware group test can be obtained with **status hardware-group**.

When **test hardware-group all-ports** is canceled, the internally generated port translations for previously untranslated ports are removed. If **resume hardware-group** is then entered, only customer-administered ports will then be tested. **resume** does *not* reinstate the port translations that were removed by cancellation of the test.

Output

When a test that was executing in the background is resumed, a success message is displayed. When a test that was executing in the foreground is resumed, test results are displayed.

save announcements

save announcements **[active | standby | spe-a | spe-b | both | either] [disk | removable-media]**

CAUTION:
*Do not execute **save announcements** if there is an unresolved problem with the HOST-ADAPTR maintenance object. Save translations should not be done to a removable media or disk device with unresolved problems. Doing so may destroy a good copy of the files.*

CAUTION:
The option to save announcements to only one SPE in a duplicated system should be used with care since it causes two inconsistent versions to exist in storage.

CAUTION:
The save command can take up to 40 minutes to complete. Avoid pressing ENTER *during this time since doing so will cause the result messages to be lost.*

The save announcements command copies announcement data from the TN750B Integrated Announcement circuit pack to the Mass Storage System (MSS). Default devices are the disk in a disk/removable media system, and the devices in both SPEs in a duplicated system. Other options are available as described below.

Save announcements writes two identical copies of the announcement data to each specified device. Each copy bears the same time-stamp, (the time at which the first copy was written). Each copy is also marked with the state of the copy ("good" or "bad").

Execution of this command requires the presence of a TN750B circuit pack and an administered announcement data module and associated system port.

The command is disallowed or aborts if:

- An announcement data module and system port data module are not administered.
- The announcement data module port is out of service or already in use.
- No announcements are on the board.
- An integrated announcements session is in progress.
- The board is currently being uploaded or downloaded.
- The removable media drive is specified and no removable media cartridge is in the removable media drive or the removable media cartridge is write-protected.
- No system access port is available.
- The MSS is in use by another user or by maintenance.
- The specified device or SPE is not in service.
- The standby SPE is specified and shadowing is not enabled.

A user cannot record announcements while a save announcements command is in progress. However, 15 channels are still available for announcement playback (one is reserved for uploading and downloading).

When MSS devices on both SPEs in a duplicated system are specified, **save announcements** will save data from the announcement board to the active and standby devices in parallel. The status of each save operation is reported separately. If one save operation fails, the save to the other device continues. Thus, the data is not lost. In this case, announcement date is inconsistent between the two devices. In case of a failure due to hardware faults or spontaneous SPE interchange, the user must make the announcement files on the two MSS devices consistent.

If a hardware failure occurs during a save announcements operation, software will log a hardware error. Maintenance software will invoke tests to diagnose and attempt to correct the problem. If corrective action fails, an alarm is raised against the ANNOUNCE maintenance object. Follow procedures recommended under ANNOUNCE in Chapter 9.

If a good copy of the announcement file is not available on the MSS, the **restore announcements** command can not be executed until after a successful **save announcements** is completed. The announcements on the board are still accessible and usable.

Parameters

active	This option specifies writing to the specified device in the currently active SPE.
standby	This option specifies writing to the specified device in the standby SPE.
spe-a	This option specifies writing to the specified device in the SPE on the A carrier.
spe-b	This option specifies writing to the specified device in the SPE on the B carrier.
both	This option specifies writing to the specified device in each SPE concurrently. A failure in accessing either device causes the entire operation to fail and neither device is written to.
either	This option specifies writing to the specified device in both SPEs concurrently. If there is a failure in accessing one of the devices, the announcement data will still be written to the other one.
disk	This option specifies writing to the disk drive. Disk is the default device.
removable-media	This option specifies writing to the removable media drive.

Examples

save announcements
save announcements active disk
save announcements standby removable-media
save announcements spe-a disk

Output

`Processor`	The SPE(s) to which announcement data was written (SPE-A or SPE-B).
`Command Completion Status`	The result of command execution, with a self-explanatory message explaining any failure or abort.
`Error Code`	Each device holds two copies of the announcements file. This field indicates whether both copies on the device were successfully stored: 0 = save was successful 1 = unable to save to the active spe device 2 = unable to save to the standby spe device

The following display shows a typical result when **save announcements** is entered on a system with simplex SPE.

```
save announcements                                      Page   1 of   1   SPE A

                              SAVE ANNOUNCEMENTS

 Processor  Command Completion Status                Error Code

 SPE-A      Success                                       0
```

save translation

save translation **[active | standby | spe-a | spe-b | both | either] [disk | removable-media]**

NOTE:
The save command can take up to 15 minutes to complete. Avoid pressing the ENTER key on the keyboard during this time, since doing so will cause the result messages to be lost.

All translation data is kept in volatile system memory during normal operation. In the event of a power outage or certain system failures, data in memory is lost. The save translation command allows the user to store on disk or removable media the translation data currently in memory. This operation can be executed as part of scheduled background maintenance or on demand. The defaults are to save to disk and, on a system with duplicated SPEs, to both SPEs.

CAUTION:
Save translation should not be executed if there is an unresolved problem with the HOST-ADAPTR maintenance object. Save translations should not be done to a R-MEDIA or DISK device with unresolved problems. Doing so may destroy a good copy of the files.

CAUTION:
On systems with duplicated SPEs, the capability to save translation to only one SPE should be used with extreme caution since it results in the two SPEs having inconsistent translation data in storage.

The save translation cannot be executed if translation data is being changed by an administration command.

Parameters

spe-a	This specifies saving translation data to the MSS device on the SPE in carrier A only.
spe-b	This specifies saving translation data to the MSS device on the SPE in carrier B only.
active	This specifies saving translation data on the active SPE only.
standby	This specifies saving translation data on the standby SPE only.
both	This specifies saving translation data on both SPEs concurrently (the default). The command will fail if the specified device on either SPE is inaccessible, and neither device will be saved to.
either	This specifies saving translation data on both SPEs. If the standby is inaccessible, the save will still be done on the active SPE.
disk	This specifies saving translation data to the disk drive. Disk is the default device.
removable-media	This specifies saving translation data to the removable media drive.

Examples

save translation disk
save translation either removable-media

Output

Results are displayed for each SPE.

`Processor`	This identifies the SPE to which translation data was saved (SPE-A or SPE-B).

`Command Completion Status`	One of the following results is displayed:
	`Success`
	`Disk device is out of service`
	`Removable Media device is out of service`

The following display shows a typical result of entering **save translation** on a duplex system.

```
save translation

                         SAVE TRANSLATION

Processor     Command     Completion Status

SPE-A         Success
SPE-A         Success

Command Successfully Completed
```

set options

This command allows the user to administer whether certain alarms are reported to INADS or whether they are downgraded to a minor alarm, warning alarm, or no alarm.

Synopsis

set options

Permissions

The following default logins may execute this command: **inads, init**.

Examples

set options

Description

This special command enables the technician (that is, remote user with INADS permission) to select which types of maintenance categories report alarms automatically and which types require the customer to call in. Judicious use of this command can reduce the number of ineffective alarms to the TSC. For the **set options** command to be effective, the default settings specified in this section should always be used. These settings are not intended to be changed on a per-system basis. Special circumstances (for example, special studies) may require temporary changes under the guidance of Tiers 3 and 4.

NOTE: Alarms can't be upgraded.

Defaults

Initially, the alarm reporting options for On-board Trunk Alarms (Alarm Group 1), both Major and Minor, are set to “yes” (y); all others are set to “warning” (w). All trunk groups are associated with alarm severity group 1 by default.

Parameters

None.

Help Messages

If the user presses HELP after entering **set options**, the following message is displayed:

```
Entry is not required
```

Error Messages

If the command entered is in conflict with another currently executing command, then a message is displayed showing the login id of the conflicting user and the conflicting command. The message is as follows:

```
’login id’:’command’ has a command conflict
```

If during the execution of a command a resource problem occurs that requires the user to restart the command, then the following message is displayed:

```
Command resources busy;
Press CANCEL to clear, and then resubmit
```

If all of the available maintenance resources are currently in use, then the following message is displayed:

```
All maintenance resources busy; try again later
```

Form Input

After entering the command **set options**, the user is presented with the following form.

```
set options                                                   Page 1 of  8

                              ALARM REPORTING OPTIONS

                                                       Major  Minor
                          On-board Station Alarms:  w      w
                         Off-board Station Alarms:  w      w
            On-board Trunk Alarms (Alarm Group 1):  y      y
           Off-board Trunk Alarms (Alarm Group 1):  w      w
            On-board Trunk Alarms (Alarm Group 2):  w      w
           Off-board Trunk Alarms (Alarm Group 2):  w      w
            On-board Trunk Alarms (Alarm Group 3):  w      w
           Off-board Trunk Alarms (Alarm Group 3):  w      w
            On-board Trunk Alarms (Alarm Group 4):  w      w
           Off-board Trunk Alarms (Alarm Group 4):  w      w
                          On-board Adjunct Alarms:  w      w
                         Off-board Adjunct Alarms:  w      w
                             Off-board DS1 Alarms:  w      w
                        Off-board PGATE-PT Alarms:  w      w
                         Off-board Alarms (Other):  w      w
```

```
set options                                                     Page  2 of  8

                                 TRUNK GROUP ALARM OPTIONS
                                        (Alarm Group)

```

NOTE:
The remaining Trunk Group information is shown on the next 6 pages and is not documented in this Manual.

On the first page of the Alarm Reporting Options Form, the user selects the alarm severity options for station alarms, the four trunk alarm severity groups, the adjunct alarms, off-board DS1 alarms, off board PGATE-PT alarms, and other off-board alarms. On the second page, known as the Alarm Reporting Options Form, the user assigns an alarm severity group to each trunk group. This feature enables the technician to reduce the level of alarms reported for on-board or off-board trouble conditions.

The following alarm options are available:

- Minor

  Alarms are raised as maintenance testing discovers them but the severity of the alarm is downgraded to a minor. Alarmed resources that would have normally been taken out of service are still taken out of service. LEDs on the port board and maintenance board follow the normal Minor alarm LED strategy and there is a call to the receiving OSS.

- Warning

  Alarms are raised as maintenance testing discovers them, but the severity of the alarm is downgraded to a warning. The advantage to the technician here is that the Alarm Log can still be used to pinpoint trunk or station problems reported by the customer. Alarmed resources that would normally have been taken out-of-service are still taken out-of-service. Alarm LEDs light on the port circuit pack and Maintenance circuit pack as before, but no attendant LEDs or stations reporting alarms are affected. There is no call to INADS.

- Report

  This option treats the alarms in the same way as the warning category with one exception: alarms are reported to INADS using a special WARNING category. When an alarm of this type is received, INADS logs the occurrence and either creates a trouble ticket or closes it immediately. The retry strategy for a call of this type is similar to normal Major or Minor alarm reports. However, the acknowledgment LED on the attendant console or alarm reporting station does not reflect the status of the call.

- Yes

  Alarms are raised in the normal manner. There is no filtering of alarm data.

- No

  Alarms raised on a trunk, station, or adjunct in this category are dropped. Error information is provided as before, but there is no trace of an alarm. There is no LED activity and no call to INADS. Because resources are taken out-of-service without any record, this option is recommended only when other options do not provide the desired result.

The alarm options can be administered only on a system-wide basis for the following alarm categories:

- Major on-board station alarms
- Minor on-board station alarms
- Major off-board station alarms
- Minor off-board station alarms

Four alarm severity groups are provided for trunk alarms. You can administer the alarm options for the categories listed below in each alarm severity group. However, in G1, the alarm options can be administered only on a system-wide basis for the following categories:

- Major on-board trunk alarms
- Minor on-board trunk alarms
- Major off-board trunk alarms
- Minor off-board trunk alarms

For Adjuncts, an alarm severity option is assigned to each of the following categories:

- Major on-board adjunct alarms
- Major off-board adjunct alarms
- Minor on-board adjunct alarms
- Minor off-board adjunct alarms

You can also administer the options on a system-wide basis for Minor off-board DS1 Interface circuit pack alarms.

Alarm reporting options information in the Alarm Reporting Options Form is considered translation data and, thus, is preserved through all levels of restart.

This feature affects the alarming of the MOs listed below. Neither the trunk nor the station category applies to alarms raised on the common portion of the circuit pack.

In all cases, if the option associated with the alarm type is set to “n,” the alarm report is dropped. All error information about the alarm is intact, but there is no record of an alarm and no LEDs light on the port circuit pack, the Maintenance circuit pack, the attendant console, or alarm reporting station to indicate a problem.

If the option is set to “warning” or “report,” port circuit pack LEDs and LEDs on the Maintenance circuit pack are affected the same as normal warning alarms.

The default parameters are as follows:

- Downgrade all station, trunk (except on-board trunk alarms), and Minor DS1-BD alarms to warning alarms.
- On-board Major and Minor trunk alarms, should continue to raise alarms and report to INADS.

Station MOs Affected By This Command

NOTE:
Although alarms on these MOs may appear as warnings, the alarms should be investigated with user-reported problems.

- Analog Lines (ANL-LINE, ANL-NE-L, ANL-16-L)
- Digital Lines (DIG-LINE)
- Hybrid Lines (HYB-LINE)
- MET Lines (MET-LINE)
- ISDN-BRI Lines (BRI-PORT, BRI-SET)

Trunk maintenance is characterized by an escalation of a Minor alarm to a Major alarm if more than 75 percent of the members of the trunk group are alarmed. If the option for the trunk category is set to “warning,” “minor,” “report,” or “no,” this no longer happens. Maintenance removes an individual trunk member out-of-service according to the normal criteria used for Major and Minor alarms.

Trunk MOs Affected By This Command:

NOTE:
Although alarms on these MOs may appear as warnings, the alarms should be investigated with user-reported problems.

- Auxiliary Trunks (AUX-TRK)
- Central Office Trunks (CO-TRK)
- Direct Inward Dialing Trunks (DID-TRK)
- Direct Inward and Outward Dial Trunks (DIOD-TRK)[G1.2SE only]
- DS1 Central Office Trunks (CO-DS1)
- DS1 Direct Inward Dialing Trunks (DID-DS1)
- DS1 Tie Trunks (TIE-DS1)
- ISDN Trunks (ISDN-TRK)
- Tie Trunks (TIE-TRK)

Circuit Pack MOs Affected By This Command

NOTE:
Although alarms on these MOs may appear as warnings, the alarms should be investigated with user-reported problems.

NOTE:
Trunks that are not members of Trunk Groups, (e.g. PCOLs) are downgraded according to the alarm severity of group one.

- DS1 Interface Circuit Pack (DS1-BD)

Adjunct-Related MOs Affected by this Command

NOTE:
Although alarms on these MOs may appear as warnings, the alarms should be investigated with user-reported problems.

- ASAI Adjunct (ASAI-ADJ)
- Lucent Adjunct Port (ATT-PORT)
- Ethernet ASAI Port (LGATE-PT)
- Ethernet ASAI Adjunct (LGATE-AJ)
- Ethernet Lucent Port (ATTE-PT)
- Ethernet Lucent Adjunct (ATTE_AJ)
- ISDN-BRI Ports connected to Adjuncts (ABRI-PORT)

Although adjuncts are administered as stations, the administration of alarm severity for the station alarm group does not affect the alarm severity levels of the adjuncts. Similarly, the administration of alarm severity for the adjunct alarm group does not affect the alarm severity levels for other types of stations.

PGATE-PT and associated Link MOs Affected by this Command

NOTE:
Although alarms on these MOs may appear as warnings, the alarms should be investigated with user-related problems.

- *See* Packet Gateway Port (PGATE-PT) *for other Link associated MOs affected by this Command*

NOTE:
Although alarms on these MOs may appear as warnings, the alarms should be investigated with user-related problems.

- EPN Maintenance Circuit Pack (MAINT)

- Expansion Interface (EXP-INTF)
- ISDN-PRI Signaling Group (ISN-SGR)
- Journal Printer (JNL-PRNT)
- PMS Link (PMS-LINK)
- PMS log printer (PMS-LOG)
- Primary CDR Link (PRI-CDR)
- Secondary CDR Link (SEC-CDR)
- SPE Select Switches (SPE-SELEC)
- Synchronization (SYNC)
- Packet Gateway Port (PGATE-PT)
- System Printer (SYS-PRNT)
- TDM Clock (TDM-CLK)
- Tone Generator Circuit Pack (TONE-BD)

Field Help

Since all fields on the first page may have the same values, then pressing HELP in any field on the first page presents the following field help message:

```
m(inor) n(o) r(eport) w(arning) y(es)
```

The following is a description of the values:

`m(inor)`	Downgrade the major alarm to a minor alarm and report the alarm to INADS.
`n(o)`	Do not log the alarm or report it to INADS.
`r(eport)`	Downgrade the alarm to a warning and report the warning to INADS.
`w(arning)`	Downgrade the alarm to a warning, log it but do not report the alarm to INADS.
`y(es)`	Log and report the alarm to INADS.

All fields on page 2 may have the same values. Pressing HELP in any field on page 2 gives the following field help message:

```
Enter alarm group number: 1 to 4
```

The alarm group number is a way of distinguishing four different groups of alarms. These alarm groups allow the user to specify that alarms in different groups are handled differently from those in other groups.

Field Error Messages

All of the fields on the first page allow the same values. Only one error message is printed for all first page fields. If the value is not one of the listed characters (m,n,r,w,or y) then the following message is displayed:

`“X” is an invalid entry; please press HELP key`

All of the fields on page 2 allow the same values. If the value in one of these fields is not numeric, the following message is displayed:

`Entry must be all digits`

All of the fields on pages page 2 allow the same values. If the value in one of these fields is a digit other than 1, 2, 3, or 4, the following message is displayed:

`Entry out of range`

Output

After the user has entered in the changes to the options and pressed SUBMIT, the following message appears at the bottom of the screen:

`Command successfully completed`

Feature Interactions

None.

set pnc

set pnc lock | unlock

On Critical Reliability systems (duplicated PNC), **set pnc lock** locks the active port network connectivity in the active state. PNC interchanges will be prevented and the active port network connectivity will remain active regardless of its state of health. Duplicate call setup will still take place, though the standby is not available for service. This condition can also be initiated by the **reset pnc interchange override-and-lock** command. You can tell if the PNC is locked by looking at the `Software Locked?` field on the **status pnc** screen. (The `Interchange Disabled?` field refers to the antithrashing mechanism.)

Set pnc unlock releases the lock and enables subsequent interchanges to take place.

If the health of the active pnc has degraded to worse than that of the standby pnc, unlocking the active port network connectivity can cause an immediate PNC interchange This condition can be foreseen by use of **status pnc**.

System restarts remove a PNC lock.

CAUTION:
If the active PNC experiences problems while in the locked state, service disruptions may occur that would ordinarily be avoided by PNC interchange.

Parameters

lock PNC interchanges will be prevented, and the active port network connectivity will be locked on-line.

unlock Releases the PNC lock.

set signaling-group

set signaling-group group#

The set signaling-group command sets the secondary D-Channel in the specified signaling group to be the primary D-Channel. The primary D-Channel becomes the secondary D-Channel. A signaling group is a collection of B-channels signaled for by a designated single D-channel or set of D-channels over an ISDN-PRI link.

Parameters

group# The signaling group identifier is an administered number assigned to each signaling group.

set snc

set snc UUCSS [override]

This command sets which switch node clock (SNC) circuit pack in a given switch node carrier is active.

NOTE:
This command is valid only on a High Reliability system with a Center Stage Switch (duplicated SPE, simplex PNC). In this configuration, SNCs are duplicated on each switch node carrier.

Parameters

override This qualifier will force execution of the set command regardless of the health of the standby SNC circuit pack.

set synchronization

This command sets a specific DS1 trunk, tone-clock circuit pack, or ATM switch as the reference source for system synchronization signals. It is permitted only after synchronization has been disabled with **disable synch**. Any administered DS1 trunk or *active* tone-clock may be entered with the set command. The DS1 or tone-clock will remain the synchronization reference until either the set command specifies another circuit pack, or **enable synchronization** is entered.

After an **enable synchronization**, the administered primary or secondary synchronization source will become the synchronization reference. If no primary or secondary source is administered, the active tone-clock is used as the synchronization reference.

NOTE:
This command is not supported when ATM-PNC is enabled.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set synchronization	***print***		init inads craft	none	none

set tdm

set tdm port-network PN# bus a | b [override]

This command determines which of the paired TDM buses (A or B) on a port network will carry the control channel and dedicated tone time slots. Each port network has a 512 time-slot TDM bus configured as two separate 256 time-slot buses. This division allows for duplication of control channels and time slots dedicated for use by system tones. On power-up, the control channel is carried on the A bus, and the tone time slots are carried on the B bus. Execution of this command puts both the control channel and the tone time slots on the specified bus.

Under extremely heavy traffic load, tone time slots on the bus that is not currently carrying the tones may be used for call processing. Use of the override command under these conditions will cause calls to be dropped.

See TDM-BUS in Chapter 9 for details.

Parameters

PN#	The Port Network number of the TDM bus to be set. **List cabinet** displays port network numbers for a given cabinet.
bus	One of the paired TDM buses, a or b.
override	This option forces the setting of a bus which is out of service or a bus whose dedicated tone time slots are in use by call processing.

CAUTION:
Use of this option disrupts service.

Examples

set tdm port-network 2 bus a

set time

set time

This command brings up a form showing the current day, date, month, year and time kept by the system clock. These entries can be edited to update the system time. The second field is set to zero whenever the time on the clock is altered. If no new entries are made, system time remains unchanged.

Input Form

An input form with the following fields is displayed. The current time, or default time will be displayed in the fields.

`Day of the Week:`	Valid entries are Monday through Sunday.
`Day of the Month:`	1-31 are valid entries. A check for leap year is also made.
`Month:`	January through December.
`Year:`	The year must be saved as translation data and passed to the kernel whenever kernel memory is corrupted (system reboot or cold I restart), or the data is changed.
`Hour:`	0-23 are valid entries.
`Minute:`	0-59 are valid entries.
`Second:`	This field is reset automatically and cannot be altered.

```
set time                                                    Page 1 of 1
                              DATE AND TIME
        DATE

            Day of the Week: _________      Month: _________
           Day of the Month: __              Year: ____

        TIME
                       Hour: __            Second:
                     Minute: __
```

set tone-clock

set tone-clock UUC [override]

On port networks with duplicated Tone-Clocks, this command is used to select which of the two Tone-Clock circuit packs is to be active.

In EPNs, the A-carrier Tone Clock is the *preferred* Tone-Clock. It is always active unless a failure, maintenance testing, or use of this set command has caused an interchange to the B-carrier Tone-Clock. If you have used this command during a maintenance session, set the EPN Tone-Clock back to the A carrier when you are finished, assuming it is healthy. Tone-Clock interchanges executed by scheduled daily maintenance cause the standby to become active for 20 seconds and then interchange back to whichever Tone-Clock was originally active.

Cabinet number defaults to 1.

Parameters

override This qualifier forces execution of the set command regardless of the health of the Tone-Clock circuit pack.

CAUTION:
Use of this option is destructive to an entire port network for EPNs and for the entire system for PPN Tone-Clocks.

Examples

set tone-clock 01c override
set tone-clock a

set vector

set vector reset-level# [spe-standby | spe-active | spe-maint | spe-smm]

The set vector command specifies the reset levels which will activate a core dump. When a designated reset occurs, a current copy of the system's memory is stored on the disk device, allowing the information to be examined later for troubleshooting purposes.

To force an immediate core dump, set the appropriate bit using this command and then execute **reset system** of the corresponding level, *but* be aware of possible disruption as a result of the reset.

CAUTION:
Note that level 1 (WARM) resets may result in a more destructive level 2 (COLD2) reset for certain settings of the vector.

CAUTION:
Service is disrupted whenever an active SPE is performing a core dump.

Execution

The following actions are taken in response to the vector settings listed below when a designated reset takes place. In all cases after a core dump has been performed, the vector will be cleared.

Simplex SPE

When a system restart occurs on a system with simplex (SPE) with the corresponding vector bit set, the core dump is written to the primary MSS device. Once the core dump is written, the vector is cleared and the restart is performed. When a WARM restart (reset system 1) is performed and the vector is set for WARM restarts, a COLDII is executed after the WARM restart in order to recover the packet interface circuit pack. Packet interface recovery is necessary due to delays of writing the core dump.

Duplicated SPE Options

spe-active The active SPE will perform a core dump. When a WARM restart (reset system 1) is performed and the vector is set for WARM restarts, a COLDII is executed after the WARM restart in order to recover the packet interface circuit pack. This packet interface recovery is necessary due to the delays of writing the core dump

spe-standby The standby SPE will perform a core dump after its memory has been refreshed. When a WARM restart (reset system 1) is performed and the vector is set for WARM restarts, a COLDII is executed after the WARM restart in order to recover the packet interface circuit pack. This packet interface recovery is necessary due to the delays of refreshing the standby processor.

spe-maint The standby SPE will perform a core dump without refreshing its memory first. This option is the default on a duplicated system.

spe-smm The standby SPE will perform a core dump. This allows a dump of the Standby Maintenance Monitor (SMM) when the standby SPE is experiencing problems. If an interchange occurs after the standby (spe-smm) SPE vector has been set, a core dump will not be performed on either the new active SPE or the new standby SPE regardless of the level of restart that occurs. However, if another interchange occurs making the new active SPE the standby SPE once again, a core dump on the standby SPE will occur if the standby restarts at the appropriate level.

Feature Interactions

In a simplex SPE system, service will be disrupted while a core dump is being written to the primary Mass Storage System device. In addition, service will continue to be disrupted until the software is restarted at an appropriate level. These “disruption” times will vary depending upon the particular switch configuration.

If a core dump file already exists, a subsequent core dump will overwrite it.

If the disk is not accessible, a core dump cannot be executed.

A core dump file can overwrite other files on removable media. Caution must be exercised when generating a core dump on removable media.

The vector will be cleared when a system restart of the proper level is performed regardless of whether the core is actually dumped.

If handshake is down in a duplicated system, while spe-active, spe-standby, or spe-maint is set, the active vector will be set, but the standby vector will retain its former value. This could lead to different vectors on the active and standby SPEs. **Set vector** should be reentered after handshake is back up. (Setting spe-smm while handshake is down returns an error message.) If handshake is up, the selected vector (active or standby) will be set and the other cleared.

If an interchange occurs after the spe-smm vector has been set, a subsequent restart will not trigger a core dump. However, if *another* interchange occurs, a core dump on the standby SPE will take place in response to a reset of the appropriate level on the standby.

Parameters

condition A hexadecimal value representing the combination of reset levels (1= warm restart, 2= cold-2 restart, 3=cold-1 restart, and 4=reboot) that are enabled to initiate a core dump, as illustrated in the following table.

Vector Value	Reset Levels	Vector Value	Reset Levels
0	none	8	4
1	1	9	1, 4
2	2	a	2, 4
3	1, 2	b	1, 2, 4
4	3	c	3, 4
5	1, 3	d	1, 3, 4
6	2, 3	e	2, 3, 4
7	1, 2, 3	f	1, 2, 3, 4

spe-standby This is the default for duplicated systems. If a restart of a designated level occurs on the active SPE and the corresponding vector bit is set, a core dump will be taken on the standby SPE after the standby SPE has performed a refresh of memory.

spe-active On duplicated systems, a restart on the active SPE will cause a core dump to be taken on the active SPE.

CAUTION:
*A core dump performed with the **spe-active** option causes a service disruption.*

spe-maint	On a duplicated system, if a restart of a designated level occurs on the active SPE, a core dump will be taken on the standby SPE without a refresh of its memory first.
spe-smm	On a duplicated system, if a restart of a designated level occurs on the standby SPE, a core dump will be taken on the standby SPE. This can be useful to debug Standby Maintenance Monitor (SMM) problems.

status access-endpoint

status access-endpoint extension [print]

This command displays the operational of a non-signaling port on a DS1 interface or on an analog tie trunk circuit pack.

Output

`Extension`	The extension number of the specified port.
`Port`	The physical location (cabinet-carrier-slot-circuit) of the port.
`Communication Type`	The type of communication supported by the channel: 56k-data, 64k-data, or voice-band-data.
`Service State`	The operational status of the access-endpoint channel: in-service/idle, out-of-service, maintenance-busy or disconnected.
`Connected Ports`	The location of any facility/endpoint to which this access-endpoint is connected.

The following display shows a typical result when **status access-endpoint 2300** is entered.

```
status access-endpoint 2300                                   SPE A

                 ACCESS END-POINT STATUS

                    Extension: 2300
                         Port: 02B0905
           Communication Type: 56k-data

                Service State: disconnected

              Connected Ports:
```

status administered-connection

status administered-connection adm-conn# [print]

This commands displays the operational status of an administered connection. To view administrative information for administered connections, use **list administered-connection** and **display administered-connection**.

Parameters

adm-conn#	The number (1-128) of the administered connection as assigned during administration.

Output

`Connection Number:`	The number assigned to the administered connection.
`Enabled?`	Whether the administered connection is enabled.
`Originator:`	The extension of the access or data endpoint that originates the connection.
`Destination:`	The destination address used to route the administered connection.
`Connection State:`	The current status of the administered connection as follows: `connected` = A connection between the originating and destination endpoints is currently active. `restored` = The connection has been restored. The session may or may not have been preserved. `failed` = The connection failed due to either an administrative error such as a wrong number or a service-blocking condition such as barring of outgoing calls. Recovering from such a failure requires manual intervention. No further attempt is made by the system to re-establish the administered connection until the **change administered- connection** command is executed. If the failure was caused by a transient condition, you may be able to re-establish the connection by first disabling and then enabling the connection via the “Enable?” field on the **change administered connection** form. (The **enable admin** and **disable admin** *commands* affect only maintenance processes).

`Connection State:` *(cont'd.)*	The cause of the failure is reported as an ISDN cause value that is recorded in the error log. Refer to the Hardware Error Log Table for ADM-CONN in Chapter 9 to identify failure causes. `waiting to retry` = The system is waiting between attempts to restore the connection. The amount of time between attempts to restore is administered on the administered connections form. Check the contents of the Failure Cause field for information about why the administered connection failed. `attempting to connect/attempting to restore` = These are transitional states during which an attempt is made to connect or restore the administered connection. If an administered connection remains in this state for longer than 1 minute, disable and then re-enable the connection. If the problem still persists, or if the administered connection has retried a number of times with `administered connection origination attempt timed out` reported in the Failure Cause field, then make sure that the originating data module is connected and the destination access endpoint is not out-of-service. `not scheduled` = The administered connection is enabled but is not scheduled to be active at the current time.
`Failure Cause:`	This field displays a self-explanatory message indicating the reason for a current state of `attempting to connect`, `attempting to restore`, or `failed`. If the administered connection should be active but is not connected, then this field shows the most recent reason for failure. See also the above description of "Connection State: failed."
`Number of Retries:`	The number of consecutive failed attempts to establish the connection.
`Auto Restorable?`	When an administered connection fails, the system can automatically attempt to restore the connection. This field indicates whether this capability is activated on the administered connections administration form.

The following display shows a typical result when **status administered-conn 3** is entered. In this example, destination is another switch, and the destination number consists of a trunk access code (512) and extension (26001).

```
status administered-connection 3                    page 1 of 1

                ADMINISTERED-CONNECTION STATUS

                Connection Number: 3
                          Enabled? y
                       Originator: 71001
                      Destination: 51226001

                 Connection State: connected
                    Failure Cause:
                Number of Retries:
                  Auto Restorable? y
```

status attendant

status attendant console# [print]

The status attendant command displays the operational state of the specified attendant console. This information can help in trouble diagnosis and in locating facilities to which the attendant console is connected.

status bri-port

status bri-port UUCSSpp [print]

The status bri-port command displays the service state, maintenance state and layer 1 state of an ISDN-BRI port. Also displayed on this form is information on the point-to-point signaling links carried over the port. For more information, see BRI-PORT in Chapter 9, “Maintenance Object Repair Procedures”.

Output

An extra section describing how to interpret the results of this command follows the screen display.

`Port`	The location of the ISDN-BRI port.
`Service State`	Whether the ISDN-BRI port is ‘‘in-service’’ or ‘‘out-of-service.’’
`Maintenance Busy?`	Whether maintenance testing is currently being performed on the port.

`Layer 1 State`	The operational state of the physical connection (Layer 1) of the ISDN link carried over the port: `activated` = Layer 1 frames are being passed between the port and BRI endpoints. `pend-activation` = The port is in service, the layer 1 interface device is turned on and layer 1 frames are being sent from the port, but the BRI endpoints are not responding. `deactivated` = The layer 1 interface device on the BRI has been turned off due to the port being out of service.
`TEI Value`	The Terminal Endpoint Identifier (TEI) is a layer 2 addressing parameter used by the switch to exchange information with BRI endpoints over the point-to-point signaling link. The TEI is a number from 1 to 127.
`Layer2 State`	The operational state of the point-to-point signaling link (Layer 2): `assigned` = The link is currently in the AWAIT_EST (Await Establish) state at layer 2. If the BRI endpoint supports TEI allocation procedures, those procedures have been successfully executed and a TEI has been assigned to the endpoint by the switch. `established` = The link is in the MF_EST_NORM (Multi-Frame Established Normal) state at layer 2. The switch has successfully started the link and is now capable of exchanging layer 3 frames with the endpoint. If the endpoint does not support SPID initialization procedures, the voice extension of the endpoint associated with the link is also displayed. This is the normal state for a link in a point-to-point wiring configuration. `L3-established` = The link is in the MF_EST_NORM state at layer 2 and SPID initialization procedures have been successfully completed. The voice extension of the endpoint associated with the link is also displayed. This is the normal state for a link in a multi-point wiring configuration. `hyperactive` = Traffic on this link has exceeded the threshold and the link has been suspended.
`Endpt Extension`	The extension of the voice/data endpoint associated with the link. This field is blank if the link is not in the `established` or `L3-established` state.
`Endpt SPID`	The SPID (Service Profile Identifier) administered for the voice/data endpoint. This field is blank if the link is not in the `established` or `L3-established` state.
`Service SPID?`	If the link is associated with the Service SPID this field displays `yes` and the Endpoint Extension field is blank. Otherwise this field is blank. Service SPID is a feature used by service technicians to check building wiring between the switch and the BRI endpoint.

The following display shows a typical result when **status bri-port** is entered.

Table 8-9. Interpreting BRI-Port Status Reports

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
ASAI, BRI	0-126	Assigned	blank	blank	This is a transitory state for BRI endpoints and ASAI adjuncts. The switch is attempting to establish the link. 1. Check the endpoint and wiring by following the SPID Facility Test Procedure described in the BRI-SET section of Chapter 9. 2. Repeat **status bri-port** to determine that the Layer 2 state of the signaling link is either `L3-Established` (for ASAI adjuncts and BRI endpoints supporting MIM initialization) or `Established` (for fixed TEI BRI endpoints and automatic TEI BRI endpoints not supporting MIM initialization). If it is not, follow normal escalation procedures. (A MIM or management information message is a level-3 message that conveys management and maintenance information between a communications system and a BRI terminal.)
ASAI	0-63	Established	blank	blank	This is a transitory state for ASAI adjuncts. ASAI signaling is connected at Layer 2 but the Layer 3 Restart procedure has not been completed between switch and adjunct. 1. Check the adjunct by following the recommended repair procedures of the manufacturer. 2. Repeat **status bri-port** and determine whether the L2 state of the signaling link is L3-Established. If it is not, follow normal escalation procedures.
BRI	0-126	Established	ext#	blank	This is the normal state for non-MIM initializing, fixed, and automatic TEI BRI endpoints.

Continued on next page

Table 8-9. Interpreting BRI-Port Status Reports — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
BRI, ASAI	64-126	Established	blank	blank	This is a transitory state for automatic TEI BRI endpoints that support MIM initialization. 1. Verify that SPID administration on the switch and the endpoint are consistent. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. 2. Try replacing the endpoint. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, follow normal escalation procedures.
BRI	64-126	L3-Established	ext#	blank	This is the normal state for automatic TEI BRI endpoints that support MIM initialization.
BRI, ASAI	64-126	L3-Established	blank	yes	A demand SPID Facility Test is in progress on the port, and the link is not currently associated with a BRI endpoint. See SPID Facility Test Procedures described in the BRI-SET section of Chapter 9, "Maintenance Object Repair Procedures".
BRI	64-126	L3-Established	ext#	yes	A demand SPID Facility Test is in progress on the port, and the link is associated with an endpoint on the port. See SPID Facility Test Procedures described in the BRI-SET section of Chapter 9.
BRI	0-126	L3-Established	blank	blank	An invalid SPID is assigned to link. 1. Change the SPID value in the BRI endpoint to match the SPID administered to the BRI endpoint on the port. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, follow normal escalation procedures.

Continued on next page

Table 8-9. Interpreting BRI-Port Status Reports — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
BRI	0-126	L3-Assigned	ext#	blank	This is a transitory state for BRI endpoints that support MIM initialization. 1. Wait 5 seconds and repeat the command. If the state has not changed, continue with Step 2. 2. Make sure SPID administration on the switch and endpoint are consistent. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, go to Step 3. 3. Try replacing the endpoint. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, follow normal escalation procedures.
BRI	0-126	L3-Assigned	ext#	yes	This is a transitory state for BRI endpoints that support MIM initialization when a SPID Facility Test has been used to initialize the station. 1. Wait 5 seconds and repeat the command. If the state has not changed continue with Step 2. 2. Make sure SPID administration on the switch and endpoints are consistent. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, go to Step 3. 3. Try replacing the endpoint. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, follow normal escalation procedures.

Continued on next page

Table 8-9. Interpreting BRI-Port Status Reports — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
ASAI BRI	0-126	Hyperactive	ignore	ignore	Link has sent too many messages per unit time. Signaling has been suspended. After 60 seconds, the system attempts to put the link into service. If a link remains in this state while there is no activity at the BRI endpoint, take the following steps: 1. Make sure SPID administration on the switch and endpoints are consistent. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, go to Step 2. 2. Try replacing the endpoint. Repeat **status bri-port** to determine whether the Layer 2 state of the signaling link is `L3-Established`. If it is not, follow normal escalation procedures.
ASAI	0-126	L3-Restarting	ext#		The switch has sent a Restart message to the adjunct but has not yet received a Restart Acknowledgment message from the adjunct.
ASAI	0-126	L3-Restarted	ext#		After receiving a Restart Acknowledgment message, the switch has sent a Heartbeat message to the adjunct and is waiting for a response.
ASAI	0-126	L3-Established	ext#		This is the normal state for ASAI adjunct.

Interpreting Results of BRI-Port Status Reports

Table 8-9 will help to interpret results of the **status bri-port** command. Find the combination of output field values contained in your report and follow the recommendations for the type of endpoint connected to the portStatus Cabinet

status cabinet UU [print]

This command displays the operational status and attributes of the specified cabinet. The output screen displays configuration information for each carrier, connectivity and alarm information for each port network or switch node, and the emergency transfer status of the cabinet.

The cabinet number defaults to 1.

Output

Carrier Location	The cabinet number and carrier letter of each carrier in the cabinet.
`PN/SN Number`	The Port Network number (1-22) or Switch Node number (1 or 2) of the indicated carrier.
`Carrier Type`	The type of the indicated carrier: processor, port, expansion-control, switch-node, dup-sw-node or not-used.
`Cabinet Type`	One of the following types: MCC Multicarrier cabinet SCC Single carrier cabinet S75XE System 75 (pre-R1V4) single carrier XE cabinet blank The cabinet type could not be determined.

`PN/SN`	Each Port Network and Switch Node located in the cabinet is identified by its PN number or its SN number and PNC designation (A or B).
`Connectivity Status`	**For PNs** connectivity status refers to the availability of the Expansion Archangel Link (EAL) and Indirect Neighbor Link (INL) to the carrier for both active and standby PNCs (if duplicated). Possible values are: up EAL and INL are both available. downEAL and INL are both unavailable. near-endThe EAL is available and the INL is unavailable. far-endThe INL is available and the EAL is unavailable. blankIn the standby column, this means PNC is not duplicated. **For SNs** connectivity status indicates circuit pack insertion on the Switch Node as follows: up At least one switch node interface circuit pack in the Switch Node is inserted. downThere are no switch node interface circuit packs inserted on the Switch Node. blankIn the active column, this indicates that the Switch Node carrier is currently the standby in a critical reliability system. In the standby column, this indicates that the Switch Node carrier is currently active (whether or not PNC is duplicated).
`Emergency Transfer`	The location of the circuit pack containing the emergency transfer select switch (EPN maintenance or SYSAM). In PPN cabinets with duplicated SPEs, there are two such circuit packs. In this case, if the standby Emergency Transfer Select switch is changed while handshake is down, switch setting displayed will be incorrect until handshake comes back up.
`Select Switch`	The current setting of the emergency transfer switch: on Emergency transfer has been manually activated. off Emergency transfer is being manually prevented. auto+ The cabinet is controlling emergency transfer and it is currently activated. auto- The cabinet is controlling emergency transfer it is not currently activated. unavail The current setting of the emergency transfer switch is not available.
`PN/SN`	Each Port Network and Switch Node located in the cabinet is identified by its PN number or its SN number and PNC designation (A or B).
`Mj, Mn, Wn`	The number of major, minor and warning alarms currently logged against the Port Network or Switch Node.

The following display shows a typical result when **status cabinet 1**is entered.

```
status cabinet 1

CABINET CONFIGURATION STATUS              CABINET CONNECTIVITY STATUS

Carrier   PN/SN  Carrier      Cabinet  PN/SN      Connectivity Status
Location  Number Type         Type                  Active     Standby

01A       PN 1   processor    MCC      PN 1           up         up
01B       PN 1   processor             SN 1  B-PNC               up
01C       PN 1   port                  SN 1  A-PNC    up
01D       SN 1   dup-sw-node
01E       SN 1   switch-node

CABINET EMERGENCY TRANSFER               CABINET ALARM STATUS

```

status cdr-link

status cdr-link [print]

The status cdr-link command displays the status of the call detail recording (CDR) links. If a link is down, the report includes the number of times the switch has tried to re-establish the link.

The CDR link is the physical link that the SPE uses to send call detail records to an output device such as a Call Detail Recording Utility (CDRU). CDR links use System Ports which are described in the PDATA-PT section of Chapter 9. A system may have up to two CDR links, a primary and a secondary. See PRI-CDR in Chapter 9.

Output

The following information is displayed for both the Primary and Secondary CDR links, whether or not both are used.

`Link State`	The operational status of the link as follows: up The link is established and is capable of supporting the application. This is the normal operational state. down The link is physically down. `extension not administered` An extension number for the output device has not been assigned on the CDR system parameters form.
`Number of Retries`	The number of times the switch has tried to set up the link.
`Maintenance Busy`	Whether the link is busied out for testing.

The following is an example of the fields contained on the output form.

```
status cdr-link                                          SPE A

                          CDR LINK STATUS

                   Primary                 Secondary

      Links state: up                      extension not administered

 Maintenance Busy? no
```

status cleared-alarm-notif

This command returns the status of `Cleared Alarm Notification`.

Synopsis

status cleared-alarm-notif [1 **|** 2]

Examples

status cleared-alarm-notif
status cleared-alarm-notif 1
status cleared alarm-notif 2

Description

This command is intended to be used by Expert System to detect a chronic alarming condition. If this command returns `Feature is suspended`, Expert System can then identify an open trouble ticket as a chronic problem for special considerations.

Defaults

The test defaults to return the status of Cleared Alarm Notification of the first OSS telephone number.

Parameter

1 This option returns the status of Cleared Alarm Notification of the first OSS telephone number.

2 This option returns the status of Cleared Alarm Notification of the second OSS telephone number.

Help Messages

`['1' or '2']`

Output

The command returns one of the following messages:

1. If Cleared Alarm Notification is enabled and has not been suspended:

   `Feature is enabled`

2. If Cleared Alarm Notification is disabled:

   `Feature is disabled`

3. If Cleared Alarm Notification is enabled and has been suspended:

   `Feature is suspended`

Feature Interactions

None.

status conference

This command is a troubleshooting aid to help identify problems with a multimedia conference and can help solve more complex problems.

Synopsis

The first screen appears when **status conference** is entered and at least 1 valid conference is found.

Permissions

The following default logins may execute this command: system technician, inads, init.

Examples

status conference
status conference 2 print
status conference [all \ conference-ID] [print \ schedule]
status conference [all \ conference-ID] [endpoint \ endpoint id]
(see "Field Descriptions (status conference endpoint)" on page 8-256)

Description

Use the **status conference** command to solve the following multimedia problems:

1. A user unable to join or remain joined to a conference.
2. A conference having poor video quality due to it being downgraded because of the automatic algorithms - audio AUTO mode and the Px64 video picture specifications.
3. A user not receiving full service, such as being an audio-only endpoint (no video).
4. An audio add-on user unable to join or remain joined to a conference.
5. A conferee not being seen by other users due to interworking problems.
6. A user not able to participate in the Muiltpoint Communications Service conference.
7. A continuous conference not switching endpoints in or out of quadrants.

Defaults

The default for the conference-ID is **all** (all stored data).

Parameters

status conference	Displays all stored conference data.
status conference 2 print	Displays data on conference 2 (current or last completed), and sends it to the SAT printer.

Feature Interactions

None.

Output

Depending on the command entered, it is possible to have many records display. Active conferences display first (in order of conference-ID), followed by completed conferences (most recently completed first). There is no data or information about conferences not yet begun.

The data for each conference displays in 2 parts: the first screen describes the status of the conference and indicates the modes and levels of the conference. It also shows certain endpoint information such as which endpoints are in use and which endpoint caused the conference operating mode to change. This screen is similar to the administration screens. The remainder of the screens display endpoint level data (up to 8 endpoints per screen), displaying the ports and drop reasons.

Screen 8-6 shows page 1 of a typical administration screen. The first screen appears when **status conference** is entered and at least 1 valid conference is found.

```

sddfsoc KLC 010397

Screen 8-6. status conference: page 1 of 2

Field Descriptions (status conference, page 1)

`status`	The current status of the conference - `active, in-use, complete`
`conference name`	Always set as `MMCH DYNAMIC`
`conference mode`	Always set as `voice-activated`
`password`	Not Applicable
`password scope`	Not Applicable
`cascade mode`	Conference cascade mode - blank
`audio mode`	The current operating audio mode - `G.711-A, G.711-mu, G.728. G.722`

`class`	The type of conference - `dedicated`
`data mode`	Data mode capability for this conference - `none, any-mlp, ww-pcs`
`MLP rate`	MLP Data Rate for this conference - blank.
`start time/date`	Conference start time in 24-hour notation with month and day.
`stop time/date`	End of conference in 24-hour notation with month and day. It is the actual end time if `Status` is `complete`; otherwise it is blank.
`admin bandwidth`	The channel bandwidth as administered on the Conference Record form - `64k`.
`no of channels`	The number of channels (transfer rate) required for each Px64 endpoint - 2.
`Chair`	Identifies the current chair token holder. This field is always blank.
`conf bandwidth`	The current operating channel conference bandwidth. This can be different from the administered bandwidth because of Rate Adaptation.
`Rate adaptation`	Does this conference support Rate Adaptation? - n, y.
`Format (in/out)`	For single-screen conference, the video format of the conference, `CIF`, `QCIF, QCIF/CIF, H.CTS, H.CTX+`, and `SG4`. For conferences other than H.261, the input and output formats are always symmetric and the mode is the same for input and output. These display as H.CTX, H.CTX+, and SG4. For H.261 mode non-continuous presence conferences, the format is always symmetric and displays as CIF and QCIF. The same is true for the non-presentation, continuous presence conference in single-screen. For presentation mode H.261 single screen continuous presence capable conferences, the input and output formats may be symmetric QCIF/CIF (displayed as CIF) or asymmetric QCIF/CIF, depending on if the format is administered as upgradeable. For quad-screen conferences, the format is QCIF/CIF to reflect the input of QCIF from all participants and output of CIF to all participants. For presentation mode quad-screen conference, the format is also QCIF/CIF to reflect the input/output of all participants except the presenter. In quad-screen mode, the input from the presenter is always CIF.
`FPS`	The CIF frame rate (frames per second) - `'-', 30, 15, 10, 7.5`. FPS indicates the rate that an endpoint is capable of receiving frames. Note that there is no indication of the maximum transmit frame rate nor the current frame rate that the MCU can detect. The frame rate changes as a function of the amount of motion in the input image.

`QFPS`	The ACIF frame rate (frames per second) `-` ' `-` ', `30`, `15`, `10`, `7.5`. QFPS indicates the rate that an endpoint is capable of generating/receiving frames. For quad-screen VAS conferences, QFPS reflects the highest common QCIF frame rate of all endpoints and the rate of the video mixer board, which may be lower than the rest of the participants. Note that QCIF calculation takes into account the highest common CIF frame rate declared by all conference participants, since QCIF rate cannot be greater than that of the highest common CIF rate. For quad-screen presentation conferences, QFPS reflects the highest common QCIF frame rate of all participants and the rate of the video mixer board. Note that the QFPS cannot be greater than the CIF frame rate announced by the presenter. QFPS field is `blank` for proprietary modes.
`lo/hi interworking`	Does this conference support Low Speed/High Speed Interworking? - This field will always have a value of `n`.
`Type`	The type of conferee, either Audio/Video (`P64`), Audio Add-on (`AUD`), Cascade Link (`CAS`), BONDing Call (`BOND`), BONDing Cascade Link (`BCAS`), UCC Controller (`UCC`), or Dedicated Access (`DA`). BONDing calls use up to 12 channels to form a single multimedia pipe.
`Ext`	Endpoint extension chosen at administration. This field is blank.
`Meet-me number`	The Meet-Me Number administered for the Meet-Me Extension. This field is blank.
`Dial Type`	Indicates whether dial-in or dial-out is used to join the endpoint to the conference - `in`, `out`. The value `in` is for dial-in, and `out` is for dial-out.

`In Use`	Is the endpoint currently participating in the conference or in process of connecting to the conference? - `y`, `c`, `e`, `f`, `n`, `blank`.
	`y` means that the endpoint is in use and is fully connected on all media in an active conference.
	`c` means that the endpoint is in use and is fully connected, however the endpoint has changed the conference audio or video capability or has changed the rate of the conference because of rate adaptation. This condition requires analysis of this endpoint's capabilities and mode fields to identify which capability was reduced.
	`e` means that the endpoint is in use but the endpoint had capability problems. The endpoint does not have one of the required capabilities (Vid, Bhl, MLP) to be a full participant. For MLP capabilities, see the "T120" field. This condition requires analysis of this endpoint's capabilities and mode field to identify the missing capability.
	`f` means that the endpoint is in use but is not connected to all media. This indicates that the endpoint has declared all the required capabilities (channel/video/ audio/data) but is not fully connected to all conference media at this time. This endpoint may be in the process of connecting, has failed to connect, or is not a valid video source. This condition requires analysis of this endpoint's capabilities and mode fields to identify the problem.
	`n` means that the endpoint was connected in a conference but has/was disconnected or attempted to connect to a conference but was unsuccessful.
	`blank` means the field is blank until the first call is made from/to the endpoint.
`Chl`	Data on the quantify and quality of channels (transfer rate)? - `y`, `e`, `n`, `blank`
	`y` the endpoint has the required number of channels.
	`e` means that the endpoint has not declared support for the correct number of channels and cannot participate fully in the conference.
	`n` means that the endpoint has declared the correct number of channels, but all the channels have not yet joined the conference, due to either a network or endpoint problem.
	`blank` Audio add-on endpoints always have the `Chl` field set to `blank`.

`Aud`	Does it have the required audio capability? - y, c, e, `blank` y the endpoint has the required audio capability. Audio add-on endpoint always have the Aud field set to y once the endpoint has joined the conference. c this endpoint is PCM only and it changed the video quality of the conference by changing the operating audio from G.728 to G.711. If the administered audio mode is auto and the administered bandwidth is 112 kbps (56 k/channel) or 128 kbps (64 k/channel), the system starts out with the highest common audio of G.728. When the administered bandwidth is greater than 128 kbps, the system starts out with the highest common bandwidth of 7 kHz. e A PCM-only endpoint that did not have the capability of supporting the administered audio mode of G.728 (such as a data conference), or G. 278/G.711 endpoint that did not have the capability of supporting the administered audio mode of 7 kHz. Such endpoints operate with PCM audio and interwork with the current operating audio mode. `blank` the field is blank until the first call is made from/to the endpoint.
`Vid`	Does it have the required video capability and is receiving video? - y, c, e, n, `blank` y the endpoint has the required video capability and should be receiving video if the Chl, Aud, and Dat fields are y. c means it downgraded the conference’s video quality - either from CIF to ACIF or by decreasing the frame rate. The conference video mode is set by default to CIF and if a QCIF-only endpoint joins the conference, then the entire conference is made to operate in QCIF, with the video clarity downgraded. Also, the conference frame rate is initially set to the highest frame rate that can then be reduced by any endpoint. If the conference video mode is not administered with upgrade capability, then if the video parameters for a conference have been “downgraded,” they are not “upgraded” until all endpoints disconnect from the conference. e means that the endpoint has not declared any video capability in its cap-set. n means audio only, not receiving video, possibly due to an audio or data problem. `blank` Audio add-on endpoint always have the Vid field set to `blank`.
`Mlp`	The state of the Control Link to the ESM (T.120 stack terminator), the endpoint MLP data capability, and the state of the data connection in the T.120 stack. This field value is always `blank`, indicating that the Data Mode for the conference is none, and therefore, the data does not apply, or the endpoint has never joined the conference.

`Gx`	Does it have the Still Frame Graphics capability? - `y`, `e`, `blank` `y` This endpoint has this capability. `e` This endpoint did not declare this capability. The conference retains the still frame graphics capability when a non-compliant endpoint joins the conference. `blank` This endpoint has never joined the conference.
`Rate Adpt`	Rate adaptation/Interworking indicator - `5`, `6`, `y`, `c`, `e`, `n`, `blank`. Values of 5 and 6 apply only to Low Speed/High Speed Interworking. All other values apply only to Rate Adaptation. `5` A 56-kbps (Low Speed) endpoint has joined a High Speed (128 kbps or above) conference. This endpoint is connected with audio only capability but is not a valid video source and destination. `6` A 64-kbps (Low Speed) endpoint has joined a High Speed (128 kbps or above) conference. This endpoint is connected with audio only capability but is not a valid video source and destination. `y` This endpoint has joined the conference at the administered rate of 64 kbps, but because rate adaptation to 56 kbps was triggered by another endpoint, this endpoint has successfully rate adapted to 56 kbps. `c` The administered bandwidth of the conference is 64 kbps and this endpoint has joined the conference at 56 kbps. The first 56 kbps endpoint that joins 64 kbps rate adaptable conference triggers rate adaptation (see `Join Time` below). `n` A 64-kbps conference was triggered to rate adapt to 56 kbps by some other endpoint. This endpoint joined the conference at the bandwidth of 64 kbps, but encountered problems in rate adapting down to 56 kbps. This endpoint may have the audio and may be receiving video, but is not a valid video source. `blank` Rate adaptation was never triggered by any endpoint, and if this endpoint is in use and connected, then it has joined the conference at the administered bandwidth.
`Bond Mode`	BONDing Mode - blank. This field is blank for calls that are not related to bonding.

`Ts`	Indication of the talking state of the endpoint - `t`, `m`, `M`, `S`, `blank`. `t` At the time the command was invoked, voice energy (talking) was detected from the endpoint. `m` At the time the command was invoked, the endpoint indicated to the MCU that it was muted. It is possible that an endpoint may mute, but not send any indication to the MCU. In this situation the MCU does not display a mute indication. `M` At the time the command was invoked, the endpoint's audio was muted via UDD/CRCS Agent interface. M displays when both the endpoint and the UCC/CRCS Agent have muted the endpoint audio. `S` At the time the command was invoked, the endpoint's audio was muted because of solo-audio state set by UCC/CRCS Agent. While in solo-audio state, new endpoints joining the conference are automatically muted. `blank` At the time the command was invoked voice energy (talking) was not being detected from the endpoint.
`Vs`	Indication of the MCU video state for this endpoint - `a`, `b`, `B`, `c`, `i`, `r`, `R`, `s`, `S`, `u`, `U`, `v`, `blank`. For quad-screen conferences an `*` is affixed before the value of Vs to indicate that an endpoint is currently part of the mixed image. A # may be affixed before the value of Vs to indicate that an endpoint was fixed to be in the mixed image (via administration or UCC/CRCS Agent), but instead, a `Fill` video is shown in its place. This occurs when the video of an endpoint that is fixed in a quadrant cannot be used as a video source because the endpoint is currently not joined to the conference, has suppressed its video, or has invalid video to be the video source. Notice that at most four endpoints have an `*` or # affixed before the Vs field value. For quad-screen conference in VAS mode, the mixed image is broadcast to all endpoints. For quad-screen conference in presentation mode, the mixed image is return video to the presenter.

Vs *(cont'd.)*	a This value applies only to quad-screen conferences. *a indicates that an endpoint is part of the current mixed image and is fixed in one of the quadrants via administration. A value of *a indicates that the endpoint is fixed in a quadrant but is not currently connected (Fill image displays). b For full-screen conference it indicates that at the time the command was invoked, this endpoint's video was being broadcast to other sites. This conference was in VAS, broadcast, or presentation mode. For quad-screen VAS conference it is prefixed with an asterisk (*) and indicates that this endpoint's video is part of the mixed image because of VAS. For quad-screen presentation conferences, b (without an asterisk) identifies the presenter as the broadcaster. B At the time the command was invoked the endpoint's video was being broadcast to other sites because of the UCC roll call feature. UCC roll call feature can only be performed in full-screen mode. c At the time the command was invoked this endpoint's video was being broadcast to other sites. The conference was in chair mode and the broadcaster was designated by the chair. Chair features can only be performed in full-screen mode. i At the time the command was invoked the endpoint was not a valid video source. For continuous presence conference, if this endpoint is fixed in a particular quadrant, an asterisk (#) is affixed before i. r For full-screen conferences, at the time the command was invoked the endpoint's video was the return video to the broadcaster. For continuous presence conference in presentation mode, *r represents a VAS quadrant that is part of the mixed image. R At the time the command was invoked, the endpoint's video was the return video to the broadcaster because of the UCC browse feature. UCC Browse feature can only be performed in full-screen mode. s At the time the command was invoked this endpoint's video was suppressed at the request of the endpoint. For continuous presence conference with fixed quadrant participants, if this endpoint is fixed in a particular quadrant a # is affixed before s.

Vs *(cont'd)*	`S` At the time the command was invoked this endpoint's video was suppressed via UCC/CRCS Agent interface. For continuous presence conference with fixed quadrant participants, if this endpoint is fixed in a particular quadrant, # is affixed before `S`. `S` displays when both the endpoint and the UCC/CRCS Agent have suppressed the endpoint video.
	`u` For full-screen conferences, at the time the command was invoked this endpoint's video was being broadcast to other sites. The conference was in VAS mode and the broadcaster was designated by the UCC/CRSCS Agent interface. For quad-screen conferences, it indicates that UCC/CRCS Agent designated this endpoint as fixed in a quadrant. An asterisk (`*`) is affixed before `u` if the endpoint is currently part of the quad image, and # is affixed if the endpoint is not currently joined.
	`U` Applies only to quad-screen conference and indicates that UCC/CRCS Agent designated a quadrant as VAS. An asterisk (`*`) is affixed before `U` to indicate that this endpoint is part of the current quad image.
	`v` At the time the command was invoked this endpoint's video was being broadcast to other sites. The conference was in VAS mode but the endpoint has asked to be a broadcaster via "See-Me" request and was granted a MCV (Multipoint Command Visualize) token. The See-Me feature is only performed in full-screen mode.
	`blank` At the time of the request the endpoint's video was not broadcast, return, video, or part of the mixed-image, but it is a valid video source.

Screen 8-7. status conference: page 2 of 2

Field Descriptions (status conference, page 2)

`Sum Grp`	The VD audio Level 1 (L1) and Level 2 (L2) summer group parts for each assigned group (1-4). Summer parts are assigned only for conferences with over 6 participants. When a conference operates at an audio mode of 7 kHz (administered audio mode is 7 kHz, or auto with the bandwidth greater than 128 kbps), the system allocates “primary” and “secondary” L1 and L2 summer parts. These primary and secondary parts are allocated as adjacent port slots on the same board. Status conference only displays the primary summer ports. The secondary summer ports are always one slot higher than the displayed primary summer port.
`Join Time`	Time (in 24-hour notation) when the channel joined the conference.
`Drop Time`	Time (in 24-hour notation) when the channel disconnected. If the first channel has a drop time, then it means that the endpoint is not in use. If there is a drop time without a join time, it means that the call disconnected without being joined to the conference.

`Drop Reason` The reason for the channel's disconnect:

`2-pri` This drop reason occurs when an administration error causes a mismatch in primary-secondary designation for a cascade link. This mismatch shows that both MCUs are administered as primaries (see "Cascading" for a description of primary-secondary compatibility).

`2-sec` This drop reason occurs when an administration error causes a mismatch in primary-secondary designation for a cascade link. This mismatch shows that both MCUs are administered as secondaries (see "Cascading" for a description of primary-secondary compatibility).

`Agent` The reservation agent has caused the call to disconnect (for example, the agent has changed a connected dial-out destination number).

`Bandwidth` mismatch between a call and the conference it attempted to join. For example, a 56-kbps call attempted to join a 64-kbps conference that does not allow rate adaptation.

`BondHshake` BONDing handshake drop reason can be caused due to the following reasons: information channel parameter not supported or invalid, parameter negotiation terminated out of sequence, timer expired because of the secondary channels did not establish, or BONDing framing was not detected for one of the other channels.

`Busy` This dial-out drop reason occurs when the MCU detects that the conferee's terminal equipment is busy. This drop reason is detected by an ISDN cause value (for example h0). See "Dial-out" for a description of CPTR usage.

`Chair` disconnected the endpoint, using either Chair Command Disconnect (CCD) or Chair Command Kill (CCK) signals.

`Conf End` The conference was ended due to reaching stop time for a reserved conference or due to an active conference being converted to file.

`Drop Reason` *(cont'd)*	`Endpoint` Clearing received from DS1 - the disconnect came from the endpoint. The endpoint notified the MCU that it intended to disconnect. `Far-end` Clearing received from DS1 - the disconnect came from either the network or the endpoint. `Handshake` Either framing was never found (the endpoint could not complete initialization - problems finding Frame Alignment Signal (FAS), Multi Frame Alignment (MFA) and getting a corrected coded cap-set) or framing was lost for some time (over 40 seconds) and the endpoint was disconnected. `IDtimeout` The MCU has not received response to the UIN/password Query from the H.320 user after three attempts. Each attempt has a system administered timeout period. `Internal` MCU has a problem allocating trunk resources necessary to route the dial-out call for the specified dial-numbers. This problem can be associated with routing pattern or trunk associated translation (for example, TAC specified in the dial-out number or routing pattern points to a trunk group without members), or it can indicate a lack of trunk resources (for example, all trunk members are maintenance busy or all in-service members are busy on a call). `Network` Clearing received from DS1 - the disconnect came from the network. The endpoint that had the disconnect notification capability disconnected without notifying the MCU. `Not-MCU` The dial-out destination number(s) of the “CAS” extension has terminated to a number that is not a dial-in cascade MCU extension. `No-ring` This dial-out drop reason occurs when the call has been up for 30 seconds and no ringing is detected. `Reorder` This dial-out drop reason occurs when the MCU detects that there are no available trunks in the network to place the call. This drop reason is detected by MCU CPTR resources. See “Dial-out” for a description of CPTR usage.

`Drop Reason` *(cont'd)*	`Pre-AnsDrop` The call disconnected before answer by an endpoint. The cause of the disconnect may be the network, an endpoint, or a terminal adapter. This drop reason is different from 'No-answer,' which indicates that a 60-second timeout occurred while alerting. In this case, the call drops before the 60-second timer has expired. Some busy endpoints connected through terminal adapters display this behavior. `Resource` MCU could not provide resources (VC or MMI) when the call arrived or lost the resources during the call. This could be due to them being Out of Service, busied out by craft, or being used by system maintenance. This drop reason could also occur if the DS1/MMI cable is disconnected. If there was a resource problem when the call arrived, it would get reorder (fast busy) and not get disconnected by the MCU. `Password` Either the user entered the wrong password or the audio add-on user did not enter it within the specified time period. Note that the audio add-on user gets one attempt to enter a correct password and inter-digit timing for each digit (that is, about 10 seconds between digits). `System` An MCU restart (level 2) disconnected all calls. `UIN-Inv` The user entered an invalid User Identification Number. `Unknown` The system could not determine the cause of the disconnect. `Wrong-num` This dial-out drop reason occurs when the MCU detects the wrong destination number was dialed. This drop reason is detected by MCU CPTR resources SDN cause value. See "Dial-out" for details. `UCC` controller intentionally disconnected the endpoint.
`AC Num`	Administered Connection Number - from 1 to 128. AC number can be used to further diagnose a problem by combining status conference information with the **status administered connection** command and data stored in the error and alarm logs.
`Ports Trunk`	The data endpoint that the channel is using.
`Ports Video`	The MMI port for the channel.
`Ports Aud`	If the endpoint type is not "UCC," the VC audio encoder port (which is always paired to a decoder port) for the channel (only the first channel). Because only one audio encoder port is allocated per endpoint, it appears together with the ESM data port in the endpoint's channel 1 port slot position of the `Port Aud/ESM` column. For "UCC" endpoint type, the channel 1 port slot position displays the allocated Call Classifier resource.
`Ports ESM`	The Expansion Service Module MMI data port. This field is always blank.
`Sum Grp`	Endpoint's assigned summer group number. The summer group port assignments are on screen 1.
`software`	For Lucent Technologies use only.

Field Descriptions (status conference endpoint)

status conference *x* endpoint *y*

The first screen appears when **status conference *x* endpoint *y*** is entered and the specified conference is found. Data relevant for each endpoint displays in 6 pages. If the endpoint-ID of **all** is used, all possible endpoints associated with the specified conference display.

Screen 8-8. Page 1 of 6: status conference x endpoint y

`Endpoint`	Endpoint-ID is a slot number associated with the endpoint entered on the conference forms.
`Product`	Product identification number obtained from the endpoint.
`Manufacturer/ Country`	Manufacturer identification number and manufacturer's country code obtained from the endpoint.
`Terminal Name`	This field is always blank.
`Sum Grp`	Summer group number to which this endpoint belongs and the VC Audio Level (L1) and Level 2 (L2) summer ports for this group. These fields have an entry only for conferences with over 6 participants.
`Dial Out #1`	Blank
`Dial Out #2`	Blank

`In Use`	Is the endpoint currently participating in the conference or in process of connecting to the conference? - `y`, `c`, `e`, `f`, `n`, `blank`. `y` means that the endpoint is in use and is fully connected on all media in an active conference. `c` means that the endpoint is in use and is fully connected, however the endpoint has changed the conference audio or video capability or has changed the rate of the conference because of rate adaptation. This condition requires analysis of this endpoint's capabilities and mode fields to identify which capability was reduced. `e` means that the endpoint is in use but the endpoint had capability problems. The endpoint does not have one of the required capabilities (Vid, Bhl, MLP) to be a full participant. For MLP capabilities, see the "T120" field. This condition requires analysis of this endpoint's capabilities and mode field to identify the missing capability. `f` means that the endpoint is in use but is not connected to all media. This indicates that the endpoint has declared all the required capabilities (channel/video/ audio/data) but is not fully connected to all conference media at this time. This endpoint may be in the process of connecting, has failed to connect, or is not a valid video source. This condition requires analysis of this endpoint's capabilities and mode fields to identify the problem. `n` means that the endpoint was connected in a conference but has/was disconnected or attempted to connect to a conference but was unsuccessful. `blank` means the field is blank until the first call is made from/to the endpoint.
`Enh BAS`	EnhancedBasic Service Flag - `n`, `y` `y` means that the endpoint supports the enhanced BAS commands/caps; `n` means that the endpoint only supports the basic BAS commands/caps.
`Chl`	Data on the quantify and quality of channels (transfer rate)? - `y`, `e`, `n`, `blank` `y` the endpoint has the required number of channels. `e` means that the endpoint has not declared support for the correct number of channels and cannot participate fully in the conference. `n` means that the endpoint has declared the correct number of channels, but all the channels have not yet joined the conference, due to either a network or endpoint problem. `blank` Audio add-on endpoints always have the `Chl` field set to `blank`.

`Aud`	Does it have the required audio capability? - y, c, e, `blank` y the endpoint has the required audio capability. Audio add-on endpoint always have the Aud field set to y once the endpoint has joined the conference. c this endpoint is PCM only and it changed the video quality of the conference by changing the operating audio from G.728 to G.711. If the administered audio mode is auto and the administered bandwidth is 112 kbps (56 k/channel) or 128 kbps (64 k/channel), the system starts out with the highest common audio of G.728. When the administered bandwidth is greater than 128 kbps, the system starts out with the highest common bandwidth of 7 kHz. e A PCM-only endpoint that did not have the capability of supporting the administered audio mode of G.728 (such as a data conference), or G. 278/G.711 endpoint that did not have the capability of supporting the administered audio mode of 7 kHz. Such endpoints operate with PCM audio and interwork with the current operating audio mode. `blank` the field is blank until the first call is made from/to the endpoint.
`Vid`	Does it have the required video capability and is receiving video? - y, c, e, n, `blank` y the endpoint has the required video capability and should be receiving video if the Chl, Aud, and Dat fields are y. c means it downgraded the conference's video quality - either from CIF to ACIF or by decreasing the frame rate. The conference video mode is set by default to CIF and if a QCIF-only endpoint joins the conference, then the entire conference is made to operate in QCIF, with the video clarity downgraded. Also, the conference frame rate is initially set to the highest frame rate that can then be reduced by any endpoint. If the conference video mode is not administered with upgrade capability, then if the video parameters for a conference have been "downgraded," they are not "upgraded" until all endpoints disconnect from the conference. e means that the endpoint has not declared any video capability in its cap-set. n means audio only, not receiving video, possibly due to an audio or data problem. `blank` Audio add-on endpoint always have the Vid field set to `blank`.
`Mlp`	The state of the Control Link to the ESM (T.120 stack terminator), the endpoint MLP data capability, and the state of the data connection in the T.120 stack. This field value is always `blank`, indicating that the Data Mode for the conference is none, and therefore, the data does not apply, or the endpoint has never joined the conference.

`Gx`	Does it have the Still Frame Graphics capability? - `y`, `e`, `blank` `y` This endpoint has this capability. `e` This endpoint did not declare this capability. The conference retains the still frame graphics capability when a non-compliant endpoint joins the conference. `blank` This endpoint has never joined the conference.
`Rate Adpt`	Rate adaptation/Interworking indicator - `5`, `6`, `y`, `c`, `e`, `n`, `blank`. Values of 5 and 6 apply only to Low Speed/High Speed Interworking. All other values apply only to Rate Adaptation. `5` A 56-kbps (Low Speed) endpoint has joined a High Speed (128 kbps or above) conference. This endpoint is connected with audio only capability but is not a valid video source and destination. `6` A 64-kbps (Low Speed) endpoint has joined a High Speed (128 kbps or above) conference. This endpoint is connected with audio only capability but is not a valid video source and destination. `y` This endpoint has joined the conference at the administered rate of 64 kbps, but because rate adaptation to 56 kbps was triggered by another endpoint, this endpoint has successfully rate adapted to 56 kbps. `c` The administered bandwidth of the conference is 64 kbps and this endpoint has joined the conference at 56 kbps. The first 56 kbps endpoint that joins 64 kbps rate adaptable conference triggers rate adaptation (see `Join Time` below). `n` A 64-kbps conference was triggered to rate adapt to 56 kbps by some other endpoint. This endpoint joined the conference at the bandwidth of 64 kbps, but encountered problems in rate adapting down to 56 kbps. This endpoint may have the audio and may be receiving video, but is not a valid video source. `blank` Rate adaptation was never triggered by any endpoint, and if this endpoint is in use and connected, then it has joined the conference at the administered bandwidth.
`Bond Mode`	BONDing Mode - blank. This field is blank for calls that are not related to bonding.

`Ts`	Indication of the talking state of the endpoint - `t`, `m`, `M`, `S`, `blank`. `t` At the time the command was invoked, voice energy (talking) was detected from the endpoint. `m` At the time the command was invoked, the endpoint indicated to the MCU that it was muted. It is possible that an endpoint may mute, but not send any indication to the MCU. In this situation the MCU does not display a mute indication. `M` At the time the command was invoked, the endpoint's audio was muted via UDD/CRCS Agent interface. M displays when both the endpoint and the UCC/CRCS Agent have muted the endpoint audio. `S` At the time the command was invoked, the endpoint's audio was muted because of solo-audio state set by UCC/CRCS Agent. While in solo-audio state, new endpoints joining the conference are automatically muted. `blank` At the time the command was invoked voice energy (talking) was not being detected from the endpoint.

`Vs`	Indication of the MCU video state for this endpoint - `a`, `b`, `B`, `c`, `i`, `r`, `R`, `s`, `S`, `u`, `U`, `v`, `blank`. For quad-screen conferences an `*` is affixed before the value of Vs to indicate that an endpoint is currently part of the mixed image. A # may be affixed before the value of Vs to indicate that an endpoint was fixed to be in the mixed image (via administration or UCC/CRCS Agent), but instead, a `Fill` video is shown in its place. This occurs when the video of an endpoint that is fixed in a quadrant cannot be used as a video source because the endpoint is currently not joined to the conference, has suppressed its video, or has invalid video to be the video source. Notice that at most four endpoints have an `*` or # affixed before the Vs field value. For quad-screen conference in VAS mode, the mixed image is broadcast to all endpoints. For quad-screen conference in presentation mode, the mixed image is return video to the presenter. a This value applies only to quad-screen conferences. *a indicates that an endpoint is part of the current mixed image and is fixed in one of the quadrants via administration. A value of `*a` indicates that the endpoint is fixed in a quadrant but is not currently connected (Fill image displays). b For full-screen conference it indicates that at the time the command was invoked, this endpoint’s video was being broadcast to other sites. This conference was in VAS, broadcast, or presentation mode. For quad-screen VAS conference it is prefixed with an asterisk (*) and indicates that this endpoint’s video is part of the mixed image because of VAS. For quad-screen presentation conferences, b (without an asterisk) identifies the presenter as the broadcaster. B At the time the command was invoked the endpoint’s video was being broadcast to other sites because of the UCC roll call feature. UCC roll call feature can only be performed in full-screen mode. c At the time the command was invoked this endpoint’s video was being broadcast to other sites. The conference was in chair mode and the broadcaster was designated by the chair. Chair features can only be performed in full-screen mode.

`Vs` *(cont'd.)*	`i` At the time the command was invoked the endpoint was not a valid video source. For continuous presence conference, if this endpoint is fixed in a particular quadrant, an asterisk (#) is affixed before i.
	`r` For full-screen conferences, at the time the command was invoked the endpoint's video was the return video to the broadcaster. For continuous presence conference in presentation mode, *r represents a VAS quadrant that is part of the mixed image.
	`R` At the time the command was invoked, the endpoint's video was the return video to the broadcaster because of the UCC browse feature. UCC Browse feature can only be performed in full-screen mode.
	`s` At the time the command was invoked this endpoint's video was suppressed at the request of the endpoint. For continuous presence conference with fixed quadrant participants, if this endpoint is fixed in a particular quadrant a # is affixed before `s`.
	`S` At the time the command was invoked this endpoint's video was suppressed via UCC/CRCS Agent interface. For continuous presence conference with fixed quadrant participants, if this endpoint is fixed in a particular quadrant, # is affixed before `S`. `S` displays when both the endpoint and the UCC/CRCS Agent have suppressed the endpoint video.
	`u` For full-screen conferences, at the time the command was invoked this endpoint's video was being broadcast to other sites. The conference was in VAS mode and the broadcaster was designated by the UCC/CRSCS Agent interface. For quad-screen conferences, it indicates that UCC/CRCS Agent designated this endpoint as fixed in a quadrant. An asterisk (`*`) is affixed before `u` if the endpoint is currently part of the quad image, and # is affixed if the endpoint is not currently joined.
	`U` Applies only to quad-screen conference and indicates that UCC/CRCS Agent designated a quadrant as VAS. An asterisk (`*`) is affixed before `U` to indicate that this endpoint is part of the current quad image.
	`v` At the time the command was invoked this endpoint's video was being broadcast to other sites. The conference was in VAS mode but the endpoint has asked to be a broadcaster via "See-Me" request and was granted a MCV (Multipoint Command Visualize) token. The See-Me feature is only performed in full-screen mode.
	`blank` At the time of the request the endpoint's video was not broadcast, return, video, or part of the mixed-image, but it is a valid video source.

Screen 8-9. Page 2 of 6: status conference *x* endpoint *y*

`Join Time` Time (in 24-hour notation) when the channel joined the conference.

`Drop Time` Time (in 24-hour notation) when the channel disconnected. If the first channel has a drop time, then it means that the endpoint is not in use. If there is a drop time without a join time, it means that the call disconnected without being joined to the conference.

`Drop Reason` The reason for the channel's disconnect:

`2-pri` This drop reason occurs when an administration error causes a mismatch in primary-secondary designation for a cascade link. This mismatch shows that both MCUs are administered as primaries (see "Cascading" for a description of primary-secondary compatibility).

`2-sec` This drop reason occurs when an administration error causes a mismatch in primary-secondary designation for a cascade link. This mismatch shows that both MCUs are administered as secondaries (see "Cascading" for a description of primary-secondary compatibility).

`Agent` The reservation agent has caused the call to disconnect (for example, the agent has changed a connected dial-out destination number).

`Bandwidth` mismatch between a call and the conference it attempted to join. For example, a 56-kbps call attempted to join a 64-kbps conference that does not allow rate adaptation.

`BondHshake` BONDing handshake drop reason can be caused due to the following reasons: information channel parameter not supported or invalid, parameter negotiation terminated out of sequence, timer expired because of the secondary channels did not establish, or BONDing framing was not detected for one of the other channels.

`Busy` This dial-out drop reason occurs when the MCU detects that the conferee's terminal equipment is busy. This drop reason is detected by an ISDN cause value (for example h0). See "Dial-out" for a description of CPTR usage.

`Chair` disconnected the endpoint, using either Chair Command Disconnect (CCD) or Chair Command Kill (CCK) signals.

`Conf End` The conference was ended due to reaching stop time for a reserved conference or due to an active conference being converted to file.

`Drop Reason` *(cont'd)*	`Endpoint` Clearing received from DS1 - the disconnect came from the endpoint. The endpoint notified the MCU that it intended to disconnect. `Far-end` Clearing received from DS1 - the disconnect came from either the network or the endpoint. `Handshake` Either framing was never found (the endpoint could not complete initialization - problems finding Frame Alignment Signal (FAS), Multi Frame Alignment (MFA) and getting a corrected coded cap-set) or framing was lost for some time (over 40 seconds) and the endpoint was disconnected. `IDtimeout` The MCU has not received response to the UIN/password Query from the H.320 user after three attempts. Each attempt has a system administered timeout period. `Internal` MCU has a problem allocating trunk resources necessary to route the dial-out call for the specified dial-numbers. This problem can be associated with routing pattern or trunk associated translation (for example, TAC specified in the dial-out number or routing pattern points to a trunk group without members), or it can indicate a lack of trunk resources (for example, all trunk members are maintenance busy or all in-service members are busy on a call). `Network` Clearing received from DS1 - the disconnect came from the network. The endpoint that had the disconnect notification capability disconnected without notifying the MCU. `Not-MCU` The dial-out destination number(s) of the "CAS" extension has terminated to a number that is not a dial-in cascade MCU extension. `No-ring` This dial-out drop reason occurs when the call has been up for 30 seconds and no ringing is detected. `Reorder` This dial-out drop reason occurs when the MCU detects that there are no available trunks in the network to place the call. This drop reason is detected by MCU CPTR resources. See "Dial-out" for a description of CPTR usage.

`Drop Reason` *(cont'd)*	`Pre-AnsDrop` The call disconnected before answer by an endpoint. The cause of the disconnect may be the network, an endpoint, or a terminal adapter. This drop reason is different from 'No-answer,' which indicates that a 60-second timeout occurred while alerting. In this case, the call drops before the 60-second timer has expired. Some busy endpoints connected through terminal adapters display this behavior. `Resource` MCU could not provide resources (VC or MMI) when the call arrived or lost the resources during the call. This could be due to them being Out of Service, busied out by craft, or being used by system maintenance. This drop reason could also occur if the DS1/MMI cable is disconnected. If there was a resource problem when the call arrived, it would get reorder (fast busy) and not get disconnected by the MCU. `Password` Either the user entered the wrong password or the audio add-on user did not enter it within the specified time period. Note that the audio add-on user gets one attempt to enter a correct password and inter-digit timing for each digit (that is, about 10 seconds between digits). `System` An MCU restart (level 2) disconnected all calls. `UIN-Inv` The user entered an invalid User Identification Number. `Unknown` The system could not determine the cause of the disconnect. `Wrong-num` This dial-out drop reason occurs when the MCU detects the wrong destination number was dialed. This drop reason is detected by MCU CPTR resources SDN cause value. See "Dial-out" for details. `UCC` controller intentionally disconnected the endpoint.
`Drop Code`	A detail code complementing the Drop Reason (see above). Additional bonding related information may be obtained from supplementary BONDing Drop Codes described above.
`AC Num`	Administered Connection Number - from 1 to 128. AC number can be used to further diagnose a problem by combining status conference information with the **status administered connection** command and data stored in the error and alarm logs.
`Ports Trunk`	The data endpoint that the channel is using.
`Ports Video`	The MMI port for the channel.

`Ports Aud`	If the endpoint type is not “UCC,” the VC audio encoder port (which is always paired to a decoder port) for the channel (only the first channel). Because only one audio encoder port is allocated per endpoint, it appears together with the ESM data port in the endpoint’s channel 1 port slot position of the `Port Aud/ESM` column. For “UCC” endpoint type, the channel 1 port slot position displays the allocated Call Classifier resource.
`Ports ESM`	The Expansion Service Module MMI data port. This field is always blank.
`Ports BONDng`	The MMI port used for BONDing for the channel.
`Fr Err`	Frame error counter. A circular hex counter (0-FF) to indicate the occurrence of framing errors.

Screen 8-10. Page 3 of 6: status conference *x* endpoint *y*

Conference Info. This information applies mostly to full-screen conferences. The `Broadcaster` field also applies to quad-screen presentation mode conferences.

`Broadcaster`	Indicates the endpoint number that is the current broadcaster. The Broadcaster can be qualified with the following keywords: 1. `Broadcast` - indicates a broadcast mode broadcaster. 2. `Chair` - indicates that the broadcaster was designated by the chair. 3. `See-Me` - indicates that the broadcaster is a result of MCV request from an endpoint. 4. `Presenter` - indicates a presentation mode broadcaster. 5. `Rollcall` - indicates that the broadcaster was designated by the UCC via the Rollcall feature. 6. `UCC` - indicates that the broadcaster was designated by the UCC. 7. `VAS` - indicates a Voice Activated Switching broadcaster.
`Next Broadcaster`	Indicates the endpoint number that is selected to be the next broadcaster.
`Return Vid`	Indicates the endpoint number that is the current return video. The return video can be qualified with the following keywords: 1. blank - indicates that the return video is the previous broadcaster forced to be return video because of VAS, action by Chair, action by UCC, or endpoint MCV request. The broadcaster qualifier identifies which action forced this endpoint to become return video. 2. `Autoscan` - indicates auto scan return video. This is true only when conference mode is broadcast with auto scan. 3. `Browse` - indicates that the return video was designated by the UCC via the Browse feature. 4. `VAS` - indicates a Voice Activated Switching return video.
`Next Return Vid`	Indicates the endpoint number that is selected to be the next return video.

Mode Commands/Communication Modes. This is a collection of both incoming and outgoing bandwidth allocations for the multiplex. The Incoming data is the rate at which the MCU thinks the endpoint is communicating based on the Bit-rate Allocation Signal (BAS) codes received from the endpoint/codec and the capabilities the MCU has declared. The Outgoing data is the rate from the MCU toward the endpoint. The following are column definitions for this section of page 3.

`CONF`	The desired conference operating mode. This may be different from the endpoint in (`EPT-IN`) or endpoint out (`EPT-OUT`) modes.
`CMD`	labels for the various types of mode commands
`STAT`	indicates if the conference and the incoming modes are compatible. A value of y indicates mode compatibility; a value of n indicates that the modes are not compatible.
`EPT-IN`	defines the communication modes coming in from an endpoint.
`EPT-OUT`	defines the communication modes sent out to an endpoint based on the number of channels connected and the capabilities of the endpoint.

The following are field definitions for the Mode Commands/Communication Modes section of Page 3.

`XRATE` One of the supported rates in Table 8-10:

Table 8-10. Supported Transfer Rates

XRATE	Bandwidth of the Call
2x64	2B (2x56 or 2x64)
128	112kbps or 128kbps
196	168kbps or 196kbps
256	224kbps or 256kbps
320	280kbps or 320kbps
384	336kbps or 384kbps
512	512kbps
768	768kbps
1472	1472kbps
1536	1536kbps‘
1920	1920kbps

`XRATE` *(cont'd.)* XRATE may be 64 when the endpoint is just dialing in, or in the event of problems. It implies that only one B channel is being used.

`AUDIO` Audio rate (kbps bandwidth) of the conference and the endpoint must be the same but not necessarily their mode. When the audio rate of the conference and the endpoint are different the endpoint's audio will interwork but the endpoint's video will be invalid. MCU may or may not send video to such an endpoint.

Table 8-11 summarizes expected endpoint audio mode with different configurations of transfer rate, facility bandwidth, conference mode, and whether or not all endpoints support the highest common audio mode (HC audio) when the administered mode is `auto`. The highest common conference mode is dependent on the administered bandwidth. A '-' in the table indicates 'does not apply.'

Table 8-11. Audio Mode Configurations

Admin Mode (HC Audio)	All Support HC Audio	Xfer Rate	Facility BW	Conf Mode	Expected Endpoint Mode
auto (G.728)	yes	<=128k	-	G.728	G.728
auto (G.728)	no	<=128k	64k	G.711-A-56k	G.711-A-56k B.711-Mu-56k
auto (G.728)	no	<=128k	56k	G.711-A-48k	G.711-A-48k G.711-MU-48k
auto (G.722)	-	>128k	64k	G.722-56k	G.722-56k G.711-A-56k G.711-Mu-56k
auto (G.722)	-	>128k	56k	G.722-48k	G.722-48k G.711-A-48k G.711-Mu-48k
G.728	-	-		G.728	G.728
G.711	-	-	64k	G.711-A-56k	G.711-A-56k G.711-Mu-56k
G.711	-	-	56k	G.711-A-48k	G.711-A-48k G.711-Mu-48k
G.722	-	-	64k	G.722-56k	G.722-56k G.711-A-56k G.711-mu-56k
G.722	-	-	56k	G.722-48k	G.722-48k G.711-A-48k G.711-Mu-48k

`AUDIO` *(cont'd.)* Other possible AUDIO mode values include `neutral` (neutralized I-channel) and `Au-off, Frm` (no audio signal) which never match conference mode and are not supported by MCU.

`56/64`	The `65/64` field is `derestrict` when operating at per-channel speeds of 64kbps, 128kbps, 192kbps, 256kbps, 320kbps, 384kbps, 512kbps, 768 kbps, 1472kbps, 1536kbps, or 1920kbps; it is `restrict` when operating at 56kbps, 112kbps, 168kbps, 224kbps, 280kbps, 336kbps, 448kbps, and 672kbps. Note that if the conference is configured for Nx56kbs operation, the endpoint may signal either via capabilities or modes that is operating at the proper rate. In such a case, even when we receive `derestrict` command which does not match the conference communication mode of `restrict`, if the capability indicates `restrict` (`MISC` capability has `restrict` displayed on Page 4) the `STAT 56/64` is set to `y` to indicate 56/64 compatibility between the conference and the endpoint.
`VIDEO`	The Video mode: `H.261` (recommended), `H.CTX` (proprietary), `H.CTX+` (proprietary), or `SG4` (proprietary) indicate that video is on in the direction indicated; `video-off` when the video is off.
`MLP`	Multi Layer Protocol data mode. When `Data Mode` is administered as `any-mlp` or `ww-pcs`, the MLP mode should be `var-MLP`. Other values will affect video status. The `MLP` mode should be `MLP-off` when Data Mode is administered as `none`. Again, other values in this mode will affect video status.
`H_MLP`	The High Speed MLP mode. The HMLP mode should be `H-MLP-off`. Other values in this mode will affect video status.
`LSD`	Low Speed Data mode. The LSD mode should be `LSD-off`. Other values in this mode will affect video status.
`HSD`	High Speed Data mode. The HSD mode should be `HSD-off`. Other values in this mode will affect video status.
`CRYPT`	Encryption mode. The CRYPT mode should be `encrypt-off`. Other values in this mode will affect video status.
`S/M`	Single/Multi channel interoperability mode. `6B-H0-comp` indicates that the sender is interoperating multiple channels and a single channel (for example, 6B and H0). `Not-comp-6B-H0` indicates that the sender is not interoperating between 6B and H0. Normally this value is `Not-comp-6B-H0`. Other values in this mode will affect video status.

Endpoint Miscellaneous (EPT MISC) Information. EPT MISC contains miscellaneous states and counters for an endpoint. The flags can be a value of y or n. The counters start with initial value of `0x00`, they increment to 0xff, and then wrap around to 0x01. `AIM` and `VIS` are BAS commands which can be sent as input (I) to MCU from an endpoint or as output (O) from MCU to an endpoint.

`AIM`	Audio Indicate Muted. Value of y on input (I) indicates that this endpoint has muted its audio. MCU will not VAS to an endpoint displaying mute indicate. Value of n on input indicates that this endpoint has not muted (only if endpoint audio mode is turned on). Value of y on output (O) indicates that all other endpoints in the conference have muted their audio (have sent AIM to MCU). MCU in turn tells this endpoint (by sending it AIM) that there is no audio output from MCU. A value of n on output indicates that there is an audio path open across the bridge.
`VIS`	Video Indicate Suppressed. Value of y on input (I) indicates that this endpoint has suppressed its video (indicated video is muted). Value of y on output (O) indicates that the MCU is not sending video to this endpoint because there is no video broadcaster (broadcaster has not joined or broadcaster's video is not valid).
`MIS`	Multipoint Indicate Secondary-status. This command is only sent as output (O) to an endpoint. A value of n indicates that the endpoint is viewed as capable of being a valid source (although not necessarily at this moment). A value of n is the correct state to be in for video. A value of y indicates that MIS was sent to an endpoint and that this endpoint is viewed as a secondary endpoint. The endpoint is included in the audio portion of the conference but not the video portion. Video will not be sent.
`MCV`	Multipoint Command Visualize. This command is only sent as input (I) from an endpoint. A value of y indicates that an endpoint has requested to become a broadcaster. This is used during Still Frame Graphics and to force “presentation” mode.
`TALK`	A value of y indicates that the VC board is detecting voice energy from the endpoint. The TALK counter indicates the number of times a start/stop was detected.
`VRCV`	Value of y indicates if the endpoint is receiving video (MMCH is sending video to the endpoint). The VRCV counter indicates the number of times video was sent/not sent to this endpoint.
`BCTK`	Applies to single screen and quad-screen presentation mode conferences. A value of y indicates that the endpoint is the video broadcast source. The BCTK counter indicates the number of times this endpoint was the video broadcast source.
`RTTK`	Applies only to single screen conferences. A value of y indicates that the endpoint is the return video source. The RTTK counter indicates the number of times this endpoint was the return video source.

`BCLS`	Applies to single screen and quad-screen presentation mode conferences. A value of y indicates that the endpoint is watching the video of the broadcast source.
`RTLS`	Applies only to single screen conferences. A value of y indicates that the endpoint is watching the video of the return source.
`HYPR`	A value of y indicates hyperactivity from an endpoint (MCU isolated endpoint from the MCU conference due to “thrashing” behavior) and affects endpoint’s status as a video source (for 5 seconds of hyperactivity timer). The HYPR counter indicates the number of times this endpoint was hyperactive.
`DMUTE`	A value of y indicates that the decoder was muted by the VC board or the software in the MCU. VC board mutes the decoder when it loses MMI or endpoint framing is lost, when it receives an invalid audio code word, and when endpoint is hyperactive. The only time that the MCU software mutes the decoder of an endpoint is to mute all endpoints, other than the broadcaster, when a mode of a conference is “broadcastw/scan” (broadcast with auto scan). The DMUTE counter indicates the number of times this endpoint’s decoder was muted by the VC board.
`VFMT`	The video format applicable only to quad-screen conferences. This field always has a value of n, indicating QCIF format.
`H.261`	A value of y indicates video framing loss. The H.261 counter indicates the number of times the framing was lost.

Frame Alignment Word (FAW) Information. The FAW section of page 3 provides the channel Frame Alignment Word information for the communication paths labeled CHL 1 and 2. For 2B calls, both CHL 1 and 2 are used. For 1-channel calls (112,bps, 128kbps, 168kbps, 196kbps, 224kbps, 256kbps, 280kbps, 320kbps, 336kbps, 384kbps, 768kbps, 1472kbps, 1536kbps, and 1920kbps) only CHL 1 is used. `A-OUT`, `A-IN`, `M-FRM`, `MFA`, and `MFN` are flags with values of y or n.

`A-OUT`	MCU has endpoint framing.
`A-IN`	Endpoint has MCU framing
`M-FRM`	Multichannel frame alignment is present (alignment of both channels in 2B).
`MFA`	Multiframe alignment word is present (required in 2B call).
`MFN`	Multiframe numbering is present (required in 2B call).
`FAS`	Frame Alignment Signal (FAS) channel number (1 or 2). This number should match the column header.

`MCUFAL` MCU Frame Alignment Loss (MCUFAL). A counter of the number of times the MCU indicates to the endpoint that it has lost endpoint FAW or multichannel synchronization (M-FRM). The MCU a-bit toggles when the MCU gains or loses endpoint multichannel synchronization. This counter starts with an initial value of 0x00, increments to 0xff, then wraps around to 0x01. The MCUFAL count is also shown in the `Fr Err` field on Page 2

`FEFAL` Far End Frame Alignment Loss (FEFAL). A counter of the number of changes the MCU detects in the endpoint's a-bit (A-OUT). The endpoint a-bit toggles when an endpoint gains or loses MCU framing. This counter starts with an initial value of 0x00, increments to 0xff, then wraps around to 0x01.

Page 4 - Endpoint Capability Information

This section only describes the fields that are specific to the endpoint-level command output.

Screen 8-11. Page 4 of 6: status conference *x* endpoint *y*

Endpoint Capability Information. Fields on this page will only be displayed if an endpoint declares the specific capability. For example, if an endpoint does not declare the VID H.CTX capability, the `H.CTX` field will not be displayed.

VID	Provides information about the type of video and frame rate the endpoint supports. vfmt - does not display if the endpoint has no video capability. All values are blank if there is an active call or this is an audio-only endpoint. Otherwise, values for this field include: ■ FCIF for full CIF ■ QCIF for quarter CIF. Support of CIF implies support of QCIF. In general, for larger screens, CIF displays sharper resolution video, which ZCIF is blocked, but may run at higher frame rates and less clear. The differences are less observable on very small displays. ■ cfps and qfps are the maximum frame rate (frames/second) at which the endpoint can receive video for CIF and QCIF operating modes. CIF frame rate values are 30fps, 15fps, 10fps, and 7.4fps. If the endpoint does not support CIF (that is, the vfmt field is QCIF), the cfps value should be blank. ■ da_sfg indicates support for H.261 Still Frame Graphics transfers. ■ H.CTX, H.CTX+ and SG4 are proprietary video format capabilities. ■ SG4_sfg indicates support for SG4 Still Frame Graphics
MISC	The restrict field is 1 way for an endpoint to indicate that it is operating at 56 kbps per channel, the other way is the 56/64 command mode with a value of restrict. An endpoint on a 56 kbps conference must send one or both of the 2 indications that they are operating at 56 kbps before they become a video source in a 56 kbps conference. If they signal either way that they are operating at 56 kbps in a 64 kbps or 384 kbps conference, they are an audio-only source, but the MCU continues to send Selected Communication Mode (SCM) toward them when possible. A MISC capability of derestrict and a 56/64 command of derestrict together indicate that an endpoint is operating at 64 kbps. If either is restrict, the conference operates at 56 kbps. Other field values include: ■ dcomp indicates support for WorldWorx PCS data compliance. ■ mbe indicates support for Multi Byte Extension. MBE capability is used for the exchange of passwords, terminal names, and other special capabilities, such as, support of WorldWorx PCS specific features. ■ cic (Chair Indicate Capability) indicates chair control capability.

XR	Transfer rate capabilities are statement about the speeds at which the endpoint can operate over the current connection and operate a Px64 Multiplex. For a 384 kbps (H0) call, the endpoint sends its capabilities to indicate 384 kbps support, which displays as 384. On a 336 kbps call, the endpoint must signal 384 kbps support. If an endpoint does not indicate support for 384 kbps on a 384/336 kbps conference, the MCU provides Audio Only Communications Mode (ACOM). For a 2B conference, the MCU sets the rate to 2x64, expecting the endpoints to do likewise (64x2 is displayed; if this is not displayed, there is no 64x2 capability). Endpoints may occasionally take 2x64 (or the current channel rate: 384, 768, 1472, 1536) out of their capability. This is Mode 0 forcing and is part of normal procedures. The MCU will provide AOCM if the endpoint does not signal support matching the configuration of the conference.
AUD	The audio fields are statements of the audio protocols that the endpoint supports. 711m and 711a are PCM (G.711) and support Mu and A-law, respectively, and at least one is required of endpoints. The g728 field indicates whether G.728 is supported (LB_CELP). This value depends upon the type of the endpoint and how that endpoint is currently configured. The g722_48 field indicates endpoint support for G.722 (7 kHz) at both 48 kbps and 56 kbps. Therefore, g722_48 indicates that the endpoint supports G.722 audio at both rates. The g722_64 field indicates endpoint support for G.722 at 64 kbps in an unframed (not supported by the MCU) mode.
LSD	The LSD fields indicate the capabilities for Low Speed Data conferencing.
HSD	The HSD fields indicate the capabilities for High speed Data conferencing.
MLP	The MLP fields indicate the capabilities for Multi Layer Protocol Data capabilities.
HMLP	The HMLP fields indicate the conference's capability for High Speed MLP data conferencing.

Page 5 - Endpoint Call Status Information

This page summarizes such call-related status as per-channel join counts, join/drop time, drop reason, drop code, and auxiliary bonding drop code. In addition, it contains a drop code and software fields from the previous call. The data on the page is always retained. The Endpoint Call Status Information section groups together all call-related fields. The only new field in this section is `Join Count`; all other fields are described in Screen 8-8 and Screen 8-9.

```

Screen 8-12. Page 5 of 6: status conference *x* endpoint *y*

`Join Count` This field displays a count of the number of times this endpoint joined this conference during this conference session. This counter starts with an initial value of 0, can increment to 64, and wraps around back to 1.

Page 6 - Administered Connections

This page summarizes information on the administered connections associated with this endpoint. This data can only be viewed while the conference is active.

```

Screen 8-13. Page 6 of 6: status conference *x* endpoint *y*

`Dial-out number` The actual numbers that are dialed out by the administered connections for each channel in the call. Note that the dial Out #1 and #2 on page 1 of the forms display the DCP endpoint number. This is particularly useful with bonding dial-out calls.

`Connection State`	Indicates the current call state of the AC. The following are connection states associated with dial-out ACs: ■ `enabled` - is transient in nature and indicates that an AC is about to enter the attempting to connect state. ■ `disabled` - this may mean one of three things: — The AC has reached an administered retry threshold, and all retries are stopped. Verify this by checking the Error Log and checking whether an error type of 9 is logged against the AC. — The AC was in a connected state and the far end disconnected. — The initial channel call has not yet connected. No dial out call attempt is made for the additional channel(s) until the initial channel has reached a connected state. ■ `not scheduled` - is transient in nature and indicates that an AC is about to enter the “attempting to connect” state. ■ `waiting to retry` - means that the AC is inactive (sleeping) and waiting for the retry timer to expire. Once the timer expires, the AC sends a dial out call and enters the “attempting to connect” state. ACs in this state indicate that the dial out call has failed at least once. ■ `attempting to connect` - means that the AC is active on a call, but the call has not yet connected. ■ `connected` - means that the call associated with the AC has been answered and join cut-thru to the conference.
`Retry Count`	This field indicates how many retries have been attempted for this AC during this join attempt. This field does not clear when the AC connects. However, it clears when a new join attempt is made via a Redial feature. Note that this is different from the `Join Count` which counts the number of times the channel joined the conference during this conference session.
`Failure Cause`	This field shows an ISDN or CPTR cause value (values lower than 0x7f) recorded when the last dial out call was dropped. Values above 0x7f are generated internally. Table 8-12 lists all possible failure cause values displayed by this field and its associated description. The `Failure Cause` value is logged in the Error Log and can be displayed via the display errors command. (`Err Type` is normally displayed as a decimal.)

Table 8-12. Status AC - Failure Cause Values

Failure Cause (hexadecimal)	Description
0x00 (0t0)	N/A
0x01 (0t1)	Incorrect destination address
0x02 (0t2)	Reason unknown
0x06 (0t6)	Reason unknown
0x10 (0t16)	Normal call clearing
0x11 (0t17)	Endpoint not available
0x12 (0t18)	ISDN timer expired
0x15 (0t21)	Reason unknown
0x12 (0t22)	Destination address changed
0x1C (0t28)	Bad destination or access denied
0x1D (0t29)	Access denied
0x1F (0t31)	Reason unknown
0x22 (0t34)	Trunks unavailable
0x26 (0t38)	Temporary or facility failure
0x29 (0t41)	Temporary or facility failure
0x2A (0t42)	Resources unavailable
0x2C (0t44)	Resources unavailable
0x32 (0t50)	Access denied
0x34 (0t52)	Access denied
0x36 (0t54)	Access denied
0x3A (0t58)	Resources unavailable
0x41 (0t65)	Required capability not implemented
0x42 (0t66)	Required capability not implemented
0x45 (0t69)	Required capability not implemented
0x51 (0t81)	ISDN protocol error
0x52 (0t82)	Required capability not implemented
0x58 (0t88)	Incorrect destination number
0x60 (0t96)	ISDN protocol error
0x61 (0t97)	ISDN protocol error
0x62 (0t98)	ISDN protocol error

Continued on next page

Table 8-12. Status AC - Failure Cause Values — *Continued*

Failure Cause (hexadecimal)	Description
0x64 (0t100)	ISDN protocol error
0x66 (0t102)	ISDN timer expired
0x7f (0t127)	Reason unknown
0xC2 (0t194)	Ring no answer
0xC8 (0t200)	Hi and dry - no feedback detected
0xC9 (0t201)	Cascade link administered wrong
0xCA (0t202)	CPTR not available to detect failure

status data-module

status data-module extension [print]

This command displays internal software states of a specified data-module port. It is useful for diagnosis and locating facilities to which the data module is connected.

```
                            DATA-MODULE STATUS

Data Ext/Stn Ext for Stn DM: 301             Service State: out-of-service

      Port/Channel Number: 01C1103     Maintenance Busy? no

       CF Destination Ext:

          Connected Ports:

              Associated C-LAN Modem: 1

                       Connect speed: 9600

                                  V42? yes

                               V42bis? no
```

Output

`Data Ext/Sta Ext for Stn DM`	The data module's extension number. For DTDMs, the connected station extension is shown instead.
`Port/Channel Number`	The location of the port connected to the data module. For data channels, the channel number is shown instead.
`Service State`	The operational state of the data-module: `in-service/idle` The data module is connected but not in use. `in-service/active` The data module is connected and in use. `out-of-service` The data module has been removed from service.

If the specified port is administered as a system port, the following fields will be displayed at the bottom of the screen. See PDATA-PT in Chapter 9 for more information.

`CF Destination Ext`	The call-forwarding destination, if any, of the port.
`Maintenance Busy`	Whether the port is busied out for testing.
`Connected Ports`	Locations of ports to which the data module is currently connected.
`Associated PDATA Port`	The location of a port on a TN553 Packet Data Line circuit pack to which this data-module port is connected.
`Service State`	The operational state of the associated PDATA port.
`Maintenance Busy`	Whether the PDATA port is busied out for testing.

status hardware-group

status hardware-group [print]

Summary information on the active or last hardware group tests will be displayed. This display includes the number and percentage of maintenance objects tested, the percentage of tests passed/failed/aborted, the time elapsed since initiating the hardware group test, the specific hardware group test command (see test hardware-group command) initiated, and the state (active/canceled/complete) of the hardware-group test.

Output

`Hardware Group Command State:`	The state of a hardware-group command: active: testing is in progress; canceled: testing has been canceled; complete the command has completed and there is no testing going on.
`Number of MOs Tested:`	The number of MOs in the specified group (refer to test hardware-group command) that have had been tested by the current hardware-group command. This includes all MOs that were either actually tested or were aborted due to resource contention.
`Total Number of MOs to be Tested:`	The total number of MOs in the group that was specified in the "test hardware-group" command.
`Percent Complete:`	A ratio of the number of MOs completed and the total number of MOs to test in the command.
`Elapsed Test Time:`	The duration of the hardware-group test. If a test was canceled and then restarted this time excludes the cancel period. If the hardware-group command has finished it will indicate the length of time it took to complete the command. The time is displayed in the HH:MM:SS format where HH is hours, MM is minutes, and SS is seconds.
`Repetition Number`	The number of iterations that have been completed corresponding to the 'repeat' or the 'continuously' option.
`Percentage of Tests Passed:`	The percentage of tests that passed.
`Percentage of Tests Failed:`	The percentage of tests that failed.
`Percentage of Tests Aborted:`	The percentage of tests that were aborted.
`Command:`	The hardware-group action object and qualifiers that were entered.
`Test sequence:`	This will display either short or long.
`Test repetition:`	This will display either continuously or the keyword repeat along with the repeat value entered.
`Output options:`	This will display the selections that were chosen on the input form: auto-page, background, or failures.
`Hardware options:`	This will display the selections that were chosen on the input form, (all-ports or SPE-interchange).

The following display shows a typical result when **status hardware-group** is entered.

```
status hardware-group                                  page 1 of 1
                          HARDWARE GROUP STATUS

                  Hardware Group Command State:   active
                          Number of MOs Tested:    11070
              Total Number of MOs to be Tested:    12300
                              Percent Complete:        90%
                Elapsed Test Time (hr:min:sec):  4:15:30
                             Repetition Number:        1
                    Percentage of Tests Passed:        82%
                    Percentage of Tests Failed:        11%
                   Percentage of Tests Aborted:         7%

                         ENTERED HARDWARE GROUP Command

         Command: test hardware-group system
   Test sequence: short
 Test repetition: repeat 3
  Output Options: failures
Hardware Options: SPE-interchange
```

status health

This command lists various performance measurements in the system.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status health	***print***		init inads craft	none	none

Output

The following example shows the output for the **status health** command.

```
status health                                                          SPE B

44  auto-  0| 0| 6 up/up
```

Field descriptions

`Major`	Number of major alarms logged up to 2000
`Minor`	Number of minor alarms logged up to 2000
`Warning`	Number of warning alarms logged up to 2000
`Trunks`	Number of busied-out trunks
`Stations`	Number of busied-out stations
`Others`	Number of busied-out maintenance objects, excluding trunks and stations
`Static`	Percentage of CPU time currently dedicated to high priority items such as the operating system, rounded to the nearest whole number
`SM`	Percentage of CPU time currently dedicated to system management or periodic and scheduled maintenance, rounded to the nearest whole number If a large amount of periodic or scheduled maintenance testing is being performed, this number can be high without affecting service.
`CP`	Percentage of CPU time currently dedicated to call processing, rounded to the nearest whole number Call processing has priority over system management and will draw occupancy from the SM or IDLE categories.
`Idle`	Percentage of CPU time currently idle and available for use, rounded to the nearest whole number
`Active SPE`	Always A for a simplex SPE, otherwise: A or BThe currently active SPE lockedThe SPE is locked by the SPE-Select switches on the Duplication Interface circuit packs. autoThe switches are set to allow the system control of active SPE selection.
`Active PNC`	Always A for a simplex PNC, otherwise: A-PNC The currently active PNC or B-PNC lockedThe PNC is locked via the **set pnc** command. autoThe system is controlling selection of the active PNC.
`Duplicated?`	Whether the SPE and PNC are duplicated

`SPE Power`	Current source of power to the PPN commercialThe SPE is currently powered by the normal external power source. backupThe SPE is currently powered by the backup batteries. This is usually due to a failure of the external power source.
`Time Source`	The current source of timing signals used for system synchronization For systems with a Stratum 3 clock: externalNormal operating condition internalAnother source besides the Stratum 3 clock, such as a Tone-Clock circuit pack, is providing the master timing signal. For systems with Stratum 4 timing: primaryThe primary administered timing source secondaryThe secondary administered timing source localAnother source besides the administered ones, such as a Tone-Clock circuit pack, is providing the master timing signal.
`# Logins`	Number of current users
`Cab`	Cabinet number Cabinet numbers can be related to port network numbers with the **list cabinet** command.
`Emerg Trans`	The current setting of the switches on the SYSAM and EPN Maintenance circuit packs that control Emergency Transfer See EMG-XFER in Chapter 9. For a PPN cabinet with duplicated SPEs, settings for both SYSAM circuit packs are displayed; `auto` is then abbreviated to a, and `off` to `of`. If the Emergency Transfer switch setting on a standby SYSAM is changed while handshake is down, this field will display the prior value until handshake is restored. `auto -` Emergency Transfer is under system control and is not currently activated (normal operating state). `auto +` Emergency Transfer is under system control and is in effect. on Emergency Transfer has been manually activated. This setting should only be in effect during an emergency. `off`Emergency Transfer is manually prevented from occurring. This setting should only be in effect when a technician is on site. `n.a.`The setting of the switch in this EPN is not available to the switch. The Expansion Archangel Link may be down.
`Mj, Mn, Wn`	Number of Major, Minor or Warning alarms associated with the cabinet An asterisk indicates that the number exceeds 99.

`PNC`	Current Port Network Connectivity (PNC) status for each of the port networks in the cabinet When multiple port networks exist within a cabinet, Carriers A, B, and C are listed first and separated from Carriers D and E by a slash (e.g. up/up). `up` Both the Expansion Archangel Link (EAL) and the Indirect Neighbor Link (INL, if applicable) are available. `dn` Both EAL and INL (if applicable) are not available. `ne` (Near End) The EAL is available but the INL is not available. `fe` (Far End) The INL is available but the EAL is not available. `up/up` When two port networks share a cabinet, the port network in carriers A, B, and C is listed first and separated from the one in carriers D and E by a slash.
`Time of Day`	Current system time

Feature Interactions

In a High or Critical Reliability System, if the standby SPE Emergency Transfer Select Switch is changed and the handshake is down, the displayed Emerg Trans field will be incorrect until the handshake comes up again.

status isdn-testcall

status isdn-testcall group# / member# [print]

Examples

status isdn-testcall 78/1 print

This command displays the progress of an outgoing ISDN-PRI test call on the trunk specified. The tested ISDN-PRI B-channel port number, bit error rate, number of bits transmitted, block error rate, number of blocks transmitted, start time, duration specified, duration of test call and reason of termination are displayed on the status form.

If the bit error rate or block error rate is greater than zero, the ISDN-PRI trunk “may” be in a troubled state. Based on the statistical information displayed on the terminal, it can be decided to take the ISDN trunk out of service. This is subjective data because the ISDN trunk may be used for data or voice. If the trunk is used for data and the rates are high, the trunk should be taken out of service. If the trunk is used for voice, the trunk may not have to be taken out of service. High rates may also be due to some type of power hit on the line.

Output

`Port`	This field specifies the physical address of the ISDN-PRI B-channel.
`Bit Error Rate`	The measured bit error count according to the comparison of the sent and received bit pattern. The number is displayed in scientific notation.
`Number of Bits`	The number of bits generated. The number is displayed in scientific notation.
`Block error Rate`	The measured block error count according to the comparison of the sent and received bit pattern. The number is displayed in scientific notation.
`Number of Blocks`	The number of blocks generated. The number is displayed in scientific notation.
`Start Time`	The time the test call started (dd/hh:mm).
`Duration Specified`	The duration specified in minutes for how long the test call should run. Valid durations are 1-120 (minutes) or blank (to indicate the default amount of minutes was used to run the test).
`Duration of Test`	The duration specified in minutes for how long the test call has been running. A blank indicates that the default amount of time was used to run the test.
`Reason of Termination`	The reason of termination indicates why the test call has terminated. Valid reasons of termination are "finished," "canceled," "overflow," "no bits," "transmission," "internal fail," "data corrupt," and "in progress." A termination reason of "finished" means the test finished in the specified time. A termination reason of "canceled" means the test call has been canceled with the "clear isdn-testcall" command. A reason of "overflow" denotes that the bits transmitted have overflowed buffer allocation. A reason of "no bits" means that no bits have been received because the ISDN-PRI test call circuit connection is bad. A reason of "transmission" means there has been a data transmission interruption, probably caused from a power hit. A termination reason of "internal fail" specifies that there is an internal error on the Maintenance/Test circuit pack. A reason of "in progress" means the test is still running and a reason of "data corrupt" is used for any other error condition.

The following display shows a typical result when **status isdn-t 80/1** is entered.

```
status isdn-testcall 80/1                                 Page 1 of   1   SPE A

status journal-link

status journal-link wakeup-log | pms-log [print]

This command displays the operational status of a wakeup-log or a pms-log printer link. If the link is down, the number of times the switch has tried to re-establish the link will be shown.

A journal printer is used to document automatic wake-up events, emergency access to attendant events and, if the Property Management System is not functional, housekeeping events. When the system includes two printers, one is for the housekeeping events and the other is used for automatic wake-up events and emergency access events.

Parameters

wakeup-log The printer that handles automatic wakeup events, emergency access events and scheduled reports.

pms-log The printer that handles housekeeping events while the PMS is down.

print This qualifier sends output to a printer connected to the terminal and to the screen.

Examples

status journal-link wakeup-log
status journal-link pms-log print

Output

`Link State`	The operational status of the link as follows: up The link is established and is capable of supporting the application. This is the normal operational state. down The link is physically down. `extension not administered` An extension number for the printer administered has not been assigned on the hospitality system parameters.
`Maintenance Busy`	Whether there is any maintenance testing being performed upon the link.

The following display shows a typical result when **status journal-link wakeup-log** is entered.

```
status journal-link wakeup-log                                 SPE A

                            JOURNAL LINK STATUS

          Link State: down
   Number of retries: 1
    Maintenance Busy? no
```

status link n

(csi, si, r models with C-LAN circuit pack - Ethernet connection)

This command displays:

- static information about the link
- the modem used, connect speed, and protocol information
- a counter of CHAP failures for PPP links
- time information for PPP and Ethernet links (includes the time of the last reset, the last hour start time, and end time for the error counter statistics).

The same information that is displayed by the status link command can also be invoked with:

- **status pgate-port** for PGATE links
- **status clan-port** or **netstat link n** for C-LAN links.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status link	***n***	Number of the administered link. Example: **status link 1**	init inads craft	none	none

Output

The following example shows page 1 of the output from the **status link *n*** command (si w/ TN794 Net Packet/Packet Interface circuit pack).

Link/Port Status form (page 1)

Example below from Berlin (4-15-99):

```
status link 1                                                  Page   1 of   3
                               LINK/PORT STATUS
                 Link Number: 1
                 Link Status: connected
                   Link Type: ethernet
                   Link Name: ethernet on link 1
       Service Port Location: 01A0917
 Service Port Data Extension: 2991
               Service State: in-service/idle
                   Node Name: ber1
           Source IP Address: 192.168.10.11
                 Subnet Mask: 255.255.255.0
           Broadcast Address: 255.255.255.255
            Physical Address: 00:00:00:00:00:00
                    Enabled? yes
            Maintenance Busy? no
             Active Channels: 0
```

Field descriptions (page 1)

`Link Number`	Administered link number (assigned by **add/change data-module** command)
`Link Status`	Displays no, yes, unavail, connected, disconeected, enabled, out-of-service, or restarting
`Link Type`	The type of interface according to the physical/link protocol(s) immediately “below” the network layer in the protocol stack (ethernet, ppp, bx.25)
`Link Name`	Administered link name (assigned by **add/change data-module** command)
`Service Port Location`	Administered port location (assigned by **add/change data-module** command)

`Service Port Data Extension`	Administered extension number (assigned by **add/change data-module** command)
`Service State`	Displays: in-service/idle, in-service/active, disconnnected, out-of-service, maintenance busy, in-service, inactive, active, idle
`Node Name`	Administered node name (assigned by **add/change data-module** command)
`Source IP Address`	Administered IP address (assigned with **change node-name** or **add/change data-module** commands)
`Subnet Mask`	Administered subnet mask address (assigned by **add/change data-module** command)
`Broadcast Address`	Administered broadcast address (assigned by **add/change data-module** command)
`Physical Address`	The interface's address (CLAN circuit pack) at the protocol layer immediately "below" the network layer in the protocol stack.
`Enabled`	y (yes) or n (no)
`Maintenance Busy?`	y (yes) or n (no)
`Active Channels`	Number of active channels

Error Counters form (page 2)

```
status link 1                                                  Page   2 of   3
                           ERROR COUNTERS

    Since Reset
    Last Hour
  Incoming Dropped:        Error Pkts     Discard Pkts
    Since Reset
    Last Hour
  Outgoing Transmitted:    Unicast Pkts   Multicast Pkts   Octets
    Since Reset
    Last Hour
  Outgoing Dropped:        Error Pkts     Discard Pkts
    Since Reset
    Last Hour
  CRC Check: 0           Collision Count: 0
```

Field descriptions, page 2

`Incoming received Unicast packets`	The number of subnetwork-unicast packets delivered to a higher-layer protocol.
`Incoming received multicast packets`	The number of non-unicast (subnetwork-broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol.
`Incoming dropped octets`	The total number of octets received on the interface, including framing characters.
`Incoming errored packets`	The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol.
`Incoming packets discarded`	The number of inbound packets which were chosen to be discarded even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space.
`Outgoing Transmitted unicast packets`	The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent.
`Outgoing multicast packets`	The total number of packets that higher-level protocols requested be transmitted to a non- unicast (subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent.
`Outgoing transmitted octets`	The total number of octets transmitted out of the interface, including framing characters.
`Outgoing errored packets`	The number of outbound packets that could not be transmitted because of errors.
`Outgoing packets discarded`	The number of outbound packets which were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space.

Processor Channel Status form (page 3)

The example below is for processor channels (page 3 of the form). Information about administered hop channels displays on page 4 of the form.

The processor or hop channel status information can take either 1 or 2 pages on this form, depending on the number of links being reported and their condition. Hop channel information (shown only for BX.25 links using the Processor Interface or PGATE circuit packs) uses only 1 page.

```
status link 1                                               Page   3 of   3
                         PROCESSOR CHANNEL STATUS

UP: 001, 007, 010-115
199, 300:310

DN: 001-002

PND: 003, 216-220, 299
```

Field descriptions, page 3

NOTE:
A dash (-) or a colon (:) between numbers indicates all numbers including and between the indicated numbers.

`UP:` Channels are up.

`DN:` Channels are down.

`PND:` Channels are in a pending state from the down to the up state (processor channels only)

status link (with PGATE)

(r model with PGATE circuit pack)

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status link	***n***	Number of the administered link. Example: **status link 1**	init inads craft	none	none

Output

The following example shows the output from the **status link 1** command.

```
                                                           Page   1 of   4

                              LINK / PORT STATUS

                           Link Number: 1
                           Link Status: disconnected
                             Link Type: x.25
                             Link Name: audixa
                 Service Port Location: 01C0301
           Service Port Data Extension: 4011
                         Service State: in service/idle
                               Enabled: y
                     Maintenance Busy? n
                       Active Channels: 0

                               CONNECTED TO:

                  Destination: TDMODULE                 Destination Port: 1C0303
           Destination Status: in-service/active     Destination Extension: 4002
```

status logins

status logins [print]

This command will display information about all of the users that are currently logged into the system. This information will contain their login names, location of physical access, and their currently executing command.

The screen does not automatically update, and is a reflection of the system at the time the request was made. Users may have logged off, or on, or the command may have finished executing while the information is being displayed. These updates will not be reflected until the next execution of the command.

The command will take a snapshot of the commands that the users on the system are currently executing. Because of timing, the command could be terminated by the time this command finishes displaying the list (i.e. the active command may not be accurate).

status packet-interface

status packet-interface [print]

The status packet-interface command displays the status of all packet-interface circuit packs in the system along with link information. The service state is displayed for both active and standby packet-interface circuit packs. Link status information including total, active and failed links are displayed for active packet-interface circuit packs only.

If there are no standby packet interface circuit packs, or if the standby is inaccessible (due to handshake failure, incomplete memory refresh, or locking of the SPEs) the standby packet-interface circuit packs will be in the uninstalled state.

When a packet-interface circuit pack is out-of-service or uninstalled, it is not used to establish and maintain links. When the circuit pack returns to in-service status, new links are again assigned to it.

For simplex SPE systems, information for only the A carrier packet-interface is displayed. For duplicated SPE systems, if the standby is inaccessible because of handshake failure or locking of carriers, the standby packet-interface circuit packs will be in the uninstalled state.

Output

Separate columns identify each packet interface circuit pack slot. Service state is displayed for both active and standby packet-interface circuit packs. Dashes in output fields for the standby SPE indicate that link information is not applicable to standby packet-interface circuit packs.

`Location`	The packet-interface cabinet, carrier and circuit pack position number.
`Service State`	One of the following states is displayed: "in-service", "out-of-service" or "uninstalled". The "standby" state is used in place of "in-service" for standby packet-interface circuit packs.
`Total links`	The total number of links.
`Active links`	The number of links that are in use.
`Failed links`	The number of links that failed to be established. These links are in a recovery state and not active. The failures can arise from problems in the packet-interface, EI or center stage hardware. The number of failed links is the number of total links minus the number of active links.

The following display shows a typical result when **status packet-interface** is entered.

```
status packet-interface

                     PACKET INTERFACE STATUS

     Location:       01A1             01A2             01A3
Service State:       in-service       uninstalled      uninstalled

  Total Links:       32                -                -
 Active Links:       32                -                -
 Failed Links:       0                 -                -

     Location:       01B1             01B2             01B3
Service State:       standby          uninstalled      uninstalled

  Total Links:       -                -                -
 Active Links:       -                -                -
 Failed Links:       -                -                -
```

status periodic-scheduled

status periodic-scheduled [print]

The status periodic-scheduled command displays summary information on currently active and recently completed background testing. Periodic tests are run every hour, and scheduled tests are run daily. Starting and stopping times, and other parameters for daily scheduled testing are administered on the **change system parameters maintenance** form.

Output

`Percentage Complete`	The ratio of the number of maintenance objects tested to the total number of maintenance objects tested during a cycle. For periodic tests, the ratio is for the current cycle, if active; or for the last completed cycle if not. For scheduled tests, the ratio is for the last completed cycle.
`System Critical`	System critical resources are those whose health affects the entire system such as the processor. These are always tested first.
`Shared Resource`	Shared resources are those that are used by many users, such as trunks. These are tested after system critical resources.
`Single User`	Single User resources are those whose health affects only one user, such as voice stations.

`Pre- SCHEDULED MAINTENANCE`	The system can be administered to perform interchanges of duplicated components and backup of data to disk before daily scheduled maintenance begins. This is pre-scheduled maintenance and is administered on the **change system-parameters maintenance** form.

The following display shows a typical result when **status periodic-scheduled** is entered.

```
status periodic-scheduled

               MO            Current   Current    Previous Cycle   Rate of
               Type          Cycle %   Cycle      Duration         Completed

       Start Time of Current or Previous Cycle: 11/18/22:00
```

status pgate-port

status pgate UUCSSpp [print]

The status pgate-port command displays the operational status of a a specified Packet Gateway port. Such ports support the connection of X.25 adjunct applications to the system. If the technician knows the X.25 link number associated with the connection, but not the port number, then the “status link” command may be used to access exactly the same information.

Adjunct Applications supported over X.25 connections include:

- AUDIX
- Calling Party Billing Number (CPN/BN or ISDN Gateway)
- CMS
- DCS
- Gateway Channels for DCS over ISDN-PRI
- Message Server

See *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, for details. Status information provided by the command is restricted to the switch hardware and extends no further than the Packet Gateway circuit pack port.

The screen output for this command is the same as that for the **status link** command.

status processor-channel 1

The following screen applies to processor channels carried over link type of Ethernet or ppp (using the TCP/IP protocol).

```
                           PROCESSOR CHANNEL STATUS

            Channel Number: 1

            Channel Status: Administered but not connected

               Link Number: 3

                 Link Type: ethernet

     Message Buffer Number: 0

               Reset Count: 0

      Retransmission Count: 0
```

status pms-link

status pms-link [print]

The status pms-link command displays the status of the property management system interface link. If the link is up, whether or not a data base swap is taking place between the switch and PMS, will be shown. If the link is down, the number of times the switch has tried to set up the link will be shown.

A property management system (PMS) is a stand alone computer system which can be integrated with the switch to enhance the service capability for a hotel/motel.

Output

`Physical Link State`	Up, down, or extension not administered will be displayed. The PMS link is considered administered only if an extension is given in the system hospitality form.
`Protocol State`	
`Maintenance Busy`	Whether there is any maintenance testing being performed upon the link.

The following display shows a typical result when **status pms-link** is entered.

```
status pms-link

                            PMS LINK STATUS

        Physical Link State: extension not administered
             Protocol State:

           Maintenance Busy?
```

status pnc

status pnc [print]

The status pnc command displays a summary of conditions on the active and standby Port Network Connectivities. If the PNC is not duplicated, the screen displays blanks in the PNC-B and other duplication-related fields.

Output

Most fields on this screen display blanks when the PNC is not duplicated.

`Duplicated?`	Whether or not the system has a duplicated PNC (Critical Reliability option).
`Software Locked?`	On a system with duplicated PNC, whether the PNCs are locked by means of the **set pnc lock** or **reset pnc override-and-lock** commands. When this field displays “yes”, spontaneous or demand PNC interchanges are not possible. To enable interchanges, use the **set pnc unlock** command.
`Standby Busied?`	On a system with duplicated PNC, whether or not the standby PNC is busied out with the **busy pnc** command. Interchanges are prevented when the standby is busied out.
`Direct Connect?`	Whether the system uses direct-connect connectivity or a center stage switch.
`Standby Refreshed?`	On a duplicated system, this field indicates whether the standby PNC has completed a global refresh of duplicated call setup after being released from a busyout, or after a system reset. **NOTE:** This field does not indicate if a partial unrefresh has taken place in response to a problem on the standby. Only a “functional” state of health on the standby (all zeros in the state of health vector) guarantees that the standby’s call setup matches completely that of the active.
`Interchange Disabled?`	This field displays “yes” when the anti-thrashing mechanism is in effect, preventing PNC interchanges. This is the case for 5 minutes after a spontaneous PNC interchange, and for 30 seconds after a demand interchange. The **reset pnc interchange override-and-lock** command overrides antithrashing. This field does not indicate whether a PNC interchange is currently prevented by a software lock, by insufficient state of health of the standby, or by busyout of the standby.

In a duplicated system, each PNC has a separate entry for the following fields, representing conditions for only that particular PNC.

`Mode`	This field displays "active" or "standby", depending on whether or not that PNC controls active call processing.

`State of Health`	On a system with duplicated PNC, the state of health of each PNC. For the standby PNC, service effects mentioned below are those that would occur if that PNC were to become active via an interchange. Functional: the indicated PNC has no service disrupting alarms against it. The state of health vector is all zeros, and call setup on the standby PNC matches that of the active. Partially functional: the health of the PNC is less than perfect. The source and severity of the problem is indicated by the state of health vector (Inter-PN and Inter-SN Indexes). Whenever the standby's state of health is partially functional, duplicated call setup on the standby probably does not match that on the active. Not functional: Expansion Archangel Links to all EPNs are down on this PNC. No service is possible to any EPNs via this PNC.
`Inter PN Index, Inter SN Index`	The Inter-PN and Inter-SN Indexes form the state of health vector, which is used to track and compare the states of health of both PNCs. The fields making up the indexes are two digit numbers separated by periods (.), with each field representing a different class of faults. The fault class fields are arranged in order of decreasing importance from left to right. In other words, each field in the index supersedes the following fields in determining which PNC is healthiest. The Inter-PN Index contains five fields (XX.XX.XX.XX.XX), and the Inter-SN Index has two (XX.XX). The Inter-PN Index reports faults in connectivity between port networks and supersedes the Inter-SN Index, which reports faults in connectivity between switch nodes. (The Inter-SN Index is only meaningful for systems with a center stage switch having 2 switch nodes, each of which is duplicated). The meaning of each fault class field is given in Table 8-13 below. A zero entry indicates that there are no such faults reported. Higher numbers indicate increasing number of faults. All zeros indicates perfect state of health. Unless the PNCs are locked, the active PNC's state of health should always be equal to or better than the standby's. (Otherwise, the system would perform a spontaneous interchange.) After a PNC-related alarm is cleared, the system performs a partial refresh of the standby PNC. The corresponding fault class field is not updated to reflect the improved state of health until the refresh is done. The state of health indexes will not agree with the current alarm status during this period.

Table 8-13. Fault Class Field Descriptions

Fault Class	Priority	Description	MOs
FC_EAL	1	Number of PNs with EALs down	EXP-PN
FC_INL	2	Number of PNs with LINL, RINL, or EI-SNI neighbor link faults	EXP-PN SN-CONF
FC_HW	3	Number of PNs affected by hardware faults in a link having an EI as an endpoint (Endpoints can be determined with **list fiber-link**.)	EXP-INTF SN-CONF FIBER-LK SNI-BD DS1C-BD
FC_PER	4	Number of PNs affected by SNI peer link faults for SNIs connected to EIs	SNI-PEER
FC_DS1	5	Number of PNs affected by DS1C facility faults	DS1FAC
FC_SNIL	6	Number of inter-switch-node fibers affected by peer or neighbor link faults	SNI-PEER
FC_SNIHW	7	Number of inter-switch-node fibers affected by hardware faults	SN-CONF SNI-BD FIBER-LK

`Major Alarms, Minor Alarms, Warning Alarms`	The number of major, minor, or warning alarms logged against DS1C-BD, SNI-BD, SNC-BD, EXP-INTF, FIBER-LK, DS1C-FAC, SNC-LINK, SN-CONF, SNC-REF, SYNCH, and SNI-PEER on the indicated PNC.
`Switch Node Locations`	The locations of all Switch Nodes comprising the indicated PNC.

The following display shows a typical result when **status pnc** is entered on a system with a single switch node CSS and duplicated PNC.

```
status pnc
                         PORT NETWORK CONNECTIVITY

                                Duplicated? yes
                           Software Locked? no
                            Standby Busied? no
                            Direct Connect? no
                         Standby Refreshed? yes
                      Interchange Disabled? no

            A-PNC                                   B-PNC

            Mode: active                            Mode: standby
 State of Health: functional             State of Health: functional

```

status port-network

This command lists port network(s) in the system.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status port-network	***print***		init inads craft	none	none

Output

The following example shows the output for the **status port-network** command.

```
status port-network                                                      SPE B

                              PORT NETWORK STATUS

Field descriptions

PN	The Port Network number associated with the Port Network for which status is being displayed.
Major Alarms	The number of major alarms logged against the Port Network that is being displayed.
Minor Alarms	The number of minor alarms logged against the Port Network that is being displayed.

`Warning Alarms`	The number of warning alarms logged against the Port Network that is being displayed.
`Carrier Locs`	The cabinet and carrier locations of each carrier in the Port Network.
`PNC Status`	Active (and Standby if PNC is duplicated) Port Network Connectivity (PNC) status for the specified port network is displayed. The PNC Status of a port network is determined by the availability of the Expansion Archangel Link (EAL) and Indirect Neighbor Link (INL) to the port network. A status of "up" denotes that the EAL and INL are both available. A status of "down" is displayed when the EAL and INL are both unavailable. When the EAL is available, but the INL is unavailable, a status of "near-end" is displayed. A status of "far-end" is displayed when the INL is available and the EAL is unavailable. When the EAL is unavailable (far-end), tone clock, tdm bus, and packet bus information will be blank.
`FIBER-LINK`	This field displays the fiber-link number associated with all fiber links having an Expansion Interface circuit pack endpoint residing in the specified Port Network. The fiber connectivity side will also be displayed (i.e. "A-PNC" or "B-PNC").
`Endpoints`	The physical position of each Expansion Interface board that is an endpoint for a fiber link in the specified Port Network is displayed as “UUcSS.” “UU” represents the cabinet number, “c” represents the carrier, and “SS” represents the slot position. The simplex PNC configuration will display only one Expansion Interface pair, while the duplex PNC configuration will display two Expansion Interface pairs separated by a hyphen (-). If blanks are displayed it means the endpoints could not be retrieved by software.
`Mode`	The mode is the current role of the link. A mode of "active" means the link is providing normal circuit and control functions for the Port Network. A mode of "standby" means the link is part of a duplicated system and is ready to perform its functions but is not active. If blanks are displayed it means that PNC is not duplicated, or the mode could not be retrieved from software.
`TDM Bus`	The TDM bus identifier associated with the Port Network is displayed. The TDM bus ("a" or "b") specifies which half of the TDM bus is being displayed.
`Service State`	The operational state of the TDM bus. A TDM bus service state of "in" means the bus is in normal operation. A TDM bus service state of "out" means the bus has failed certain maintenance tests and has been taken out of service, or the maintenance object has been demand busied out.
`Control Channel`	This field shows whether the TDM bus has the control channel on it (“y”/”n”). Only one TDM bus of a TDM bus pair on each Port Network can have the control channel on it at a given time. If the system does not contain an EPN, blanks appear in this field.

`Dedicated Tones`	This field shows whether the TDM bus has the system tones on it ("y"/"n"). Only one TDM bus of a TDM bus pair can have system tones on it at a given time. If the system does not contain an EPN, blanks appear in this field.
`TONE/CLOCK`	The location of the tone-clock circuit packs in the specified Port Network. The location is represented using the cabinet and carrier where the tone-clock resides (e.g. 1a, 1b, 2a, 2b, etc.).
`Service State`	This field represents the operational state of the tone-clock circuit pack. A service state of "in" means the tone-clock has been installed and is in normal operation. A service state of "out" means that the tone-clock is out of service and has failed certain maintenance tests.
`System Clock`	This field shows which tone-clock circuit pack supplies the system clock for that port network by displaying the mode of the tone-clock. An "active" mode means that the tone-clock supplies the system clock. Only one tone-clock in each Port Network can have a mode of "active" at any given time. A "standby" mode means the tone-clock is part of a duplicated clock system and is ready to supply the system clock, but is not currently "active." A "down" mode means the tone-clock is not operational.
`System Tones`	This field shows which tone-clock circuit pack supplies the system tones for that port network by displaying the mode of the tone-clock. An "active" mode means that the tone-clock supplies the system tones. Only one tone-clock in each Port Network can have a mode of "active" at any given time. A "standby" mode means the tone-clock is part of a duplicated clock system and is ready to supply system tones, but is not currently "active." A "down" mode means the tone-clock is not operational.
`PKT`	This field contains the Packet Bus identifier, which is the same as the Port Network number.
`Service State`	This field represents the operational state of the packet bus. A service state of "in" means the packet bus has been installed and is in normal operation. A service state of "out" means that the packet bus is out of service and has failed certain maintenance tests, or the maintenance object has been demand busied out. A service state of "reconfig" means that the Maintenance/Test circuit pack has swapped one or more signal leads because of lead faults detected during testing (Duplex System Only). A service state of "open lds" means the Maintenance/Test circuit pack query was run and open bus leads were found. A service state of Blanks in this field means the system does not have the Packet Bus feature optioned.
`Major Alarms`	Whether major alarms are logged against the packet bus that is being displayed ("y" or "n").
`Minor Alarms`	Whether minor alarms are logged against the packet bus that is being displayed ("y" or "n").

`Bus Faults`	This field indicates the number of faulty bus leads, where a fault is defined as either shorted to another lead or stuck at some value. This field may take on any integer value between 0 and 24. The field contains a blank if the Maintenance/Test circuit pack is not present or has been taken out of service.
`Open Bus Leads`	This field indicates the number of bus leads that have an open circuit between the Maintenance/Test circuit pack and bus terminator. This information is determined by testing performed on the bus leads; bus leads test open as a result of physical damage to the backplane or the backplane's connectors, or because a bus terminator is missing. This field may contain integer values between 0 and 24. This field contains a blank if the Maintenance/Test circuit pack is not present or has been taken out of service.

status processor-channel

status processor-channel channel# [print]

The status processor-channel command displays the status of the specified processor channel and the values of its various counters. A processor channel is one of 128 logical channels associated with an SCI link. Each processor channel terminates in the switch processing element with a session.

Parameters

channel number	The processor channel number (1-128).

Output

`Channel Number`	The processor channel number 1-128.
`Channel Status`	The state that the channel is in: 1-16. The following describes the various channel states:
`Reset Count`	The number of times that the reset has been issued for this channel.
`Message Buffer Number`	The number of message buffers currently allocated for communications on this channel.
`Link Number`	The physical BX.25 interface link, 1-16, associated with the channel.
`Retransmission Count`	The number of times that message retransmission has occurred.

The following display shows a typical result when **status processor-channels 1** is entered.

```
status processor-channels 1

                     PROCESSOR CHANNEL STATUS

                  Channel Number: 1
                  Channel Status: 11: Administered but not connected
                     Reset Count: 0
           Message Buffer Number: 0
                     Link Number: 3
            Retransmission Count: 0
```

status signaling-group

status signaling-group group# [print]

This command displays the service state, type, port location, and of the primary and secondary D-Channels within an ISDN-PRI signaling group. A signaling group is a set of B-channels signaled for by a designated single D-channel or combination of D-channels.

Parameters

group# An administered number associated with each signaling group.

Output

`Group ID:` An administered number from 1 to 666 that identifies the signaling group.

`Type:` See “ISDN-SGR (ISDN-PRI Signaling Group)” in Chapter 9 for more information about group types.

facility All members are carried on a single DS-1 associated facility. Facility-associated signaling groups support only simplex D-channel configuration.

non-facility Members can include trunks on several different associated DS-1 facilities. The DS-1 facility is identified signaling across the ISDN-PRI using an explicit facility identifier. A single D-channel on one of the facilities is used to signal for all members. In a duplex configuration, a second D-channel is assigned to act as a backup in case the primary signaling channel fails.

`Group State:` The operational state of D-channel providing signaling for the group: `in-service` or `out-of-service`. In duplex configurations, this field displays `in-service` if either D-channel is functioning.

The following information is given for both primary and secondary D-channels, if any.

`Link:` The number of the link carrying the D-channel.

`Port:` The location of the port carrying the D-channel.

`Level 3 State:` The operational state of the primary and secondary D-channels:

`in-service` The D-channel is functioning.

`standby` the link is established but the D-channel is not currently being used for layer 3 signaling.

`wait` This is a transitional state in the process of progressing to the in-service state. The switch has sent an ISDN SERVICE message requesting establishment of layer 3 communications, and is awaiting a SERVICE ACKNOWLEDGE message from the far end to put the D-channel into service.

`maintenance busy` The D-channel is no longer in the multiple-frame-established state at layer 2. When an active D-channel in a duplex signaling group fails, it is placed into this state and an interchange to the standby D-channel takes place. When layer 3 signaling is re-established over the new D-channel, the failed D-channel is moved from this state to out-of-service and restarted. If the link is successfully re-established, it is put into the standby state.

`manual-out-of-service` The link carrying the D-channel has been busied-out by command.

`out-of-service` The D-channel is down.

`no-link` A link has not been administered for this D-channel on the signaling-group form.

The following display shows a typical result when **status signaling-group 1** is entered.

```
status signaling-group 1                                Page 1 of   1   SPE A
                          STATUS SIGNALING-GROUP

        Group ID: 1
            Type: facility associated signaling
     Group State: in-service

                            Primary D-Channel

   Link: 1      Port: 01C1924    Level 3 State: in-service

                           Secondary D-Channel

   Link:        Port:            Level 3 State:
```

status spe

status spe [print]

The status spe command displays a page of output summarizing the condition of the active and standby (if the system is duplicated) SPE(s) in the system. If the SPEs are not duplicated, the fields in the standby SPE column will be blank.

Output

`Duplicated?`	This field specifies whether the system is a duplex SPE system ("yes" or "no").
`SPE Selected:`	If the system is a duplex SPE system, this field displays which SPE is locked active by the position of the duplication interface circuit pack Select-switches. If "spe a locked active" is displayed, then the SPE in cabinet 1 and carrier A has been locked active (both duplication interface circuit pack switches are switched left). If "spe b locked active" is displayed, then the SPE in cabinet 1 and carrier B has been locked active (both duplication interface circuit pack switches are switched right). If "auto" is displayed, it means the switches are in any other combination of positions besides both left or both right. If blanks are displayed, the system is not a duplex SPE system (there are no duplication interface boards).

`Standby Busied?`	This field specifies whether the standby SPE is busied out ("yes" or "no"). Blanks are displayed if the system is not a duplex SPE system.
`Standby Refreshed?`	This field specifies whether the standby SPE's memory has been completely refreshed ("yes" or "no"). Blanks are displayed if the system is not a duplex SPE system.
`Standby Shadowing:`	This field specifies whether the standby SPE's memory is currently being updated when changes are made to the active SPE's memory ("on" or "off"). Blanks are displayed if the system is not a duplex SPE system.
`Standby Handshake:`	This field specifies whether the software running on the standby SPE's duplication interface board is communicating to the software on the active SPE's duplication interface board ("up" or "down"). Blanks are displayed if the system is not a duplex SPE system.
`Recent Spontaneous Interchange?`	This field specifies whether a spontaneous interchange has occurred within the last hour. If this field displays "yes," a spontaneous interchanges has occurred within the last hour. If the field displays "no" a spontaneous interchange has not occurred within the last hour, or a technician has purposely reset this field in the software. Immediately following a spontaneous interchange, the field is set to "yes." While the field displays "yes," the health of the standby SPE can never be better than "partially functional," and an interchange can not occur unless the health of the active SPE drops below "partially functional." Recent interchange mode can be cleared by either **test spe-standby long** or **busyout spe-standby**. This condition clears automatically one hour after the interchange occurred. This field will be blank in a simplex SPE system.
`Mode:`	The mode is the current role of the SPE. "`active`" indicates that this SPE is controlling the network and providing services for the system. `standby` indicates that this SPE is part of a duplicated system and is not currently active. Blanks indicate that the system has a simplex SPE.
`Select Switch:`	This field shows the position of the SPE Select-switch on the duplication interface circuit pack. The Select-switch can be in three different positions. A position of "spe a" means the switch is switched left. A position of "spe b" means the switch is switched right. A position of "auto" means the switch is in the center position. "unavail" means the duplication interface circuit pack has been removed (the board has been unseated). Blanks mean that the system is not duplicated and there is no Select-switch due to there being no duplication interface boards.
`Major Alarms:`	The number of major alarms logged against the SPE are displayed in this field. Blanks in the standby fields mean that the system is not duplicated and a standby SPE does not exist. The category **spe** may be entered on the **display alarms** or **display errors** forms to view all alarms or errors logged against SPE maintenance objects.

`Minor Alarms:`	The number of minor alarms logged against the SPE are displayed in this field. Blanks in the standby side mean that the system is not duplicated and a standby SPE does not exist. The category **spe** may be entered on the **display alarms** or **display errors** forms to view all alarms or errors logged against SPE maintenance objects.
`Warning Alarms:`	The number of warning alarms logged against the SPE are displayed in this field. Blanks in the standby side mean that the system is not duplicated and a standby SPE does not exist. The category **spe** may be entered on the **display alarms** or **display errors** forms to view all alarms or errors logged against SPE maintenance objects.
`State of Health:`	On a duplicated SPE system, these fields each display one of the following states of health for each SPE: "functional," "partially functional," "not refreshed," or "not functional". If the system has a simplex SPE, the state of health fields for both the active and the standby SPEs will display nothing. A health of "functional" means that the SPE has no service disrupting alarms. A health of "partially functional" means that the health of the SPE has been degraded (possibly service disrupting). A health of "not functional" means that the associated SPE is not cycling at all (no service). A health of "not refreshed" means that the standby SPE's memory has not been refreshed with the active SPE's memory, but it is otherwise healthy and cycling correctly.
`R-Media State:`	This field represents the operational state of the removable media device. A service state of "in-service" means the removable media has been installed and is in normal operation. A service state of "out-of-service" means that the removable media is out of service and has failed certain maintenance tests. A state of "maintenance-busy" means the removable media is busied out. Blanks mean the removable media device is not installed or the system has a simplex SPE.
`Disk Present?`	If a disk device resides on the SPE this field will display "yes," otherwise, the field will display "no." A blank in the SPE-B side indicates the system has a simplex SPE.
`Disk State:`	This field represents the operational state of the disk device. A service state of "in-service" means the disk has been installed and is in normal operation. A service state of "out-of-service" means that the disk is out of service and has failed certain maintenance tests. A state of "maintenance-busy" means the disk is busied out. Blanks are displayed on the SPE-B side when the system is not duplicated.

The following display shows a typical result when **status spe** is entered on a duplicated system.

```
status spe                                                         page 1 of 1
                                PROCESSOR COMPLEX

                                  Duplicated? yes
                                SPE Selected: auto
                              Standby Busied? no
                           Standby Refreshed? yes
                           Standby Shadowing: on
                           Standby Handshake: up
              Recent Spontaneous Interchange? no

                  SPE-A                                   SPE-B

            Mode: active                            Mode: standby
   Select Switch: auto                     Select Switch: auto

    Minor Alarms: 0                         Minor Alarms: 0
  Warning Alarms: 0                       Warning Alarms: 0
 State of Health: functional             State of Health: functional
   R-Media State: in-service             R-Media State: in-service
    Disk Present? yes                       Disk Present? yes
      Disk State: in-service                  Disk State: in-service
```

status sp-link

status sp-link [print]

This command displays a summary of the operational state of the system printer link.

Output

`Link State:` The operational state of the link:

up A call is currently set up to the system printer.

down The link is administered but a call is not currently set up to the printer.

`extension not administered` An extension has not been administered for the system printer on the features-related system parameters form.

`Number of Retries:` The number of times the switch has tried to establish the link since a request to set it up has been received. This field is displayed only when the link is down. The maximum value displayed is 999.

`Maintenance Busy?` Whether maintenance testing is being performed on the system printer link. A blank is displayed if the system printer link is not administered.

The following display shows a typical result when **status sp-link** is entered.

```
status sp-link                                                SPE A

                      SYSTEM PRINTER LINK STATUS

        Link State: down
 Number of Retries: 0
  Maintenance Busy? no
```

status station

status station extension [print]

The status station command displays internal software state information for diagnosis. This command can help locate facilities to which the station is communicating.

Output

Type	The type of equipment administered for the extension.
Extension	The extension number specified on the command line.
Port	The location of the port assigned to the station.
Call Park	Whether the station has a call parked.
Ring Cut Off Activated	Whether ring cut-off is activated.
CF Destination Ext	The extension of the call forwarding destination.
Message Waiting	The location of any active messages for the station: AUDIX, PMS or AP-SPE. The field is blank if no messages are waiting.
Connected Ports	Locations of ports currently connected to the station.
Agent Logged In	Numbers of hunt groups that the agent is currently logged into. A maximum of three groups is displayed.
On ACD Call?	Whether the agent is currently on an ACD call.
Work Mode	Work mode of each hunt group that an agent is logged into.

`Service State`	The service state of the station: in-service/on-hook, in-service/off-hook, in-service/in-tsa (Terminal Self Administration - see DEFINITY ECS Release 6, *Administration and Feature Description*, 555-230-522), out-of-service, or disconnected.
`Maintenance Busy?`	Whether maintenance is currently testing the object.
`SAC Activated`	Whether send-all-calls is activated.
`User Cntrl Restr`	Which, if any, restrictions are placed on the individual terminal: `total` The station cannot originate or receive any calls. `stat` The station cannot originate or receive calls to other stations. `outward` The station cannot originate calls to the public network. `toll` The station cannot make toll calls. `term` The station cannot receive calls. `none`
`Group Cntrl Restr`	Whether the station is restricted as part of a restricted group. Values are the same as for the above field, `User Cntrl Restr`.
`AWU Call at`	If an automatic wakeup call is scheduled, this field displays the time scheduled for the call.
`DND`	Status of the do not disturb feature.
`Room Status`	Whether a room is `occupied`, `vacant`, or a `non-guest room`.

The following display shows a typical result when **status station 1002** is entered.

```
status station 1002

                           GENERAL STATUS

            Type: 7405D          Service State: in-service/on-hook
       Extension: 1002              Maintenance Busy? no
            Port: 01C0702              SAC Activated? no
     Call Parked? no                User Cntrl Restr: none
  Ring Cut Off Act? no             Group Cntrl Restr: none
CF Destination Ext:
   Message Waiting:
   Connected Ports:

             ACD STATUS                        HOSPITALITY STATUS
    Agent Logged In   Work Mode           AWU Call At:
                                                  DND: not activated
                                          Room Status: non-guest room

       On ACD Call? no
```

status switch-node

status switch-node SN# [print]

This command displays the operational status and attributes of the user specified switch node. The operational status of the active and standby switch node Clock(SNC) circuit packs for the switch node are displayed along with any alarms logged against the specified switch node.

Parameters

SN number	Normally switch node 1 is located in the PPN cabinet, and switch node 2, if present, is located in the nearest EPN cabinet. The switch node number defaults to 1.

Output

A line of information is displayed for each switch node carrier.

`Switch Node`	The switch node number, 1 or 2. If the PNC is duplicated, the A and B PNCs are each reported separately.
`Location`	The physical position of the switch node carrier represented as "UUc". Where "UU" represents the cabinet number and "c" represents the carrier. The simplex PNC configuration will display only one switch node location, while the duplex PNC configuration will display the active and standby switch node locations.
`Mode`	The mode is the current role of the switch node carrier. A mode of "active" means the SN is providing normal circuit and control functions for PNC. A mode of "standby" means the SN is ready to become active, but is currently not active. If blanks are displayed it means that PNC is not duplicated.
`Major Alarms`	The number of major alarms logged against the switch node carrier that is being displayed.
`Minor Alarms`	The number of minor alarms logged against the switch node carrier that is being displayed.
`Warning Alarms`	The number of warning alarms logged against the switch node carrier that is being displayed.
`Active SNC Location`	The physical position of the active switch node Clock circuit pack, per administration, represented as "UUcSS." "UU" represents the cabinet number, "c" represents the carrier, and "SS" represents the slot position. If an SNC is administered but not inserted, "no board" will be displayed.

`Standby SNC Location`	The physical position of the standby switch node Clock circuit pack, per administration, represented as "UUcSS." "UU" represents the cabinet number, "c" represents the carrier, and "SS" represents the slot position. Blanks will be displayed if there is no standby switch node Clock for a given switch node. If an SNC is administered but not inserted, "no board" will be displayed.

The following display shows a typical result when **status switch-node** is entered.

```
status switch-node 1                                                page 1 of 1

                               switch node STATUS

                               Major   Minor   Warning  Active SNC  Standby SNC
Switch Node  Location  Mode    Alarms  Alarms  Alarms   Location    Location

 1  A-PNC      01E     active    0       0       0      01E10       01E12
 1  B-PNC      01D     standby   0       1       2      01D10       01D12
```

status synchronization

This command lists the synchronization source for the system.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status synchronization	***print***		init inads craft	none	none

Output

The following example shows the output for the **status synchronization** command.

```
status synchronization                                              SPE B

                          SYNCHRONIZATION STATUS

                Stratum Level: 4
      Inferred Sync Reference: UDS1-BD     Location: 01C20
Excessive Reference Switching: No
```

status sys-link

status sys-link UUCSSpp [channel channel#] [print]

The status sys-link command displays status data for a specified system link. The report includes the type and operational state of the link, the associated processor channel, if any, active alarms and path status, and a list of all hardware components making up the link's path. If in addition to the current path a faulted path exists, the components making up the faulted path are displayed on page 2 of the report.

Parameters

UUCSSpp The link is specified by giving the location of the port associated with the link.

channel# If the link is an X.25 link (to an adjunct or another switch), you must specify a processor channel number (1-128) associated with the link.

Examples

status sys-link 1e0201
status sys-link 1c17 channel 2

Output

`Location` The location of the port associated with the system link (cabinet-carrier-slot-circuit).

`Type/Chan` The type of system-link and the channel number of the link (for X.25 links) as follows:

EALExpansion Archangel Link

INLIndirect Neighbor Link (Center Stage Switch)

PGCPacket Gateway Call-Control Link

PRIISDN-PRI signaling Link

SAPSystem Access Port Link

X25X.25 Link to an adjunct or DCS

`Alarms` The highest level of alarm currently logged against the components making up the link.

`Current Path` The operational status of the current path:

noneThe link is down.

presentThe current path displayed below is valid.

`Faulted Path`	The status of the faulted path, if any: presentThe path of the link has been faulted at least once. noneThere is no record of the link having gone down. defaultThe default faulted path is being used.
`Last Fault`	The date and time at which the most recent fault occurred.
`State`	Whether the system link is "up" or "down."
`Current Hardware Path`	The location, maintenance name, and alarm information for each hardware component making up the current path of the link. The path begins at the Packet Interface in the SPE and terminates at the circuit path that terminates the other end of the link.
`Faulted Hardware Path`	If the link encounters a fault, the system will reroute it if possible over an alternate route. If this has taken place, the faulted path is displayed on page 2 of the report. The location, maintenance name, and alarm information for each hardware component making up the most recent faulted path is shown.

The following display shows a typical result when **status sys-link 2a0101** is entered. In the following case, the link encountered a fault and recovered by switching to a different inter-switch-node fiber.

```
status sys-link 2a0101                                   Page   1 of   2   SPE A
     Location: 02A0101       Type/Chan: EAL              Alarms: none
 Current Path: present    Faulted Path: present     Last Fault: 12/30/1991 14:18
        State: up
                              Current Hardware Path

             Maintenance                                  Maintenance

```

status trunk

status trunk group# [/ member#] [print]

The status trunk command displays information about the operational status of a single trunk or of all members of a trunk group. You can also use it to locate facilities with which the trunk is communicating.

The **monitor trunk** command displays the same information and updates the screen automatically every minute or on demand.

Parameters

group#/member# If you enter a trunk group number without a member number, then information for all members of that group is displayed as shown in the second screen shown below. If you enter a trunk group and a member number separated by a slash (/), then information for only that member, including some additional fields, is displayed as shown in the first screen shown below. If you enter a group number followed by only a slash (/), then the system defaults to member number 1 and displays the member report.

Examples

status trunk 78
status trunk 80/2 print

Output

`Trunk Group/Member`	Group and member numbers of specified trunks.
`Port`	The location of the port associated with the trunk.
`Signaling Group ID`	For ISDN trunks, the number of the signaling group to which the trunk group belongs. For other trunk types, the field is blank.
`Connected Ports`	Locations of ports currently connected to the trunk.
`Service State`	One of the following states is displayed: in-service/active, in-service/idle, out-of-service, out-of-service-NE (Near End), out-of-service-FE (Far End), maint-NE/active, maint-FE/active, maint-NE/idle, maint-FE/idle, pending-in-service, pending-maint, or disconnected. NE (Near End) and FE (Far End) refer to which end of the trunk has placed the facility in its current state. Explanations of these service states for each type of trunk appear in the maintenance object descriptions in Chapter 9, “Maintenance Object Repair Procedures”.
`Maintenance Busy`	Whether maintenance testing is currently being performed upon the trunk.
`CA-TSC State`	The status of the call-associated temporary signaling connection, if any. A TSC is a temporary connection set up to pass call information over ISDN-PRI signaling links.

The following display shows a typical result when **status trunk 20/1** is entered.

```
status trunk 20/1
                                TRUNK STATUS

Trunk Group/Member: 020/001                      Service State: in-service/idle
              Port: 01D0801                 Maintenance Busy? no
Signaling Group ID: 1                           CA-TSC State: none
   Connected Ports:
```

The following display shows a typical result when **status trunk 1** is entered for a trunk group with two members.

```
status trunk 1

                      TRUNK GROUP STATUS

Member    Port      Service State     Mtce Busy  Connectd Ports
01/01     01A0101   in-service/idle    no        01A0501  02B0607
01/02     04A0702   in-service/idle    no        04C0604
```

status tsc-administered

status tsc-administered signaling-group# [/tsc-index] [print]

This command displays the operational status of temporary signaling connections (TSCs) administered for a specified signaling group.

Examples

status tsc-administered 1
status tsc-administered 1/2 print

Parameters

signaling-group#	An administered number associated with each signaling group.
tsc-index	A number associated with each TSC in a signaling group.

Output

`TSC Index`	The administered TSC index (1-759).
`TSC State`	A state of "inactive" means that the administered TSC is not functioning (i.e. D-Channel out-of-service, or disabled, etc.). A state of "active" indicates that the administered TSC is up and user information can be exchanged end-to-end. A state of "pending-inactive" shows that the TSC is being released. A state of "pending-active" means that the TSC is about to come up.

`Establish` This field pertains to the switch responsible for the origination of the administered TSC. A state of "as-needed" shows that the TSC is established on an as needed basis. A state of "permanent" shows that the TSC is permanently established.

`Enabled` “Y” indicates that the administered TSCs have been enabled.

`Congested` A congested state indicates that the network cannot handle the receipt of USER INFORMATION messages for the administered TSC. "Yes" indicates that the administered TSC is congested. "No" indicates that the administered TSC is not congested. "Clear" indicates that TSC was congested during its active period and the congestion has been cleared.

The following display shows a typical result when **status tsc-administered 1/1** is entered.

```
status tsc-administered 1/1
                 ADMINISTERED NON-CALL-ASSOCIATED TSC STATUS

TSC         TSC
Index       State             Establish     Enabled      Congested

1           inactive          as-needed     yes          no
```

status tti

status tti [print]

This command displays the operational status of the Terminal Translation Initialization (TTI) background maintenance task. The TTI Background maintenance task is activated by enabling the TTI feature on the system-parameters features administration form.

Output

`TTI Background Task State:`	One of the following:
	`generating TTI ports`
	`removing TTI ports`
	`suspended`
	`not active`
	`completed - all ports translated`
	The last execution of the background task completed normally.
	`completed - some ports not trans`
	The task completed due to resource exhaustion with some ports left untranslated.

`TTI State:`	`off`The TTI feature is not enabled. `voice, data`The type of TTI ports that are being generated or removed
`# of Boards Completed:`	Number of TTI-supported circuit packs that have been processed by the background maintenance task. A “completed” circuit pack has either had all its unadministered ports translated as TTI ports or its TTI ports have been removed and are now unadministered ports.
`# of Boards Left to Process:`	Number of TTI-supported circuit packs that have not yet been processed by the background maintenance task.
`Percent Complete:`	A ratio of the of number of circuit packs completed to the total number.
`Elapsed Time Since Task Started:`	Elapsed time in hours:minutes:seconds since the TTI background task was started. This field is blank if the task is not active. If the task is completed or suspended, this field displays the elapsed time up to when the job finished or was suspended.

The following display shows a typical result when **status tti** is entered.

```
status tti
                                TTI STATUS
          TTI Background Task State:  completed - all ports translated
                          TTI State:  voice
              # of Boards Completed:  30
        # of Boards Left to Process:  0
                   Percent Complete:  100
    Elapsed Time since Task Started:  0 :0 :1
```

test alarms

This command tests the hardware associated with selected alarms

Synopsis

test alarms ***auto-page failures step [short | long][repeat number | clear]***

Permissions

The following default logins may execute this command: system technician, inads, init, nms.

Examples

test alarms
test alarms step failures
test alarms long clear auto-page
test alarms long failures

Description

This command allows the technician to automatically test all of the hardware that is associated with the active alarms in the alarm log. This command provides a query form to help the user narrow the selection of alarmed objects. Once the form is filled out, the user presses ENTER and the hardware associated with the selected alarm log entries is tested. The results will be displayed in standard test output and status information will be displayed on the message line as the command progresses.

Several alarms may be logged against a single maintenance object, each alarm representing a different problem. Even if there are multiple entries in the alarm log for a single object, the test alarms command will only test each physical object once.

Defaults

The default options for this command are: short, repeat of 1.

Parameters

auto-page This option provides the ability to continue testing and displaying test results, by providing a new screen every time the SAT screen is filled with test results. The screen does not scroll to accommodate new results; instead a new screen is provided after the current screen fills up.

If the auto-page option is not specified, the SAT screen will not be refreshed once it is filled with test results and testing will stop until the user enters the "PAGE" key to continue or the "CANCEL" key to halt the testing.

failures This requests that only the failures be displayed on the screen. All passes will not be displayed on the output screen. Hardware failures as well as aborts, conflicts and EPN-down failures will be displayed.

step This option will allow the user to step to the next or previous alarm and not have the current alarm tested. When this option is specified, the user is presented with the alarm information and prompted for a keypress. The user may enter CANCEL to abort the command, ENTER to test the currently displayed alarm, NEXT ALARM (function key) to move to the next alarm, PREV ALARM (function key) to move to the previous alarm without testing the currently displayed alarm. If this option is given, then the NEXT ALARM (function key) or PREV ALARM (function key) may be pressed at any time during the command (even during test results). If the NEXT ALARM or PREV ALARM is pressed during a test, the test is aborted, testing of the current alarm stops, and the next alarm or previous alarm is displayed. If the first alarms is displayed, and the PREV ALARM is pressed, then the last alarm is displayed. Also, if the last alarm is currently displayed, and the NEXT ALARM is requested, then the first alarm will be shown.

NOTE:
When this option is given the only way to terminate this command is to press CANCEL**.**

short This will cause the command to execute a series of nondestructive diagnostic tests.

long This will execute a more comprehensive and longer version of the diagnostic tests. This may involve both destructive and nondestructive tests.

repeat number The "number" specifies how many times each test in the sequence is to be repeated. "Number" may be any integer between 1 and 100.

clear This option causes the test sequence (short or long) to repeat until the alarm is cleared or a single test in the sequence fails. The long clear option forces a clear of all alarms if no errors are encountered during testing. The short clear option only clears alarms pertinent to tests in the short sequence.

WARNING:
Executing a clear with short option, may not clear all alarms even if all tests pass.

WARNING:
Since the "clear long" options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Help Messages

If the technician presses HELP after entering “test alarms” the following message will be displayed:

```
Enter ['auto-page'], ['failures'], ['step'],
['short' or 'long'], ['repeat' (1-100) or 'clear']
```

Error Messages

If the command entered is in conflict with another currently executing command, then a message will be displayed showing the login id of the conflicting user and the conflicting command. The message is as follows:

```
'login id':'command' has a command conflict
```

If during the execution of a command a resource problem occurs that requires the user to restart the command, then the following message will be displayed:

```
Command resources busy;
Press CANCEL to clear, and then resubmit
```

If all of the available maintenance resources are currently in use, then the following message will be displayed:

```
All maintenance resources busy; try again later
```

Query From Input

After entering the command **test alarms**, the system technician will be presented with an options form for alarm selection.

`Alarm Types` The type of alarm to be tested is specified by placing a 'y' or 'n' in the alarm type fields. The technician can choose a combination of active alarms: major, minor, and/or warning.

`Interval` Test alarms for records for the last hour (h), last day (d), last week (w) or all (a). The default is all.

`From` Test alarm associated with records from the time specified by mm/dd/hh/mm, where mm month, dd is the day, hh is the hour and mm is the minute. If no "from" date is entered, then no checking is done. This will give the user all the alarms active since a month prior to the current time.

`To` Test alarms associated with records to the time specified by mm/dd/hh/mm, where mm is the month, dd is the day, hh is the hour and mm is the minute. If no "to" date is entered, any alarm which is active after the from date will be selected.

`Equipment Type` The technician can choose between five different equipment types. If there is no input to any of these fields, the system will default to all the equipment. The user can select one of the following fields:

- Cabinet: This allows the technician to test all alarms associated with a particular cabinet. Alarms for a cabinet are referenced by a number ranging from 1 to 3 which is assigned during cabinet administration.
- Port Network: This allows the technician to test all alarms associated with a particular port network. Alarms for a port network are referenced by a number ranging from 1 to 3.
- Board Number: This allows the technician to choose all alarms associated with a particular circuit pack for testing. Alarms for a circuit pack are referenced by circuit pack location (cabinet-carrier-slot). If the cabinet number is omitted, the system will default to 1.
- Port: This allows the technician to choose all alarms associated with a particular port on a circuit pack for testing. Alarms for a port circuit are referenced by port location (cabinet-carrier-slot-circuit). If the cabinet number is omitted, the system will default to 1.
- Category: Alarms for a particular equipment category.
- Extension: Alarms associated with an extension number.
- Trunk (group/member): The technician can choose to test all alarms associated with a particular trunk group or trunk group member. The group identifier should be entered to test all alarms associated with a trunk group (XX/__). The group identifier and member identifier should both be entered to test all alarms associated with a specific trunk group member (XX/XX).

```
test alarms repeat 1

             HARDWARE TEST ALARM QUERY

    The following options control which alarms will be tested.

    ALARM TYPES
          Major? y_      Minor? y_     Warning? y_

        REPORT PERIOD
         Interval: m_   From: __/__/__:__   To: __/__/__:__

    EQUIPMENT TYPE ( Choose only one, if any, of the following )
                               Cabinet: __
                          Port Network: __
                          Board Number: ____
                                  Port: ______
                              Category: ________
                             Extension: _____
             Trunk ( group/member ): __/__
```

Field Help

Following are the help messages that the system technician will see upon tabbing to the specified field and pressing the HELP key.

`Major?`	"n(o) y(es)"
`Minor?`	"n(o) y(es)"
`Warning?`	"n(o) y(es)"
`Interval:`	"m(onth), h(our), d(ay), w(eek), a(ll)"
`From month`	"Enter month between 1-12"
`From (day)`	"Enter day between 0-31"
`From (hour)`	"Enter hour between 0-23"
`From (minute)`	"Enter minute between 0-59"
`To (month)`	"Enter month between 1-12"
`To (day)`	"Enter day between 0-31"
`To (hour)`	"Enter hour between 0-23"
`To (minute)`	"Enter minute between 0-59"
`Cabinet:`	"Enter cabinet number (1-3)"
`Port Network:`	"Enter port network number (1-3)"

`Board Number:`	"Enter 4 character board number; [cabinet(1-3)]:carrier(A-E):slot(0-21)"
`Port:`	"Enter port number; [cabinet(1-3)]:carrier(A-E):slot(0-21):circuit(1-24)"
`Category:`	“adm-conn, announce, bri/asai, card-mem, cdr, data-mod, detector, dup-spe, environ, ext-intf, ext-dev, generatr, inads-link, infc, maint, mbus, memory, misc, mnt-test, modem, netcon, pkt, pkt_ctrl, quick-st, pms/jrnl, procr, s-syn, stabd, stacrk, stations, sys-prnt, removable media, tdm, tone, trkbd, trkcrk, trunks and wideband” (For a table describing the category entries in greater detail, see the “display errors” command.)
`Extension:`	"Enter assigned extension, or blank"
`Trunk (group)`	"Enter group number between 1-99"
`Trunk (member)`	"Enter group member between 1-99, or blank"

Field Error Messages

Following are the error messages that will be displayed on the screen. The messages are displayed when the system technician tabs out of a field and the validation routines are executed. In the following messages, an “x” represents the character that was entered by the user.

`Major?`	`""x" is an invalid entry; please press HELP"`
`Minor?`	`""x" is an invalid entry; please press HELP"`
`Warning?`	`""x" is an invalid entry; please press HELP"`
`Interval:`	`""x" is an invalid entry; please press HELP key"`
`From (month)`	`"Entry must be all digits"`
`From (day)`	`"Entry must be all digits"` `"Day invalid"`
`From (hour)`	`"Entry must be all digits"` `"Hour invalid"`
`From (minute)`	`"Entry must be all digits"` `"Minute invalid"`
`To (month)`	`"Entry must be all digits"`
`To (day)`	`"Entry must be all digits"` `"Day invalid"`

`To (hour)`	`"Entry must be all digits"` `"Hour invalid"`
`To (minute)`	`"Entry must be all digits"` `"Minute invalid"`
`Cabinet:`	`"Invalid entry"`
`Port Network:`	`"Port Network invalid"`
`Board Number:`	`"Invalid entry"`
`Port:`	`"Port invalid"`
`Category:`	`"xxxxxxxx" is an invalid entry; please press HELP"`
`Extension:`	`"Entry must be all digits"` `"Extension not assigned"`
`Trunk (group)`	`"Entry must be all digits"` `"Group not assigned, or group assigned but with no member"`

`Trunk (member)`	`"Entry must be all digits"`
	`"Number invalid""`
	`"Group member not assigned"`
	`"Trunk or trunk group invalid"`

Output

The responses, with normal output, will be displayed on a test-by-test basis with one line of data displayed for each test result. With the failures option only the tests that have failed will be displayed.

The following output fields are for the ALARM ENTRY section:

`Port`	The location of the alarmed object (cabinet-carrier-slot-circuit). This is the same identifier as used by the alarm log.
`Maintenance Name`	The logical name of the maintenance object which has been alarmed.
`On Board`	Whether the fault detected is on the associated circuit pack, or an off board element connected to the circuit pack.
`Alt Name`	Terminal extension numbers or trunk group numbers.

`Alarm Type`	Major, Minor, or Warning. This is an indicator to the seriousness of the alarm raised.
`Service State`	RDY (ready for service), OUT (out of service), or IN (in service). This is the current service state of the station and trunk ports shown.
`Ack`	The columns under the “1” and “2” headings denote if the alarm has been acknowledged by the first and second OSS telephone numbers, respectively.
`Date Alarmed`	Day, hour, and minute of alarm.
`Alarm Count`	This field contains the count of the current alarm entry verses the total number of alarms to be tested.

The following fields are displayed for the test results:

`Port`	The port address (cabinet-carrier-slot-circuit) of the maintenance object that is being tested.
`Maintenance Name`	The type of maintenance object that is being tested.
`Alt. Name`	The alternate means of identifying the maintenance object. This field contains the extension when the object is a station, and it contains xxx/yyy when the object is a trunk, where xxx is the trunk group number and yyy is the member number. It contains P/xxx when the object is a private CO line, where xxx is the private CO line group number.
`Test No`	The actual test that is being executed.
`Result`	An indicator as to whether the test failed, passed, aborted or no hardware was available (no board). If this field has conflict, this means that another user was testing this hardware. If this field has epn-down it means that the epn is inaccessible at this time.
`Error Code`	A numerical description of why the test failed or was aborted.

When errors are encountered preparing a particular object to be tested (not inserted, contention, etc.) the an error message will be displayed. This error message will be displayed in the TEST RESULTS data.

For the following output example, assume that only one alarm was in the alarm log and it is on the board in cabinet 1, carrier c, slot 7. The command that was entered was "test alarms" and the query form was left empty by just pressing ENTER.

```
test alarms                                                         Page    1

Testing completed for this object.
```

Feature Interactions

With the enhancement of multiple maintenance users, there may be a possibility of two users attempting to test the same physical hardware (e.g. one via the test alarms command and another through the test board command). If this command should attempt to test a board that is currently being tested by another user, a error message is displayed.

test analog-testcall

test analog-testcall	**trunk group# / member# | port UUCSSpp | board UUCSS [full | supervision | no-selftest | no-return-loss | no-st-or-rl] [repeat #] [schedule]**

The **test analog-testcall** command causes the Automatic Transmission Measurement System (ATMS) to originate a test calls over analog trunks. ATMS collects performance measurements on the test call and compares them to administered thresholds. Detail and summary reports of these measurements are generated with the **list testcalls** command.

You can specify testing of an entire trunk group or an individual trunk using either group/member addresses or port and circuit pack location. The type of test call, the number of the testing line on the far-end switch and various other parameters must be administered on the trunk group form before the command can execute.

ATMS, the operation of this command, and the measurement reports are described in Automatic Transmission Measurement System (ATMS) in Chapter 6, "Additional Maintenance Procedures".

test board

test board UUCSS [short | long] [repeat # **| clear] [schedule]**

The **test board** command will validate that the board exists at the specified location. Based on the logical type (e.g., Analog, Digital, Hybrid, etc.) of board a series of tests will be executed. Each individual test will exercise diagnostics on the board and then return results of the test along with any possible error codes.

Destructive long tests on a Switch Node Interface (SNI) board are not allowed unless the board has been busied out.

For more information see Common Input Parameters and Common Output Fields at the beginning of this chapter.

The following display shows a typical result when **test board 1D07** is entered and slot 1D07 hods a Digital Line circuit pack with 7 ports administered.

```
test board 1d07 short                                          SPE B

Command Successfully Completed
```

test cdr-link

test cdr-link **primary | secondary**
[short | long] [repeat number | clear] [schedule]

The **test cdr-link** command validates that a call detail recording link has been administered and established.

Parameters

[primary | secondary] A system may have up to two CDR links: a primary that is normally used and a secondary that serves as a backup in case the primary fails. This qualifier specifies which link to test. Primary is the default.

For more information see "Common Input Parameters" and "Common Output Fields" at the beginning of this chapter.

test customer-alarm

test customer-alarm UUC [short | long] [repeat # | clear] [schedule]

The **test customer-alarm** command performs hardware diagnostic tests on the leads of the SYSAM or EPN Maintenance circuit pack in a specified cabinet. These leads are connected to customer equipment and provide a means of alerting the system administrator and INADS when that equipment fails. The alarm is activated when a relay on the connected equipment is closed for 1 minute.

The cabinet default is 1. The carrier needs be specified only for PPNs with duplicated SPEs.

test data-module

test data-module extension [short | long] [repeat # | clear] [schedule]

The **test data-module** command performs hardware diagnostic tests on a data module or a data channel. Test results are determined by the interface to the digital switch-data line port, digital line port, or network control data channel.

test disk

test disk [C] [short | long] [repeat # | clear] [schedule]

The **test disk** command performs a series of tests on the disk circuit pack and the disk media itself. The cabinet is always 1 and need not be entered. Carrier a or b must be specified only for duplicated SPEs. This command will abort if any other MSS operation has already begun.

Failure of the disk test may result in the disk being taken out of service. In this state, access to the disk by all system software except maintenance is blocked. When the host-adapter is taken out of service due to test or reset failures and becomes uninstalled, the disk is also placed in the uninstalled state and all access by system software, maintenance tests, commands (including resets) is blocked.

test ds1-facility

test ds1-facility UUCSSf [short | long | external loopback] [repeat #] [schedule]

The **test ds1-facility** command performs a series of tests on the specified facility. Each individual test will exercise diagnostics on the facility and then return results of the test along with any possible error codes. The **long** test is destructive and is not allowed unless the facility has been busied out.

Parameters

UUCSSf A DS1 facility is specified by the location of the DS1 Converter circuit pack and a letter from **a** to **d** corresponding to the four facilities connected to the circuit pack.

external loopback This specifies a destructive test that sends a test pattern to an external device and returns it for comparison to the original. Configure the external device to loop back the signal. See “DS1-FAC (DS1 Facility)” and “DS1C-BD (DS1 Converter)” in Chapter 9.

Examples

test ds1-facility 04a01d
test ds1-facility 03a01a sh c

test ds1-loop

test ds1-loop - For TN464F or TN767E or later suffix DS1 Interface circuit packs. This command is used for loopback and one-way span testing of the DS1 span.

Synopsis

test ds1-loop location [cpe-loopback-jack-test-begin [number-of-bits bit-pattern] | far-csu-loopback-test-begin | one-way-span-test-begin | end-loopback/span-test | inject-single-bit-error | ds1/csu-loopback-tests]

Permissions

Logins with the following service levels may execute this command: system technician, inads, init, super-user, or logins with Maintain Switch Circuit Packs permissions enabled.

Examples

test ds1-loop 01c08
test ds1-loop 1-3c03 cpe-loopback-jack
test ds1-loop 1-3c03 cpe
test ds1-loop 10c03 end
test ds1-loop 02d12 fa
test ds1-loop 02d12 inj

Description

The **test ds1-loop** command will validate that the board exists at the specified location, that the board is a TN464F or TN767E or later suffix DS1 Interface board. Based on the command parameter, a long-duration loopback/span test or series of short-duration loopback tests will be executed.

Long-duration loopback tests execute for an extended period of time until the system technician terminates it. Short-duration loopback tests return the result of the test to the screen when finished executing. The **list measurements ds1 summar**y command should be used to monitor the status of a long-duration loopback/span test.

Defaults

The default for the command is ds1/csu-loopback-tests.

Parameters

location	A [location] represents the physical position of the board to be tested. For Standard cabinets a location is entered as [UUcSS] where "UU" represents the cabinet number, "c" represents the carrier, and "SS" represents the slot position. A single digit cabinet (1-3) are entered with or without a leading zero (0).
cpe-loopback-jack-test-begin[1]	For TN464F or TN767E or later suffix DS1 boards, this causes a long-duration loopback test to be setup through the Customer Premises Equipment (CPE) Loopback Jack. The command allows you to specify a loop-up code for the CPE loopback jack if it differs from the default of 0x47F. Specify the number of bits in the loop-up code as well as the actual bit-pattern (in hexadecimal).
far-csu-loopback-test-begin[1]	For TN464F or TN767E or later suffix DS1 boards, this causes a long-duration loopback test to be setup through the far-end Channel Service Unit (CSU).
one-way-span-test-begin[1]	For TN464F or TN767E or later suffix DS1 boards, this begins execution of a long-duration one-way span test.
end-loopback/span-test	For TN464F or TN767E or later suffix DS1 boards, this parameter terminates long-duration one-way span and loopback testing.
inject-single-bit-error	For TN464F or TN767E or later suffix DS1 boards, this parameter causes a single bit error to be sent within an active framed 3-in-24 test pattern used in long-duration loopback and span testing.
ds1/csu-loopback-tests	For TN464F or TN767E or later suffix DS1 boards, this parameter executes the following loopback tests: DS1 Board LoopBack, CSU Module Equipment LoopBack, and CSU Module Repeater LoopBack. These tests are performed sequentially for a short duration each, and individual PASS/FAIL/ABORT test results are reported following each test.

1. The test will abort if the busyout command has not been set

Help Messages

If the system technician presses HELP after entering "test ds1-loop" the following message will be displayed:

```
Enter DS1 board location,
['cpe-loopback-jack-test-begin [number-of-bits bit-pattern]' or
'far-csu-loopback-test-begin' or'one-way-span-test-begin' or
'end-loopback/span-test' or'inject-single-bit-error' or
'ds1/csu-loopback-tests']
```

Error Messages

If the format for the board location is incorrect, the following error message will be displayed:

```
Port/Board invalid
```

If the EPN in which the specified board resides is not available, the following message will be displayed:

```
EPN is not available
```

If the specified board is not inserted in the system, the following message will be displayed:

```
Board not inserted
```

If the command entered is in conflict with another currently executing command, then a message will be displayed showing the login id of the conflicting user and the conflicting command. The message is as follows:

```
'login id':'command' has a command conflict
```

If during the execution of a command a resource problem occurs that requires the user to restart the command, then the following message will be displayed:

```
Command resources busy; Press CANCEL to clear, and then resubmit
```

If all of the available maintenance resources are currently in use, then the following message will be displayed:

```
All maintenance resources busy; try again later
```

If the **test ds1-loop** command is executed and the “G3 Version” field on the “system-parameters customer-options” form is not V3 or later, then the following message will be displayed:

```
G3 Version must be V3 or later
```

If the **test ds1-loop** command is executed on a circuit pack other than TN464F or TN767E or later DS1 board, then the following message will be displayed:

```
Command valid for TN464F or TN767E or
later release DS1 circuit packs
```

If the [inject-single-bit-error] parameter is selected, but no CPE Loopback Jack, far-end CSU, or one-way span test is active on the DS1 circuit pack, then the following message will be displayed:

```
Parameter valid only if a loopback/span test is active on the DS1
```

Output

The responses will be displayed on a test-by-test basis with one line of data displayed for each test result.

`Port`	The port address (cabinet-carrier-slot-circuit) of the maintenance object that is being tested.
`Maintenance Name`	The type of maintenance object that is being tested.
`Alt. Name`	The alternate means of identifying the maintenance object.
`Test No`	The actual test that is being executed.
`Result`	The result of the individual test - PASS, ABORT, FAIL, NO BOARD, DISABLED, EXTRA BD.
`Error Code`	A system-generated number that tells why the release failed or aborted. A detailed list of the codes according to “Test No.” is provided for each MO.

For the following output example, assume that the board in cabinet 1, carrier c, slot 7 is a TN767E DS1 board. The command that was entered was test **ds1-loop 1c07**.

```
test ds1-loop 01C07 ds1/csu-loopback-tests

                                 TEST RESULTS

  Port       Maintenance Name  Alt. Name Test No. Result        Error Code
  01C07      DS1-BD                      1209     PASS
  01C07      DS1-BD                      1210     PASS
  01C07      DS1-BD                      1211     PASS

Command Successfully Completed
```

Feature Interactions

Loopback or span tests will not be allowed on DS1 boards unless the board has been busied out.

Only one of the CPE Loopback Jack, far-end CSU, one-way span, or DS1/CSU loopback tests may be active at any given time on a DS1 span.

test duplication-interface

test duplication-interface [short | long] [repeat # **| clear] [schedule]**

The **test duplication-interface** command performs hardware diagnostic tests on the system's dupint circuit packs and interconnecting cable (DUPINT and DUP-CHL maintenance objects). Testing is under control of the active SPE. See descriptions of these maintenance objects in Chapter 9 for more details.

The DUP-CHL maintenance object is associated with both active and standby DUPINT boards and the interconnecting cable. The DUPINT maintenance object is associated with the active dupint board. There are five tests for the DUPINT maintenance object and an additional eight tests for the DUP-CHL maintenance object.

When testing the active and standby dupint circuit packs and the interconnection cable for an active SPE carrier, duplication channel components are only tested in one direction. By performing an SPE interchange, the duplication channel components can be tested in the other direction for complete testing. Further testing of the standby dupint board can also be done through the SPE-down Command Interface with carriers locked. This interface can be used for general testing of the standby SPE when the SPE handshake is not functioning.

The duplication-interface test is invalid for an SPE simplex system. For SPE duplex systems, the presence of both DUPINT boards is assumed. In duplex SPE systems, any DUPINT communication failures will give FAIL or ABORT results on the output screen.

Loss of handshake between active and standby SPEs prevents testing of standby SPE components unless the SPE-down interface is used.

The **long** test sequence is destructive and requires that **busyout spe-standby** be executed first.

Output

`Port`	The physical address of the maintenance object that is being tested. For DUPINT the address is the cabinet (1) and carrier (A or B) of the active SPE. For DUP-CHL, the address is the cabinet and carrier of the standby SPE.
`Maintenance Name`	The type of maintenance object that is being tested.
`Alt. Name`	Not applicable.
`Test No.`	The number of the test being executed.
`Result`	An indicator as to whether the test failed, passed or was aborted.

`Error Code` A numerical description of why the test failed or was aborted.

The following display shows a typical result when **test duplication-interface** is entered and A is the active carrier of a duplicated SPE system.

```
test duplication-interface

                              TEST RESULTS

Port  Maintenance Name  Alt. Name  Test No.    Result   Error Code

01B       DUPINT                      979      PASS
01A       DUP-CHL                     980      PASS
01A       DUP-CHL                     874      PASS
01A       DUP-CHL                     875      PASS
01A       DUP-CHL                     876      PASS

Command Successfully Completed
```

test eda-external-device-alrm

test eda-external-device-alrm all | physical location [repeat number | clear][schedule]

This test will perform hardware diagnostic tests on an individual external-device-alarm port or on all external-device-alarm ports.

The **test eda-external-device-alrm** command performs a hardware diagnostic test on all administered external device alarms if all is entered. If an administered external device alarm port is entered, the test external-device-alarm command performs a hardware diagnostic test on that port. The test PASSES if the external device is not reporting an external device alarm and FAILS if the external device is reporting an external device alarm. If the technician specifies the port it must be administered as an external device alarm port on a maintenance board or on an analog line port carrier board.

Defaults

The default for this command is a repeat of 1.

Parameters

physical location	In addition to entering the word "physical" the system technician must specify the physical location. For an administered external device alarm analog line port, a "physical location" represents the physical position of the port to be tested and is entered as **UUcSSpp** where "**UU**" represents the cabinet number (1-MAX_ CABS), "**c**" represents the carrier, "**SS**" represents the slot position, and "**pp**" represents the circuit. Since the "maintenance board" alarm connections connect to control carrier boards that are in unnumbered slots, the standard port format cannot be used to designate these alarm connections. The special ports **UUmajor** and **UUminor** are used designate the major or minor maintenance board alarm connection for cabinet UU. **NOTE:** The special locations `UUmajor` and `UUminor` designate the name of the major or minor maintenance circuit pack alarm connection for cabinet UU (depends upon the auxiliary connector of the Port Network). Thus, both a "major" and "minor" port can be administered with major, minor, or warning alarms. The "all" location is used to test all administered external device alarm ports on analog line boards and maintenance boards.
repeat number	The "number" specifies how many times the "test physical location" is to be repeated. "Number" may be any integer between 1 and 100.
clear	This option causes the test sequence (short or long) to repeat until the alarm (if one exists against the MO) is cleared or a single test in the sequence fails. If no alarms are registered against the maintenance object then the test sequence will be exercised only once.
schedule	When the "schedule" option is specified, the command is validated and then a scheduling form is displayed to allow the technician to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. Refer to the Report Scheduler and System Printer feature specifications [1] for more details.

Examples

test eda-external-device-alrm all
test eda-external-device-alrm all schedule
test eda-external-device-alrm physical 1major r 10
test eda-external-device-alrm physical 2c1101 c

Output

For the following output example the command that was entered was **test external-device-alarm all**:

```
test eda-external-device-alrm all

                             TEST RESULTS

  Port      Maintenance Name  Alt. Name Test No. Result          Error Code

   03major   EXT-DEV           CMS1      120      PASS
   03A2102   EXT_DEV           CMS2      120      FAIL
   01major   EXT-DEV           UPS1      120      PASS
   01minor   EXT-DEV           UPS1      120      PASS
   01c1201   EXT-DEV           UPS1      120      PASS
   03A2101   EXT_DEV           CC temp   120      PASS
   01c1202   EXT-DEV           Audix1    120      PASS
   03minor   EXT-DEV           Audix2    120      FAIL
   04major   EXT-DEV           unknown   120      FAIL

Command successfully completed
```

The responses are displayed on a test-by-test basis with one line of data displayed for each test result.

Field definitions:

`Port`	The port address (cabinet-carrier-slot-circuit) of the maintenance object that is being tested.
`Maintenance Name`	The type of maintenance object that is being tested.
`Alt. Name`	The alternate means of identifying the MO. This is an administered more descriptive name of the external device alarm
`Test No`	The actual test that is being executed.
`Result`	The result of the individual test -PASS, ABORT, FAIL,NO BOARD, DISABLED, EXTRA BD.
`Error Code`	A system-generated number that tells why the release failed or aborted. A detailed list of the codes according to “Test No.” is provided for each MO.

test environment

test environment UU [short | long] [repeat # | clear] [schedule]

The **test environment** command performs hardware diagnostic tests of the environment monitoring and control, and emergency transfer functions of a specified cabinet. This command tests both PPN and EPN cabinets. Circuit packs involved are the SYSAM (PPN) EPN Maintenance, and tone/clock (for the ring generator test.

CAUTION:
*The **long** test recycles power on all port circuit pack carriers and is destructive. It does not recycle power on active or standby PPN or EPN control carriers or switch node carriers. When a port carrier is recycled, all service and links to ports on the carrier are dropped. If a carrier containing an active EI or tone-clock is recycled, all service to that cabinet will be disrupted.*

There are nine Maintenance Objects involved in this test:

EMG-XFER	POWER	RING-GEN
AC-POWER	DC-POWER	CUST-ALARM
CARR-POW	CABINET	EXT-DEV

Note that although the CUST-ALARM maintenance object is part of the environment functionality, it is not actually tested using the ‘test maintenance’ command. See ‘test customer-alarm’ for details on testing this particular MO.

Output

The following display shows a typical result when **test environment 1** is entered in order to test the PPN cabinet.

```
test environment 1

                                 TEST RESULTS

Port   Maintenance Name  Alt. Name   Test No.  Result  Error Code

01        POWER                       5         PASS
01        AC-POWER                    78        PASS
01E       CARR-POW                    127       PASS
01D       CARR-POW                    127       PASS

test fiber-link

test fiber-link#	**[a-pnc | b-pnc] [short | long] [repeat # | clear] [schedule]**

The **test fiber-link** command validates that the optical fiber connection between switch node interfaces (SNI) and expansion interfaces (EI), or a combination thereof, are administered. If the fiber link is administered, a series of hardware diagnostic tests are performed on the specified fiber link. The test results along with any possible error codes are displayed on the MT. The long test sequence includes destructive tests. All destructive tests abort unless the fiber link is first busied out. The short test sequence is non-destructive and can be performed regardless of whether the fiber link is busied out.

A fiber link is a connection between port networks (PNs), switch nodes (SNs), or between a PN and the Center Stage Switch (CSS). This connection is comprised of a bi-directional optical fiber connection (optionally extended via a DS1 Converter Complex), with each end terminated on either an Expansion Interface (EI) or a Switch Node Interface (SNI). Fiber links provide the medium for circuit and packet connections between PNs and for communication between the SPE and Expansion PNs (EPNs) for the CSS.

The **long** sequence includes destructive tests and requires that the fiber link be busied out first. When a fiber is busied out, all calls over that fiber are dropped.

clear firmware-counters clears the firmware counters of specified SNI, SNC or DS1C circuit packs, or of an the entire PNC (A or B).

Parameters

link# The number associated with a fiber link or fiber link pair (on duplicated PNCs). **List fiber-link** displays the location of endpoints for each fiber link.

a-pnc | b-pnc On Critical Reliability systems (duplicated PNC) this identifier is used to distinguish between the two fibers of a duplicated fiber pair.

Examples

Simplex PNC:
test fiber-link 1 l schedule
test fiber-link 10 sh r 25 sch

Duplicated PNC:
test fiber-link 1 a-pnc schedule
test fiber-link 03 b-pnc sh r 3

Output

Port	On Critical Reliability systems (duplicated PNC) there are two fibers associated with every fiber link number. A-PNC and B-PNC distinguish one from the other.

The following display shows a typical result when **test fiber-link 1 b-pnc** is entered.

```
test fiber-link 1 b-pnc                                    SPE B

                                 TEST RESULTS

```

test hardware-group

test hardware-group **[system | carrier UUC | cabinet UU | port-network PN# | pnc a-pnc | b-pnc | board UUCSS | spe]**
[print | schedule]

This command runs a series of demand maintenance tests on all hardware in a specified group: a carrier, cabinet, port network, PNC (A or B), SPE, circuit pack or the entire system. The tests executed vary depending on the options chosen and types of hardware in the group. Some tests are run concurrently to speed execution, so test results for several maintenance objects may be intermixed.

A hardware-group command running in the foreground can be aborted by pressing Cancel or by entering **cancel hardware-group** at another terminal. The cancel command must be used for a test running in the background. You can restart a canceled hardware-group test at the point it left off by entering **resume hardware-group**. Hardware group tests started with the all-ports or spe-interchange options can be resumed, but they will not always test every port that originally would have been tested.

Feature Interactions

Test hardware-group	Only one "test hardware-group" command can be active at any given time.
TTI	If the test hardware-group command is issued with the all-ports option while the TTI background task is active, some unadministered ports may not be tested. In addition, active alarms on line ports may be cleared by this task. The status tti command may be used to determine the state of the TTI background task.
Add Station	If the add station command is entered for an untranslated port at the same time as it is being tested by the test hardware-group command with the all-ports option, the request to add station will fail and the following message will be displayed: `Object in use; please try later`
Trunk Administration	If an attempt is made to add an unadministered trunk port to a trunk group at the same time as it is being tested because of the test hardware-group command with the all-ports option, the request will fail and the following message will be displayed: `Object in use; please try later`
Save Translation	If the test hardware-group command is issued with the all-ports option when a translation save operation is active, some unadministered ports may not be tested. All other hardware will be tested normally.
Hardware Alarms	When a hardware error is detected by the test hardware-group command the hardware goes through the standard escalation strategy. Alarms will be raised on hardware that manifest hard errors. This alarming strategy is the same, regardless of whether the ports are translated or not.
System Interaction	The performance of test hardware-group is affected by call processing traffic, administration activity, choice of the short or long option, whether the all-ports option was chosen, whether the spe-interchange option was chosen, and other demand maintenance activity.

Scheduled and Periodic Maintenance	When a test hardware-group command is entered, all activity related to scheduled background maintenance, periodic background maintenance, and data audits is suspended for the duration of the execution of the test hardware-group command. When a test hardware-group command is canceled or when the test hardware-group command completes, all suspended periodic, scheduled, and data audits background maintenance activity will be restarted where it left off.
Demand Testing of SPE Components	When a test hardware-group command is entered with the SPE-interchange option, demand tests of SPE components may abort while the interchange is in progress.

Parameters

All maintenance objects included in the specified hardware group are tested, including all circuit packs and ports. When a cabinet or larger entity is specified, environmental MOs are tested (see **test environment**).

Examples

test hardware-group system
test hardware-group port-network 11
test hardware-group pnc a-pnc
test hardware-group board 01c07
test hardware-group spe

Form Input

When you enter the command, an input form is displayed upon which you can specify certain options.

`Test sequence`	Specify the short or long test sequence. The **long** sequence is more comprehensive and is not destructive.
`Test Repetition`	Specify **repeat** to enter a number of times that the entire test sequence is to be repeated. Specify **continuously** to cause the test sequence to be repeated until the command is canceled.
`count`	When the previous field is set to **repeat**, specify the number of repetitions here.
`Auto-page?`	Specifying **y** causes a whole new screen to be displayed automatically whenever the screen fills up with results. This option is incompatible with the background option. If you do not specify the auto-page option, once the screen fills with results, testing will stop until you press Page or Cancel. Specifying **print** on the command line automatically engages auto-page.

`Background?`	Specifying **y** causes the tests to run in the background, freeing up the terminal for other tasks. Error results are logged in the error log but not displayed on the screen. This option is incompatible with the auto-page and "continuously" options.
`Failures?`	Specifying **y** causes only failure results to be displayed on the screen.
`All-ports?`	Specifying **y** causes testing of all customer-translated line and trunk ports and, for the following circuit packs, untranslated ports as well:

TN#	Description	TN#	Description

TN746	16 port Analog line	TN2149	Analog Line [G3r V2]
TN747B	Central Office Trunk	TN2180	16 port Analog line [G3r V2]

SPE-interchange?	Specifying **y** causes the system to perform a planned SPE interchange so that both SPEs can be fully tested.

```
test hardware-group system                             Page 1 of 1

               TEST HARDWARE-GROUP SELECTIONS

     Select the desired options for the specified test.

                  Test sequence: short
               Test repetition: repeat        count: 1

             Output OPTIONS:               HARDWARE OPTIONS:

              Auto-page? n                       All-ports? n
             Background? n                 SPE-interchange? n
               Failures? n
```

Output

When the test is run in the foreground, test results are displayed in the normal format. In addition, the message line displays a running count of the number of maintenance objects already tested, the total number included in the tests, percent completed and repetition count.

The following display shows a typical result when **test hardware-group system** is entered.

```
test hardware-group system

Testing system, 68 of 342 (19%) MOs tested for repetition 1
```

test host-adapter

test host-adapter [C] [short | long] [repeat # | clear] [schedule]

The test host-adapter command performs a series of tests on the host-adapter portion of the specified MSSNET circuit pack. This command will abort if any other MSS operation has already begun.

Failure of the host-adapter test may result in disabling access to the host-adapter by all system software except maintenance. Such a failure of the host-adapter also denies access to the related removable media and disk until the host-adapter is fully in service.

The cabinet is always **1** and need not be entered. Carrier **a** or **b** must be specified only for systems with duplicated SPEs.

test inads-link

This command will perform hardware diagnostic tests from the inads port that is accessible through the maintenance board to an OSS telephone number.

Synopsis

test inads-link [1 | 2]

Permissions

The following default logins may execute this command: system technician, inads, init, nms.

Examples

test inads-link
test inads-link 1
test inads-link 2

Description

The test inads-link command attempts to make a call over the inads port on the maintenance board to verify the INADS alarm notification process. By default, the link to the first OSS telephone number is tested. If there is an alarm pending to be reported or the call is in progress or up, then the test will be aborted. If the alarm origination to the OSS telephone number to be tested is disabled, the test generates an informative error and the test continues. The test will wait 2 minutes before executing to allow the remote maintenance technician to logoff freeing the line. The line must be free so the system can place a call to INADS. A local SAT user entering the **test inads-link** command need not log off for the system to place a call to INADS, but the2 minute delay still exists.

Once the call is answered by INADS, the system will send a message with a test alarm type. INADS acknowledges receipt of the message and creates a trouble ticket. The trouble ticket will be closed immediately and have a “INADS LINK TEST” message entered in the description field. If an alarm is raised while the test call is up, the system will not send an alarm message over the existing link. The normal retry mechanism will be followed, which means an attempt to make a call to INADS to report the error will take place 7 minutes later. An INADS trouble ticket will be created only if the connection is successfully established, and a message is sent to the system acknowledging that INADS received the system message.

The “Maintain Process Circuit Packs” field must be set to yes on the inads and technician permission forms. This will provide permissions to execute the **test inads-link** command. The field can be changed by executing a **change permission login** command.

There will be no alarms raised on the system as a result of the “test inads-link” command. Attendant alarm and acknowledgment lamp states will not be changed as a result of the command. The test will not be run during periodic or scheduled maintenance.

Defaults

The test will default to test the link to the first OSS telephone number.

Parameter

1	This option will cause testing of the link to the first OSS telephone number.
2	This option will cause testing of the link to the second OSS telephone number.

Help Messages

If the system technician presses HELP after entering test **inads-link** the following message will be displayed:

```
['1' or '2']

Or press CANCEL to cancel the command
```

If the command entered is in conflict with another currently executing command, then a message will be displayed showing the login id of the conflicting user and the conflicting command. The message is as follows:

```
'login id':'command' has a command conflict
```

If during the execution of a command a resource problem occurs that requires the user to restart the command, then the following message will be displayed:

```
Command resources busy;
Press CANCEL to clear, and then resubmit
```

If all of the available maintenance resources are currently in use, then the following message will be displayed:

```
All maintenance resources busy; try again later
```

Output

If the test passed then the following message will be displayed:

```
Command successfully completed
```

If the test failed, because the link was up or because there was an active alarm that the switch needs to report or there was a problem with the call, the following message will be displayed:

```
Command failed
```

NOTE:
An entry is made in the error log describing why the inads-link test failed.

Feature Interactions

None

test isdn-testcall

test isdn-testcall group#/member# [minutes #] [schedule]

The **test isdn-testcall** command starts an outgoing ISDN-PRI test call using the asynchronous method.

Only 1 ISDN trunk in each port network can be tested at one time. The maximum number of asynchronous outgoing test calls that can be run simultaneously depends on the number of Maintenance/Test circuit packs in the system.

For more information, see Test #258 under "ISDN-TRK (DS1 ISDN Trunk)" in Chapter 9.

Parameters

group#/member#	Specify the trunk over which to originate the test call.
minutes #	Specify the duration of the test call in minutes from 1 to 120. The duration defaults to 8.4 or 9.6 seconds.

For more information, see "Common Input Parameters" at the beginning of this chapter.

Examples

test isdn-testcall 78/2 minutes 10

Output

`Result`	PASS - The test call was successfully initiated.
	ABORT - Resources were not available (for example, a B-channel or Maintenance/Test circuit pack).
	FAIL - An outgoing test call could not be initiated.

test journal-printer

test journal-printer pms-log | wakeup-log
[short | long] [repeat number| clear] [schedule]

The test journal-printer command performs hardware diagnostics on the link between the switch and a specified journal printer link to either the PMS-log printer or the wakeup-log printer.

Parameters

One of the 2 journal printers must be specified:

pms-log This specifies the link to the Property Management System printer, whose maintenance name is PMS-PRNT.

wakeup-log This specifies the wakeup-log printer, whose maintenance name is JNL-PRNT.

Output

`Maintenance Name` PMS-PRNT designates the PMS-log printer. JNL-PRNT designates the wakeup-log printer.

Background maintenance activity on a link can interfere with testing and recovery of a particular component of the link. For example, as part of a test, maintenance software may busy out a component of the link, causing the link to drop. The system may then perform frequent attempts to re-establish the link. This can delay recovery of the component, since it must be idle for certain tests to take place. Busying out the link will prevent the system from these attempts to set up the link. Remember that a busyout will tear down a link if it is not already down.

test led

test led [all | cabinet UU | port-network PN# | switch-node SN# | a-pnc | b-pnc] [repeat #]

This command verifies that a specified cabinet, port network, PNC or switch node is recognized by the system. It is also useful for identifying a port network, cabinet, or PNC (A or B).

When **test led** is entered, the red, green and yellow circuit pack LEDs are turned on until all administered carriers in the specified group have been lit for 2 seconds. They are then turned off in the same order in which they came on. The cycle can be repeated a number of times with the **repeat** option. Once all of the repeat cycles are completed, all affected LEDs are restored to reflect their current status.

test link

test link link [short | long] [repeat | clear] [schedule]

This command verifies that the specified link is administered and performs a series of tests on the link.

Parameters

Port Each link is identified by a number (1-16) assigned on the Communication-Interface Links form. **Display communication-interface links** shows the location and identification of each link.

Output

`Port` The location of the port on a Packet Gateway circuit pack associated with the link being tested.

The following display shows a typical result when **test link 1 long** is entered.

```
test link 1 long                                              SPE B

                           TEST RESULTS

Port       Maintenance Name  Alt. Name Test No. Result   Error Code

01C2001    PGATE-PT          5464      610      ABORT       1000
01C2001    PGATE-PT          5464      611      ABORT       1000

test maintenance

test maintenance [C] [short | long] [repeat # | clear] [schedule]

The test maintenance command performs hardware diagnostic tests on a the SYSAM (PPN) and EPN Maintenance circuit packs.

On the SYSAM, this command tests system maintenance, ACTIVE and STANDBY terminal ports, and the SYSAM refresh, dual port RAM, system reset and sanity timer functions. On the SYSAM, the long test sequence resets the circuit pack, terminating any local or remote SYSAM logins. To see if the last 2 tests pass, you must log in again. The Outpulse Relay Test and the Analog Loop Around Test are not run on the standby SYSAM in a duplicated SPE.

On EPN Maintenance circuit packs, the MT interface, EI link, reset and sanity functions are tested. The long test resets the EPN Maintenance circuit pack, causing a local EPN Maintenance login to drop.

The cabinet number defaults to 1. Carrier **a** or **b** must be specified only for PPN cabinets with duplicated SPEs.

Output

The following display shows a typical result when **test maintenance a** is entered.

```
test maintenance

                      TEST RESULTS

Port    Maintenance Name  Alt. Name   Test No.    Result   Error Code

01A      SYSAM                         911         PASS
01A      SYSAM                         913         PASS
01A      SYSAM                         915         PASS

Command Successfully Completed
```

The following display shows a typical result when **test maintenance 2** is entered.

test mass-storage

test mass-storage [C] [short | long] [repeat | clear] [schedule]

This command performs tests on each of the 3 components of the Mass Storage System (MSS): the host adapter circuit on the MSSNET circuit pack, the removable media circuit pack and the disk circuit pack. Each of the 3 objects is tested using the same sequence used when individual components are tested separately.

This command aborts if any other mass-storage operation has already begun.

Failure of the host-adapter test may result in the disabling of periodic and scheduled testing of the failed host-adapter and the related removable media and disk. Failure of a removable media or disk test may result in the disabling of periodic and scheduled testing of the component.

The cabinet is always **1** and need not be entered. Carrier **a** or **b** must be specified only for systems with duplicated SPEs.

The following display shows a typical result when **test mass-storage a** is entered.

```
test mass-storage

test memory

test memory CSS [short | long] [repeat # | clear] [schedule]

This command performs hardware diagnostic tests on any or all Memory circuit packs in the specified carrier. All tests in both sequences are non-destructive.

The short test takes about 2 minutes to complete. The long test on a single circuit pack takes about 2.5 minutes. The long test takes an additional 2 minutes on circuit pack 1 for the Checksum Test.

Parameters

CSS The cabinet is always 1 and need not be specified. Carrier a or b must be specified only for duplicated SPEs. You can specify one of the Memory circuit pack slots (1-4) on the PPN control carrier. If the slot is not specified, all memory circuit packs are tested.

Output

`NOT ASSIGNED` indicates that the specified slot is not administered.

test mssnet

test mssnet C [short | long][repeat |clear][schedule]

The **test mssnet** command runs a series of diagnostic tests on the MSSNET circuit pack. Tests are run on both maintenance objects located on the MSSNET circuit pack: host-adapter (H-ADAPTR) and switch control (SW-CTL).

Parameters

C The cabinet is always 1 and need not be entered. The carrier, **a** or **b**, must be specified in a duplicated SPE system.

clear The clear option does not provide a useful function for this command. MSSNET is used only as a command object to run tests of the MSSNET circuit pack. Failures of circuits on the MSSNET board cause alarms against H-ADAPTR and SW-CTL. Individual demand tests of those maintenance objects should be used to clear associated alarms.

Output

The following display shows a typical result when **test mssnet 1a** is entered.

```
test mssnet 1a                                                      SPE A

                                  TEST RESULTS

 Port      Maintenance Name  Alt. Name Test No. Result       Error Code

  01A        H-ADAPTR                    822      PASS
  01A        H-ADAPTR                    823      PASS
  01A        H-ADAPTR                    824      PASS
  01A        H-ADAPTR                    825      PASS
  01A        SW-CTL                      92       PASS

Command Successfully Completed
```

test packet-interface

test packet-interface [CSS] [short | long] [repeat # |clear] [schedule]

This command performs hardware diagnostic tests on any or all of the packet interface circuit packs in a specified carrier. Tests performed include local memory checksum tests, loop-around tests, and checks of failure counters.

The Maintenance Loop-Around Test (#886) is included in the test sequences of *active* packet-interface circuit packs only. The Active-Standby Peer Link Test (#888) is included in the test sequences of the *standby* packet-interface circuit packs only.

If the packet-interface circuit pack is in the “out-of-service” or “uninstalled” states, no demand tests as well as scheduled, periodic and error tests will run. See also **reset packet-interface** and **status packet-interface**.

Parameters

CSS The cabinet is always 1 and need not be entered. The carrier, **a** or **b**, must be entered only for duplicated SPEs. Slot number ranges from 1 to 3, corresponding to the dedicated PKT-INTFC slots on the control carrier. If omitted, all Packet Interface circuit packs on the specified carrier are tested.

test pkt

The test runs a series of tests on the Packet bus of the specified PPN or EPN.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test pkt port-network	pn number	The Packet bus to be tested: *nn* (1-44)	init inads craft	Test Sequence = short; Repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails.[1]			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen.[2]			
		Examples: **test pkt port-network 1 l** **test pkt port-network 2 sh r 2** **test pkt port-network 2 sh schedule** **test pkt port-network 1 l r 25** **test pkt port-network 2** **test pkt port-network 1 c**			

1. If no alarms are registered against the maintenance object, then the test sequence is run only once. The ***long clear*** option forces a clear of all alarms if no errors are encountered during testing. The ***short clear*** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

WARNING:
*Since the **clear long** options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.*

Output

The following example shows the output for the **test pkt port-network 1** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test pkt port-network 1

                 TEST RESULTS

  Port     Maintenance Name  Alt. Name Test No. Result        Error Code
  PN 01    PKT-BUS                     571      PASS
  PN 01    PKT-BUS                     572      PASS
  PN 01    PKT-BUS                     573      PASS

Command successfully completed
```

Field descriptions

`Port`	A port network number (1-44).
`Maintenance Name`	The name of maintenance object being tested.
`Alt. Name`	Not applicable.
`Test No`	The test being executed.
`Result`	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
`Error Code`	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test processor

test processor [C] [short | long] [repeat # | clear] [schedule]

The test processor command performs hardware diagnostic tests on a specified processor circuit pack.

test signaling-group

test signaling-group group#[short | long] [repeat# | clear][schedule]

The test signaling-group validates the administration of a signaling group and runs a series of diagnostic tests on it.

An ISDN-PRI signaling group is a set of B-channels whose signaling messages are carried together on a designated D-channel or set of D-channels.

Parameters

group#	An administered number associated with each signaling group.

test spe-standby

test spe-standby [short | long] [repeat # | clear][schedule]

This command is valid only on systems with duplicated SPE. The test spe-standby command performs hardware diagnostic tests on each component of the standby Switch Processing Element (SPE). This command is also used with the long option to remove a standby from recent interchange mode. The sequence begins with testing of the STBY-SPE maintenance object to determine the availability of the standby SPE. The following tests are run on STBY-SPE:

1. Standby SPE status query
2. Standby SPE handshake test
3. Standby SPE time of day comparison (standby in synch with active)
4. Standby SPE configuration matchup test

The last test is run only in the long sequence. After the above sequence, tests of each component on the standby SPE are run.

Testing the standby SPE does not affects the availability of the standby SPE for service only in that execution of the long sequence takes the standby out of recent interchange mode.

Output

The following display shows a typical result when **test spe-standby** is entered.

```
test spe-standby                                  Page   1   SPE B

 TEST RESULTS

Port      Maintenance Name  Alt. Name Test No. Result   Error Code

test stored-data

test stored-data [short | long] [repeat # | clear] [schedule]

The **test stored-data** command performs a set of consistency checks of the boot images and translation data on removable media and disk. In particular, software vintage numbers and translation time stamps are compared.

The short test sequence includes only inter-device tests. These include a removable media-to-removable media, disk-to-disk and two removable media-to-disk tests for SPE duplex systems with removable media and disk devices on both carriers. The long test sequence includes up to four intra-device consistency checks, one for each device. Another check of the system boot source is included in the long sequence.

For SPE simplex systems, only one removable media-to-disk inter-device test and two intra-device consistency checks along with the boot source check are run. The other tests simply do not appear in the short or long test sequences.

The lack of the optional disks does not affect which tests are run. For both SPE simplex systems and SPE duplex systems, aborts are returned for those tests which require a disk.

This command will abort if any other MSS operation has already begun.

If translations have been saved to disk since the last time the disk was backed up to removable media (a normal situation during work sessions), tests executed by this command will fail.

test switch-control

test switch-control [C] [short | long] [repeat # | clear] [schedule]

The **test switch-control** command performs hardware diagnostic tests of the PPN Archangel, or SW-CTL circuit, on a specified MSSNET circuit pack. The PPN Archangel is responsible for transmitting messages back and forth between the SPE and the port circuit packs. For the short test of the active PPN Archangel, a loop-around test and a Control Channel test are performed. For the short test of the standby PPN Archangel, only the loop-around test is performed.

The long test includes a reset. When applied to the active PPN Archangel, this momentarily prevents call origination from stations or trunks connected to ports in the PPN. It is non-destructive for existing calls.

Parameters

C The cabinet is always **1** and need not be entered. Carrier **a** or **b** must be specified only for systems with duplicated SPEs.

long This will execute a more comprehensive and longer version of the diagnostic tests. When applied to the active PPN Archangel, this momentarily prevents call origination from stations or trunks connected to ports in the PPN. It is non-destructive for existing calls.

test synchronization

test synchronization [short | long] [repeat # | clear] [schedule]

The **test synchronization** command checks the timing synchronization source and updates circuit packs with the correct synchronization parameters. The tone-clocks, DS1s, and EIs are sent down-link messages to place them in the correct synchronization configuration given the current on-line synchronization reference.

The synchronization subsystem provides error-free digital communication between the switch and other PBXs, COs, or customer premises equipment. The subsystem is made up of the TDM bus clock, DS1 trunk circuit packs, and maintenance and administration software resident in the SPE.

Parameters

long Both long and short sequences run Test #417. If Stratum 3 synchronization is administered, an additional non-destructive test (#649) is run by the long sequence.

test sys-link

test sys-link UUCSSpp [channel #] [current | faulted]
[short | long][repeat # | clear] [schedule]

The **test sys-link** command will validate the existence of the specified link and run diagnostic tests on the hardware path that comprises the system link. If the "current" or "faulted" option is specified, tests are run on all hardware objects that comprise the specified link. If "current" or "faulted" is not specified, only the end-to-end sys-link connection will be tested.

The hardware path that comprises a system link consists of up to 21 hardware components that affect the behavior of the link. The number of components of a given system link hardware path depends on the system configuration and type of system link. The following links are examples of system links: Expansion Archangel Links (EAL), Indirect Neighbor Links (INL), Processor Gate Control links (PGC), PRI signaling links (PRI), System Access Port links (SAP), X.25 adjunct links (X25).

Parameters

UUCSSpp The location of the port associated with the system link.

channel number The processor channel (1 to 128) associated with an X.25 adjunct link to be tested.

current This specifies testing of the current hardware path of the system link.

faulted This specifies testing of the hardware path of the system link as it was constituted when a fault last caused the link to go down. For more information, see ''Common Input Parameters'' at the beginning of this chapter.

Examples

test sys-link 2e0201 current l schedule
test sys-link 2e0201 faulted r 10
test sys-link 1c1701 channel 3 r 10

Output

The following display shows a typical result when **test sys-link 1e0201 current** is entered.

```
test sys-link 1e0201 current                                   Page   1   SPE A

                                 TEST RESULTS

  1 A-PNC    FIBER-LK                     238       PASS

                press CANCEL to quit -- press NEXT PAGE to continue
```

test removable-media

test removable-media [C] [short | long] [repeat # | clear] [schedule]

The **test removable-media** (test rem) command performs a series of tests on the removable media circuit pack and removable media cartridge. The standard cartridge used for backups of the disk is compatible with this test. The removable media cartridge is rewound and a specific portion of the removable media is used for test reads and writes. Removable Media used for core dumps have an incompatible file system and should not be used for this test.

The cabinet is always **1** and need not be entered. Carrier **a** or **b** must be specified only for systems with duplicated SPEs.

This command aborts if any other MSS operation has already begun.

Failure of the removable media test may result in the removable media being placed in an out-of-service state. In this state, access to the removable media by all system software except maintenance is blocked.

When the host-adapter is taken out of service due to failures of its tests, or fails a reset and becomes uninstalled, the removable media is also placed in the uninstalled state and all access by system software, maintenance tests and commands including reset are blocked from execution.

Removable Media used for core dumps have an incompatible file system and cannot be tested by this command.

test tdm

test tdm port-network PN# [short | long] [repeat # | clear] [schedule]

The **test tdm** command performs hardware diagnostic tests on the time slots of the specified TDM bus. Both halves (“a” and “b”) of the TDM bus are tested.

test tone-clock

test tone-clock UUC [short | long] [repeat # | clear] [schedule]

The **test tone/clock** command performs hardware diagnostic tests on the 3 maintenance objects on a specified tone/clock circuit pack: TONE-BD, TONE-GEN, TDM-CLK.

test trunk

test trunk group# [/ member#] [short | long] [repeat # | clear] [schedule]

The **test trunk** command performs hardware diagnostic tests on an entire trunk group or an individual trunk group member, depending on the options entered.

test tsc-administered

test tsc-administered signaling-group# / tsc-index [repeat#] [schedule]

The **test tsc-administered** command runs diagnostic tests on any type of administered Temporary Signaling Connections (TSCs) on a signaling group. A switched services request to run the TSC heartbeat test is also performed.

traceroute

This command provides the ability to trace the route of packets originated from DEFINITY IP boards through the LAN. The output shows the ip address of each router or host (hop) that the packets encounter and the time elapsed between each hop. If a DEFINITY IP board has trouble communicating with a far-end device, the traceroute command can determine “how far” packets get toward the destination.

DEFINITY IP boards include:

- TN799B (or later suffix) CLAN board
- TN802B Medpro board

The output form lists:

- Hops traversed from source to destination
- IP addresses of the hop points and the final destination
- Observed round-trip delay from the source to each hop point

If no reply is received from a potential hop point, the `IP Address` field contains stars (*), which indicates a timeout condition.

The primary use of this command is to determine quickly and unambiguously if the fault lies within Lucent-provided equipment or if the fault is with the LAN or LAN administration to which the DEFINITY ECS switch is connected.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
traceroute	***ip-address***	where IP address is www.xxx.yyy.zzz	init inads craft customer	Primary	None
	node-name	from node-name form			
	board	cabinet-carrier-slot address of the IP circuit pack			
	clan-port	port 1-17 Example: **traceroute ip-address 123.4.56.789 board 1C14**			

Output

The following shows an example output for the C-LAN **traceroute** command. For Medpro or Prowler boards, the **clan-port (1-17)** qualifier does not appear.

```
traceroute ip-address 135.9.1.22 board 1C14  clan-port (1-17)

                            TRACE ROUTE RESULTS

Hop            Time(ms)            IP Address

0              from address        135.9.1.22
1              03,10,05            134.9.14.23
2              11,20,03            134.9.5.103
3              22,01,25            106.245.27.205
4              22,01,25 !N         106.245.27.205
```

Field descriptions

`clan-port`	This CLAN entry identifies the port on the CLAN board from which the traceroute command is issued. This field appears *only* if the board is a CLAN board.
`Hop`	The node number (in sequence). The first node (0) is the address from which the traceroute command is issued.
`Time (ms)`	Time from the board to each intermediate destination in milliseconds. If an error occurs at a node, the entry is repeated with an error code immediately following the time. Error codes and their meanings are:

- ! Unable to reach port
- !N Unable to reach network
- !H Unable to reach host
- !P Failure between endpoints
- !F Need fragmentation of data packet
- !S Source return failure
- !X Packet blocked by filter

`IP Address`	The 32-bit network address.

upgrade software

Simplex:

upgrade software to-version [version-override] [save-translation | no-translation]

Duplex:

upgrade software to-version [call-override] [no-interchange] [version-override] [preserve-calls | no-calls] [save-translation | no-translation]

This command is a single user command; that only **status** commands may be executed while this command is running; all other commands will be blocked.

Simplex: In a simplex system this command will result in translation being saved to the primary device, followed by a reboot of the processor with loading of the new software and translation data, and any field updates from the primary MSS device. When completed, service is restored.

Duplex: In a duplicated SPE system, the upgrade software command will save translation, reboot the standby SPE with new software from its primary MSS device, load translations, apply any field updates, initiate an interchange of the SPE's, and begin providing service to the system. Normally the interchange of the SPEs will result in minimal service disruption. In cases where the new software load is incompatible with the existing load, the system may perform a service-disrupting reboot.

Parameters

to-version This qualifier identifies the software version. This qualifier is checked against the data on the MSS device to verify that the correct software version is being loaded and that the software version is the same or newer that the version in memory.

no-interchange This option is only available in duplicated systems and provides the technician the ability to reboot the standby processor with the software on the standby primary MSS device, apply any field-updates and yet have the standby SPE remain the standby.

The duplex default is to interchange the processors, upon a successful boot of the standby SPE.

call-override This option is only available in duplicated systems and allows the command to continue, even if the command will result in a reset level 2 of the processor. Normally, the command would print an error message if it was able to determine if the reset was necessary. This reset would cause all calls in the system to be dropped.

version-override This option allows the command to continue if the version specified is older than the version in memory. This would normally result in the command aborting because the upgrade is not moving to a newer version of the software. If the version-override option is used and the version on the primary MSS device is older than the current version in memory then the save translation step will be skipped.

save-translation This option will override the internal system and save translation. The switch will not save translation if the version in memory is newer than the version to be booted. With this option the translation will be saved regardless of the software version.

no-translation This option will cause the system not to save translation. When the upgrade is from an older to a newer release, the system will save translation, even if the translation is incompatible between the two particular releases. There may be rare occasions when there may be this incompatibility and therefore this option will keep the translation from being saved on the new version.

preserve-calls The system may automatically not preserve calls because of the compatibility index, which signals a potential memory mismatch across the processors. Compatibility index major numbers must be identical, and the minor must either be identical or greater going forward for the upgrade to automatically be call preserving. This option will override the software determination of call preservation, and force the memory from the active to be sent to standby processor in an attempt to preserve calls. This option should be used with care, because attempting to preserve calls when the internal memory layout is not compatible will result in processor escalation to an eventual reboot.

Examples

Duplex
upgrade software DG3v02.03.0.01.0
upgrade software DG3v02.03.0.01.0 no-interchange no-translation
upgrade software DG3v02.03.0.01.0 call-override version-override

Input

Due to the complexity of this command and the options available, the system will display the following screen and ask for input (ENTER or CANCEL) from the user to either proceed with the command or to cancel the request.

The following display shows a typical result when **upgrade software DGv01.02.1.13.0** is entered on a system with simplex SPE:

```
upgrade software DG3v01.02.1.13.0

 This upgrade software command will result in the following actions:

      From software version: DG3v01.02.1.13.0
        To software version: DG3v01.03.4.13.0

      Save CURRENT translation to MSS? yes

Press ENTER to continue or CANCEL to abort the command
```

The following display shows a typical result when **upgrade software DG3v01.02.1.13.0** is entered on a system with duplicated SPE.

```
upgrade software DG3v01.02.1.13.0

 This upgrade software command will result in the following actions:

      From software version: DG3v01.02.1.13.0
        To software version: DG3v01.03.4.13.0

      From compatibility index: 2.2
        To compatibility index: 2.2

      Save CURRENT translation to both active and standby MSS? yes

      Attempt to preserve calls across interchange? yes

Press ENTER to continue or CANCEL to abort the command
```

If the user presses ENTER, then the command will proceed. If, however, the user presses the CANCEL key then the command will be terminated.

Output

NOTE:
After initiating an **upgrade software**, do not touch the keyboard while waiting for the command to execute. Entering a carriage return will cause the progress and diagnostic messages to be lost. If the upgrade is successful, `Command successfully completed` is *not* displayed. Instead, the terminal is logged off the system and must be logged in again.

As the command progresses, results of each step are displayed with corresponding error codes. The entire process takes about 10 minutes. While the system is saving translations the following progress message is displayed and updated every 10 seconds:

```
Maximum remaining translation save time: 03 mins 20 secs
```

A success or failure result is displayed. If the following message appears, system software is corrupted; follow normal escalation procedures.

```
Error encountered; can't complete request
```

Simplex SPE

The following display shows a typical result when **upgrade software** is executed on a system with a simplex SPE.

```
upgrade software

                              UPGRADE RESULTS

 Upgrade Step                              Results       Error Code

 disable maintenance                       PASS
 save translation                          PASS
 reboot processor                          PASS
```

`Upgrade Step`	Each step in the upgrade execution is displayed after it occurs: 1. disable maintenance: This step prevents periodic maintenance from interfering with the upgrade (similar to the **disable all** command). 2. save translation: Saves a copy of the current translation to the primary MSS device 3. reboot processor: Reboots the processor, causing a temporary service outage. 4. If the upgrade is successful, `Command successfully completed` is *not* displayed. Instead, the terminal is logged off the system and must be logged in again.
`Results`	This displays whether the step was successful or not. Possible values are: PASS, FAIL, or SKIPPED. SKIPPED only occurs for the save translation step when the current version is newer than the version on the primary MSS device, causing this step to be bypassed.
`Error Code`	If a step fails, this field displays a code indicating the reason. See the following table.

Upgrade Step	Error Code	Description
Disable maintenance	6	Internal software error
Save translation	6	Internal software error
	7	Storage device currently in use
	8	Removable Media/disk access failure
	9	Internal translation data is corrupted
	10	Storage device has corrupted translation
	2000	The save was not completed in the allotted time
	6	Internal software error
Reboot processor	11	Could not load the boot image from the storage device
	12	Could not reboot the processor

Duplicated SPE

The following display shows a typical result when **upgrade software** is entered on a system with duplicated SPE.

```
upgrade software

                              UPGRADE RESULTS

 Upgrade Step                              Results       Error Code

 disable maintenance                       PASS
 save translation                          PASS
 busyout standby processor                 PASS
 translation load and reboot standby       PASS
 change memory shadow bounds               PASS
 release standby processor                 PASS
 refresh standby memory                    PASS
 request an SPE interchange                PASS
```

Upgrade Step — Each step in the upgrade execution is displayed after it occurs:

1. disable maintenance: This prevents periodic maintenance from interfering with the upgrade (similar to the **disable all** command).
2. save translation: save a copy of the current translation to the primary MSS device
3. busyout standby processor: This busies out the standby SPE, preventing spontaneous interchanges while the new software load is booted on the standby processor. This also turns off memory shadowing from active memory to the standby.
4. translation load and reboot standby: This causes the standby processor to load the boot image and translation on its primary device. The SPE remains standby, and starts running the Standby Maintenance Monitor (SMM).
5. change memory shadow bounds: This adjusts the range of memory transmitted from the active to the standby SPE to include only the information pertaining to active calls so as to preserve stable calls across the interchange.

6. release standby processor: This releases the standby SPE from busyout, allowing resumption of handshake and memory shadowing, with transfer of active call status to the standby.
7. refresh standby memory: The system waits for refresh to complete and reports the result.
8. request an SPE interchange: An interchange is executed into the standby SPE with the new load. If this step succeeds, the terminal is logged off. Otherwise, a failure code is returned.
9. If the upgrade is successful, `Command successfully completed` is *not* displayed. Instead, the terminal is logged off the system and must be logged in again.

Results — Result of the execution of the corresponding step: PASS, FAIL, or SKIPPED. SKIPPED occurs only for the save translation step when the current version is newer than the version on the primary MSS device.

Error Code — If a step fails, this field displays a code indicating the reason according to Table 8-14:

Table 8-14. Upgrade Software Error Codes—Duplicated SPE

Upgrade Step	Error Code	Description
disable maintenance	6	Internal software error
save translation	6	Internal software error
	7	Storage device currently in use
	8	Removable Media/disk access failure
	9	Internal translation data is corrupted
	10	Storage device has corrupted translation
	2000	The save was not completed in the allotted time
busyout standby processor	6	Internal software error
	2010	Standby is already busied out

Continued on next page

Table 8-14. Upgrade Software Error Codes—Duplicated SPE — *Continued*

Upgrade Step	Error Code	Description
translation load and reboot standby	1	Could not create software processes on the standby
	2	Not all processes on the standby were able to start
	3	Standby LMM detected hardware failures on processor complex
	4	Software update file on standby corrupted
	5	Translation on standby was not able to load correctly
	6	Internal software error
	2000	The load and reboot was not completed in the allotted time, or communication with the standby was corrupted
	2500	Internal software error with standby communication
change memory shadow bounds	6	Internal software error
	2500	Internal software error with standby communication
release standby processor	6	Internal software error
	2011	Standby processor was not busied out.
refresh standby memory	6	Internal software error
	2000	The refresh of the standby was not completed in the allotted time
request an SPE interchange	6	Internal software error
	2000	The load and reboot was not completed in the allotted time, or communication with the standby was corrupted
	2300	Communication failure with standby resulted in interchange failure
	2360	LMM attempt to interchange processors failed
	2500	Internal software error with standby communication

Feature Interactions

System Restarts

An upgrade causes in a system restart. For a complete description of effects, see “Software Updates” in Chapter 6.

Error and Alarm Log

Error and alarm logs are cleared.

Busyouts

Maintenance objects that have been busied out by command are released during the reboot or interchange. If the upgrade command is canceled, all busyouts are preserved.

Multi-User Contention

While the upgrade command is executing, all other administration and maintenance commands except **status** reports are blocked.

Periodic and Scheduled Maintenance

Periodic and scheduled maintenance are suspended while the upgrade command is processing.

Command History Log

Unlike other commands, the upgrade software command is logged into the history log *before* it completes, prior to the save translation step. A record of the upgrade is saved on the new active SPE.

Alarm Origination

To prevent reporting of alarms generated by the upgrade, alarm origination is suspended during the execution of the command. After a successful interchange on a system with duplicated SPE, alarm origination remains suspended for approximately 5 minutes, or until the newly active SPE is ready to begin normal maintenance.

Enable All

All previously disabled maintenance objects are re-enabled following the upgrade. If the command is canceled, disables are preserved.

Parameters

UUCSSf The location of a DS1 Converter facility. F represents a letter (a-d) used to identify the separate DS1 facilities connected to the DS1 Converter.

override This option must be used to busyout the facility on a DS1 Converter that is carrying the packet traffic and control messages. See the caution note above.

Output

`Port` The DS1 facility as described above in UUCSSf.

The following display shows a typical result when **busyout ds1-facility 2e1a** is entered.

```
busyout ds1-facility 02e01a

                          COMMAND RESULTS

  Port    Maintenance Name  Alt. Name   Result    Error Code

  02E01A  DS1-FAC                       PASS

Command successfully completed
```

For more information see the following sections at the beginning of this chapter: "Busyout and Release Commands" and "Common Output Fields".

Maintenance Object Repair Procedures

9

NOTE:
This chapter does not contain maintenance objects for the DEFINITY Wireless Business System (DWBS). Refer to the appropriate maintenance documentation that accompanies DWBS products.

Escalation Procedures

This document is not intended to solve all levels of trouble. When the limits of these procedures have been reached and the problem has not been resolved, it is the technician's responsibility to escalate to a higher level of technical support.

Escalation should conform to the procedures in the *Technical and Administration Plan*.

ABRI-PORT (ASAI ISDN-BRI Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ABRI-PORT [1]	MAJ/MIN/WRN	test port UUCSSpp l [2]	ASAI ISDN-BRI Port

1. The alarm level for ABRI ports may be administered using the **set options** command. The alarm level can be set independently for off-board and on-board alarms to WARNING, MINOR, or MAJOR for all ABRI ports in the system.
2. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

Refer to BRI-PORT (ISDN-BRI Port) information for repair procedures.

AC-POWER

AC Power for AC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
AC-POWER	WARNING	test environment UU[1]	AC Power

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs).

DEFINITY systems support two different cabinet types: Multi-Carrier Cabinets and Single-Carrier Cabinets. Single-Carrier Cabinets are used only for EPNs. Both cabinet types may be powered by either AC or DC power source. Environmental maintenance differs according to cabinet type and power supply.

CAUTION:
Before powering down a cabinet or carrier that contains DEFINITY AUDIX circuit packs (TN566), first power down the AUDIX unit to avoid damaging the AUDIX software. Instructions for powering down this unit are in the *"DEFINITY AUDIX System Power Procedures" in Chapter 5, "Alarms, Errors, and Troubleshooting"**, on the circuit pack, and in DEFINITY AUDIX documentation.*

Single-Carrier Cabinet Power Systems

Each Single-Carrier Cabinet has one power supply that distributes DC power and AC ringing voltage to the circuit pack slots in the cabinet.

AC Power Supply (WP-91153)

In an AC-powered cabinet, a single, plug-in, multi-output AC power supply is in the power supply slot. A power cord, with a three-prong plug on one end and an appliance connector on the other end, connects the supply to a dedicated AC power source. The inputs to the power supply can be (depending on list version):

- 120 VAC, 60 Hz, 15 Amp to 20 Amp; three wires in the power cord: one hot wire, one neutral wire, and one ground wire
- 220 VAC or 240 VAC, 50 Hz, 10 Amp; three wires in the power cord: one hot wire, one neutral wire, and one ground wire

The AC power supply produces the following DC outputs: +5 VDC, -5 VDC, -48 VDC, +12 VDC, and a battery-charging voltage. The DC outputs distribute power on the cabinet backplane to the circuit pack slots.

The AC power supply also produces AC ringing voltage. The AC ringing voltage output value and frequency depend on the country of use. The power supply has a circuit breaker and EMI filtering.

Nominal Power Holdover

Multi-Carrier Cabinets

Two types of battery holdover are available:

- The small battery assembly provides short-term battery holdover. If AC power fails, 48 VDC batteries power the system for 10 seconds in a PPN cabinet, for 15 seconds in an EPN cabinet, and for 10 minutes in the control carrier in a Standard Reliability system. The batteries also provide system power for 5 minutes in the control carrier in High and Critical Reliability systems, and for 10 minutes in the expansion control carrier in the "A" position of an EPN cabinet (Release 5r and higher).
- Some AC-powered Multi-Carrier Cabinets contain three 48V batteries and a battery charger (397C) to provide backup power in case power is interrupted. The holdover times are identical to those above.

Single-Carrier Cabinets

A holdover circuit in the power supply allows a system to operate normally during AC power interruptions. When AC input power fails, reserve batteries supply power to the memory and processor circuit packs and fans for two minutes. All port circuit packs are inactive during this time. The power supply contains a battery charger to charge the holdover batteries.

Error Log Entries and Test to Clear Values

Table 9-1. AC Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment UU sh r 1
513	Any	AC Power Query Test (#78)	WARNING	OFF	test environment UU sh r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order shown in the table below. By clearing error codes associated with the *Battery and Battery Charger Query Test*, for example, you may also clear errors from other tests in the testing sequence. Refer to the appropriate sections of this chapter for descriptions of each test.

NOTE:
The following tests apply to J58890CE, J58890CF, and J58890CH.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query Test (#5)	X	X	ND
AC Power Query Test (#78)	X	X	ND
Power Unit Query Test (carrier E) (#127)	X	X	ND
Power Unit Query Test (carrier D) (#127)	X	X	ND
Power Unit Query Test (carrier A) (#127)	X	X	ND
Power Unit Query Test (carrier B) (#127)	X	X	ND
Power Unit Query Test (carrier C) (#127)	X	X	ND
Emergency Transfer Query Test (#124)	X	X	ND
Cabinet Temperature Query Test (#122)	X	X	ND
External Alarm Lead Query Test (#120)	X	X	ND
Analog Ring Generator Initialization Test (#117)	X	X	ND
Analog Ring Generator Query Test (#118)	X	X	ND

1. D = Destructive; ND = Nondestructive

AC Power Query Test (#78)

This test queries the SYSAM in the PPN or the EPN maintenance circuit pack in an EPN Multi-Carrier Cabinet system for the status of AC power to the cabinet.

Table 9-2. TEST #78 Power Query Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
100 2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Resolve all AC-POWER and CARR-POW alarms. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, check for and resolve all SYSAM errors in a PPN or MAINT errors (EPN maintenance circuit pack) in an EPN. Then, repeat the test.
2029 2319 2320 2500	ABORT	Internal system error
1	FAIL	**NOTE:** For a J58890CE, skip to step 2. 1. Procedures for a Global MCC (J58890CH): a. For a nominal holdover system if there is no AC power at the wall outlet, have a qualified electrician restore power to the outlet. Power should range from 170 to 264 VAC. b. If there is AC power at the wall outlet, then there could be a problem with the RM0850 Rectifiers, BU3200A Battery Interface Unit (BIU), or battery. Resolve all alarms logged against the POWER maintenance object, and rerun the test. If the test still fails, the BIU may be defective. Check the BIU. If the BOD alarm LED is on, replace the BIU. If the BOD LED is off and the BOK LED is on, then the SYSAM or the EPN maintenance circuit pack may be incorrectly reporting the problem. Resolve all alarms against these MOs and rerun the test.

Continued on next page

Table 9-2. TEST #78 Power Query Test — *Continued*

Error Code	Test Result	Description/Recommendation
1 (Continued)	FAIL	2. Procedures for a J58890CE: The cabinet is currently without AC power. 1. Check for AC at the wall outlet (99-127 VAC, or 200 - 250 VAC). a. If there is no AC power at the wall outlet, then the problem is not with the system itself. Power must be restored to the wall outlet. b. If there is AC power at the wall outlet, then there could be a problem with the Battery or Battery chargers. Resolve all alarms logged against POWER (Battery & Battery Charger), and rerun the test. If the test still fails, the fuse F5 may have opened. **WARNING:** *Turn off the 397C Battery Charger before inserting or removing Fuse F5.* Replace fuse F5 and rerun the test. If the test still fails, then the SYSAM or the EPN Maintenance circuit pack may be incorrectly reporting the problem. Resolve all alarms against these MOs, and rerun the test. There are failures that can occur on the SYSAM and EPN Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many, if not all, environment tests to fail. If more than two environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.
100	FAIL	The cabinet is currently without AC power, and AC power maintenance is in the middle of timing the NPH interval. 1. Follow the repair steps for error code 1.
	PASS	The SYSAM in the PPN or the EPN MAINT (maintenance) circuit pack in an EPN has reported that the cabinet has AC power. If there is no AC power at the wall outlet, then look for and resolve all alarms against the appropriate MO listed.

AC-POWER for DC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
AC-POWER	WARNING	test environment UU[1]	AC Power

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs).

NOTE:
In a DC-powered Multi-Carrier Cabinet, the AC-POWER maintenance object exists, but serves no functional purpose. Because the system cannot determine the type of power used, the AC-POWER test should always pass or abort. The maintenance strategy for power components in DC cabinets is described in the "CARR-POW (Carrier Power Supply)" section.

DEFINITY supports two different cabinet types: Multi-Carrier Cabinets and Single-Carrier Cabinets. Single-Carrier Cabinets are used only for EPNs. Both cabinet types may be powered by either AC or DC power source. Environmental maintenance differs according to cabinet type and external power supply.

Error Log Entries and Test to Clear Values

Table 9-3. AC Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment UU sh r 1
513	Any	AC Power Query Test (#78)	WARNING	OFF	test environment UU sh r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *AC Power Query Test*, for example, you may also clear errors generated from other tests in the testing sequence. Refer to the appropriate sections of this chapter for descriptions of each test.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query Test (#5)	X	X	ND
AC Power Query Test (#78)	X	X	ND
Power Unit Query Test (carrier E) (#127)	X	X	ND
Power Unit Query Test (carrier D) (#127)	X	X	ND
Power Unit Query Test (carrier A) (#127)	X	X	ND
Power Unit Query Test (carrier B) (#127)	X	X	ND
Power Unit Query Test (carrier C) (#127)	X	X	ND
Emergency Transfer Query Test (#124)	X	X	ND
Cabinet Temperature Query Test (#122)	X	X	ND
External Alarm Lead Query Test (#120)	X	X	ND
Analog Ring Generator Initialization Test (#117)	X	X	ND
Analog Ring Generator Query Test (#118)	X	X	ND

1. D = Destructive; ND = Nondestructive

AC Power Query Test (#78)

This test is not valid for DC-powered cabinets and should always abort or pass.

Table 9-4. TEST #78 Power Query Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run test are not available.
100 2000	ABORT	Response to the test request was not received within the allowable time period.
2029 2319 2320 2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN is incorrectly reporting an AC power problem. If this test fails, there is a problem with the SYSAM OR EPN Maintenance circuit pack. Replace the suspect circuit pack and run the test again. (b)
	PASS	Since this test is invalid for DC-powered cabinets, this result simply indicates that the SYSAM or EPN Maintenance circuit pack is handling this test properly

ADM-CONN (Administered Connection)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ADM-CONN	MAJOR, MINOR, or WARNING	status administered-connection N [1]	Administered Connection

1. Where N is an administered connection number indicated in the PORT field of the Alarm or Error Log.

An administered connection provides an end-to-end connection between two access endpoints or data modules on either the same or different switches. The connection is automatically established when it is administered and scheduled to be active.

An error is logged whenever an administered connection fails or cannot be established. Failures to establish a connection generate an error whether they occur on an initial try, a retry, a fast retry, a redial or an auto-restoration. A failed connection generates an error whether or not the connection is subsequently reestablished by fast retry, redial, or auto restoration.

An alarm is logged when an administered connection cannot be established either initially or after failure of a connection. Both the alarm level (none to major) and a failure threshold can be administered for each administered connection. An alarm is raised when either of the following occurs:

- The number of consecutive failed attempts to establish a connection reaches the administered threshold.
- Software determines that failure to establish a connection is due to a mistake in administration. See Table 9-5.

Error Log Entries and Test to Clear Values

Table 9-5. Administered Connection Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0, or 29	Any	None	Any	OFF	None
1, or 28 (a,b)	Any	None	Any	OFF	None
2 (c)	Any	None	Any	OFF	None
6,21,31, or 127(d)	Any	None	Any	OFF	None

Continued on next page

Table 9-5. Administered Connection Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
16 (a)	Any	None	Any	OFF	None
17 (e)	Any	None	Any	OFF	None
18, or 102 (f)	Any	None	Any	OFF	None
22 (a,g)	Any	None	Any	OFF	None
34,42,44, or 58 (h)	Any	None	Any	OFF	None

91,95,96,97,98,99,100, or 111	Any	None	Any	OFF	None

For all ADM-CONN errors:

All of the above errors have no specific test associated with them and, except for errors 17 and 127, are valid only for administered connections established over ISDN-PRI facilities. Error 127 is valid for administered connections established over non-ISDN facilities or between two endpoints on the same switch.

Notes:

a. These errors are typically associated with administration problems and are not expected to be of a temporary nature. The administered connection is not retried and the failure is alarmed immediately. The alarm threshold specified by the customer is ignored.

b. The address of the destination endpoint is: an unassigned number (1), has an invalid number format (28), or is restricted from terminating calls due to Class of Restriction (“Access Denied”). Verify that the destination address is correct and that the destination endpoint is administered. The destination endpoint is not administered on the switch where this error is logged.

c. A request has been made to use a transit network or common carrier that cannot be accessed. Check the routing pattern used by this administered connection and verify that the inter-exchange carrier specified is correct.

d. The exact failure cause is unknown or has been mapped to one of these values. If this is not a temporary condition, try reversing the direction of the Administered Connection (originate the administered connection from the destination switch). This may yield another failure cause.

e. The destination endpoint is not available. Check the status of the destination endpoint at the far-end switch. The status for the destination endpoint will not be available on the switch where this error is logged. At the far end, use **status access-endpoint** or **status data-module** to see whether the endpoint is busy, out-of-service or otherwise unavailable.

f. This switch sent an ISDN message to another switch, which either did not respond (18) or did not respond within the allotted time (102). This could be due to link failure or congestion or outage at the other switch.

g. The address of the destination endpoint has changed. Change the administered connection accordingly. The destination endpoint will not be administered on the switch where this error is logged.

h. These errors indicate that a resource (for example, a circuit or bearer capability) required by the administered connection is not presently available.

i. A network failure (38) or temporary failure (41) has occurred. Error Log entries for other MOs (for example, DS1-BD) may indicate a local problem.

ADX8D-BD (AUDIX Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ADX8D-BD	MINOR or WARNING	test board UUCSS sh	AUDIX Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The ADX8D-BD maintenance object represents a TN566/TN2169 DEFINITY AUDIX circuit pack (sometimes called Embedded AUDIX) operating in digital-port (DP) mode. For circuit-pack-level problems, see ‘‘XXX-BD (Common Port Circuit Pack)’’. Port-level problems are covered by ADX8D-PT.

DEFINITY AUDIX consists of two circuit packs that occupy 5 slots on a port carrier. The tests described in this manual apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

ADX8D-PT (AUDIX Digital Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ADX8D-PT	MINOR	test port UUCSSpp l	AUDIX Digital Port
ADX8D-PT	WARNING	test port UUCSSpp sh	AUDIX Digital Port

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The ADX8D-PT maintenance object represents a port on a TN566/TN2169 DEFINITY AUDIX circuit pack (sometimes called Embedded AUDIX) operating in digital-port (DP) mode. The maintenance strategy for ports on the TN566 operating in control-link mode is described in ADX16A-PT.

The tests described in this section apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction Board (MFB) and the TN2169 Alarm Board (ALB). Because of its size this combination occupies 5 slots, but only 1 slot is functional as far as the switch is concerned. The other 4 slots are seen by the switch as ‘‘AUDIX-reserved’’ slots (or ADXDP-RS/ADX8D-RS.)

In DP mode the TN566 pack supports up to 8 voice ports, each with a primary information channel and a secondary information channel. Ports are administered in increments of two. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, DEFINITY AUDIX is not an adjunct.

CAUTION:
Never do any of the following without first shutting down AUDIX. Follow instructions on the TN566/TN2169 faceplate:

- *Remove DEFINITY AUDIX circuit packs*
- *Cycle power to a carrier containing DEFINITY AUDIX circuit packs*
- *Remove power to a carrier containing DEFINITY AUDIX circuit packs*

Error Log Entries and Test to Clear Values

Table 9-6. DEFINITY AUDIX Digital Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	40987	None	WARNING	OFF	
1(b)	1 to 20	None	WARNING	OFF	
15(c)	Any	None			
18(d)	0	busyout port UUCSSpp	WARNING	OFF	release port UUCSSpp
23(e)	0	None	WARNING	OFF	
130(f)		None	WARNING	ON	test port UUCSSpp sh
257(g)	40971	None			
513(h)	Any	None			
1537(i)	40968	None	WARNING	OFF	
1793		Voice & Ctrl. Local Loop Test (#13)	MIN/WRN[2]	ON	test port UUCSSpp l r 3
2049		NPE Crosstalk Test (#9)	MIN/WRN[2]	ON	test port UUCSSpp l r 3
2305(j)	40967	None			
3840(k)	40965	None			
3840(l)	41029	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. The user may experience a noisy port or link. This is an off-board problem that is detected by the port circuit. If this problem exists, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a predetermined time.

b. At least 15 off-board problems have been detected with the link to the voice port. When an error with the link is detected, an on-board counter is incremented. Also see Note (a).

c. This is an internal type error that occurs when an audit request fails.

d. The port is busied-out by command. You can release the port via the **release port** UUCSSpp command.

e. The circuit pack is administered but not physically installed. The alarm will clear when a circuit pack is inserted.

f. The circuit pack has been removed or has been insane for more than 21-minutes. To clear the error, reinsert or replace the AUDIX circuit pack (see pcaution at the beginning of this section).

g. Something is interfering with transmitting to the voice port. This is usually an on-board problem and can be ignored if no user complaints are received.

h. AUDIX is not available to the switch, possibly due to a busyout on the AUDIX system. Check out the AUDIX system referring *DEFINITY AUDIX System Maintenance*, 585-300-110, if necessary.

i. An in-line maintenance error has generated an off-board warning due to some problem with the link to the voice port. This can be ignored if no user complaints are received. If the problem persists, replace the circuit pack (see precaution at the beginning of this section). Once the problem is resolved, the alarm is retired after a certain period of time.

j. The link between the circuit pack and the voice port is successfully reset. No craft action is necessary.

k. No voice ports are connected to the DEFINITY AUDIX circuit pack. No maintenance action is required.

l. The message buffer in the circuit pack is full.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when you are inspecting errors in the system. By clearing error codes associated with the *Voice and Control Channel Local Looparound Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Voice and Control Channel Local Looparound Test (#13)		X	ND
NPE Crosstalk Test (#9)		X	ND

1. D = Destructive; ND = Nondestructive

NO-OP Tests

The maintenance strategy for DEFINITY AUDIX emulates the one for DIG-LINE. The tests listed below apply only to DIG-LINE and not to DEFINITY AUDIX. These are referred to as *NO-OP* tests, and they always return PASS.

- Electronic Power Feed Test (#11)
- Station Lamp Updates Test (#16)
- Station (Digital) Audits Test (#17)

NPE Crosstalk Test (#9)

This test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence, and it takes about 20 to 30 seconds to complete.

Crosstalk testing is performed on both the primary information channel (voice) and on the secondary information channel (data) associated with each DEFINITY AUDIX port. If this test fails on either channel, the voice port is taken out-of-service.

Table 9-7. TEST #9 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available. Also, the port may have been busy during the test. 1. Check the port status. 2. Use the **display port UUCSSpp** command to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
2	ABORT	System resources may not have been available, or the port may have been busy during the test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use. 1. Use the **display port UUCSSpp** command to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors, and if it is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present, or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was put in use during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing.

Continued on next page

Table 9-7. TEST #9 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
1020	ABORT	Test disabled by background testing. Use the **status station** command to determine when the voice port is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1 2	FAIL	The NPE of the tested port is transmitting in error. This causes noisy and unreliable connections. Failure code 1 indicates that the Crosstalk test failed on the primary channel. Failure code 2 indicates that the Crosstalk test failed on the secondary channel. 1. Replace the circuit pack .
	PASS	The port is using its allocated time slots correctly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist, examine the connections.

Voice and Control Channel Local Loop Test (#13)

This test checks the information and control channels between the Switch Processing Element (SPE) and the DEFINITY AUDIX port circuit. First, the primary information (voice) channel loop back test is run.

While the primary information channel is still looped around, the Control Channel Looparound Test is performed. The Looparound Test for the secondary information (data) channel is then performed. This test is the same as the primary information channel loop around test.

Next, a Conference Test is implemented for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of the four tests run. If any test fails or aborts, the sequence is stopped.

Table 9-8. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times. Then try (b).
1000	ABORT	System resources required to run this test are not available. The port may be in use. 1. Use the **display port UUCSSpp** command to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or may have time slots that are out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors, and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present, or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was put in use during the test. 1. Use the **display port UUCSSpp** to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-8. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/Recommendation
7	FAIL	Conference Test failed on the primary channel. Some users may not notice a disruption in service. In extreme cases, the conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
15	FAIL	The control channel between the processor and DEFINITY AUDIX circuit pack is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port. This failure could also be disruptive to other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
None	FAIL	The test failed for reasons external to the DEFINITY AUDIX circuit pack. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack by using the **test board UUCSS s** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and if the test still fails, replace the DEFINITY AUDIX circuit pack (see precaution at the beginning of this section).
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to 10 times and see if it continues to pass. 2. If complaints still exist, examine the connections.

ADX16D-B (16 Port AUDIX Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ADX16D-B	MINOR	test board UUCSS sh	AUDIX Circuit Pack
ADX16D-B	WARNING	test board UUCSS sh	AUDIX Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The ADX16D-BD maintenance object represents a TN566/TN2169 DEFINITY AUDIX circuit pack combination operating in 16 port mode digital (DP). For circuit-pack-level problems, see “XXX-BD (Common Port Circuit Pack)”. Port-level maintenance is covered by ADX16D-PT.

DEFINITY AUDIX consists of 2 circuit packs that occupy 5 slots on a port carrier. The tests described in this manual apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy of its own that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

ADX16A-BD (AUDIX Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ADXCL-BD or \ADX16A-BD	MINOR, or WARNINGS	test board UUCSS sh	AUDIX Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The ADX16A-BD maintenance object represents a TN566/TN2169 DEFINITY AUDIX circuit pack combination operating in control-link (CL) mode. For circuit-pack-level problems, see "XXX-BD (Common Port Circuit Pack)". Port-level maintenance is covered by ADX16A-PT.

DEFINITY AUDIX consists of 2 circuit packs that occupy 5 slots on a port carrier. The tests described in this manual apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

ADX16D-P (16-Port AUDIX Digital Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ADX16D-P	MINOR or WARNINGS	test port UUCSSpp l	AUDIX Digital Port

1. UU is the universal cabinet number (1 for PPN, 2-44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

CAUTION:
Never do any of the following without first shutting down AUDIX. Follow the instructions on the TN566/TN2169 faceplate:

- *Remove DEFINITY AUDIX circuit packs*
- *Cycle power to a carrier containing DEFINITY AUDIX circuit packs*
- *Remove power to a carrier or cabinet containing DEFINITY AUDIX circuit pack.*

The ADX16D-P maintenance object represents a port on a TN566/TN2169 DEFINITY AUDIX circuit pack operating in digital-port (DP) mode. The maintenance strategy for ports on the TN566 operating in control-link mode is described in ADX16A-PT.

The tests described in this section apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction Board (MFB) and the TN2169 Alarm Board (ALB). Because of its size this combination occupies 5 slots, but only 1 slot is functional as far as the system is concerned. The other 4 slots are seen by the switch as “AUDIX-reserved” slots (or ADX16-RES/ADX16D-RS).

In 16 Port DP mode, the TN566 pack supports up to 16 voice ports, each with a primary information channel and a secondary information channel. Ports are administered in increments of two. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, DEFINITY AUDIX is not an adjunct.

Error Log Entries and Test to Clear Values

Table 9-9. DEFINITY AUDIX Digital Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1

2305(j)	40967	None			
3840(k)	40965	None			
3840(l)	41029	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. The user may experience a noisy port or link. This is an off-board problem that is detected by the port circuit. If this problem exists, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a predetermined time.

b. At least 15 off-board problems have been detected with the link to the voice port. When an error with the link is detected, an on-board counter is incremented. Also see Note a, above.

c. This is an internal type error that occurs when an audit request fails.

d. The port is busied-out by command. Release the port with the **release port UUCSSpp** command.

e. The circuit pack is administered but not physically installed. The alarm will clear when a circuit pack is inserted.

f. The circuit pack has been removed or has been insane for more than 21-minutes. To clear the error, reseat or replace the AUDIX circuit pack (see caution at the beginning of this section).

g. Something is interfering with transmitting to the voice port. This is usually an on-board problem and can be ignored if no user complaints are received.

h. AUDIX is not available to the switch, possibly due to a busyout on the AUDIX system. Refer to *DEFINITY AUDIX System Maintenance*, 585-300-110, if necessary.

i. An in-line maintenance error has generated an off-board warning due to some problem with the link to the voice port. This can be ignored if no user complaints are received. If the problem persists, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a certain period of time.

j. The link between the circuit pack and the voice port is successfully reset. No craft action is necessary.

k. No voice ports are connected to the DEFINITY AUDIX circuit pack. No maintenance action is required.

l. The message buffer in the circuit pack is full.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Voice and Control Channel Local Looparound Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Voice and Control Channel Local Looparound Test (#13)		X	ND
NPE Crosstalk Test (#9)		X	ND

1. D = Destructive; ND = Nondestructive

NO-OP Tests

The maintenance strategy for DEFINITY AUDIX emulates the one for DIG-LINE. The tests listed below apply only to DIG-LINE and not to DEFINITY AUDIX. These tests always return PASS.

- Electronic Power Feed Test (#11)
- Station Lamp Updates Test (#16)
- Station (Digital) Audits Test (#17)
- Digital Terminal Remote Looparound Test (1201)

NPE Crosstalk Test (#9)

This test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence, and it takes about 20 to 30 seconds to complete.

Crosstalk testing is performed on both the primary information channel (voice) and on the secondary information channel (data) associated with each DEFINITY AUDIX port. If this test fails on either channel, the voice port is taken out-of-service.

Table 9-10. TEST #9 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available. Also, the port may have been busy during the test. 1. Check the port status. 2. Use the **display port UUCSSpp** command to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, it is unavailable for this test. Wait until the port is idle. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
2	ABORT	System resources may not have been available, or the port may have been busy during the test. 1. Check if port is being used. 2. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-10. TEST #9 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use. 1. Use the **display port UUCSSpp** command to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Refer to “Status” commands in Chapter 8, for a full description of all possible states. Wait until the port is idle before testing. 2. If the port status is idle,retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors, and if it is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors.
1004	ABORT	The port was put in use during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the voice port extension of the port. Use the **status station** command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Refer to “Status” commands in Chapter 8, “Maintenance Commands” for explanations of all possible states. Wait until the port is idle before testing.
1020	ABORT	Test disabled via background testing. Use the **status station** command to determine when the voice port is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1 2	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. Failure code 1 indicates that the Crosstalk test failed on the primary channel. Failure code 2 indicates that the Crosstalk test failed on the secondary channel. 1. Replace the circuit pack (see caution at the beginning of this section).

Continued on next page

Table 9-10. TEST #9 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
	PASS	The port is using its allocated time slots correctly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist, examine the connections.

Voice and Control Channel Local Loop Test (#13)

This test checks the information and control channels between the Switch Processing Element (SPE) and the DEFINITY AUDIX port circuit. The SPE sends a message to loop around both the information and control channels for the port. First, the primary information (voice) channel loop back test is run.

While the primary information channel is still looped around, the Control Channel Looparound Test is performed. The Looparound Test for the secondary information (data) channel is then performed. This test is the same as the primary information channel loop around test.

Next, a Conference Test is implemented for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of the four tests run. If any test fails or aborts, the sequence is stopped.

Table 9-11. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use. 1. Use **display port UUCSSpp** command to determine the voice port extension of the port. Use **status station** command to determine the service state of the port. Wait until the port is idle before testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-11. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots that are out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and if it is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was put in use during the test. The test has been aborted. 1. Use **display port UUCSSpp** to determine the voice port extension of the port. Use **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources for this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-11. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/Recommendation
7	FAIL	Conference Test failed on the primary channel. In some cases, users may not notice a disruption in service. In extreme cases, the conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
15	FAIL	The control channel between the processor and AUDIX is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port. This failure could also be disruptive to other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
None	FAIL	The test failed for reasons external to the AUDIX. 1. Run circuit pack tests to check the tone generator circuit pack and the tone detector circuit pack using **test board UUCSS s**. 2. Resolve any problems detected on the tone generator circuit pack or tone detector circuit pack. 3. If the tone generator and tone detector circuit packs are functioning properly, and if the test still fails, replace the AUDIX (see caution at the beginning of this section).
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to 10 times and see if it continues to pass. 2. If complaints still exist, examine the connections.

ADX16A-PT (AUDIX Analog Line/Control Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ADXCL-PT or ADX16A-PT	MINOR	test port UUCSSpp l	AUDIX Analog Line/ Control Link
ADXCL-PT or ADX16A-PT	WARNING	test port UUCSSpp sh	AUDIX Analog Line/ Control Link

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

CAUTION:

Never do any of the following without first shutting down AUDIX. Follow the instructions on the TN566/TN2169 faceplate:

- *Remove DEFINITY AUDIX circuit packs*
- *Cycle power to a carrier containing DEFINITY AUDIX circuit packs*
- *Remove power to a carrier containing DEFINITY AUDIX circuit packs*

The ADX16A-PT maintenance object represents a port on a TN566/TN2169 DEFINITY AUDIX circuit pack that is operating in control-link (CL) mode. For circuit-pack-level problems (ADX16A-BD or ANL-16-BD), see “XXX-BD (Common Port Circuit Pack)”. For port-level problems with AUDIX operating in digital-port mode, see ADXDP-PT/ADX8D-PT.

The tests described in this section apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction Board (MFB) and the TN2169 Alarm Board (ALB). Because of its size this combination occupies 5 slots, but only 1 slot is functional as far as the switch is concerned. The other 4 slots are seen by the switch as ‘‘AUDIX-reserved’’ slots.

In CL mode the TN566 pack supports up to 16 voice ports. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, DEFINITY AUDIX is not an adjunct.

Error Log Entries and Test to Clear Values

Table 9-12. DEFINITY AUDIX Analog Line/Control Link Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1 (a)	40977	None			
18	0	busyout station <*extension*>	WRN	ON	release station <*extension*>
23 (b)	0	None	WRN	OFF	
130 (c)		None	WRN	ON	test port UUCSSpp sh
257 (d)	40973	None			
513 (e)	Any	None			
1025 (f)		Looparound Test (#161)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1281		Conference Test (#7)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1537		NPE Crosstalk Test (#6)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. This is an in-line error and can only be resolved over time. This indicates that no terminal equipment was present when ringing was attempted. Execute the short **test port UUCSSpp** command.
b. The circuit pack has been logically administered but not physically installed. The alarm will be cleared when the circuit pack is installed.
c. The circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reseat or replace the circuit pack.
d. This is an in-line error and can only be resolved over time. This error indicates that ringing voltage is absent. If only one analog circuit pack in the system has this problem, then replace the circuit pack. If only analog circuit packs on a particular carrier have this error, then the ringing generator may not be connected to this carrier. If analog circuit packs on many carriers have this error, check the ringing generator.
e. AUDIX is not available to the switch. Check the AUDIX system, referring to *DEFINITY AUDIX System Maintenance*, 585-300-110.
f. The TDM bus is out of service. See the “TDM-BUS” section.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Looparound Test #161* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Looparound Test (#161)		X	ND
Conference Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND

1. D = Destructive; ND = Nondestructive

NO-OP Tests

The maintenance strategy for DEFINITY AUDIX emulates the one for ANL-16-L. The tests listed below apply only to ANL-16-L and not to DEFINITY AUDIX. These tests always return PASS.

- Battery Feed Test (#35)
- Audits and Updates Test (#36)
- Station Present Test (#48)

Tests 36 and 48 ABORT when AUDIX is not running.

NPE Crosstalk Test (#6)

This test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of the long test sequence and takes about 25 seconds to complete.

Table 9-13. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-13. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Wait until the port is idle before testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test.[1]
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, then retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Wait until the port is idle before testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	This condition indicates that the test is not applicable when the analog port is used in a combined modem pool. This error can be ignored.
1018	ABORT	Test disabled via administration. 1. To enable the test for the particular analog station being tested, enter the **change station *extension*** command and change the `Test?` field on the Station Form to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2012	ABORT	System could not respond to this request.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-13. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.

Conference Circuit Test (#7)

This test verifies that the NPE channel for the port being tested can correctly perform the conferencing function.

Table 9-14. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until it is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until it is idle before testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1018	ABORT	Test disabled by administration. This only applies to analog stations. 1. To enable the test for the analog station being tested, enter the **change station <extension>** command and change the `Test?` field on the Station Form from to **y**.

Continued on next page

Table 9-14. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources for this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.

Looparound Test (#161)

This test is designed to check the on-board transmission capabilities of the NPE on the analog port.

Table 9-15. TEST #161 Looparound Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources for this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until it is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-15. TEST #161 Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1018	ABORT	Test disabled by administration. To enable the test for the particular analog station, enter the **change station <extension>** command and change the “Test?” field on the Station Form from “n” to “y.”
2000 2100	ABORT ABORT	Response to the test was not received within the allowable time period. Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The reflective Looparound Test failed. This causes noisy or unreliable connections or other users calling this port may hear an echo. 1. Replace the circuit pack.
	PASS	The port is able to provide an analog transmission path to the station equipment. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.

ALARM-PT (ALARM PORT)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ALARM-PT	MIN	test port UUCSSpp l	Alarm-Port
ALARM-PT	WRN	test port UUCSSpp sh	Alarm-Port

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The Alarm Port MO provides on-board maintenance for an analog line port that is administered as an external device alarm port. Test are provided to verify the analog line ports ability to detect an external device alarm. The external device alarm (EXT-DEV) MO is used for the off-board external device alarm.

Error Log Entries and Test to Clear Values

Table 9-16. 8-Port Analog Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
15 (a)	Any	Audits and Updates Test (#36)			
18	0	busy-out station *extension*	WARNING	OFF	release station *extension*
130 (b)		None	WARNING	ON	test port UUCSSpp sh
769		Battery Feed Test (#35)	MINIOR	ON	test port UUCSSpp sh r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures

Notes:

a. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate errors.

b. Indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reseat or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Battery Feed Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery Feed Test (#35)	X	X	ND
Station Status and Translation Audits and Updates Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

Battery Feed Test (also called Port Diagnostic Test) (#35)

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switchhook capabilities of the battery feed chip by terminating the port, applying battery, and trying to detect a current.

Table 9-17. TEST #35 Battery Feed Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be reporting an external device alarm. 1. Enter **test external-device-alarm port UUCSSpp** to determine if the port is reporting an EXT-DEV failure before retesting. 2. When the port has no EXT-DEV failure, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port received an EXT-DEV failure during the test. The test has been aborted. 1. Enter **test external-device-alarm port UUCSSpp** to determine if the port is reporting an EXT-DEV failure before retesting. 2. If the port has no EXT-DEV failure, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-17. TEST #35 Battery Feed Test — *Continued*

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The port's battery feed chip is unable to supply sufficient power to sense the external device alarm. This may occur when the test is performed at the same time that the external device contact closure occurred. 1. Enter **test external-device-alarm port UUCSSpp** to determine if the port is reporting an EXT-DEV failure before retesting. Wait until the port has no EXT-DEV failure before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	The port's battery feed chip is able to provide power to the external device alarm to detect contact closure.

Station Status and Translation Audits and Updates Test (#36)

For an analog line port that is administered as an external alarm, this test is limited to updating the software with the switchhook state.

Table 9-18. TEST #36 Station Status and Translation Audits and Updates

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port received an EXT-DEV failure during the test. The test has been aborted. 1. Enter **test external-device-alarm port UUCSSpp** to determine if the port is reporting an EXT-DEV failure before retesting. 2. If the port has no EXT-DEV failure, retry the command at 1-minute intervals for a maximum of 5 times.
1006	ABORT	This port has been busied out by command. 1. Check Error Log for Error Type 18 (port busied out). If present, release the port with the **release port UUCSSpp** command and run the test again.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1	FAIL	This failure does not indicate a hardware problem. The switchhook audit failed, this condition may occur when the audit is performed at the same time that the terminal equipment goes off-hook. 1. Enter **test external-device-alarm port UUCSSpp** to determine if the port is reporting an EXT-DEV failure before retesting. Wait until the port has no EXT-DEV failure before retesting 2. If the port has no EXT-DEV failure, retry the command at 1-minute intervals for a maximum of 5 times.
7	FAIL	The translation update failed. This does not indicate a hardware problem but may be an internal software error.
	PASS	The software and the port processor have the same status.

ANL-16-L (16-Port Analog Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ANL-16-L	MIN	test port UUCSSpp l	16-Port Analog Line
ANL-16-L	WRN	test port UUCSSpp sh	16-Port Analog Line

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The circuit packs listed below provide 16 analog line ports for single-line voice terminals. The table below indicates which circuit packs are equipped with lightning protection (for off-premises, out-of -building stations), and which ones support the neon message waiting lamp feature.

16-Port Analog Line Circuit Packs

Circuit Pack	Off-Premises	Neon
TN468B	y	
TN479		
TN746		y
TN746B	y	y
TN2135	y	
TN2144	y	
TN2149	y	
TN2180	y	

No maintenance of the terminal connected to the 16-Port Neon Analog Line circuit pack is performed, except to determine whether or not the terminal is connected. Failures of the neon message waiting lamp power and the common ringing application circuitry are reported as part of common port circuit pack errors; see errors 1281 and 1793 in the “XXX-BD (Common Port Circuit Pack)” section.

Ringing Caused by Maintenance Testing

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled in the `Tests` field of the **change station** extension form. Be aware that this action will also disable Tests #6, 7, 161 and 35.

Error Log Entries and Test to Clear Values

Table 9-19. 16-Port Analog Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	40960 40975 40977	none			
15(b)	Any	Audits and Updates Test (#36)			
18	0	busy-out station *extension*	WRN	ON	release station *extension*
130(c)		None	WRN	ON	test port UUCSSpp sh
257(d)	40973	none			
513(e)		Station Present Test (#48)	WRN	OFF	test port UUCSSpp sh r 2
769		Battery Feed Test (#35)	MIN/ WRN[2]	ON	test port UUCSSpp sh r 2
1025		Looparound Test (#161)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1281		Conference Test (#7)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1537		NPE Crosstalk Test (#6)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. These are in-line errors and can only be resolved over time.

Aux Data 40960 indicates that too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call causes an inline error from the board.

Aux Data 40975 indicates that the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance. Call the terminal equipment and verify that the terminal rings. If the terminal does not ring, then replace it. Otherwise, issue the **test port UUCSSpp** command, and follow the procedure for Test #48.

Aux Data 40977 indicates that no terminal equipment was connected when ringing was attempted. Run the short test via the **test port UUCSSpp** command, and follow the procedure for the results of Test #48.

b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reseat or replace the circuit pack.

d. This is an in-line error and can only be resolved over time. This error indicates that ringing voltage is absent. If only 1 analog circuit pack in the system has this problem, then replace the circuit pack. If only analog circuit packs on a particular carrier have this error, then the ringing generator may not be connected to this carrier. If analog circuit packs on many carriers have this error, then it is probably a problem with the ringing generator.

e. Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this disturbs the customer or the terminal equipment, disable it by setting the `Tests` field on the **change station** extension form to n. On some software releases, this will also disable Tests #6, 7, 161, and 35.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery Feed Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery Feed Test (#35)	X	X	ND
Station Present Test (#48)	X	X	ND
Looparound Test (#161)		X	ND
Conference Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND
Station Status and Translation Audits and Updates Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

This test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of the long test sequence and takes about 20 to 30 seconds to complete.

Table 9-20. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run test are not available. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. Enter **status station** extension to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required to run test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-20. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1018	ABORT	The test has been disabled by administration. The default for the `Test` field on the station form is **y**. Determine why this field has been set to “no” on this station (this may be due to the ringing application Test #48, that can be customer or terminal disturbing. 1. To enable the test for a particular station being tested, enter **change station extension** and set the “Test?” field on the station from “n” to “y.”
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-20. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. A TDM-BUS problem is usually the result of a faulty board connected to the backplane, or bent pins on the backplane. 1. Resolve any EXP-PN or EXP-INTF errors. 2. Resolve any TDM-BUS errors. 3. Resolve any TONE-BD or TONE-PT errors. 4. Test the board when the faults from Steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Conference Circuit Test (#7)

This test verifies that the NPE channel for the port being tested can correctly perform the conferencing function.

Table 9-21. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. Enter **status station** extension to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1018	ABORT	The test has been disabled via administration. The default for the `Test` field on the station form is **y**. Determine why this field has been set to "n" on this station (this may be due to the ringing application Test #48, which can be customer or terminal disturbing). 1. To enable the test for the particular analog station being tested, enter **change station extension** and set the `Test?` field on the station to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Resolve any TONE-PT errors. 2. Resolve any TONE-PT errors.

Continued on next page

Table 9-21. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/Recommendation
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Issue the **display port** and the **status station** commands to determine if the station is idle. If the station is idle, issue the **test port** command for this port. 2. If the test continues to fail, issue the **busyout port** and the **release port** commands, and then retest. 3. If the test still fails, replace the board.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Battery Feed Test (also called Port Diagnostic Test) (#35)

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switchhook capabilities of the battery feed chip by terminating the port, applying battery and detecting the resulting current.

For the TN746B, Test #35 does not actually run and instead always returns PASS. Test #35 operates in the normal manner for TN746.

Table 9-22. TEST #35 Battery Feed Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. This result is also reported for the system’s Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station’s extension. Enter **status station** extension to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1018	ABORT	The test has been disabled via administration. The default for the “Test” field on the station form is **y**. Determine why this field has been set to “n” on this station (this may be due to the ringing application Test #48, which can be customer or terminal disturbing). 1. To enable the test for the particular analog station being tested, enter **change station extension** and set the `Test?` field on the station to **y**.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct for the test, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-22. TEST #35 Battery Feed Test — *Continued*

Error Code	Test Result	Description/Recommendation
	FAIL	The port's battery feed chip is unable to supply sufficient power to the terminal equipment. This could be a marginal test, and the terminal equipment may be operating satisfactorily. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail, determine whether the customer is experiencing problems on this line. Replace the circuit pack only if the customer is experiencing problems.
	PASS	The port's battery feed chip is able to provide power to the station equipment to detect on-/off-hook, but may not be able to supply power for touch-tones. If touch-tones are inoperative on this station, then replace the circuit pack because this port is inoperative. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Station Status and Translation Audits and Updates Test (#36)

This test updates the analog port's message lamp state (if it has one) and translations with information in the software.

Table 9-23. Test #36 Station Status and Translation Audits and Updates

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1006	ABORT	This port has been busied out by command, or taken out-of-service by the failure of the NPE Crosstalk Test. 1. Look in the error log for error type 18 (port busied out) for this port. If this error is present, release the port with the **release station extension** command, and run the test again. 2. Check the error log for error type 1025 (NPE crosstalk test failed) for this port. If this error is present, investigate the errors associated with the NPE Crosstalk Test 6. 3. Make sure that the terminal is connected and in service, and then retest.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1	FAIL	This does not indicate a hardware problem. The switchhook audit failed. The other updates were not performed because of this failure. This may occur when the audit is performed at the same time the terminal equipment goes off-hook. 1. Use the **status station** command to determine when the port is available. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
5	FAIL	This may be an internal software error. The message waiting lamp update failed. The translation and ringer updates were not performed because of this failure.
7	FAIL	The translation update failed. There may be an internal software error. The ringer update was not performed because of this failure.

Continued on next page

Table 9-23. Test #36 Station Status and Translation Audits and Updates — *Continued*

Error Code	Test Result	Description/ Recommendation
8	FAIL	This does not indicate a hardware problem. There may be an internal software error. The ringer update failed. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	The software and the port processor have the same status. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure the board translations are correct. Use the **list config** command and resolve problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Station Present Test (also called Ringing Application Test) (#48)

This test applies momentary ringing voltage to the terminal equipment and monitors resulting current flow to determine whether terminal equipment is connected to the port. This test may cause some terminal equipment to ring briefly during daily maintenance. If this ringing disturbs the customer or the terminal equipment, you can disable it via the Tests field on the **change station** form. However, on some software releases, Tests #6, 7, 161, and 35 are disabled.

Table 9-24. TEST #48 Station Present Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, wait until the port is idle. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1008	ABORT	Could not allocate a ringing circuit. Either all the ringing circuits are in use or the ringing generator is defective or it is not wired correctly. Retry the command at 1-minute intervals for a maximum of 5 times. 1. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or is not wired correctly. If it does not occur on other ports, then all four ring phases are in use.
1018	ABORT	The test has been disabled by administration. The default for the `Test?` field on the station form is **y**. Determine why this field has been set to “n” on this station (this may be due to the brief ringing disturbance that this test may cause). 1. To enable the test for the particular analog station being tested, enter **change station extension** and set the `Test?` field on the station to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-24. TEST #48 Station Present Test — *Continued*

Error Code	Test Result	Description/Recommendation
	FAIL	The terminal equipment is not connected to the circuit pack. Some terminal equipment, such as modems, may fail even when connected properly. 1. Remotely test the equipment. 2. If the test fails again, look for RING-GEN errors in the Error Log. 3. Check all of the wiring between the station equipment and the switch. Then, run the test again. 4. If the test still fails, the set may be defective. Check the set, and replace it, if necessary. 5. Some terminal equipment could fail even when it is connected properly. If this is the case, disable the test using the **change station extension** command (enter **n** into the `Test?` field). Note that this action also disables Tests 6, 7, 161, and 35 on this port.
	PASS	The station is connected properly to the switch. This test may also pass if no terminal equipment is connected and the terminal is located very far from the switch. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Looparound Test (#161)

This test checks the on-board transmission capabilities of the NPE, the codec, and the battery feed chip of the analog port. The test passes if the signal measured by the tone detector is within acceptable limits.

Table 9-25. TEST #161 Looparound Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	This test is not run on ports administered as External Alert, Announcement or combined modem pool ports. This error can be ignored.
1018	ABORT	The test has been disabled by administration. The default for the `Test?` field on the station form is **y**. Determine why this field has been set to “n” on this station (this may be due to the ringing application Test #48, which can be customer or terminal disturbing). 1. To enable the test for the particular analog station being tested, enter **change station extension** and set the Test? `field` on the station to **y**.

Continued on next page

Table 9-25. TEST #161 Looparound Test — *Continued*

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The reflective loop around test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board. 1. Since the test may be affected by a line seizure, repeat the test at 1-minute intervals for a maximum of 5 times. 2. Run circuit pack tests to check the tone generator circuit pack and the tone detector circuit pack by using the **test board UUCSS short** command. 3. Resolve any problems on the tone generator circuit pack or the tone detector circuit pack. 4. If the tone generator and tone detector circuit packs are functioning properly and the test still fails and a voice terminal is connected and wired properly, replace the analog line circuit pack.
	PASS	The port is able to provide an analog transmission path to the station equipment. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

ANL-24-L (24-Port Analog Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ANL-24-L	MIN	test port UUCSSpp l	24-Port Analog Line
ANL-24-L	WRN	test port UUCSSpp sh	24-Port Analog Line

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs); C is the carrier designation (A, B, C, D, or E); SS is the number of the slot in which the circuit pack resides (01 to 21); and pp is the two digit port number (01, 02, ...).

The 24-Port Analog Line circuit pack (TN793) provides 24 ports for voice terminals and supports both on-premises and off-premises analog voice terminals.

No maintenance of the terminal connected to the 24-Port Neon Analog Line circuit pack is performed, except to determine whether or not the terminal is connected. Failures of the neon message waiting lamp power and the common ringing application circuitry are reported as part of common port circuit pack errors. See errors 1281 and 1793 in the “XXX-BD (Common Port Circuit Pack)” section.

NOTE:
This analog line circuit pack supports analog data modules. When assigned, analog data modules provide access to the Net Pkt (TN794) data ports. To activate an analog data module you must assign the port location on the data form and connect a modem to the port. (The analog data module may be used for connection to a CDR output or other adjuncts as needed.) These ports are tested the same as all other analog ports on the circuit pack.

Ringing Caused by Maintenance Testing

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled in the `Test?` field of the **change station** extension form. Be aware that this action also disables Tests #6, 7, 161, and 35.

Error Log Entries and Test to Clear Values

Table 9-26. 24-Port Analog Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	40960 40975 40977	none			
15(b)	Any	Audits and Updates Test (#36)			
18	0	busy-out station *extension*	WRN	ON	release station <*extension*>
130(c)		None	WRN	ON	test port UUCSSpp sh
257(d)	40973	none			
513(e)		Station Present Test (#48)	WRN	OFF	test port UUCSSpp sh r 2
769		Battery Feed Test (#35)	MIN/ WRN[2]	ON	test port UUCSSpp sh r 2
1025		Looparound Test (#161)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1281		Conference Test (#7)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1537		NPE Crosstalk Test (#6)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. These are in-line errors and can only be resolved over time.

Aux Data 40960 indicates that too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call will cause an inline error from the board.

Aux Data 40975 indicates that the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance.

Call the terminal equipment and verify that the terminal rings. If the terminal does not ring, then replace it. Otherwise, issue the **test port UUCSSpp** command, and follow the procedure for Test #48.

Aux Data 40977 indicates that no terminal equipment was connected when ringing was attempted. Run the short test via the **test port UUCSSpp** command, and follow the procedure for the results of Test #48.

b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reseat or replace the circuit pack.

d. This is an in-line error and can only be resolved over time. This error indicates that ringing voltage is absent. If only 1 analog circuit pack in the system has this problem, then replace the circuit pack. If only analog circuit packs on a particular carrier have this error, then the ringing generator may not be connected to this carrier. If analog circuit packs on many carriers have this error, then it is probably a problem with the ringing generator.

e. Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this disturbs the customer or the terminal equipment, disable it by setting the `Tests` field on the **change station** extension form to n. On some software releases, this also disables Tests #6, 7, 161, and 35.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery Feed Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery Feed Test (#35)	X	X	ND
Station Present Test (#48)	X	X	ND
Looparound Test (#161)		X	ND
Conference Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND
Station Status and Translation Audits and Updates Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

This test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of the long test sequence and takes about 20 to 30 seconds to complete.

Table 9-27. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run test are not available. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. 2. Enter **status station** extension to determine the service state of the port. 3. If the port is in use, wait until the port is idle. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required to run test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-27. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1018	ABORT	The test has been disabled by administration. The default for the `Test` field on the station form is **y**. Determine why this field has been set to n on this station (this may be due to the ringing application Test #48, that can be customer or terminal disturbing). 1. To enable the test for a particular station being tested, enter **change station extension** and set the `Test?` field on the station from n to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-27. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. A TDM-BUS problem is usually the result of a faulty board connected to the backplane, or bent pins on the backplane. 1. Resolve any EXP-PN or EXP-INTF errors. 2. Resolve any TDM-BUS. 3. Resolve any TONE-BD or TONE-PT errors. 4. Test the board when the faults from Steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Conference Circuit Test (#7)

This test verifies that the NPE channel for the port being tested can correctly perform the conferencing function.

Table 9-28. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. 2. Enter **status station** extension to determine the service state of the port. 3. If the port is in use, wait until the port is idle and retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle and retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1018	ABORT	The test has been disabled via administration. The default for the `Test` field on the station form is **y**. Determine why this field has been set to n on this station (this may be due to the ringing application Test #48, that can be customer or terminal disturbing). 1. To enable the test for a particular station being tested, enter **change station extension** and set the `Test?` field on the station from n to **y**.
2000 2100	ABORT ABORT	Response to the test request was not received within the allowable time period. System resources required to run this test are not available. 1. Resolve TONE-PT errors. 2. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-28. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/Recommendation
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Issue the **display port** and the **status station** commands to determine if the station is idle. If the station is idle, issue the **test port** command for this port. 2. If the test continues to fail, issue the **busyout port** and the **release port** commands, and then retest. 3. If the test still fails, replace the board.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Battery Feed Test (also called Port Diagnostic Test) (#35)

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switchhook capabilities of the battery feed chip by terminating the port, applying battery and detecting the resulting current.

For the TN746B, Test #35 does not actually run and instead always returns PASS. Test #35 operates in the normal manner for TN746.

Table 9-29. TEST #35 Battery Feed Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle and retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1018	ABORT	The test has been disabled via administration. The default for the `Test` field on the station form is **y**. Determine why this field has been set to n on this station (this may be due to the ringing application test 48, that can be customer or terminal disturbing). 1. To enable the test for a particular station being tested, enter **change station extension** and set the `Test?` field on the station from n to **y**.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct for the test, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-29. TEST #35 Battery Feed Test — *Continued*

Error Code	Test Result	Description/Recommendation
	FAIL	The port's battery feed chip is unable to supply sufficient power to the terminal equipment. This could be a marginal test, and the terminal equipment may be operating satisfactorily. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail, determine whether the customer is experiencing problems on this line. Replace the circuit pack only if the customer is experiencing problems.
	PASS	The port's battery feed chip is able to provide power to the station equipment to detect on-/off-hook, but may not be able to supply power for touch-tones. If touch-tones are inoperative on this station, then replace the circuit pack because this port is inoperative. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Station Status and Translation Audits and Updates Test (#36)

This test updates the analog port's message lamp state (if it has one) and translations with information in the software.

Table 9-30. Test #36 Station Status and Translation Audits and Updates

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. 3. If the port is in use, wait until port is idle and retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1006	ABORT	This port has been busied out by command, or taken out-of-service by the failure of the NPE Crosstalk Test. 1. Look in the Error Log for error type 18 (port busied out) for this port. If this error is present, release the port with the **release station extension** command, and run the test again. 2. Check the Error Log for error type 1025 (NPE crosstalk test failed) for this port. If this error is present, investigate the errors associated with the NPE Crosstalk Test #6. 3. Make sure that the terminal is connected and in service, and then retest.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1	FAIL	This does not indicate a hardware problem. The switchhook audit failed. The other updates were not performed because of this failure. This may occur when the audit is performed at the same time the terminal equipment goes off-hook. 1. Use the **status station** command to determine when the port is available and retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-30. Test #36 Station Status and Translation Audits and Updates — *Continued*

Error Code	Test Result	Description/ Recommendation
5	FAIL	This may be an internal software error. The message waiting lamp update failed. The translation and ringer updates were not performed because of this failure.
7	FAIL	The translation update failed. There may be an internal software error. The ringer update was not performed because of this failure.
8	FAIL	This does not indicate a hardware problem. There may be an internal software error. The ringer update failed. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	The software and the port processor have the same status. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure the board translations are correct. Use the **list config** command and resolve problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Station Present Test (also called Ringing Application Test) (#48)

This test applies momentary ringing voltage to the terminal equipment and monitors resulting current flow to determine whether terminal equipment is connected to the port. This test may cause some terminal equipment to ring briefly during daily maintenance. If this ringing disturbs the customer or the terminal equipment, you can disable it via the Tests field on the **change station** form. However, on some software releases, Tests #6, 7, 161, and 35 are disabled.

Table 9-31. TEST #48 Station Present Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle and retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or Music On Hold).
1008	ABORT	Could not allocate a ringing circuit. Either all the ringing circuits are in use or the ringing generator is defective or it is not wired correctly. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or is not wired correctly (see errors for RING-GEN). If it does not occur on other ports, then all four ring phases are in use.
1018	ABORT	The test has been disabled by administration.The default for the `Test` field on the station form is **y**. Determine why this field has been set to n on this station (this may be due to the brief ringing disturbance that this test may cause). 1. To enable the test for a particular station being tested, enter **change station extension** and set the `Test?` field on the station from n to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-31. TEST #48 Station Present Test — *Continued*

Error Code	Test Result	Description/Recommendation
	FAIL	The terminal equipment is not connected to the circuit pack. Some terminal equipment, such as modems, may fail even when connected properly. 1. Remotely test the equipment. 2. If the test fails again, look for RING-GEN errors in the error log. If present, refer to "RING-GEN". 3. Check all of the wiring between the station equipment and the switch. Refer to "LA85 Port Tester" in Chapter 5 for instructions on using the port tester. Then, run the test again. 4. If the test still fails, the set may be defective. Check the set, and replace it, if necessary. 5. Some terminal equipment could fail even when it is connected properly. If this is the case, disable the test using the **change station extension** command (enter **n** into the `Test` field). Note that this action also disables Tests 6, 7, 161, and 35 on this port.
	PASS	The station is connected properly to the switch. This test may also pass if no terminal equipment is connected and the terminal is located very far from the switch. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Looparound Test (#161)

This test checks the on-board transmission capabilities of the NPE, the codec, and the battery feed chip of the analog port. The test passes if the signal measured by the tone detector is within acceptable limits.

Table 9-32. TEST #161 Looparound Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle and retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle and retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	This test is not run on ports administered as External Alert, Announcement or combined modem pool ports. This error can be ignored.
1018	ABORT	The test has been disabled by administration. The default for the `Test` field on the station form is **y**. Determine why this field has been set to n on this station (this may be due to the ringing application test 48, that can be customer or terminal disturbing). 1. To enable the test for a particular station being tested, enter **change station extension** and set the `Test?` field on the station from n to **y**.

Continued on next page

Table 9-32. TEST #161 Looparound Test — *Continued*

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The reflective loop around test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board. 1. Since the test may be affected by a line seizure, repeat the test at 1-minute intervals for a maximum of 5 times. 2. Run circuit pack tests to check the tone generator circuit pack and the tone detector circuit pack by using the **test board UUCSS short** command. 3. Resolve any problems on the tone generator circuit pack or the tone detector circuit pack. 4. If the tone generator and tone detector circuit packs are functioning properly and the test still fails and a voice terminal is connected and wired properly, replace the analog line circuit pack.
	PASS	The port is able to provide an analog transmission path to the station equipment. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station. Refer to "LA85 Port Tester" in Chapter 5 for instructions on using the port tester.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command and resolve any problems. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

ANL-BD (Analog Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name Of MO
ANL-BD	MIN/WRN	test board UUCSS sh	16-Port Neon Analog Line Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Refer to “XXX-BD (Common Port Circuit Pack)” for circuit pack level errors. See also ANL-16-L (16-Port Neon Analog Line) maintenance information for related line information.

ANL-LINE, ANL-NE-L (8-Port Analog Line)

MO Name (in Alarm Log	Alarm Level	Initial Command To Run[1]	Full Name of MO
ANL-LINE	MIN	test port UUCSSpp l	8-Port Analog Line
ANL-LINE	WRN	test port UUCSSpp sh	8-Port Analog Line
ANL-NE-L	MIN	test port UUCSSpp l	8-Port Neon Analog Line
ANL-NE-L	WRN	test port UUCSSpp sh	8-Port Neon Analog Line

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The 8-port Analog Line circuit packs,

TN712	TN467 [G3r V2]	TN411 [G3rV2]
TN742	TN443 [G3r V2]	
TN769	TN443 [G3r V2]	

each provide eight ports for single-line, on or off-premises analog endpoints such as analog voice terminals, queue warning level lamps, recorded announcements, dictation machines, PAGEPAC paging equipment, external alerting devices, modems, fax machines, and AUDIX voice ports. Only the TN769 supports a neon message waiting lamp.[1]

Test #48 may cause some terminal equipment to ring briefly during daily maintenance, which may disturb the customer or the terminal equipment. Test #47 may cause a false alarm when the port is connected to certain off-premises equipment, non-voice terminal equipment, or loop equipment. In either case, the tests can be disabled by entering **n** in the "Tests" field on the **change station <extension>** form. Be aware that this will disable Tests 6, 35, 47 and 48.

No maintenance of the terminal connected to the 8-Port Analog Line circuit pack or 8-Port Neon Analog Line circuit pack is performed, except to determine whether or not the terminal is connected. Failures of the common ringing application circuitry and the neon message waiting lamp power (ANL-NE-L only) are reported as errors 1281 and 1793 against XXX-BD (Common Port Circuit Pack).

1. PAGEPAC is a registered trademark of Harris Corporation, Dracon Division

Hardware Error Log Entries and Test to Clear Values

1025		NPE Crosstalk Test (#6)	MIN/WRN[2]	ON	test port UUCSSpp l r 3
1281 (f)					
1793 (f)					

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. These are in-line errors that can only be resolved over time.

Aux Data 40960 Indicates that too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call will cause an inline error from the board.

Aux Data 40975 indicates that the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance. Call the terminal equipment and verify that the terminal rings. If the terminal doesn't ring, then replace it. Otherwise, issue the **test port UUCSSpp** command, and follow the procedure for Test #48.

Aux Data 40977 indicates that no terminal equipment was connected when ringing was attempted. Run the short test via the **test port UUCSSpp** command, and follow the procedure for the results of Test #48.

b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate errors (if any).

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

d. Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled via the **change station** extension command. However, on some releases of the software, this will disable Tests #6, 47, and 35 as well as Test #48.

e. Test #47 may cause a false alarm when the port is connected to off-premises equipment, some non-voice terminal equipment, and some loop equipment. If this causes a false alarm, then disable the test by changing the Tests field of the **change station** command to “no.”

f. Refer to “XXX-BD (Common Port Circuit Pack)” Maintenance documentation.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery Feed Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery Feed Test (#35)	X	X	ND
Station Present Test (#48)	X	X	ND
NPE Crosstalk Test (#6)		X	ND
Loop Around and Conference Test (#47)		X	ND
Station Status and Translation Audits and Updates Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete

Table 9-33. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. This result is also reported for the system's Music-on-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. Enter **status station** extension to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 2. When the port is idle, retry the command at 1-minute intervals up to 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve TTR-LEV errors. 2. Resolve TONE-PT errors. 3. Retry the test at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-33. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1018	ABORT	Test disabled via administration. The default for the `Test?` field on the station form is **y**; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter **change station extension** and set the `Test?` field to **y**.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-33. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Resolve EXP-PN or EXP-INTF errors. 2. Resolve TDM-BUS errors. 3. Resolve TONE-BD or TONE-PT errors. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises. **NOTE:** This test always passes for circuit packs TN712 prior to Vintage 14 and TN742 prior to Vintage 6.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Battery Feed Test (also called Port Diagnostic Test) (#35)

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switchhook capabilities of the battery feed chip by terminating the port, applying battery, and trying to detect a current.

Table 9-34. TEST #35 Battery Feed Test Results

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. This result is also reported for the system's Music-on-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. Enter **status station** extension to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 2. When the port is idle, retry the command at 1-minute intervals up to 5 times.
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to Chapter 8, "Maintenance Commands", for a full description of all possible states.) You must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code results under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5

Continued on next page

Table 9-34. TEST #35 Battery Feed Test Results — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Test disabled via administration. The default for the `Test?` field on the is **y**; thus, you may want to determine why this field has been set to “n” on this station (this may be due to the ringing application Test E48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter **change station extension** and set the `Test?` field to **y**.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct for the test, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The port’s battery feed chip is unable to supply sufficient power to the terminal equipment. This may occur when the test is performed at the same time that the terminal equipment goes off-hook. 1. Use **status station** to determine when the port is available for testing. When the port becomes available for testing, retry the command at 1-minute intervals a minimum of five times. 2. If the test continues to fail, determine whether the customer is experiencing problems on this line. Replace the circuit pack only if the customer is experiencing problems.

Continued on next page

Table 9-34. TEST #35 Battery Feed Test Results — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The port's battery feed chip is able to provide power to the station equipment to detect on-/off-hook. However, the battery feed chip may still be unable to provide power for touch-tones. If tones are heard when buttons are pressed, then the battery feed chip is functioning correctly; otherwise, replace the circuit pack because this port is defective. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises. **NOTE:** This test always passes for circuit packs TN712 prior to Vintage 14 and TN742 prior to Vintage 6.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Station Status and Translation Audits and Updates Test (#36)

This test updates the analog port's message lamp state (if it has one) and translations (such as station type, dial type, network connection) with information kept in the software. The software is updated with the switchhook state reported by the port processor. When the ringer is in the off state, this test also turns off the station's ringer to prevent constant ringing caused by defective hardware.

Table 9-35. TEST #36 Station Status and Translation Audits and Updates Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test.
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code results under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1006	ABORT	This port has been busied out by command or taken out-of-service by the failure of the NPE Crosstalk Test. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error is present, then release the port with the **release station extension** command and run the test again. 2. Look in the Error Log for Error Type 1025 (NPE Crosstalk Test failed) for this port. If this error is present, then investigate the errors associated with the NPE Crosstalk Test (#6) first. 3. Make sure that the terminal is connected and in service, and then retest.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-35. TEST #36 Station Status and Translation Audits and Updates Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	This does not indicate a hardware problem. The switchhook audit failed, and the other updates were not performed because of this failure. This condition may occur when the audit is performed at the same time that the terminal equipment goes off-hook. Use the **status station** command to determine when the port is available for testing. 1. When the port becomes available for testing, retry the command at 1-minute intervals for a maximum of 5 times.
5	FAIL	This does not indicate a hardware problem but may indicate an internal software error. The message waiting lamp update failed. The translation and ringer updates were not performed because of this failure.
7	FAIL	The translation update failed. The ringer update was not performed because of this failure. This does not indicate a hardware problem but may be an internal software error.
8	FAIL	This does not indicate a hardware problem but may be an internal software error. The ringer update failed. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	The software and the port processor have the same status. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises. **NOTE:** This test always passes for circuit packs TN712 prior to vintage 14 and TN742 prior to vintage 6.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Looparound and Conference Test (#47)

Each Analog Port consists of

- A Network Processing Element (NPE) for port connectivity and gain, and conferencing functionality
- A codec which converts TDM Bus digital signals to analog
- A battery feed chip that provides power to the telephone set for signaling, dial pulsing, transmission, and balance.

This test is designed to check the on-board transmission capabilities of the NPE, the codec, and the battery feed chip of the Analog Port. A Tone Detector and a Tone Generator talk and listen on the same pair of time slots as the Analog Port. The Analog Port is then instructed to go into loop around mode (see Figure 9-1). The test passes if the signal measured by the Tone Detector is within acceptable limits.

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. Test #47 also tests the operation of the port conference circuits in the NPE for three and four parties. In addition, a test is run to measure noise. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

The noise test is performed by filtering out the tone, and then measuring inherent port noise.

NOTE:
This Looparound Test is sensitive to the length of the loop, the equipment in the loop, or the equipment terminating the loop, such as off-premises stations. If this test is causing a false alarm, then disable the test by changing the Tests field to "no" using the **change station** command for this station.

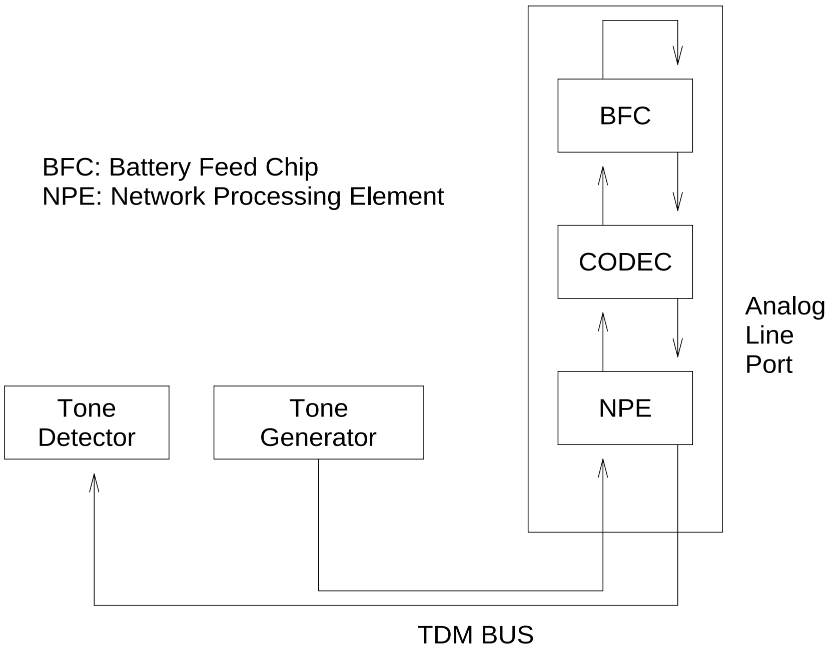

Figure 9-1. Analog Looparound and Conference Test

Table 9-36. TEST #47 Loop Around and Conference Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
7	ABORT	The port was seized by a user for a valid call. 1. Enter **display port UUCSSpp** to determine the station's extension. Enter **status station extension** to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 2. If the port is idle, retry the command at 1-minute intervals up to 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. (This could be a Music-on-Hold port.) 1. Enter **display port UUCSSpp** to determine the station's extension. Enter **status station extension** to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 2. If the port is idle, retry the command at 1-minute intervals up to 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve TTR-LEV errors. 2. Resolve TONE-PT errors. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port has been seized for a valid call during the conference or noise test. 1. If the circuit pack is a TN742 of Vintage 10 or less, this test is not valid. Otherwise, proceed with step 2. 2. When the port is available for testing, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-36. TEST #47 Loop Around and Conference Test — ***Continued***

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1018	ABORT	Test disabled via administration. The default for the `Test?` field on the is **y**; thus, you may want to determine why this field has been set to “n” on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter **change station** extension and set the ‘Test?’ field on the ‘Station Form’ to ‘y.’
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct for the test, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-36. TEST #47 Loop Around and Conference Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	The conference test or the noise test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board, as described below.
13		The reflective loop around with gain set to low and the 600-ohm balance failed. This will cause noisy or unreliable connections.
14		The reflective loop around test (with the gain set to high, using RC balance) failed. This could cause noisy or unreliable connections. The problem can also be off-board, as described below.
15		The nonreflective looparound test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board as described below. 1. Disconnect the terminal equipment from the circuit pack at the cross-connect and run the test again. 2. If the test fails again, replace the circuit pack and reconnect the terminal equipment. If the test passes the second time, then the test results were affected by the terminal equipment connected to the port; in this case, ignore the results of this test if all other tests pass or abort and the station is operating properly. Failure of test 47 does not cause an alarm. If there are failures of other tests, then investigate those errors. User reported troubles with this port should be investigated by using other port tests, by examining station wiring, and by examining the station to ensure that it is correctly translated as off-premises or on-premises. **NOTE:** If the looparound and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the ‘‘CARR-POW (Carrier Power Supply)’’ Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the ‘‘CARR-POW (Carrier Power Supply)’’ Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test.

Continued on next page

Table 9-36. TEST #47 Loop Around and Conference Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The port is able to provide an analog transmission path to the station equipment. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises. **NOTE:** This test always passes for circuit packs TN712 prior to vintage 14 and TN742 prior to vintage 6.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Station Present Test (also called Ringing Application Test) (#48)

This test provides a burst of ringing current to the terminal equipment and detects that current flows. This test is to ascertain whether or not terminal equipment is connected to the port.

This test may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled using the Tests field of the station administration screen. However, on some releases of the software, this action disables Tests #6, 47, and 35, as well as Test #48.

Table 9-37. TEST #48 Station Present Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** to determine the station's extension. Enter **status station** extension to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 2. If the port is idle, retry the command at 1-minute intervals up to 5 times. 3. Check for phone left off-hook or for wiring problems.
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1008	ABORT	Could not allocate a ringing circuit for one of the following reasons: (1) all the ringing circuits are in use, or (2) the ringing generator is defective, or (3) it is not wired correctly. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for Test #48 on other circuit packs as well, then the ringing generator may be defective or not wired correctly. If it does not occur on other ports, then that circuit pack is currently using all four ringing phases.

Continued on next page

Table 9-37. TEST #48 Station Present Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test was disabled via administration. The default for the `Test?` field is **y**; thus, you may want to determine why this field has been set to "n" on this station (this may be due to the ringing application Test #48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter **change station** extension and set the `Test?` field to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The terminal equipment is not connected to the circuit pack or the ringing generator may have failed. 1. Remotely test the equipment. 2. If the test fails again, look for RING-GEN errors in the error log. If present, refer to the RING-GEN (analog ring generator) Maintenance documentation. 3. Check all of the wiring between the station equipment and the switch. Then, run the test again. 4. If the test still fails, the set may be defective. Check the set, and replace it, if necessary. 5. Some terminal equipment (such as a modem) could fail even when it is connected properly. If this is the case, disable the test using the **change station extension** command (enter **n** into the **Test?** field). Note that this action also disables Tests 6, 7, 161, and 35 on this port.
	PASS	The station is connected properly to the switch. This test may also pass if no terminal equipment is connected and the terminal is located very far from the switch. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.

Continued on next page

Table 9-37. TEST #48 Station Present Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

AN-LN-PT (Analog Line Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
AN-LN-PT	MIN	test port UUCSSpp l	Analog Line Port
AN-LN-PT	WRN	test port UUCSSpp sh	Analog Line Port

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The TN793B/TN2793B Analog Line circuit pack (w/ Caller ID), and the TN797 Analog Trunk and Line circuit pack both support this Maintenance Object.

The TN793B/TN2793B Analog Line circuit pack (w/ Caller ID) provides 24 ports for voice terminals and supports both on-premises and off-premises analog voice terminals.

The TN797 Analog Trunk and Line circuit pack provides 8 ports, each of which may be administered in any of several ways, as described in maintenance object TR-LN-BD.

NOTE:
The TN793B/TN2793B analog line circuit pack supports analog data modules. When assigned, analog data modules provide access to the NetPkt (TN794 circuit pack) data ports. To activate an analog data module you must assign the port location on the data form and connect a modem to the port. The analog data module can be used for connection to a CDR output, or other adjuncts as needed. These ports are tested the same as all other analog ports on the circuit pack.

Ringing caused by maintenance testing

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing disturbs the customer or the terminal equipment, disable it in the `Tests` field of the **change station *extension*** form. Be aware that this action also disables Tests #6, 7, 161, and 35 on some software releases.

Error log entries and test to clear values

Table 9-38. Analog line error log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	40960 40975 40977	none			
15(b)	Any	Audits and Updates Test (#36)			
18	0	busy station *extension*	WRN	ON	release station *extension*
130(c)		None	WRN	ON	test port UUCSSpp sh
257(d)	40973	none			
513(e)		Station Present Test (#48)	WRN	OFF	test port UUCSSpp sh r 2
769		Battery Feed Test (#35)	MIN/ WRN[2]	ON	test port UUCSSpp sh r 2
1025		Looparound Test (#161)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1281		Conference Test (#7)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2
1537		NPE Crosstalk Test (#6)	MIN/ WRN[2]	ON	test port UUCSSpp l r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. **Error Type 1**: these are in-line errors and can only be resolved over time.

- Aux Data 40960 indicates that too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call will cause an inline error from the board.

- Aux Data 40975 indicates that the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance.
  1. Call the terminal equipment and verify that the terminal rings.
  2. If the terminal does not ring, then replace it.
  3. Otherwise, issue the **test port UUCSSpp** command, and follow the procedure for Test #48.
- 40977 indicates that no terminal equipment was connected when ringing was attempted.
  1. Run the short test via the **test port UUCSSpp** command, and follow the procedure for the results of Test #48.

b. **Error Type 15**: this is a software audit error that does not indicate any hardware malfunction.
   1. Run the Short Test Sequence and investigate any associated errors.

c. **Error Type 130**: this error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes.
   1. To clear the error, reseat or replace the circuit pack.

d. **Error Type 257**: this is an in-line error and can only be resolved over time. This error indicates that ringing voltage is absent.
   1. If only 1 analog circuit pack in the system has this problem, replace the circuit pack.
   2. If only analog circuit packs on a particular carrier have this error, the ringing generator may not be connected to this carrier.
   3. If analog circuit packs on many carriers have this error, it is probably a problem with the ringing generator.

e. **Error Type 513**:Test #48 can cause some terminal equipment to ring briefly during daily maintenance.
   1. If this disturbs the customer or the terminal equipment, disable it by setting the `Tests` field on the **change station *extension*** form to **n**. On some software releases, this also disables Tests #6, 7, 161, and 35.

System technician-demanded tests: descriptions and error codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery Feed Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery Feed Test (#35)	X	X	ND
Station Present Test (#48)	X	X	ND
Looparound Test (#161)		X	ND
Conference Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND
Station Status and Translation Audits and Updates Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

This test verifies that the port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of the long test sequence and takes about 20 to 30 seconds to complete.

Table 9-39. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
	ABORT	Necessary system resources could not be allocated to run this test. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources are unavailable. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. 2. Enter **status station *extension*** to determine the service state of the port. 3. If the port is in use, wait until the port is idle. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or have time slots out-of-service due to TDM-BUS errors. 1. Refer to "TDM-BUS" to diagnose any active TDM-BUS errors. 2. If the system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals no more than 5 times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-39. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors in the Error Log. 2. Resolve any TONE-PT errors in the Error Log. 3. If neither condition exists, retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	A valid call seized the port during the test and aborted the test. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station *extension*** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle before testing. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1005	ABORT	This test was aborted due to a configuration problem. The test is not applicable for this type of analog port. This error can be ignored.
1018	ABORT	Administration has disabled the test. The default for the `Test?` field on the station form is **y**. Determine why this field has been set to **n** on this station (this may be due to the ringing application Test #48, which can be disturbing to customer or terminal equipment). 1. To enable the test for a particular station being tested, enter **change station *extension***. 2. Change the `Test?` field on the station form to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-39. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems include TDM-BUS faults, EXP-PN and EXP-INTF faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. 1. A TDM-BUS problem is usually the result of a faulty board connection to the backplane, or bent pins on the backplane. Resolve any TDM-BUS errors in the error log. 2. Resolve any EXP-PN and/or EXP-INTF errors in the error log. 3. Resolve any TONE-BD and/or TONE-PT errors in the error log. 4. Test the board when the faults from Steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. Investigate user-reported troubles on this port by running other port tests, by examining station wiring, or by inspecting the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to make sure that the board translations are correct. Use the **list configuration** command, and resolve any problems. 2. If the board is correctly inserted, issue the **busy board UUCSS** command. 3. Issue the **reset board UUCSS** command. 4. Issue the **release board UUCSS** command. 5. Issue the **test board UUCSS long** command. This re-establishes the link between the internal ID and the port. 6. If this is not the case, check to make sure that a valid board is inserted.

Conference Circuit Test (#7)

This test verifies that the NPE channel for the port being tested correctly performs the conferencing function.

Table 9-40. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/Recommendation
	ABORT	Necessary system resources could not be allocated to run this test. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources are unavailable. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. 2. Enter **status station *extension*** to determine the service state of the port. 3. If the port is in use, wait until the port is idle. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	A valid call seized the port during the test and aborted the test. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station *extension*** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle before testing. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1005	ABORT	This test was aborted due to a configuration problem. The test is not applicable for this type of analog port. This error can be ignored.
1018	ABORT	Administration has disabled the test. The default for the `Test?` field on the station form is **y**. Determine why this field has been set to **n** on this station (this may be due to the ringing application Test #48, which can be disturbing to customer or terminal equipment). 1. To enable the test for a particular station being tested, enter **change station *extension***. 2. Change the `Test?` field on the station form to **y**.

Continued on next page

Table 9-40. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Resolve any TONE-PT errors in the error log. 2. If there are no TONE-PT errors, retry the command at 1-minute intervals no more than 5 times. 3. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. 1. Issue the **display port UUCSSpp** and the **status station *extension*** commands to determine if the station is idle. 2. If the station is idle, issue the **test port UUCSSpp** command for this port. 3. If the test continues to fail, issue the **busy port UUCSSpp** and the **release port UUCSSpp** commands, and then retest. 4. If the test still fails, replace the board.
	PASS	The port can correctly conference multiple connections. Investigate user-reported troubles on this port by running other port tests; by examining station, trunk, or external wiring; or by inspecting the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to make sure that the board translations are correct. Use the **list configuration** command, and resolve any problems. 2. If the board is correctly inserted, issue the **busy board UUCSS** command. 3. Issue the **reset board UUCSS** command. 4. Issue the **release board UUCSS** command. 5. Issue the **test board UUCSS long** command. This re-establishes the link between the internal ID and the port. 6. If this is not the case, check to make sure that a valid board is inserted.

Battery Feed Test (also called Port Diagnostic Test) (#35)

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switchhook capabilities of the battery feed chip by terminating the port, applying battery power, and detecting the resulting current.

Table 9-41. TEST #35 Battery Feed Test

Error Code	Test Result	Description/Recommendation
	ABORT	Necessary system resources could not be allocated to run this test. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources are unavailable. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. 2. Enter **status station *extension*** to determine the service state of the port. 3. If the port is in use, wait until the port is idle. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	A valid call seized the port during the test and aborted the test. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station *extension*** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle before testing. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1005	ABORT	This test was aborted due to a configuration problem. The test is not applicable for this type of analog port. This error can be ignored.
1018	ABORT	Administration has disabled the test. The default for the `Test?` field on the station form is **y**. Determine why this field has been set to **n** on this station (this may be due to the ringing application Test #48, which can be disturbing to customer or terminal equipment). 1. To enable the test for a particular station being tested, enter **change station *extension***. 2. Change the `Test?` field on the station form to **y**.

Continued on next page

Table 9-41. TEST #35 Battery Feed Test — *Continued*

Error Code	Test Result	Description/Recommendation
1392	ABORT	This port is currently a TTI port and the test does not execute on it. 1. Verify that the port is a TTI port: ■ Enter the **display port UUCSSpp** command (the display shows that the port is a TTI port). ■ Enter the **list configuration** command (the display shows a `t` for the port). 2. If both commands indicate that the port is a TTI port, the abort is correct for the test, and no action is necessary. 3. If either command indicates that the port is *not* a TTI port, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The port's battery feed chip is unable to supply sufficient power to the terminal equipment. This test result might be marginal, and the terminal equipment may be operating satisfactorily. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to fail, determine whether the customer is experiencing problems on this line. Replace the circuit pack only if the customer is experiencing problems.
	PASS	The port's battery feed chip is able to provide sufficient power to the station equipment to detect on-/off-hook, but may not be able to supply power for touch-tones. 1. If touch-tones are inoperative on this station, replace the circuit pack because this port is inoperative. 2. Investigate user-reported troubles on this port by running other port tests, by examining station wiring, or by inspecting the station.

Continued on next page

Table 9-41. TEST #35 Battery Feed Test — *Continued*

Error Code	Test Result	Description/Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to make sure that the board translations are correct. Use the **list configuration** command, and resolve any problems. 2. If the board is correctly inserted, issue the **busy board UUCSS** command. 3. Issue the **reset board UUCSS** command. 4. Issue the **release board UUCSS** command. 5. Issue the **test board UUCSS long** command. This re-establishes the link between the internal ID and the port. 6. If this is not the case, check to make sure that a valid board is inserted.

Station Status and Translation Audits and Updates Test (#36)

This test updates the analog port's message lamp state (if it has one) and translations with information in the software.

Table 9-42. Test #36 Station Status and Translation Audits and Updates

Error Code	Test Result	Description/ Recommendation
	ABORT	Necessary system resources could not be allocated to run this test. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	A valid call seized the port during the test and aborted the test. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station *extension*** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle before testing. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1005	ABORT	This test was aborted due to a configuration problem. The test is not applicable for this type of analog port. This error can be ignored.
1006	ABORT	The port is out-of-service. The **busy station *extension*** command has been given to this port, or it has been taken out-of-service by the failure of the NPE Crosstalk Test. 1. Look for error type 18 (port busied out) for this port. If this error is present, release the port (**release station *extension***), and run the test again. 2. Check for error type 1537 (NPE Crosstalk Test failed) for this port. If this error is present, investigate the errors associated with the NPE Crosstalk Test (#6). 3. Make sure that the terminal is connected and in service, and then retest.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-42. Test #36 Station Status and Translation Audits and Updates — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The switchhook audit failed. This result does not indicate a hardware problem. The other updates were not performed because of this failure. This may occur if the audit is performed at the same time the terminal equipment goes off-hook. 1. Use the **status station *extension*** command to determine when the port is available. 2. Retry the command at 1-minute intervals no more than 5 times. 3. If the test continues to fail, escalate the problem.
5	FAIL	The message waiting lamp update failed. This may be an internal software error. The translation and ringer updates were not performed because of this failure.
7	FAIL	The translation update failed. There may be an internal software error. The ringer update was not performed because of this failure.
8	FAIL	The ringer update failed. There may be an internal software error. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to fail, escalate the problem.
	PASS	The software and the port processor have the same status. Investigate user-reported troubles on this port by running other port tests, by examining station wiring, or by inspecting the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to make sure that the board translations are correct. Use the **list configuration** command, and resolve any problems. 2. If the board is correctly inserted, issue the **busy board UUCSS** command. 3. Issue the **reset board UUCSS** command. 4. Issue the **release board UUCSS** command. 5. Issue the **test board UUCSS long** command. This re-establishes the link between the internal ID and the port. 6. If this is not the case, check to make sure that a valid board is inserted.

Station Present Test (also called Ringing Application Test) (#48)

This test applies momentary ringing voltage to the terminal equipment and monitors resulting current flow to determine whether terminal equipment is connected to the port. This test may cause some terminal equipment to ring briefly during daily maintenance. If this ringing disturbs the customer or the terminal equipment, you can disable it via the `Tests` field on the **change station *extension*** form. However, on some software releases, Tests #6, 7, 161, and 35 also are disabled.

Table 9-43. TEST #48 Station Present Test

Error Code	Test Result	Description/Recommendation
	ABORT	Necessary system resources could not be allocated to run this test. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources are unavailable. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. 2. Enter **status station *extension*** to determine the service state of the port. 3. If the port is in use, wait until the port is idle. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	A valid call seized the port during the test and aborted the test. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station *extension*** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle before testing. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1005	ABORT	This test was aborted due to a configuration problem. The test is not applicable for this type of analog port. This error can be ignored.

Continued on next page

Table 9-43. TEST #48 Station Present Test — *Continued*

Error Code	Test Result	Description/Recommendation
1008	ABORT	A ringing circuit could not be allocated. Either all of the ringing circuits are in use, the ringing generator is defective, or it is not wired correctly. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, look for RING-GEN errors in the Error Log. 3. If ABORT 1008 occurs for this test on other circuit packs as well, the ringing generator may be defective or is not wired correctly (see RING-GEN). 4. If an ABORT 1008 does not occur on other ports, then all four ring phases are in use.
1018	ABORT	Administration has disabled the test. The default for the `Test?` field on the station form is **y**. Determine why this field has been set to **n** on this station (this may be due to the ringing application Test 48, which can be disturbing to customer or terminal equipment). 1. To enable the test for a particular station being tested, enter **change station *extension***. 2. Change the `Test?` field on the station form to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period. .
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The terminal equipment is not connected to the circuit pack. Some terminal equipment, such as modems, may fail even when connected properly. 1. Remotely test the terminal equipment. 2. If the test fails again, resolve any RING-GEN errors in the error log, if present. 3. Check all of the wiring between the station equipment and the switch. Then, run the test again. 4. If the test still fails, the terminal equipment may be defective. Check and replace it, if necessary. 5. Some terminal equipment might fail even when it is connected properly. If this is the case, disable the test using the **change station *extension*** command (enter **n** into the `Test` field). Note that this action also disables Tests 6, 7, 35, and 161 on this port.

Continued on next page

Table 9-43. TEST #48 Station Present Test — *Continued*

Error Code	Test Result	Description/Recommendation
	PASS	The station is connected properly to the switch. Investigate user-reported troubles on this port by running other port tests, by examining station wiring, or by inspecting the station. **NOTE:** This test may also pass if no terminal equipment is connected and the terminal is located very far from the switch.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to make sure that the board translations are correct. Use the **list configuration** command, and resolve any problems. 2. If the board is correctly inserted, issue the **busy board UUCSS** command. 3. Issue the **reset board UUCSS** command. 4. Issue the **release board UUCSS** command. 5. Issue the **test board UUCSS long** command. This re-establishes the link between the internal ID and the port. 6. If this is not the case, check to make sure that a valid board is inserted.

Looparound Test (#161)

This test checks the on-board transmission capabilities of the NPE, the codec, and the battery feed chip of the analog port. The test passes if the signal measured by the tone detector is within acceptable limits.

Table 9-44. TEST #161 Looparound Test

Error Code	Test Result	Description/Recommendation
	ABORT	Necessary system resources could not be allocated to run this test. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources are unavailable. The port may be busy with a valid call. This result is also reported for the system's Music-On-Hold port when it is off-hook, which it usually is. 1. Enter **display port UUCSSpp** to determine the station's extension. 2. Enter **status station *extension*** to determine the service state of the port. 3. If the port is in use, wait until the port is idle. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or have time slots out-of-service due to TDM-BUS errors. 1. Refer to "TDM-BUS" to diagnose any active TDM-BUS errors. 2. If the system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals no more than 5 times. 3. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors in the Error Log. 2. Resolve any TONE-PT errors in the Error Log. 3. If neither condition exists, retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-44. TEST #161 Looparound Test — *Continued*

Error Code	Test Result	Description/Recommendation
1004	ABORT	A valid call seized the port during the test and aborted the test. 1. Use the **display port UUCSSpp** command to determine the station extension. 2. Use the **status station *extension*** command to determine the service state of the port. 3. If the port is in use, wait until the port is idle before testing. Retry the command at 1-minute intervals no more than 5 times. 4. If the test continues to abort, escalate the problem.
1005	ABORT	This test was aborted due to a configuration problem. The test is not applicable for this type of analog port. This error can be ignored.
1018	ABORT	Administration has disabled the test. The default for the `Test?` field on the station form is **y**. Determine why this field has been set to **n** on this station (this may be due to the ringing application Test 48, which can be disturbing to customer or terminal equipment). 1. To enable the test for a particular station being tested, enter **change station *extension***. 2. Change the `Test?` field on the station form to **y**.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals no more than 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The reflective Looparound Test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board. 1. Since a line seizure may affect the test, repeat the test at 1-minute intervals for no more than 5 times. 2. Using the **test board UUCSS short** command, run circuit pack tests to check the tone generator and the tone detector circuit packs. 3. Resolve any problems on the tone generator or the tone detector circuit packs. 4. If the tone generator and tone detector circuit packs are functioning properly, determine if a voice terminal is connected and wired properly. Resolve any problems found. 5. If the test still fails, replace the analog line circuit pack.
	PASS	The port provides an analog transmission path to the station equipment. Investigate user-reported troubles on this port by running other port tests, by examining station wiring, or by inspecting the station.

Table 9-44. TEST #161 Looparound Test — *Continued*

Error Code	Test Result	Description/Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to make sure that the board translations are correct. Use the **list configuration** command, and resolve any problems. 2. If the board is correctly inserted, issue the **busy board UUCSS** command. 3. Issue the **reset board UUCSS** command. 4. Issue the **release board UUCSS** command. 5. Issue the **test board UUCSS long** command. This re-establishes the link between the internal ID and the port. 6. If this is not the case, check to make sure that a valid board is inserted.

ANN-BD (Announcement Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ANN-BD	MINOR	test board UUCSS l	Announcement Circuit Pack
ANN-BD	WARNING	test board UUCSS l	Announcement Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The TN750 contains 16 announcement ports each of which can play any recorded announcement. The circuit pack also has one data line circuit port (port 17) for uploading and downloading announcement files to and from the system's disk and removable media devices. For errors associated with port 17, refer to DAT-LINE. For errors associated with ports 1-16 refer to ANN-PT.

NOTE:
TN750C is required if the system has multiple announcement boards. To use multiple announcement boards, you must have V4 or later software, and at least one TN750C (up to ten are allowed). Only one TN750A/B may be present in the system when a TN750C is used. The announcements from a TN750A/B can be saved and restored to a TN750C — but once the announcements are recorded onto a TN750C, they are not backward compatible with the TN750A/B.

Essential Service Information

You should have an understanding of the following principles before attempting work on the TN750/B Announcement circuit pack.

NOTE:
The TN750C Announcement circuit pack has on-board non-volatile storage and does not need to be saved to disk.

- The announcement circuit pack retains all integrated announcements *as long as the circuit pack has power*. Announcements are preserved through a software reset (**reset board** command), but they are lost when the circuit pack is unseated. (Unseating is generally not recommended unless replacement is necessary.)
- Whenever new announcements are recorded on the circuit pack, save them on disk as soon as possible to ensure that they will not be lost due to a disruption. Periodic saves to removable media provide further backup if the disk files are lost or corrupted. This is also accomplished when the entire disk is backed up.

NOTE:
Unlike translations, announcements are never saved automatically by the system. so you must do it manually.

- The **save announcements** command replaces the announcement files on disk or removable media with those in Announcement circuit pack speech memory. Take care not to inadvertently destroy a valid file on removable media or disk with this command.
- The **restore announcements** command replaces announcement circuit pack speech memory with announcement files on the disk or removable media. Take care not to inadvertently destroy valid announcements on the circuit pack by restoring from a device that does not contain a current announcement file.
- Whenever the announcement circuit pack is replaced, you must re-record announcements or restore them from disk or removable media. Otherwise, the circuit pack will be unavailable to call processing service.
- If the circuit pack's speech memory is corrupted, announcements should *not* be saved (for example, when the Announcement Checksum Test (#209) fails or announcements sound corrupted when played back). This can ruin a good announcement file on disk or removable media, and potentially cause errors and alarms on any circuit pack to which the saved file is downloaded. If, however, the customer does not have a valid announcement file on removable media or disk, You may wish to save announcements in an effort to try to retain those which are not corrupted.

Announcement Session

The recording, playing back, and deleting of announcements is called an announcement session. The station used must have a class of service (COS) that includes console permissions.

1. To enter an announcement session, go off-hook on the station and enter the announcement Feature Access Code (FAC) administered on the Feature Access Codes form.
2. You should now hear dial tone. Enter the extension of the announcement to be recorded, deleted, or played back.
3. You should again hear dial tone. To record an announcement, press 1, record after the tone, and hang up when finished.
4. To play back an announcement, press 2. Announcements can also be played back by simply calling the announcement extension associated with them.
5. To delete an announcement, press 3, and confirmation tone will be given if the delete was successful.

Saving and Restoring Announcements

Integrated announcements on the announcement circuit pack can be uploaded to the system removable media or disk with the **save announcements** command. Likewise, integrated announcements can be downloaded to the announcement circuit pack with the **restore announcements** command. Both commands require a free system port, an announcement data module administered on the announcement circuit pack and, if saving to removable media, a non-write protected removable media cartridge in the removable media drive. Typical announcement uploads or downloads take 30 to 45 minutes, depending on system traffic.

The system automatically attempts to download to the announcement circuit pack 5 minutes after it is inserted. This automatic download procedure may be aborted or preempted by any of the following:

- An announcement is recorded within 10 minutes of circuit pack insertion.
- An announcement download is invoked sooner with the **restore announcements** command.
- An announcement data module is not administered or is busy.
- A system access port is not available.
- There is no removable media cartridge in the system when saving to removable media.
- The removable media or disk does not have a valid announcement file.

NOTE:
If the announcement file becomes corrupted, the only solution is to re-record all announcements.

WARNING:
All alarms are upgraded to MAJOR when the BASE Tone Generator is set to 12. (France).

Error Log Entries and Test to Clear Values

Table 9-45. Announcement Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS sh r 1
1(a)	0	Circuit pack removed or SAKI Test (#53)	MINOR	ON	
2(n)		None			
14(b)	1-128	Announcement Checksum Test (#209)			
18	0	busy-out board UUCSS	WARNING	OFF	release board UUCSS
23(c)	0	None	WARNING	OFF	
125(d)		None	MINOR	ON	
217(m)	0	None	WARNING	OFF

Table 9-45. Announcement Circuit Pack Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
	17676	In-line Error			
2817(j)		Announcement Checksum Test (#209)	MINOR	ON	test board UUCSS sh r 3
	17682	In-line Error			
	17699(j)	In-line Error			
3840(l)	Any	None			
3999 (o)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Error Type 1—This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

NOTE:
The alarm is logged about 11-minutes after the circuit pack has been removed or when the SAKI Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. If the circuit pack is in the system and the red LED is on, refer to ''LED Alarms without Alarm Log Entry or with Error Type 1'' in Chapter 7, ''LED Interpretation''.

b. Error Type 14—This error is logged whenever the Announcement Checksum Test (#209) fails. The Aux Data indicates the identifying number of the first defective announcement found. This number corresponds to the announcement numbers on the announcement administration form. The extension associated with the announcement can be determined with the **display announcement** command. This error always appears in conjunction with Error Type 2817. Follow the procedures for Error Type 2817 to troubleshoot Error Type 14.

c. Error Type 23—The circuit pack has been logically administered but not physically installed. The alarm clears when the circuit pack is installed.

d. Error Type 125—A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

e. Error Type 257—This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.

f. Error Type 513—This error, when reported with Aux Data in the range of 4352 to 4358, indicates the circuit pack has reported a hardware failure on the circuit pack. The circuit pack should be replaced.

WARNING:
Replacing the circuit pack will result in loss of integrated announcements. See Essential Service Information above.

g. Error Type 1025—This error is not service-affecting and no action is required.

h. Error Type 1281—The Speech Processor (SP) found one or more faulty memory locations in the speech main memory (SMM). Whenever this error is logged, error 2817 will also be logged (Note j), causing maintenance to run the Announcement Checksum Test (#209) to determine if the bad memory location is used by an announcement.

i. Error Type 1538—The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
   2. A busy-out/release of the circuit pack has no affect on test results.
   3. A **list configuration** command shows that the circuit pack and ports are properly installed.

   The system will try to restore the circuit pack within 15 minutes. If the error recurs after 15 minutes, then replace the circuit pack.

j. Error Type 2049 and 2817—These errors or logged in conjunction with Error Type 1281, Aux Data 17699 (Note h). Since that error means that a defective speech memory location was found, the announcement checksum error is also logged, causing the Announcement Checksum Test (#209) to run. This test determines whether the defective memory location has corrupted any recorded announcements. If the Checksum Test passes, the faulty memory location is not currently being used; the Speech Processor will then mark the location as faulty to prevent future announcements from using it.

NOTE:
As memory locations are marked faulty, the amount of available memory decreases, lowering the amount of announcement time available on the circuit pack.

k. A transient error that does not cause an alarm can occasionally occur during a SPE, TDM BUS, or Tone Clock interchange. Error Type 2049—It is possible for a marginal Tone-Clock circuit pack to cause this error against the ANN-BD without alarming the TONE-BD. If this error occurs again, replacing the Tone-Clock circuit pack may clear up this error. See the FAIL case in the Clock Match Inquiry Test (#212).

l. Error Type 3840—This error is not service-affecting and no action is required.

m. Error Type 217 and 267—Indicate that there is more than one TN750 Announcement circuit pack inserted in the system. Remove the alarmed circuit pack.

n. Error Type 2—Check the Class of Restriction (COR) administered for the Data Line extension assigned to the TN750 for uploading and downloading announcements. The extension can be found by using **list data-module**.

o. Error Type 3999—Indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Control Channel Looparound Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Looparound Test (#52)[2]		X	ND
Angel-Speech Processor (SP) Handshake		X	ND
Test (#208)			
Clock Match Inquiry (#212)	X	X	ND
Super Frame Match Inquiry (#211)	X	X	ND
140AY Looparound Test (#210)	X	X	ND
Announcement Checksum Test (#209)	X	X	ND
Network Processor Element (NPE) Audit			
Test (#50)[2]		X	ND
SAKI Test (#53)[2]		X	D

1. D = Destructive; ND = Nondestructive
2. For results of these tests, see the “XXX-BD (Common Port Circuit Pack)” section.

Angel-Speech Processor Handshake Test (#208)

This test checks the integrity of the communication link between the two processors on the Announcement circuit pack.

CAUTION:
Failure of this test indicates that the Speech Processor is insane and results in the loss of all integrated announcements on the circuit pack.

Table 9-46. TEST #208 Angel-Speech Processor (SP) Handshake Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this Error Type.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-46. TEST #208 Angel-Speech Processor (SP) Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The circuit pack cannot be used. Announcement speech memory is cleared when this test fails. When the problem has been resolved, announcements must be re-recorded or downloaded to the circuit pack. Refer to *Essential Service Information* earlier. 1. Reset the circuit pack by the **reset board UUCSS** command and then run this test again. If the test continues to fail, replace the circuit pack. 2. If there are recurring alarms on this circuit pack caused by this test failing, replace the circuit pack, *even if step 1 works.* **CAUTION:** *Replacing the circuit pack will result in loss of integrated announcements. See Essential Service Information.*
	PASS	The communications link between the two processors on the announcement circuit pack is functioning properly. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to "ANN-PT" for a description of the port tests.

Announcement Checksum Test (#209)

In this test, the Speech Processor calculates a global checksum covering the entire announcements file and compares it to a stored one. If the comparison of any announcement's checksum fails, then the total number of defective announcements found is reported. The test failure is associated with an error type 14 in the Error Log. The aux data gives the identifying number of the first defective announcement found. This number and the extension assigned to the announcement are listed on the **display announcement** command.

Table 9-47. TEST #209 Announcement Checksum Test

Error Code	Test Result	Description/ Recommendation
1023	ABORT	There are no announcements currently recorded on the circuit pack.
1024	ABORT	This abort code indicates any of the following: ■ An announcement upload or download is in progress. ■ An announcement upload or download was requested while the test was running. ■ A recording session was in progress. ■ A recording session was initiated in while this test was running.
		If an announcement upload or download is in progress, **status data-module** extension should show that the announcement data port (17) is connected to a data line port that is part of a system port, and the removable media or disk should be active. (To determine the extension of the announcement data module, use the **list data-module** command.) See also *Locked Announcement Circuit Pack* at the end of this table. 1. Wait until the cause of the abort finishes and run the test again. Upload or download can take up to 45 minutes to complete. A recording session is finished as soon as the station that was making the recording is placed on-hook. 2. If the test continues to abort, and a recording session or upload/download is not in progress, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this Error Type.
2100	ABORT	Could not allocate the necessary system resources to run test.
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-47. TEST #209 Announcement Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0-256	FAIL	The error code for this result gives the total number of defective announcements found in speech memory. When TEST #209 fails with error code 0, the global checksum failed on the board, but no individual checksum failed. **NOTE:** Since announcements are stored digitally, it is possible for the announcement checksum test to fail and still have all announcements sound uncorrupted. When an individual announcement fails the checksum test, always listen to the announcement before taking any action. If the announcement sounds corrupted, then re-record it or delete it. An announcement can be played back by dialing the extension associated with the announcement number. Use the **display announcement** command to find identifying numbers and extensions of announcements. 1. Check the aux data for error type 14 in the Error Log to determine the number of the first defective announcement encountered. Play back the announcement and re-record or delete it if it sounds corrupted. If the FAIL code for this test was greater than 1, there is more than one corrupted announcement. To get the numbers of the others, you must re-record or delete the first one and then rerun this test. 2. If, after deleting and re-recording all defective announcements, the checksum test still fails, then reset the circuit pack using the **reset board UUCSS** command and run this test again. 3. If the test continues to fail, reseat the circuit pack and restore announcements (this can take up to 40 minutes). Any announcements recorded since the last **save announcements** will be lost, and must be re-recorded. Then run this test again. 4. If the test continues to fail, replace the circuit pack. **CAUTION:** *Replacing the circuit pack will result in loss of integrated announcements. See Essential Service Information.*
	PASS	All recorded announcements checksum correctly, indicating that the speech main memory is functioning properly. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to ANN-PT (Announcement Port) Maintenance documentation for a description of the port tests.

Locked Announcement Circuit Pack

The announcement circuit pack can exhibit a rare "locked" condition that renders two of its ports unusable by software. One of these ports is the record port, thus preventing any recording of announcements or execution of the **save/restore announcements** commands. Software does not have any way of detecting this condition and will attempt to use the ports.

When the circuit pack is in this state, the following symptoms is observed:

- When attempting to record an announcement, you will hear the proper record tone, but the announcement will not record. This will not be apparent until an attempt is made to play the announcement back.
- Performing a **test board long** will yield the following abort codes:
  - Test #206 aborts on ports 1 and 9 with code 1024.
  - Test #205 aborts on ports 1 and 9 with code 2000.
  - Tests #209 and #210 abort with code 1024.
- The **save/restore announcements** commands will time out with: `Error encountered, can't complete request`

The announcement circuit pack lock-up can be cleared remotely by performing a soft reset to the circuit pack with the following sequence of commands:

1. **busy-out board UUCSS** (this command will drop all calls to the Announcement circuit pack)
2. **reset board UUCSS**
3. **release board UUCSS**

140AY Looparound Test (#210)

This test checks the integrity of the record channel on the Announcement circuit pack (announcement port 1). The main function of the 140AY device is to accept Pulse Code Modulation (PCM)/Adaptive Differential Pulse Code Modulation (ADPCM) samples and compress/expand the samples using ADPCM. This test connects a tone generator to one port (announcement port 1, the recording port), and a tone detector to another port (announcement port 9). A tone is generated by the tone generator on the first port and looped through the 140AY device to the second port. The tone detector then responds with a tone present/absent message. The 140AY Looparound Test is repeated at three different speech compression rates.

Since this test involves sending a tone through two different ports, the Playback Speech Memory Array (PSMA) Test (#206) [see "ANN-PT" for a description of this test] is run on the two ports first to make sure that they are working properly.

Table 9-48. TEST #210 140AY Looparound Test

Error Code	Test Result	Description/Recommendation
1-3	ABORT	Response to the test request was not received within the allowable time period. The error code indicates at which speech compression rate the test aborted (1 being the first rate tested, 3 being the last). 1. Retry the command at 1-minute intervals for a maximum of 5 times.
10	ABORT	The Playback Speech Memory Array (PSMA) Test (#206) failed on Announcement Port 1.
90	ABORT	The Playback Speech Memory Array (PSMA) Test (#206) failed on Announcement Port 9. 1. Refer to “ANN-PT”, Test #206.
1000	ABORT	System resources required to run this test are not available. This test needs Announcement Ports 1 and 9 to run. One of the ports may be in use on a valid call. If Ports 1 and 9 are not in use, retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1007	ABORT	The announcement circuit pack thinks that Port 1 or Port 9 is busy.
1024	ABORT	Announcement circuit pack blocked the test because an announcement download is in progress. If a download is in progress, a **status data-module** announcement data extension command should show that the announcement data port is connected to a data line port that is part of a system access port, and the removable media drive should be active (to determine the extension of the announcement data module, use the **list data-module** command). See the ‘‘Locked Announcement Circuit Pack’’ at the end of the table for Test #209. 1. Wait until download is finished (up to 45 minutes), and then run the test again.

Continued on next page

Table 9-48. TEST #210 140AY Looparound Test — *Continued*

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this error type.
2007	ABORT	The Announcement circuit pack thinks that Port 1 or Port 9 is busy. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, follow the Announcement Port maintenance procedures for Ports 1 and 9.
2100	ABORT ABORT	Could not allocate the necessary system resources to run this test. Internal system error. Retry the command at 1-minute intervals for a maximum of 5 times.
1-3	FAIL	Test failed. The error code indicates at which speech compression rate the test actually failed (1 being the first rate tested, 3 being the last). 1. Reset the circuit pack usingthe **reset board UUCSS** command and then run this test again. If the test continues to fail, replace the circuit pack. 2. If there are recurring alarms on this circuit pack caused by this test failing, replace the circuit pack even if step 1 works. **CAUTION:** *Replacing the circuit pack will result in loss of integrated announcements. See “Essential Service Information” above.*
	PASS	The record channel on the announcement circuit pack is functioning properly. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to “ANN-PT” for a description of the port tests.

Super Frame Match Inquiry Test (#211)

The super frame is a means by which the Speech Processor (SP) synchronizes with the 140AY device on the announcement circuit pack. If the super frame is not synchronized, the SP will not be able to properly process record/playback requests. Both the SP and the hardware generate a super frame pulse. When these two pulses are out of synch, the SP sets a flag to indicate the mismatch. When this test is run, the state of this flag is returned.

Table 9-49. TEST #211 Super Frame Match Inquiry

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this Error Type.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Test failed. Announcement playbacks should sound corrupted. 1. Reset the circuit pack via the **reset board UUCSS** command and then run this test again. If the test continues to fail, replace the circuit pack (see Warning). 2. If there are recurring alarms on this circuit pack caused by this test failing, replace the circuit pack even if step 1 works. **WARNING:** *Replacing the circuit pack will result in loss of integrated announcements. See Essential Service Information.*
	PASS	The speech processor can properly process record/playback requests. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to “ANN-PT” for a description of the port tests.

Clock Match Inquiry Test (#212)

This test determines the state of the clock-generating circuitry on the Announcement circuit pack. This circuitry is used to synchronize the announcement board with the TDM clock carried on the PN’s backplane.

Table 9-50. TEST #212 Clock Match Inquiry Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the procedure for that error.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-50. TEST #212 Clock Match Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The ANN-BD may be defective or the active tone-clock circuit pack in the same PN may be bad. Announcements recorded or played back while the clock circuitry is not functioning properly sound distorted. 1. Reset the Announcement circuit pack via the **reset board UUCSS** command and then run this test again. If the test continues to fail, proceed to Step 2 or 3, whichever applies. 2. If this PN has duplicated Tone-Clocks: Determine the Active TONE-BD in this PN via the **status port-network 1** command. Make the Standby Tone-Clock circuit pack active via the **set tone-clock UUC** command. Rerun the test. If the test passes, then replace the now Standby Tone-Clock circuit pack. If the test continues to fail, replace the ANN-BD circuit pack. **CAUTION:** *Replacing the announcement circuit pack results in loss of integrated announcements. See Essential Service Information. See "TONE-BD" for Tone-Clock replacement instructions.* 3. If the PN has a single tone-clock: Replace the ANN-BD. Rerun the test. If the test continues to fail, replace the Tone-Clock circuit pack located in the same PN as the ANN-BD. **CAUTION:** *Replacing the PPN Tone-Clock circuit pack in a Standard Reliability system (simplex SPE) will cause COLD 2 reset (service outage). Replacing a simplex EPN Tone-Clock will cause an EPN reset with service outage to that EPN. See How to Replace a Tone-Clock Circuit Pack in the "TONE-BD" section of this chapter. Replacing the ANN-BD will result in loss of integrated announcements. See Essential Service Information.* 4. If failures of this test continue to raise alarms, replace the circuit pack even if the previous steps were successful.
	PASS	Announcement playbacks must have clear sound quality. Investigate user-reported troubles on this circuit pack using the other circuit pack and port tests. Refer to "ANN-PT" for descriptions of the port tests.

ANN-PT (Announcement Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ANN-PT	MINOR	test port UUCSSpp l	Announcement Port
ANN-PT	WARNING	test port UUCSSpp l	Announcement Port

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs), C is the carrier designation (A, B, C, D, or E), and SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

There are 16 announcement ports on the announcement circuit pack. Each port can play any integrated announcement, independently of the other ports. In addition to the 16 ports, the announcement circuit pack also has one data line circuit port (Port 17). The data line circuit port is used for uploading/downloading the announcement memory to/from the system removable media or disk devices. If there are any errors associated with Port 17, refer to DAT-LINE maintenance information. If there are any errors associated with the circuit pack, refer to "ANN-BD" maintenance information.

Essential Service Information

There are a number of important basic principles that should be understood before undertaking work on the announcement circuit pack. These are described in *Essential Service Information* at the beginning of the "ANN-BD" section of this chapter.

Although announcement port 5 and data line circuit port 17 on the announcement circuit pack are logically two separate ports, they are physically the same port. Therefore, if one of the ports is in use, the other one will be busy. Also, if announcement port 5 is out-of-service, the data line circuit port will be taken out-of-service. However, if the data line circuit port is out-of-service, the announcement port will remain in-service.

Error Log Entries and Test to Clear Values

Table 9-51. Announcement Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1		Playback Speech Memory Array (PSMA) Test (#206)	MINOR	ON	test port UUCSSpp sh r 3
18	0	The port was busied out.	WARNING	OFF	release port UUCSSpp
130(a)		None	WARNING	ON	test port UUCSSpp sh
257		Channel Administration Memory Array (CAMA) Test (#205)	MINOR	ON	test port UUCSSpp l r 3
	17667	In-line error			
513		140AY Channel Sanity Inquiry Test (#222)	MINOR	ON	test port UUCSSpp sh r 3
	17684	In-line error			
769(b)		None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

b. This error is logged and the port is alarmed when an alarm is raised on the announcement circuit pack because of a faulty condition with a common circuit pack resource. Any one of the following alarmed errors on the announcement circuit pack causes this error to be logged against the Announcement Port: 1793, 2049, 2305, 2561. See "AN-LN-PT (Analog Line Port)" to resolve these alarms. When the corresponding circuit pack alarm is cleared, this alarm will clear.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Channel Administration Memory Array (CAMA) Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Channel Administration Memory Array (CAMA) Test (#205)		X	ND
Playback Speech Memory Array (PSMA) Test (#206)	X	X	ND
140AY Channel Sanity Inquiry Test (#222)	X	X	ND

1. D = Destructive; ND = Nondestructive

Channel Administration Memory Array (CAMA) Test (#205)

This test is a memory device that stores information used to control the 140AY device. The Angel asynchronously feeds the CAMA with the control information.

Table 9-52. TEST #205 Channel Administration Memory Array (CAMA) Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run test are not available. The port may be in use on a valid call. 1. If the circuit pack is not in use, retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. See *Announcement Board Locked Condition* at the end of this section.
2100	ABORT	Could not allocate the necessary system resources to run this test.

Continued on next page

Table 9-52. TEST #205 Channel Administration Memory Array (CAMA) Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Test failed. Announcements played back on this port may sound corrupted. 1. Reset the circuit pack using the **reset board UUCSS** command and then run this test again. If the test continues to fail, replace the circuit pack. 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works. **CAUTION:** *Replacing the circuit pack results in loss of integrated announcements. Refer to Essential Service Information at the beginning of "AN-LN-PT (Analog Line Port)" in this chapter.*
	PASS	This test verifies that the Angel processor can properly set up this port for playbacks. User-reported troubles on this circuit pack should be investigated using other port and circuit pack tests. (Refer to "AN-LN-PT (Analog Line Port)" for a description of the circuit pack tests.)

Playback Speech Memory Array (PSMA) Test (#206)

The PSMA test checks the integrity of a playback channel's interface to the speech memory and the TDM Bus. *This test is very important.* It is the only test that actually checks an announcement port's ability to play back an announcement on the TDM Bus. If the test fails, the tone detector returns the number of bytes that did not match the expected sequence. The larger the number, the more severe the problem is with that port. If this test fails, announcements played over this port sound corrupted.

Table 9-53. TEST #206 Playback Speech Memory Array (PSMA) Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. When the port is not in use, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-53. TEST #206 Playback Speech Memory Array (PSMA) Test — *Continued*

Error Code	Test Result	Description/Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1024	ABORT	Announcement circuit pack blocked the test because an announcement download is in progress. If an announcement download is in progress, a **status data-module announcement data extension** command shows that the announcement data port is connected to a system access port, and the removable media drive should be active. (To determine the extension of the announcement data module, use the **list data-module** command.) See *Announcement Board Locked Condition* at the end of this section. 1. Wait until download is finished (maximum of 45 minutes), and then run the test again.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1 to 254	FAIL	Test failed. The error code indicates the number of byte count errors found by the Tone Detector. 1. Reset the circuit pack via the **reset board UUCSS** command and then run this test again. If the test continues to fail, replace the circuit pack. 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works. **CAUTION:** *Replacing the circuit pack results in loss of integrated announcements. Refer to Essential Service Information at the beginning of “AN-LN-PT (Analog Line Port)” in this chapter.*

Continued on next page

Table 9-53. TEST #206 Playback Speech Memory Array (PSMA) Test — *Continued*

Error Code	Test Result	Description/Recommendation
255	FAIL	Test failed. The announcement port and the tone detector never synchronized. Check for active GPTD-PT errors, and refer to “GPTD-PT (General Purpose Tone Detector Port)” to diagnose them first. 1. If there are no active GPTD-PT errors, reset the circuit pack using the **reset board UUCSS** command and then run this test again. If the test continues to fail, replace the circuit pack. 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works. See Caution, above.
	PASS	This port can cleanly play announcements. User-reported troubles on this pack should be investigated using other port and circuit pack tests. Refer to “AN-LN-PT (Analog Line Port)” for a description of the circuit pack tests.

140AY Channel Sanity Inquiry Test (#222)

The Angel keeps a sanity status bit for each of the 16 channels on the 140AY device. This test queries the Angel to determine the status for a particular channel. If a channel is insane, that implies that announcements cannot be played back on that channel.

Table 9-54. TEST #222 140AY Channel Sanity Inquiry Test

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-54. TEST #222 140AY Channel Sanity Inquiry Test — *Continued*

Error Code	Test Result	Description/Recommendation
	FAIL	Test failed. Announcements cannot be played back over this port. 1. Reset the circuit pack via the **reset board UUCSS** command and then run this test again. If the test continues to fail, replace the circuit pack (see Warning). 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works. **CAUTION:** *Replacing the circuit pack will result in loss of integrated announcements. Refer to Essential Service Information at the beginning of "ANN-BD" in this chapter.*
	PASS	Announcements can be played back over this port. User-reported troubles on this pack should be investigated using other port and circuit pack tests. Refer to the ''AN-LN-PT (Analog Line Port)'' for a description of the circuit pack tests.

Announcement Board Locked Condition

The announcement circuit pack can exhibit a condition that does not allow recording.

If the circuit pack gets locked into this state (this is an extremely rare condition), two of the announcement ports on the circuit pack (one of which is the record port) will be unusable by software. Also, **save/restore announcements** will not work since the record port looks busy to the circuit pack. Note that software does not have any way of knowing this and will attempt to use the ports.

If the circuit pack is locked into this state, the following symptoms will be observed:

1. When attempting to record an announcement, users will hear the proper record tone, but the announcement will not record (they will not know it until the announcement is played back).
2. Performing a **test board long** when the circuit pack is in this state will yield the following abort codes:
   - Ports 1 AND 9 abort Test 206 with code 1024.
   - Ports 1 AND 9 abort Test 205 with code 2000.
   - Board level Tests 209 and 210 abort with code 1024.
3. The **save/restore announcements** command will time out with:

   `Error encountered, can’t complete request`

The Announcement circuit pack lock-up can be cleared remotely by performing a soft reset to the circuit pack:

- **busy-out board UUCSS** (this command drops all calls in progress on the Announcement circuit pack).
- Reset circuit pack using the **reset board UUCSS** command.
- Release board using the **release board UUCSS** command.

ANNOUNCE

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ANNOUNCE	none	none	ANNOUNCEMENT

The ANNOUNCE maintenance object logs an error in the hardware error log when either of the following occurs:

- A **save announcement** or **restore announcement** command does not complete successfully.
- The system fails to restore announcements from removable media or disk at boot time.

Hardware Error Log Entries

Table 9-55. ANNOUNCE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1(a)(f)	any	None			
257(b)(f)	any	None			
513(c)(f)	0	None			
769(d)(f)	0	None			
1025(e)(f)	any	None			

Notes:

a. Error occurred while saving announcements. See Table 9-56 for an explanation of aux data and recommended repair actions.

b. Error occurred while saving announcements to the standby SPE. (See the table in the next section for an explanation of aux data and recommended repair actions.)

c. User pressed the CANCEL key while announcement was being saved by the active SPE.

d. User pressed the CANCEL key while announcement was being saved by the standby SPE.

e. Error occurred while restoring announcements. See Table 9-56 for an explanation of aux data and recommended repair actions.

f. The PORT field for this error displays which SPE was active when the error occurred.

ANNOUNCE Error Code Aux Data

Table 9-56. ANNOUNCE Aux Data and Repair Actions

Aux Data	Description/Recommendation
30001 through 30054	Disk/Removable Media errors Check and resolve errors and alarms
32001	Internal system error Check other ANNOUNCE errors and take corrective action. If there are no other ANNOUNCE errors: 1. Retry the command at 3 minute intervals a maximum of 3 times. 2. Try the **save/restore announcement** command.
32002	Announcement circuit pack in use. 1. Retry the command at 2-minute intervals a maximum of 3 times. 2. Try the **save/restore announcement** command.
32003	Announcement port in use. 1. Wait for all Announcement ports to become available. 2. Enter the **save/restore announcement** command.
32004	No announcements on board. There are no announcements recorded on the announcement circuit pack. The **save announcement** command is not allowed to prevent the destroying of the announcement file on removable media.
32005	Integrated announcement board not present. The announcement circuit pack is not inserted, or it is defective. 1. Enter the **list config** command to check for the presence of the board in the system. 2. If the Announcement circuit pack is present, use the **test board UUCSS** command to check the status of the Announcement circuit pack.
32006	Announcement data module not available. 1. Use the **status data-module** command to check the status of the announcement data module.
32007	Announcement data module out of service. 1. Use the **status data-module** command to check the status of the announcement data module.
32008	Announcement data being saved or loaded. 1. Retry the command at two-minute intervals a maximum of three times. 2. If the **save/restore announcement** command fails, escalate the problem.

Continued on next page

Table 9-56. ANNOUNCE Aux Data and Repair Actions — *Continued*

Aux Data	Description/Recommendation
32009	No system port is available (none are administered, or all are busy). A system port is required to save or restore announcements. 1. Use **add data-module** to administer a System Port if none is administered. 2. If system ports are administered, use the **status data-module** command to check the status of all system ports. At least one system port should be in the in-service/idle state.
32010 32013	System port not administered or unavailable. A system port is required to save or restore announcements.) 1. Use **add data-module** to administer a system port if none is administered. 2. If system ports are administered, use the **status data-module** command to check the status of all system ports. At least one system port should be in the in-service/idle state.
32012	Required announcement data module not administered. 1. Add an announcement data module and repeat the command.

ASAI-BD (Multi-Application Platform Board)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run [1]	Full Name of MO
ASAI-BD	MIN	test board UUCSS pp	ASAI-BD
ASAI-BD	WRN	test board UUCSS pp	ASAI-BD

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth); and pp is the two digit port number (01, 02, 03, ...).

Maintenance testing of the common circuit pack is handled by on-board firmware and SPE-controlled tests. Maintenance software queries the firmware for error and alarm information, status, and test results. Firmware automatically reports error conditions that result in SPE-controlled testing.

For MAPD board insertion, the switch makes an additional board query if any of the following circuit packs are inserted:

Circuit Pack	Vintage
TN754	49
TN556	49, 80 or greater
TN800	any

For any of the above initial board uplinks, the switch queries the board for administration data as well as reporting the switch software release and the system type.

For the native mode, the response to the board query downlink messages consists of several CCMS uplink messages that identify the true board code, vintage, suffix, emulation type, and number of reserved slots needed.

NOTE:
See also ASAI-PT/ASAI-EPT (BRI Line) maintenance documentation for related line information. See the following exceptions listed below:

- Hyperactivity: currently, the common circuit pack is considered "hyperactive" if the Service Dispatcher receives 200 uplink messages from the circuit pack in a 10-second period. Since MAPD has 32 ports, the hyperactivity limit increases to 500 uplink messages per 10 seconds. The switch issues an alarm when the limit reaches 400; when it reaches 500 up-link messages in 10 seconds, the board is taken out of service.
- LED use: the LED Control Message 038x requests the Angel to drive the red, yellow, and green LEDs on the face plate of a typical port board on or off. On the MAPD, only the red LED is controlled by this message. Yellow and green change requests received from the switch by the MAPD drive LCD behavior rather than LED behavior. The DEFINITY switch continues to send the same LED control messages to the MAPD that the DEFINITY switch currently sends to all other port boards. The MAPD handles proper interpretation of these messages. You should note that the PC on the MAPD and the switch itself control the LEDs and the LCD on the MAPD.
- Port Administration: in Administration Without Hardware (AWOH), the switch allows administration of up to 8 ports in any of the first 12 ports. If the port type later reported by the board does not match the existing type, the switch assumes it to be a MAPD board with a different configuration and rejects the board.

  NOTE:
  Refer to the LAN-BD documentation for circuit pack level errors. For related information, see ASAI-PT and ASAI-EPT maintenance documentation.

ASAI-EPT

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-EPT	MAJOR[1]	test station extension	ASAI-Adjunct

1. The alarm level for ASAI adjuncts is administered using the **set options** command. The alarm level can be set independently for off-board and on-board alarms to WARNING, MINOR, or MAJOR for all ASAI adjuncts in the system.

The maintenance strategy for this endpoint MO is built on maintenance facilities offered in the Lucent ISDN-BRI protocol and in the ASAI adjuncts. Currently there are no facilities in the protocol that provide for maintenance of set data features.

The TN800 is a PC-based platform that allows interaction of multiple applications with DEFINITY at any time. DEFINITY Release 5 software (Native mode) supports emulation of three types of port MOs on this board. The type of ports to be emulated is defined by the applications running on the TN800.

NOTE:
If the TN800 is emulating BRI, the software/firmware supports a maximum of 12 ports, but only 8 of the 12 ports can be administered at any one time.

Error Log Entries and Test to Clear Values

Table 9-57. ASAI-EPT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level ASAI-EPT	On/ Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test ASAI-ADJ
2 (a)	2-102	None			
257 (b)	Any	BRI Layer 3 Query	MAJ/WNG[2]	OFF	test station ext r 2 test data-module ext r 2
351 (c)	0	none	WARNING	OFF	busyout and release station
513 (d)	0	None			
769 (e)	0	None	MAJOR	OFF	
2561 (f)	0	None			
2562-2566 (g)	0	None			
2567 (h)	0	None			
2568 (i)	0	None			
3329 (j)	Any	Signaling Link Status (626)	MAJ/WNG[†]	OFF	
3584-3839 (k)	Any	None			
3841 (l) 4095	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. Errors of this type indicate violations of the ISDN-BRI signaling protocol. Timers associated with certain Layer 3 messages have expired before a required response was received. In the following table, the aux data column indicates which timer has just expired. For more information, refer to the Lucent ISDN-BRI Specification.

Aux Data	Timer Type
2	First T303 (SETUP timer)
3	Second T303 (SETUP timer)
4	T305 (DISConnect timer)
5	First T308 (RELease timer)
6	Second T308 (RELease timer)
10	T316 (RESTart timer)
12	T309 (Layer 2 Failure timer)
16	TM100 (Management Information Message timer 1)
17	TM200 (Management Information Message timer 2)
102	TASAI (ASAI Routing Timer)

The switch sent a message to an endpoint that did not respond in the allotted time. This may be due to failure of the point-to-point signaling link or because of a problem in the ASAI adjunct. To repair:

- Execute the **test station extension** command and perform the associated repair procedures for those tests.

b. An endpoint is not responding to the service state query message sent to the adjunct or to the endpoint. This error causes an alarm to be raised. The alarm is retired when the switch receives a response to the service state query to the endpoint or to the adjunct.

When this error occurs for an ASAI adjunct, the Aux Data field indicates the state of the ASAI link and whether an invalid response or no response was received to the query from the switch, as shown in the following table:

Aux Data	ASAI Link State	Error
102	13-restarting	No response to RESTART message
104	13-restarting	Invalid response to RESTART message
152	13-restarted	No response to Layer 3 query
154	13-restarted	Invalid response to Layer 3 query
202	13-established	No response to Layer 3 query
204	13-established	Invalid response to Layer 3 query

See "status bri-port" in Chapter 8, "Maintenance Commands" for an explanation of the ASAI link states.

For ASAI or Lucent adjuncts, the switch queries the adjunct every two minutes. The Layer 3 Query Test is not executed for ASAI or Lucent adjuncts through a command issued from the management terminal. While alarmed for this error, the switch takes the associated port out-of-service for five seconds every 15 minutes. This action attempts to stimulate recovery actions to be taken by the adjunct.

When this error occurs for an ASAI or Lucent adjunct, the service technician should:

1. Execute the **test station extension** command and perform the associated repair procedures for those tests.
2. Check the health of the adjunct by following the recommended repair procedures of the manufacturer of the adjunct if the preceding step does not resolve the problem.

c. This error and associated warning alarm are logged against an ASAI endpoint when the adjunct has asked the switch to suspend maintenance on the ASAI endpoint. Busying out and releasing the ASAI station clears this alarm.

d. This error occurs when the endpoint sends more messages than the switch can handle. The switch suspends the reception of messages from the endpoint for a short period of time. There is no repair procedure for this error. If the condition persists, replace the endpoint.

e. This error occurs when the signaling link associated with the ASAI endpoint has too much link-establishment related traffic. This occurs if the signaling link is alternating between assigned and established states. If this problem persists, replace the endpoint.

f. This error occurs when the ASAI-EPT message is not transmitted because the PKT-CTRL (packet control circuit pack) transmit buffers are exhausted. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI adjunct. Resolve the problem by following the repair procedures for the PKT-CTRL. If these attempts fail, re-engineering the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.

g. The ASAI message is not transmitted because the transmit buffer for the ASAI link is full, causing the link to be flow-controlled. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI adjunct. Resolve the problem by following the repair procedures issued by the manufacturer of the adjunct. If these attempts fail, re-engineering of the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.

h. This version of ASAI is not supported. Check the software version that is running on the ASAI adjunct.

i. The adjunct identification is invalid. Check the vendor ID or software running on the ASAI adjunct.

j. This occurs when the point-to-point signaling link to the endpoint goes down, except when the link goes down because either a system technician has busied out the PKT-CTRL or the PKT-BUS, or they have failed. This error raises an alarm against the endpoint or adjunct. Execute the **test station extension short** command and note the results of the Signaling Link Status Test (#626). If this test fails, follow the repair procedure for Test #626. The alarm is retired when the signaling link is re-established to the endpoint or adjunct.

k. The switch software logs certain ASAI cause values. The cause value is determined from the following formulas:

— If the error type is greater than 3712, then the ASAI cause value is equal to the error type minus 3712. The switch sent this value to the adjunct.

— If the error type is less than 3712, then the ASAI cause value is equal to the error type minus 3584. The adjunct sent this value to the switch.

Table 9-58 contains a description of the various ASAI cause values and recommended system technician actions associated with the cause value. The *ISDN-BRI Specification* contains further information.

l. The switch software logs certain ASAI cause values. The cause value is determined from the following formula:

— If the error type is greater than 3968, then the ASAI cause value is equal to the error type minus 3968. The switch sent this value to the endpoint.

— If the error type is less than 3968, then the ASAI cause code is equal to the error type minus 3840. The endpoint sent this value to the switch.

Table 9-58. ASAI Cause Values

Code	Explanation	Recommendation
0	Unrecognized ASAI Protocol Operation.	Requested ASAI protocol is not implemented by switch or adjunct. Aux `Data` field of error log entry contains protocol identifier for unrecognized operation. 1. Consult switch and adjunct documentation to determine which set of operations is supported by switch and the adjunct. Turning off adjunct operations not implemented by the switch may resolve the problem.
34	No circuit or channel available	A resource on the switch is unavailable for a call. For BRI endpoints, this cause value is not logged. For ASAI, this condition means that there are no available trunks for an outgoing call request. 1. Verify that the adjunct is administered to support the trunk capabilities of the switch. 2. Investigate trunk group status by issuing the **status trunk** command from the SAT or by requesting trunk group query(ies) from the adjunct. 3. Perform trunk diagnostic procedures outlined in this manual.
40	Resources not available.	No available internal resources to service switch or adjunct request. Exceeds system transaction capacity for adjunct or switch. 1. May require re-engineering of adjunct services.

Continued on next page

Table 9-58. ASAI Cause Values — *Continued*

Code	Explanation	Recommendation
50	Requested facility not subscribed	Requested facility is implemented, but not administered. Potential administration problem with endpoint or adjunct. For BRI endpoints: 1. Verify the switch administration of endpoint using either the **display station** or **display data-module** commands. 2. If Step 1 does not resolve the problem, refer to the endpoint's service manual and verify administration on the endpoint. For ASAI adjuncts: 1. Display the Customer Optional Features Form (administration screen) on the switch to determine which ASAI capabilities are turned on in the switch. 2. Verify that the adjunct is administered to support the identical capabilities as the switch. If there is a mismatch in the administered capabilities, then readminister the switch and/or the adjunct to establish a consistent set of desired capabilities on both the switch and the adjunct.
58	Bearer capability not presently available	Requested bearer capability is implemented, but not administered. No B-channel administered. See code 50 above.
63	Service or option not available	Requested ASAI capability or resource is not available on the switch or adjunct. More than one adjunct may be contending for the same switch resource. Potential administration mismatch between the resource domains administered on the switch and those administered on the adjunct. 1. Verify that no overlapping administration of switch resources (for example, requesting notifications on a single domain by multiple adjuncts attempting to control a single call) exists across all adjuncts connected to the switch. If overlaps exist, then re-administer the adjuncts to ensure that each adjunct is associated with a unique set of switch resources.
65	Bearer service not implemented	Requested service not implemented in switch or endpoint.
69	Requested facility not implemented	Requested service not supported in switch or endpoint. 1. Consult switch and endpoint documentation to determine service support.

Continued on next page

Table 9-58. ASAI Cause Values — *Continued*

Code	Explanation	Recommendation
79	Service or option not implemented	Requested service or option (or combination of selected options) is not supported (implemented) in switch or the adjunct. 1. Consult switch and adjunct documentation to determine ASAI service and options supported by both switch and adjunct. Re-administration of the switch-administered capabilities (see Customer Optional Feature Form) or those of the adjunct may be necessary to correct the problem.
81	Invalid CRV	An invalid CRV was sent by the adjunct. 1. This may indicate a CRV inconsistency between the switch and the adjunct. See the CallVisor protocol reference manual.
87	Internal switch audit	There is an inconsistency in switch data records. 1. There is no action needed, since the switch has corrected the data inconsistency.

System Technician-Demanded Tests: Descriptions and Error Codes

When inspecting errors in the system, always investigate errors associated with the circuit pack and port first. Clearing these error codes first may also clear errors generated against the endpoint. When all circuit pack and port errors have been cleared, but errors still exist against the endpoint, investigate errors in the table below. By clearing error codes associated with the Signaling Link Status Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Signaling Link Status Test (#626)	X	X	ND

1. D = Destructive; ND = Nondestructive

BRI Layer 3 Query Test (#629)

This test is not used by the ASAI-ADJ maintenance object. For information about this test, see BRI-SET in the maintenance documentation.

Signaling Link Status Test (#626)

This test determines the current status of the signaling link. This test passes if the link is "bound" to an endpoint and fails if the link is "not bound."

The definition of the term "bound" for a link depends upon the type of endpoint and may depend on the successful completion of procedures at both Layers 2 and 3 of the protocol. The definition of "bound" for ASAI type of endpoint is:

- ASAI adjuncts and BRI endpoints not administered for MIM initialization (point-to-point):

  For endpoints of this type, the signaling link is "bound" when the link is connected at Layer 2 (L2 established).

Table 9-59. TEST #626 Signaling Link Status Test

Error Code	Test Result	Description/ Recommendation
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long UUCSSpp** command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL maintenance documentation.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. Execute the **test port long UUCSSpp** command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1187	ABORT	The circuit pack, port, or station may have been busied out. 1. Look in the Error Log for Error Type 18 (busied out) for ASAI-BD, ASAI-PT, or ASAI-EPT. 2. If this Error Type is present for ASAI-EPT only, then use the **release station** command and run the test again. 3. If this Error Type is present for ASAI-PT and ASAI-EPT, then use the **release port** command and run the test again. 4. If this Error Type is present for ASAI-BD, ASAI-PT, and ASAI-EPT, then use the **release board** command and run the test again.

Continued on next page

Table 9-59. TEST #626 Signaling Link Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1113	FAIL	The signaling link is not "bound" to the adjunct. For ASAI adjuncts this error indicates that the link is disconnected at Layer 2. Since the signaling link associated with the endpoint has been identified by administration, the link is only "unbound" from the endpoint when it is disconnected. 1. Execute the **status bri-port UUCSSpp** command and refer to the associated procedures for this command contained in “BRI-PORT”.
	PASS	The signaling link is connected at Layer 2 and "bound" to the ASAI adjunct.

ASAI-PT

MO Name (in Alarm Log	Alarm Level	Initial Command to Run[1]	Full Name of MO
ASAI-PT	MAJOR[2,3]	test port UUCSSpp l	ASAI ISDN BRI Port
ASAI-PT	WARNING	test port UUCSSpp l	ASAI ISDN BRI Port

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth); and pp is the two digit port number (01, 02, 03, ...).
2. The alarm level for ASAI adjunct ports may be administered using the **set options** command. The alarm level can be set independently for off-board and on-board alarms to WARNING, MINOR, or MAJOR for all ASAI adjunct ports in the system.
3. All alarming for an ASAI adjunct and off-board alarming for an ASAI port is disabled if the ASAI adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm is logged against the ASAI adjunct. Check the Hardware Error and Alarm Logs to see if the adjunct has disabled alarming.

Unless otherwise stated, all maintenance actions contained in this section apply to ASAI-PT and ISDN-BRI ports connected to ASAI adjuncts. This port type is administered as an ASAI-BD on the TN800 circuit pack.

The TN800 circuit pack is a PC-based platform that allows interaction of multiple applications with DEFINITY. DEFINITY software (Native mode) supports emulation of three types of port MOs on this board. The type of ports to be emulated are defined by the applications running on the TN800. The TN800 can support a maximum of 32 ports (time slots) at a time.

The TN800 connects to the switch through a single slot in the backplane, however its width is not limited to one slot. The number of slots occupied by the TN800 is supplied by the board during its insertion. The TN800 (Release 5 and higher) is 3 slots wide. The blank (reserve) slots are to the left of the functional slot.

In non-native mode the TN800 is recognized as TN556, TN2181, TN754, or TN746 based on the switch software and the application running on the TN800. In non-native mode only one type of port MO runs at any time, and the port type depends on the application running on the TN800. If the TN800 fails diagnostics in non-native mode, the system's alarm and error logs would show a failure for the board type the TN800 is emulating.

Error Log Entries and Test to Clear Values

Table 9-60. ASAI-PT Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level ASAI-PORT	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1 (a)	(a)	Level 1 Status Inquiry (#621)	MAJ[2]	OFF	test port UUCSSpp sh r 2
513 (b)	0	none	(b)	ON	
1537 (c)	46210	CRC Error Counter (#623)	MAJ[2]	OFF	
3841 (d)	46208	None			
3844 (e)	46223	None			
3845 (f)	46211	None			
3846 (g)	TEI	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major and Minor alarms may be downgraded to warning alarms based on the value used in the **set options** command.

Notes:

a. This error occurs when the Level 1 Status Inquiry fails or when the BRI circuit pack detects that Level 1 has been deactivated on the port. The `Aux Data` field contains one of the following values:

Blank	This indicates that the Level 1 Status Inquiry failed.
32773	This is a message from the ASAI-Line circuit pack indicating Level 1 has been deactivated.

Refer to the repair procedures for Test #621.

b. The circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signalling information over D-channel. This error occurs when the Packet Bus transmit FIFO buffer overflows. This condition probably indicates a hardware problem as well. The ASAI-PORT alarm level is MAJOR with aux data 0. Use troubleshooting procedures for both on-board hardware problems and potential off-board Packet Bus problems.

c. The port received an invalid frame over the D-channel. When the Cyclical Redundancy Check (CRC) errors exceed 5 within 15 minutes, the port is taken out of service for 5 seconds. If 5 more CRC errors are received within 15 minutes of the first set of 5 errors, the port is taken out of service for one minute. If 5 more CRC errors are received within 15 minutes of the last 5, the port is taken out of service for 15 minutes.

   This error is most likely due to a problem with the wiring to the set or adjunct, interference on the wiring due to a noise source, or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.

   - Check the wiring to the endpoints or the adjunct.
   - If the problem persists, replace the endpoints or adjuncts.

d. This error occurs when a Layer 1 Transmission error is detected for the port. Run the Long Test Sequence and note the results of the Layer 1 Transmission Error Counter Test (#624).

e. This error occurs when the circuit pack detects an overflow of its receive buffers. Run the Long Test Sequence and note the results of the Receive FIFO Overflow Counter Test (#625).

f. This error occurs when the BRI Port Local LAN Looparound Test (#618) fails. Run the Long Test Sequence and note the results of Test (#618).

g. The Terminal Endpoint Identifier (TEI) administered for the ASAI endpoint most likely does not match the TEI administered in the ASAI adjunct. Check the switch administration of the TEI against that of the adjunct, and make sure that both are using the same TEI.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. For example, by clearing error codes associated with the NPE Crosstalk Test, you may also clear errors generated from other tests in the testing sequence.

Table 9-61. System Technician-Demanded Tests: ASAI-PT

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
ASAI Port Local LAN Looparound Test (#618)		X	D
Level 1 Status Inquiry Test (#621)	X	X	ND
CRC Error Counter Test (#623)		X	ND
Layer 1 Transmission Error Counter Test (#624)		X	ND

Continued on next page

Table 9-61. System Technician-Demanded Tests: ASAI-PT — *Continued*

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Receive FIFO Overflow Error Counter Test (#625)		X	ND
Clear Error Counters (#270)	X	X	ND

1. D = Destructive, ND = Non-destructive

BRI Port Local LAN Looparound Test (#618)

This test is destructive.

This test verifies the connectivity of a BRI port across the LAN Bus and executes only if the port is out-of-service. The test aborts if calls associated with the port are in-progress. Failures of this test indicate either on-board faults associated with the ASAI-PT hardware on the circuit pack or problems with the LAN Bus, which is used to form connectivity between the switch and the ASAI-PT.

The dotted lines in Figure 9-2 show how a Looparound Test is performed across the Packet Bus for the D-channel.

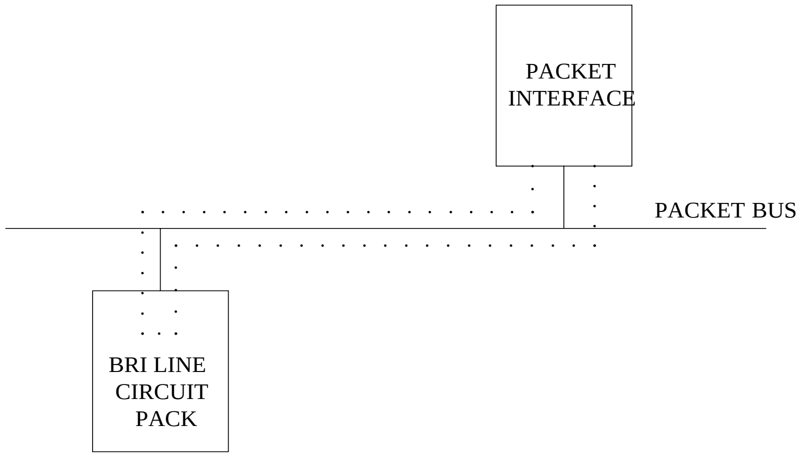

Figure 9-2. BRI Port Local LAN Looparound Path

Table 9-62. TEST #618 BRI Port Local LAN Looparound

Error Code	Test Result	Description/Recommendation
1015	ABORT	The port is not in the out-of-service state. 1. Display the Port Status form using the **status bri-port UUCSSpp** command to determine which stations or adjuncts are on this port. 2. Use the extension shown on this form in the **status station** command to determine if the station or adjunct is in use. 3. If the port is in use, wait until it is idle, and use the **busyout port UUCSSpp** command to place it in the out-of-service state and repeat this test. **WARNING:** *Since the "busyout" command is destructive, using this command prior to the port being idle causes all transactions associated with the ASAI on the port to be torn down. Note that third party calls established by an ASAI adjunct remain connected even though the port is taken out-of-service.*
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long UUCSSpp** command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Follow the repair procedures for the PKT-CTRL. 2. Issue the **test port long UUCSSpp** command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. Issue the **test port long UUCSSpp** command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-62. TEST #618 BRI Port Local LAN Looparound — *Continued*

Error Code	Test Result	Description/Recommendation
	FAIL	The Looparound test has failed. 1. If the test fails repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use. Reset the circuit pack by issuing the **busyout board UUCSS** and the **reset board UUCSS** commands. 2. If the test fails again, execute **test pkt P** on the management terminal. If this fails, follow the failure procedures the in PKT-BUS section. 3. If the tests executed in Step 2 pass, the problem is local to the BRI board. Replace the circuit pack.
	PASS	The BRI Port Local LAN Looparound test has passed.

Level 1 Status Inquiry Test (#621)

This test determines the state of the transmission facility of a BRI port at the Level 1 (L1) or physical layer. L1 can be in one of two possible states: Activated or Deactivated.

The Activated state is the correct state for an ISDN-BRI port. In this state the Level 1 interface can communicate with the BRI endpoint or ASAI adjunct administered on this port. This test passes if the state of L1 is activated. This test also passes if software has taken this port out of service.

The Deactivated state indicates a problem with the ASAI circuit pack. When in this state, the Level 1 interface is idle and is not trying to communicate with the BRI endpoints or adjunct. When an ASAI port is placed in the out-of-service state, Level 1 is also put into the deactivated state. This could be due either to the system detecting a fault with the port or in response to a **busyout port UUCSSpp** request.

Table 9-63. TEST #621 Level 1 Status Inquiry

Error Code	Test Result	Description/Recommendation
1187	ABORT	The board, port, or station may have been busied-out by a technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port and ASAI-BD (board busied out). If this error type is present for ASAI-PT only, then release the port using the **release port pp** command and run the test again. If the error is present for both ASAI-BD and ASAI-PT, then release the board with the **release port UUCSS** command and run the test again. **NOTE:** When you release a port, you release all ports associated with it. If certain ports still need to be busied out, use the **release port UUCSSpp** command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack using the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
3	FAIL	Received a status of Level 1 Deactivated; the port is out-of-service. 1. Issue the **status bri-port UUCSSpp** command to verify that the service state of the port is out-of-service. If the port is not out-of-service, escalate the problem, or else proceed to Step 2. 2. If the port has been placed out-of-service using the **busyout port UUCSSpp** command, try releasing the port by executing the **release port UUCSSpp** command. Then issue the **test port long UUCSSpp** command, and review the results of Level 1 Status Inquiry test. If this test is still failing, proceed to Step 3. 3. After executing the **test port long UUCSSpp** command, review the results of all the tests. Follow the repair procedures for any tests that fail. Verify repair of the problem by executing the **test port UUCSSpp** command and by determining that the Level 1 Status test passes. 4. If the test continues to fail for this reason, escalate the problem.
	PASS	This test indicates that Level 1 is activated, or that software has taken the port out of service.

CRC Error Counter Test (#623)

This test reads and clears the BRI port's CRC error counter maintained on the BRI-LINE circuit pack. This counter is incremented by the circuit pack when it receivs a frame from the endpoint or adjunct with a bad CRC over the D-channel. The test passes if the value of the counter is 0 (the error is cleared). If the counter is not 0, the test will fail and the value of the counter is displayed in the `Error Code` field. A CRC error is most likely due to a problem with the wiring to the set or adjunct, interference on the wiring due to a noise source (for example, electrical motors or generators), or no termination (open circuit). It usually does not indicate a problem with the BRI circuit pack. This test is used for verifying the repair of the problem.

Table 9-64. TEST #623 CRC Error Counter Test

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack using the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack. **CAUTION:** *Do not leave the circuit pack busied out.*
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The BRI circuit pack is still detecting CRC errors. The `Error Code` field contains the value of the counter. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail, review the restuls of other tests in the long test sequence. Pay particular attention to the results of the Level 1 Status Inquiry test. Follow the repair procedures for any of the executed tests if they fail; otherwise, proceed to Step 3. 3. If the tests for the endpoints or adjunct pass and the CRC error counter test continues to fail, check the wiring to the endpoints or adjunct. If the wiring appears to be OK, escalate the problem.

Layer 1 Transmission Error Counter Test (#624)

This test reads and clears the BRI port's Layer 1 Transmission error counter maintained on the ASAI circuit pack. This counter is incremented by the circuit pack when it detects a Layer 1 transmission problem. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error is most likely due to a problem with the wiring or adjunct (verify that the wiring meets the configuration rules defined in *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111). It does not indicate a problem with the TN800 circuit pack. This test is useful for verifying the repair of the problem.

Table 9-65. TEST #624 Layer 1 Transmission Error Counter Test

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack using the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate necessary system resources to run test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The TN800 circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail, review the results of other tests in the Long Test Sequence. Note the results of the Level 1 Status Inquiry test. Follow the repair procedures for any of the executed tests if they fail. Otherwise, go to the next step. 3. Replace the circuit pack.
	PASS	The Layer 1 Transmission error counter was read correctly and has a value of 0.

Receive FIFO Error Counter Test (#625)

This test reads and clears the BRI port's Receive FIFO error counter maintained on the TN800 circuit pack. This counter is incremented by the circuit pack when it detects an overflow of its receive buffers. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error can occur if signaling frames are being received from a Packet Bus at a rate sufficient to overflow the receive buffers on the circuit pack for a port or if hardware fault is causing the receive buffers not to be emptied properly. This test is useful for verifying the repair of the problem.

Table 9-66. TEST #625 Receive FIFO Error Counter Test

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack via the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate necessary system resources to run test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The TN800 circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail, review the results of other tests in the Long Test Sequence. Note the results of the Level 1 Status Inquiry test. Follow repair procedures for any of the tests that fail. Otherwise, go to the next step. 3. If the tests for the endpoints or adjunct pass and the Layer 1 Transmission Error Counter Test continues to fail, check the wiring to the endpoints or adjunct.
	PASS	The Layer 1 Transmission error counter was read correctly and has a value of 0.

Clear Error Counters Test (#270)

There are various error counters associated with each ASAI-PT. This test clears those counters and triggers the auditing of Layer 3 reinitialization. This test is used only to send messages to the ASAI-PT and, therefore, should neither abort nor fail. ASAI uses a fixed TEI value of 1.

Table 9-67. TEST #270 Clear Error Counters

Error Code	Test Result	Description/Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	The message to clear the error counters of the ASAI-PT has been sent.

ASAI-RES/E-DIG-RES (TN800 reserve slot)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-RES	NONE	NONE	TN800 ASAI reserve slot
E-DIG-RES	NONE	NONE	TN800 DIG reserve slot

There are no tests associated with these MOs. Both the **test board** and **busy out board** commands abort when either is attempted on a reserved slot. An error message indicates the slot is associated with the circuit pack that the TN800 is emulating, but the requested operation is not valid.

The TN800 MAPD (Multi-Application Platform for DEFINITY) circuit pack connects to the switch through a single slot in the backplane. The number of slots occupied by the MAPD pack is supplied by the board when inserted. The TN800 in R5EM is 3 slots wide. The TN800 requires 2 reserve slots to its left. The reserve (blank) slots are to left of the functional slot and are place holders on the switch, and do not have any interaction with the switch.

Each instance of these MOs represents a reserve slot associated with respective circuit pack mode in which the MAPD is working.

ATM-BCH (ATM B-Channel Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ATM-BCH[2]	MAJOR[3]	test port UUCSSppp l	ATM B-Channel Trunk
ATM-BCH	MINOR	test port UUCSSppp l	ATM B-Channel Trunk
ATM-BCH	WARNING	test port UUCSSppp sh	ATM B-Channel Trunk

1. UU is the universal cabinet number (1 for PPN, 2-44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot where the circuit pack resides (01-21). ppp is the 3-digit port number (9-256).
2. For additional repair information, see also ''ATM-DCH (ATM D-Channel Port)'', ''ATM-SGRP (ATM Signaling Group)'' and PKT-BUS.
3. A MAJOR alarm on a trunk means that alarms on these trunks are not downgraded by the **set options** command, and at least 75% of the trunks in this trunk group are alarmed.

This maintenance object explains how you test and repair TN230x ATM Interface circuit packs (TN2305 and TN2306) that have ATM B-channel trunks administered for ATM Circuit Emulation Service (CES).

For maintenance instructions for TN230x circuit packs that are administered as Expansion Interfaces for ATM network connectivity, see the ''ATM-INTF (TN2305/6)'' maintenance object.

ATM Circuit Emulation Service

Under ATM Circuit Emulation Service, you simulate ISDN-PRI circuits by assigning ATM ports to *signaling groups*. Each signaling group represents a PRI circuit, and the ports in the group represent the D-channel and B-channels of that circuit. B-channels must also be assigned to ISDN-PRI trunk groups. TN230x circuit packs support up to 248 ports per circuit pack.

Signaling group components

Bearer (B) channels (ATM-BCH) transmit digitized voice or data, while a separate D-channel (ATM-DCH) handles call-control signaling. One D-channel handles signaling for a group of B-channels that combine to form a signaling group (ATM-SGRP).

B-channel service states

The ISDN specification defines 2 service state categories for B-channels as listed in Table 9-68.

Table 9-68. ATM ISDN service states

Category	Description		
Service states			
In-Service (INS)	B-channel is in normal operating state	Active	A call is connected over the B-channel.
		Idle	There is no call on the B-channel.
Out-of-Service/Far-end (OOS/FE)	The switch has not successfully negotiated B-channel connection as of yet. Calls cannot be placed or received. When you first administer a B-channel, the switch initializes the B-channel to this state while it tries to negotiate a connection to the far end. If the request times out with no response from the far end, the switch leaves the B-channel in the OOS/FE state.		
Out-of-Service/Near-End (OOS/NE)	The NPE Crosstalk Test has failed or the trunk is busied out. Calls cannot be placed or received.		
Maintenance/Far-End (MTC/FE)	A request has timed out with no response from the far end after signaling is in place and B-channels are in service. Calls can be received but not placed, and stable calls are unaffected.		
Maintenance/Near-End (MTC/NE)	The signaling channel (ISDN-LNK) has been busied out, possibly after a **test trunk *grp#/mbr#* long** command. Calls cannot be placed or received, but stable calls are unaffected.		
Pending states[1]			
Pending-in-Service	The near-end is waiting for a response to a transition-to-service request.		
Pending-Maintenance	The near-end is waiting for a transition-to-maintenance-service request (US and other country-protocol-1 systems).		

1. The switch is waiting for a reply from the far-end. Pending service states remain in effect until the near end receives a response or times out.

B-channel alarms

The Maintenance/Far-End and Out-Of-Service/Far-End states generate warning alarms displayed with **status trunk *grp#/mbr#***.

Table 9-69. ATM-BCH alarms by service state

Service state	Alarm[1]	Possible cause	Possible solution
Out-of-Service/NE	Warning	Trunk busied out	Release the port (**release trunk** ***grp#/mbr#***).
	Minor	NPE Crosstalk Test (#6) failed	Replace ATM circuit pack.
	None	ATM circuit pack lost signal or there is a circuit pack problem.	Install circuit pack or cable. Check circuit pack using procedures in ATM-BCH. Check far-end switch status.
Out-of-Service/FE	Warning	Unadministered far-end	Administer the corresponding trunk on the far-end switch.
	Warning	Far-end busied out	Check the status of the far-end switch.
Pending/In-Service Pending/Maint	None	Maintenance message timed out waiting for reply	Wait 2 minutes after the pending state clears, and check the service state.
Maint/NE	None	ISDN test call in progress (**test trunk long**)	Wait for the test to finish and recheck.
	None	System link busied out	Check link status. Run **release link** ***link#***.
Maint/FE	Warning	Signaling channel down for over 90 sec.	See "ATM-SGRP (ATM Signaling Group)" or "ATM-DCH (ATM D-Channel Port)".
	Warning	Repeated lack of response to messages sent to the far end	Wait. Maintenance software resends messages periodically. Or run **test trunk** ***grp#/mb#*** or **test signaling-grp** ***grp#***.
	Warning	The far-end trunk is being tested.	Check status of the far-end switch. Wait for testing to finish.
In-Service	None	Normal operating state	

1. ATM-BCH alarms; alarms against other maintenance objects may also be present.

Error Log Entries and Test to Clear Values

Table 9-70. ATM-BCH Error Log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSppp
1(a)	Any	None			test port UUCSSppp
18	0	busyout trunk *grp/mbr*			release trunk grp/mbr
129 (b)		None	WNG	OFF	test port UUCSSppp
130 (c)					test port UUCSSppp
257(d)	Any	Service State Audit (Test #256)			test port UUCSSppp
513(e)	Any	None	WNG	OFF	test port UUCSSppp
769(f)	Any	Service State Audit (Test #256)			test port UUCSSppp
1793(g)	Any	None			test port UUCSSppp
3073(h)	Any	Service State Audit (#256)			test port UUCSSppp
3585(i)	Any	None			none
3841(j)	Any	None	WNG	OFF	none

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Error Type 1: the two ends of the ATM trunk do not agree on the ISDN call state. Possible causes:

- Received a DISConnect or RELease COMplete message with cause value 52 (outgoing calls barred)
- Received a DISConnect or RELease COMplete message with cause value 54 (incoming calls barred)
- Outgoing call renegotiated by the far end to another B-channel in the absence of SETUP message glare
- Near end attempted a call on a B-channel that the far end has marked OOS

When running the Short Test Sequence, pay close attention to the results of the Call State Audit Test (#257).

b. Error Type 129: the far-end switch changed its ISDN service state to either out-of-service or maintenance. This may be a temporary condition because the far-end is testing that trunk or a hardware problem with the trunk. Outgoing calls may not be allowed over that trunk.

   1. Investigate the trunk status (**status trunk *grp#/mbr#***).

c. Error Type 130: the circuit pack has been removed or has been insane for more than 11 minutes.

   1. Reinsert or replace the circuit pack to clear the error.

d. Error Type 257: SETUP received for a B-channel that is in an invalid service state. Service states may be incompatible at the two ends of the trunk. A normal call was received while the B-channel was MTC/FE, MTC/NE, OOS/FE, or OOS/NE or a test call was received while the B-channel was OOS/FE or OOS/NE.

e. Error Type 513: RELease COMplete message received with cause value 82 (nonexistent channel). The B-channel may not be administered at the far end. The trunk has been placed in the OOS/FE state.

f. Error Type 769: inconsistent SERVice or SERVice ACKnowledge message. Possible causes:

   - SERVice or SERVice ACKnowledge message received containing a change status that is more available than the previously-transmitted SERVice message.
   - Unsolicited SERVice ACKnowledge message received containing a change status that does not match the current B-channel state.

   ISDN-PRI service-state negotiation rules have been violated and may indicate that a pending service-state audit is failing. The system

   - cancels the maintenance timer
   - increments the Service State Audit counter
   - attempts a Service State Audit

   When running the Short Test Sequence, pay close attention to the results of the Service State Audit Test (#256).

g. Error Type 1793: TN230x circuit pack has failed. The maintenance system

   - places the trunk in the OOS/NE state
   - sends a SERvice message to the far-end (if possible) containing a change status of OOS for the B-channel
   - returns the trunk to service when the ATM trunk circuit pack reports the failure cleared

h. Error Type 3073: Service State Audit attempt failed (see Test #256). Calls can be received but not placed until the test passes and the trunk state returns to In-Service.

   1. Check the trunk status (**status trunk *grp#/mbr#***).

i. Error Type 3585: ISDN RESTART message received. Active calls have been dropped.

The following Aux Data values (Error Type 3585 only) below represent the trunk's ISDN call state at the time Error 3585 occurred. This information can be useful if users report dropped calls on the ISDN-PRI trunks.

Aux Data	Description
0	An idle trunk received a restart.
10	An ISDN RESTART from the far-end has unexpectedly cleared a call in the ACTIVE state (call stable, parties talking).
4 7 8 260 263	An ISDN RESTART from the far-end has unexpectedly cleared a RINGING call.
1 3 6 9 265	An ISDN RESTART from the far-end has unexpectedly cleared a call before the call entered the RINGING state.
11 12 19 531 267 268	An ISDN RESTART from the far-end has unexpectedly cleared a call that was already in the process of clearing. If this condition occurs frequently, the far-end may be trying to clear trunks that appear to be in the "hung" state.

j. Error Type 3841: the far-end rejected an ATM CES trunk selected by the near-end 10 times. The ATM CES trunk may not be administered on the far-end.

1. Get the physical name of the ATM trunk by noting the decimal number in the `Aux Data` field.
2. Check administration for the named trunk on the far-end.
3. If problems persist, then busyout the ATM trunk to take it out of the hunt group.

The WARNING alarm retires automatically whenever a called endpoint answers an outgoing or incoming call that uses the alarmed trunk.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate problems in the order presented in the table below. When you clear one of the error codes associated with a given test, you clear errors generated by other tests in the testing sequence. If you clear errors out of order, you can lose important information.

Table 9-71. System Technician-Demanded Tests: ATM-BCH

Order of Investigation	Short Test Sequence	Long Test Sequence	Destructive or Non-destructive
Signaling Link State Check Test (#255)	X	X	ND
Service State Audit Test (#256)	X	X	ND
Call State Audit Test (#257)	X	X	ND
ISDN Test Call Test (#258)		X	ND

Signaling Link State Audit Test (#255)

This non-destructive test checks the status of the TN230x ATM-CES Interface circuit pack and the ATM D-channel (ATM-DCH) trunk, which are both important elements to the health of the ATM-BCH trunk.

Table 9-72. TEST #255 Signaling Link State Audit Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	Internal system error
0	ABORT	
1114	ABORT	Signaling link in transitional state 1. Retry the command up to 5 times at 1-minute intervals.
1018	ABORT	Maintenance disabled 1. Enable maintenance. Enter **y** in the `Maintenance Tests?` field on page 2 of the **change trunk-group** form.
4	FAIL	Signaling channel problem 1. Look for errors or alarms against the ''ATM-SGRP (ATM Signaling Group)'' and ''ATM-DCH (ATM D-Channel Port)'' maintenance objects.
8	FAIL	TN230x circuit pack failed 1. See the ''ATM-INTF (TN2305/6)'' maintenance object.
	PASS	Signaling link OK.

Service State Audit (#256)

This test checks the service state of the trunk.

Country protocol 1. If the interface uses country protocol 1 (includes USA), the service-state audit executes in all trunk service states. It queries the service state on the far end and waits 2 minutes for a reply. If the first request times out, the service-state audit asks again. If the request times out again, it logs error 3073 and resends the request every 15 minutes. It places in-service trunks in the MAINTENANCE/FAR-END state (outgoing calls blocked, incoming calls accepted). Incoming calls trigger an immediate service-state audit without waiting for the end of a 15-minute cycle.

Any other country protocol. If the interface uses some other country protocol, the service-state audit executes only on trunks that are in the OUT-OF-SERVICE/FAR-END state. It asks the far-end switch to bring the trunk back into the IN-SERVICE state and waits 2 minutes for a reply. If the first request times out, the service-state audit asks again. If the request times out again, it leaves the trunk in the OUT-OF-SERVICE/FAR-END state and tries again in 1 hour.

NOTE:
PASS for this test only means that a message to the far-end was successfully sent.

To check the service state of the ATM-BCH trunk, run **status trunk *grp#/mbr#***.

Table 9-73. TEST #256 Service State Audit Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	Needed resources not available, port on a call or initializing 1. Run **status trunk *grp#/mbr#***. 1. Check the results of Test #255.
1018	ABORT	Maintenance disabled 1. Enable maintenance by entering **y** in the `Maintenance Tests?` field on page 2 of the **change trunk-group** form.
1113	ABORT	Signaling link failed 1. Run **status trunk *grp#/mbr#***. 2. Check the results of Test #255. 3. See the "ATM-SGRP (ATM Signaling Group)" maintenance object.

Continued on next page

Table 9-73. TEST #256 Service State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1114	ABORT	Signaling link in transitional state 1. Retry the command up to 5 times at 1-minute intervals.
1116	ABORT	Trunk not in Out-of-Service/Far-end state and country protocol other than 1
1117	ABORT	Service-state audit message outstanding 1. Wait 2 minutes, then try again.
2100	ABORT	Could not allocate needed resources 1. Retry the command up to 5 times at 1-minute intervals.
1113	FAIL	Signaling link failed 1. See the "ATM-SGRP (ATM Signaling Group)" and ISDN-LNK (ISDN Signaling Link Port) maintenance objects.
	FAIL	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
	PASS	1. Wait 4 minutes, then check the Error Log for any new Error Type 3073. ■ If there are none, both sides of the ISDN connection agree on the service state. The negotiation succeeded. ■ If there is a new 3073 error, then the negotiation failed (the request timed out).

Call State Audit Test (#257)

This test audits the internal call state by asking the far-end switch for the ISDN call state. The test is particularly useful when you are trying to clear a hung call. If the internal call state on the near-end differs from that on the far-end, the call is torn down.

The ISDN specification allows up to 2 minutes for a reply. If a reply is not received within the 2 minute window, the test logs a protocol time-out violation against the associated signaling channel (ATM-DCH, Error Type 1).

NOTE:
PASS simply means that an appropriate message was composed and sent to the far-end switch.

Table 9-74. TEST #257 Call State Audit Test

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Maintenance disabled 1. Enable maintenance by entering **y** in the `Maintenance Tests?` field on page 2 of the **change trunk-group** form.
1019	ABORT	Audit already in progress 1. Wait 2 minutes, and try again.
1113	ABORT	Signaling link failed 1. Check the results of Test #255 (Signaling Link State Check).
1114	ABORT	Signaling link in transitional state 1. Retry the command up to 5 times at 1-minute intervals.
1116	ABORT	Trunk out-of-service 1. Check the trunk service state (**status trunk *grp#/mbr#***).
2100	ABORT	Could not allocate needed resources 1. Retry the command up to 5 times at 1-minute intervals.
	FAIL	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
	PASS	1. Wait 4 minutes, then check the Error Log for call-state mismatches. If a call state mismatch is found, the call is torn down.

ISDN Test Call Test (#258)

This non-destructive test performs a far-end looparound test over an ATM-BCH trunk if

- the trunk is IN-SERVICE, MAINTENANCE/NEAR-END, or OUT-OF-SERVICE/NEAR-END
- no calls are active on the trunk
- the system uses country protocol 1 (including US) or the far-end has looparound capability

The test sets up a call to a far-end switch over the ATM-BCH trunk. Then the digital port on a TN711D Maintenance/Test circuit pack sends a bit pattern to the far-end and back. If the received pattern matches that sent, the test passes. If there are differences, it fails.

Synchronous Test Calls

You can initiate a synchronous outgoing test call (including a test call for ISDN-PRI trunks) with these commands:

- **test trunk *grp#/mbr#* long [repeat #]**
- **test board *UUCSS* long [repeat #]**
- **test port *UUCSSpp* long [repeat #]**

Table 9-75. TEST #258 ISDN Test Call

Error Code	Test Result	Description/ Recommendation
4	ABORT	Signaling channel problem 1. Look for errors or alarms against the "ATM-SGRP (ATM Signaling Group)" and "ATM-DCH (ATM D-Channel Port)" maintenance objects.
8	ABORT	TN230x circuit-pack problem 1. See the "ATM-INTF (TN2305/6)" maintenance object.
1004	ABORT	B-channel in use. 1. See if a call is active. Run **status trunk *grp#/mbr#*** command. 2. If the service state is In-Service/Idle, retry the test.
1005	ABORT	Bad configuration (for example, no Maintenance/Test circuit pack) 1. Make sure that the Maintenance/Test Circuit Pack is inserted. 2. Repeat the test.
1018	ABORT	Test call disabled 1. Enable Maintenance on the Trunk Group form.
1020	ABORT	TN230x circuit-pack problem 1. See the "ATM-INTF (TN2305/6)" maintenance object.
1024	ABORT	Maintenance/Test Digital Port in use 1. Wait until yellow and green LEDs on the Maintenance/Test circuit pack are OFF. 2. Rerun the test. 3. If the problem persists, see the M/T-DIG (Maintenance/Test Digital Port) maintenance object.
1113	ABORT	Signaling link failed 1. Check the results of Test #255 (Signaling Link State Check Test).

Continued on next page

Table 9-75. TEST #258 ISDN Test Call — *Continued*

Error Code	Test Result	Description/ Recommendation
1116	ABORT	Switch could not change the service state 1. See if calls are active. Run **status trunk *grp#/mbr#***. 2. If a call is active. proceed as for Error Code 1119. 3. If not, check the Error and Alarm Logs and refer to the ATM-TRK (Circuit Emulation Service Circuit Pack) maintenance object.
1117	ABORT	ISDN service message outstanding 1. Wait 2 minutes. Then try again.
1118	ABORT	Far-end not administered 1. Check the administration of the far-end of the ATM trunk. Run **status trunk *grp#/mbr#***. 2. Try the test again.
1119	ABORT	Test call aborted, normal call attempted 1. Wait for the call to terminate normally or drop it by running **busyout trunk *grp#/mbr#***. 2. When the trunk is idle, retry the test.
1120	ABORT	Trunk OUT-OF-SERVICE/FAR-END 1. Try to change the service state via Test #256 (Service State Audit Test). 2. Try the test again.
1122	ABORT	No test-line number for the far-end switch 1. Check the Trunk Group Administration form.
1123	ABORT	No Feature Access Code administration for this Facility Test 1. Check the Dial Plan and Feature Administration forms.
2000 2012 None	ABORT	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
2035	ABORT	Call timed out 1. Wait 1 minute, and try again.
2036-2037	ABORT	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
2038-2039	ABORT	Problem reading test data 1. Wait 1 minute, and then try again. 2. If the test aborts again, there is a serious internal problem.

Continued on next page

Table 9-75. TEST #258 ISDN Test Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2040	ABORT	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
2041	ABORT	Call timed out 1. Wait 1 minute, and try again.
2066	ABORT	Could not establish test call 1. Retry the command up to 5 times at 1-minute intervals.
2067	ABORT	Call timed out 1. Wait 1 minute, and try again.
2074	ABORT	Bit and Block Error query failed 1. Retry the command up to 5 times at 1-minute intervals. 2. If the test continues to abort, there may be a serious internal problem in the Maintenance/Test Digital Port. See the M/T-DIG (Maintenance/Test Digital Port) maintenance object.
2075	ABORT	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2201-2205	ABORT	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
2206	ABORT	Could not allocate needed resources 1. Retry the command at 1-minute intervals a maximum of 5 times.
2208	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2209-2210	ABORT	Could not allocate needed resources 1. Follow recommendations for ABORT code 2100.
2211	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2212	ABORT	Call terminated by unexpected disconnect 1. Wait 1 minute and then try again.
2213	ABORT	Call timed out 1. Wait 1 minute, and try again.

Continued on next page

Table 9-75. TEST #258 ISDN Test Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2214	ABORT	Call terminated by unexpected disconnect 1. Wait 1 minute and then try again.
2215-2219	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2220	ABORT	Call terminated prematurely 1. Wait 1 minute, and try again.
2221-2226	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2227	ABORT	Could not allocate needed resources 1. Retry the command at 1-minute intervals a maximum of 5 times.
2042	FAIL	Test data corrupt
	PASS	Test pattern intact. If the synchronous test call was performed (long test sequence), the communications path is operating properly.

ATM-DCH (ATM D-Channel Port)

MO Name (in Alarm Log)	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
ATM-DCH[2]	MINOR	test port *UUCSSpp* l	ATM D-Channel
ATM-DCH	WARNING	test port *UUCSSpp* sh	ATM D-Channel

1. pp is administered as a port in the range of 9 through 32.
2. For additional related information, see ''ATM-TRK (Circuit Emulation Service Circuit Pack)''.

NOTE:
TN230x circuit packs are not interchangeable. Always replace an ATM circuit pack with the same type.

This MO (ATM-DCH) utilizes the existing ISDN-PLK or D-channel maintenance strategy with modifications. The ATM circuit pack can be administered for up to 8 Circuit Emulation Service (CES) or signaling groups, each with its own D-channel, as opposed to one D-channel for an entire DS1 circuit pack.

NOTE:
Due to the dual personalities and the number of D channels the ATM board can possess, the in-line errors and signaling port LAN loopback test have been moved to the maintenance object ATM-TRK. When an in-line error is sent due to PACKET BUS errors, the ATM circuit pack maintenance object receives the error, not ATM-DCH.

The D-channel ISDN-PRI interface, which is emulated for ATM-CES, uses out-of-band signaling to transmit control messages between two endpoints. User information or bearer channels (B-channels) carry digitized voice and digital data and are assigned to DS1 ISDN trunks or PRI endpoints. Call control signaling for the B-channels is combined and carried over the separate ISDN-PRI Signaling Link Port D-channel.

Problems with ATM-DCH affects all of the associated B-channels, since call control signaling cannot reach the far-end switch or terminal adapter. Stable calls may remain operational, but no new calls can be made. ATM-DCH in turn depends on the TN230X ATM Trunk circuit pack it resides on and the packet bus which provides the link to the processor.

When working ATM-DCH alarms or errors, also investigate

- ''ATM-TRK (Circuit Emulation Service Circuit Pack)''
- ''PKT-BUS (Packet Bus)''

Hardware Error Log Entries and Test to Clear Values

Table 9-76. ATM D-channel Error Log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp[2]
18 (a)	0	busyout port *UUCSSpp*	WARNING	OFF	release port UUCSSpp
130 (b)		None	WARNING	ON	test port UUCSSpp
1793 (c)		Signaling Link Board Check (#643)			test board UUCSS l

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. pp is for ports 9-32.

Notes:

a. Error Type 18: D-channel busied out; no calls possible over this D-channel.

b. Error Type 130: circuit pack removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. Error Type 1793: ATM Trunk circuit pack failed the Signaling Link Board Check (#643). Resolve any ATM-TRK errors in the Error Log.

System Technician-Demanded Tests: Descriptions and Error Codes

The command to test the ATM-DCH maintenance object is **test port UUCSSpp**, where pp is for ports 9-32.

Table 9-77. System Technician-Demanded Tests: ATM-DCHL

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Signaling Link Board Check (#643)	X	X	ND

1. D = Destructive, ND = Non-destructive

Signaling Link Board Check (#643)

This nondestructive test checks the health of the ATM TN230X Trunk circuit pack hardware. The test runs on a periodic or scheduled basis, during initialization testing, and upon demand.

NOTE:
The board-level maintenance is handled independently of the ATM-CES signaling link maintenance, raising the possibility of inconsistent states.

Table 9-78. TEST #643 Signaling Link Board Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
8	FAIL	The TN230X circuit pack is not in-service. 1. Check the Error Log for ATM-TRK errors and resolve any using ''ATM-TRK (Circuit Emulation Service Circuit Pack)''.
	PASS	The ATM TN230X circuit pack is in-service.

ATM-EI (Expansion Interface Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ATM-EI	MAJOR	test board UUCSS	ATM Expansion Interface Circuit Pack
ATM-EI	MINOR	test board UUCSS	ATM Expansion Interface Circuit Pack
ATM-EI	WARNING	test board UUCSS	ATM Expansion Interface Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

This maintenance object covers the ATM circuit pack administered as an ATM-Port Network Connectivity (PNC) Expansion Interface (ATM-EI). The ATM-EI provides PNC between a DEFINITY PPN and all the EPNs through the ATM switch.

The circuit packs listed in Table 9-79 are ATM-EI boards *if they are administered to serve the ATM Port Network Connectivity (ATM-PNC) for DEFINITY*.

Table 9-79. ATM-EI circuit packs for R8

Circuit pack	Fiber	Echo cancellation
TN2305	Multi mode	Y
TN2306	Single mode	Y

NOTE:
TN230x circuit packs are not interchangeable. Always replace an ATM circuit pack with the same type.

NOTE:
ATM switch maintenance is not covered in this section. When DEFINITY ECS maintenance software suspects the ATM switch connections, it raises appropriate DEFINITY alarms.
To clear any ATM switch faults, refer to the particular ATM switch's documentation.

LEDs

The ATM Interface circuit pack has three LEDs:

- red indicates some alarm condition
- green indicates maintenance testing in progress
- yellow provides useful visual information regarding the operating mode of the ATM-EI and possible error conditions.

The possible LED states are in Table 9-80.

Table 9-80. ATMInterface LED codes

LED	LED status	Condition
Red	Steady on	Board is not healthy
	Never on	Normal conditions
Red and Green	Red LED solid on Green LED 200 ms on; 200 ms off	Board is in the processes of booting
Green	Steady on[1]	Maintenance is running tests on the board
	100 ms on - 100 ms off	No links to the board
Yellow	100 ms on -100 ms off	Fiber Loss of Signal (LOS), LOF, MS_RDI, MS_AIS, LCD, HP_RDI, HP_AIS, LOP, PSC (See Table 9-84)
Yellow	500 ms on; 500 ms off	Signal to the ATM switch is down
Yellow	2 s on; 0.2 s off	ATM-EI is Expansion Archangel (EAA)
Yellow	Steady on	ATM-EI active (PPN)
Yellow	Never on	ATM-EI standby

1. The green LED flashes between tests.

ATM-EI-related commands

The following commands may be helpful in resolving ATM-EI problems:

add atm pnc	list measurements atm
busyout/release atm pnc	remove atm pnc
busyout/release board	reset board
change system-parameters customer-options (atm pnc)	status atm-pnc
change atm pnc (pnc duplication)	status cabinet
display atm pnc	status port-network
list atm oam-statistics	test board
list atm pnc	

Replacing an ATM-EI circuit pack

Standard Reliability

1. Enter **busyout atm-pnc #** (this will affect service) at the DEFINITY SAT.
2. Replace the ATM-PNC circuit pack and re-connect the fiber.
3. Enter **release atm-pnc**.
4. Wait 2.5 minutes for board insertion.
5. Enter **list sys-link** to verify that the links are up.
6. Enter **test board UUCSS** and verify that all tests pass.

High Reliability

There are 2 ATM-EI circuit packs in the PPN, 1 in the EPN.

1. Enter **busyout atm pnc #** at the DEFINITY SAT.

NOTE:
If the ATM-EI is in an EPN, this will affect service.

2. Replace the circuit pack.
3. Enter **release atm pnc**.
4. Wait 2.5 minutes for board insertion.
5. Enter **list sys-link** to verify that the links are up.
6. Enter **test board UUCSS** and verify that all tests pass.

Critical Reliability

There are 2 ATM-EI circuit packs in the PPN, 2 in the EPN.

1. Enter **status pnc** at the DEFINITY SAT. If the board is on the active side, enter **reset pnc interchange** to switch the active ATM-EI board to the standby side.
2. Enter **busyout pnc-standby**.
3. Enter **busyout atm-pnc #** ***a-pnc*** or ***b-pnc***.
4. Replace the circuit pack.
5. Enter **release atm pnc #**.
6. Enter **release pnc-standby**.
7. Wait 2.5 minutes for board insertion.
8. Enter **test board UUCSS** and verify that all tests pass.

Basic ATM PNC administration

NOTE:
This section contains basic administration information only. Refer to *DEFINITY ECS Installation, Upgrade, and Administration for ATM* for more detailed information.

ATM PNC connections involve administering

- 1 ATM-EI board in each Port Network (Standard Reliability)
- 2 ATM-EI boards in the PPN; 1 in each EPN (High Reliability)
- 2 ATM-EI boards in every Port Network (Critical Reliability)

Adding ATM PNC connections

Standard Reliability

1. If the ATM-EI circuit pack is not present or if the circuit pack is present but is in an EPN, use the **change circuit-pack** command to add circuit pack translation.
2. Enter **add atm pnc** ***n*** (connection number), and administer the circuit pack location and ATM address.

Critical Reliability

1. Enter **change system-parameters duplication** and change the `Enable Operation of PNC Duplication` field to **n**.
2. If the ATM-EI circuit pack is not present or is present but it is in an EPN that does not yet have PNC connectivity to it, use the **change circuit-pack** command to add circuit pack translation for the missing circuit pack.
3. Enter **add atm pnc *n*** (connection number), and administer the circuit pack location and ATM address.
4. Enter **change system-parameters duplication** and change the `Enable Operation of PNC Duplication` field to **y**.

Removing ATM PNC connections

Standard Reliability

NOTE:
Standard Reliability systems are *not* equipped with PNC duplication.

1. Enter **busyout atm-pnc *n*** (connection number)
2. Enter **remove atm-pnc *n*** (connection number)

Critical Reliability

1. Enter **status pnc** and ensure that the A-PNC is active. If it is not active, request a PNC interchange using the **reset pnc interchange** command.
2. Enter **busyout pnc-standby**.
3. Enter **change system-parameters duplication** and change the `Enable Operation of PNC Duplication` field to **n**.
4. Enter **busyout atm-pnc *n*** (port network number).
5. Enter **remove atm pnc *n*** (port network number) to remove both ATM-EI boards, or enter **change atm pnc** to remove the B-side ATM-EI board.
6. Enter **change system-parameters duplication** and change the `Enable Operation of PNC Duplication` field to **y**.

Changing circuit pack location or ATM address

Standard Reliability

NOTE:
Standard Reliability systems are *not* equipped with PNC duplication.

1. Remove the ATM PNC connection (see “Removing ATM PNC connections” above).
2. Add an ATM PNC connection (see “Adding ATM PNC connections” above).

A-side ATM-EI — Critical Reliability

1. Remove the ATM PNC connection (see "Removing ATM PNC connections" above).
2. Add an ATM PNC connection (see "Adding ATM PNC connections" above).

B-side ATM-EI — Critical Reliability

1. Enter **status pnc** and ensure that the A-PNC is active.

   If it is not active, request a pnc interchange using the **reset pnc interchange** command.
2. Enter **busyout pnc-standby**.
3. Enter **list config car** and verify that an ATM circuit pack is administered for the new location. If it is not, add the ATM circuit pack translations.
4. Enter **busyout atm pnc *n*** (connection number) **b-pnc**.
5. Enter **change atm pnc *n*** (connection number) and change circuit pack location for the B side.
6. Enter **release pnc-standby**.

Changing ATM address of a Standby ATM-PNC EI — Critical Reliability

1. Enter **busy pnc-standby**.
2. Enter **change atm pnc *n*** (connection number) and change the ATM address for the standby side.
3. Enter **release pnc-standby**.

Error Log Entries and Test to Clear Values

Table 9-81. ATM-EI Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value

Table 9-81. ATM-EI Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3842 (v)					
3999 (w)	Any	None			
Any	32767[2]	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Aux Data 32767 for any error log entry indicates that an alarmed ATM-EI was busied out and then released. When this occurs, existing service-affecting alarms must be preserved. Typically, all alarms are resolved when the ATM-EI is released. Therefore, the Alarm and Error Logs must be repopulated with the alarms present at time of busyout. This Aux Data indicates that existing Error Type and Error Log time stamps are no longer valid because they were lost when the circuit pack was released.

Notes:

a. Error Type 2: on-board DUART chip failed. This results in communication failure between the port network’s maintenance board and the ATM-EI board. The Maintenance circuit pack should have a red LED lit, because the link to the ATM-EI is down in this EPN.

   1. Reset the board with the **reset board UUCSS** command.
   2. If the board does not recover, replace the board.

b. Error Type 18: the ATM-EI circuit pack has been busied out.

   1. Release the circuit pack (**release board UUCSS**).

c. Error Type 23: an ATM-EI circuit pack has been administered with the **add atm-pnc *n*** command, but the circuit pack has not been inserted into the system.

   1. Insert an ATM-EI circuit pack at this location.

d. Error Type 125: a wrong circuit pack is located in the slot where the ATM-EI circuit pack is logically administered.

   1. Either remove the wrong circuit pack and insert the ATM-EI circuit pack or remove the ATM-EI administration (see “Basic ATM PNC administration”).
   2. Remove the ATM-INTF administration and re-administer the slot (**change circuit-pack**) to match the circuit-pack that is physically present in this slot.

e. Error Type 131: an ATM-EI circuit pack has been removed from the slot for 5 minutes.

1. Insert the ATM-EI circuit pack into its administered slot.
2. Another way to resolve or prevent this alarm is to remove the ATM-EI administration (see "Basic ATM PNC administration"), then remove the ATM-INTF administration (**change circuit-pack**).

It is possible that the ATM-EI could be held in reset by the EPN Maintenance board and is not inserted in the system.

1. Try issuing the **test maint P long** command on the maintenance board in the same port network.

f. Error Type 257: Expansion Interface Control Channel Test #316 failed (board cannot communicate on the TDM bus control channel). Follow the suggested test procedures.

Error Type 258: The archangel is out of sequence (Aux Data indicates angel number).

Error type 259: the expansion archangel link (EAL) to the active ATM-EI board is down. See SYS-LINK.

g. Error Type 513: ATM Crosstalk test failed. The board is either writing to or reading from a TDM time slot that is not allocated to the board.

1. Test the board (**test board UUCSS**) and follow the test procedures suggested for this test. In random tests of a single DSP during low or high traffic, the same DSP may be tested more than once.

h. Error Type 769 and 770 (Error Type 771 below): board-degraded alarm errors that result when the ATM switch is sending corrupted cells or excessive AAL/LAPD retransmissions (off-board ATM cell corruption errors). These errors indicate the detection of a problem in handling ATM cells that are received from the fiber interface.

Aux Data:

Error Type	Aux Data	Description
769	34	AAL5 Excessive: retransmission requests
769	35	LAPD Excessive: retransmission requests
770	25	ATM Uncorrectable cell headers - threshold
771	26	VPI,VCI pair unknown

The problem is most likely *not* on the ATM-EI circuit pack reporting the errors, but it could be due to one or more of the following reasons:

- The fiber is not snugly connected to either the board or the ATM switch.
- The PN packet bus is corrupting the cells. See Packet maintenance objects (Aux Data 35 only).

- The fiber between the ATM switch and the ATM-EI is too long (greater than 2km for multimode fiber). Use loopback to see if the fiber is corrupting the cells.
- Some other ATM-EI board is not receiving the cells properly.
- The intervening ATM switch is dropping the ATM cells due to a shortage of bandwidth, or the DEFINITY is using more than the subscribed bandwidth.

Error Type 771: the ATM switch is sending cells with unknown VPI and VCI address (wrong connection).

1. Ensure that the ATM-EI board address on the ATM switch matches the ATM-EI (ATM) address on the DEFINITY side.

i. Error Type 1024-1151: These errors represent problems detected by the ATM-EI board in response to SETUP and ADDPARTY requests from software.

- The Error Types and descriptions are in Table 9-82:
- Aux Data values represent port network and angel numbers and are in Table 9-83.

Table 9-82. ATM Error Types 1024 - 1151

Error Type	Description	General problem
1024	Next node unreachable	ATM protocol stack on ATM-EI circuit pack
1056	DTL Transit not my node ID	
1088 or 1104	ATM-EI circuit pack received a request with an invalid connection identifier.	Firmware-detected problems on the ATM-EI circuit pack. Note: Error Types 1088-1103 are reported by the board that is originating the connection. Error Types 1104-1119 are reported by the board that is terminating the connection. In most cases, when the teminating board reports one of these errors, the originating board will also report an ATM-NTWK error for the same event (usually with Error Type 21).
1089 or 1105	ATM-EI circuit pack received a request with a reference to an unknown VC token.	
1090 or 1106	ATM-EI circuit pack did not have enough resources (memory) for the requested operation.	
1091 or 1107	Internal failure in the local protocol stack. This can occur when the connection to the ATM switch failed, perhaps because the: ■ ATM switch rebooted ■ fiber between the ATM switch and the ATM-EI circuit pack disconnected	
1092 or 1108	ATM-EI circuit pack received a request for which the referenced VC was in the wrong call state.	
1093 or 1109	ATM-EI circuit pack received a request for which the VPI/VCI pair was invalid or out of range.	
1094 or 1110	ATM-EI circuit pack received a request to add a party to an existing VC. The add party request failed, and a retry was not possible.	
1095 or 1111	ATM-EI circuit pack in link recovery after the lower ATM layer (Q.SAAL portion of the protocol stack) failed. This can occur when the connection to the ATM switch failed, perhaps because the: ■ ATM switch rebooted ■ fiber between the ATM switch and the ATM-EI circuit pack disconnected	
1096 or 1112	ATM-EI circuit pack received an error from the local protocol stack for which no more detailed cause was specified.	
1102	ATM-EI circuit pack asked to create more connections that it was capable of creating.	
1103	ATM-EI circuit pack detected an illegal message from software. 1. Check the Error Log for CONN-M proc errors for more information.	
1113		Problems detected by the board terminating the connection

1. Test the ATM-EI circuit pack (**test board UUCSS**) and investigate further based on each test's results. If all tests pass, the error was a transient problem.

Aux Data values: For each connection request failure type, the port network and the angel number of the destination ATM-EI circuit pack are logged Aux Data values in the form XXYYY, where

- port network number = XX
- angel number = YYY

Since you need to know the slot number also, Table 9-83 converts the Aux Data to slot numbers.

Table 9-83. Error Type 1024-1151 Aux Data values (XXYYY) converted to slot number

j. Error type 1153: the ATM connection audit found some discrepancy in the firmware's VC token numbers and live VCs. The problem is rectified in firmware and no action is needed.

k. Error Type 1281: loss of high-level signal indicating operational problems of equipment located outside of the circuit pack and the fiber connected to the board. Aux Data values are listed in Table 9-84.

Table 9-84. Error type 1281 Aux Data and repair procedures

Aux Data	Alarm Description	Repair procedure
15	SYSCLOCK failed	The board is not locked to the TDM backplane clock signal. This is probably due to a Tone Clock problem. 1. Check for TDM-BUS or TONE-BD errors in the Error Log. 2. If no other problems are present, reset the circuit pack (**reset board UUCSS**)
16	Loss of Signal: LOS	The fiber is not connected properly to the ATM-TRK board or ATM switch (or to the multiplexer section [MUX] if present).It is possible that the board transceivers are not functioning properly. 1. Run **test board UUCSS** command. 2. If Test #1259 fails, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. If it does the problem is off-board. 3. If the yellow LED continues to flash, replace the circuit pack.

Continued on next page

Table 9-84. Error type 1281 Aux Data and repair procedures — *Continued*

Aux Data	Alarm Description	Repair procedure
17	Loss of Frame: LOF	The fiber signal cannot obtain or maintain STM-1/OC-3 framing. 1. Try to move the fiber on the ATM switch side to a different port. This may require administration on the ATM switch. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**).
18	Multiplexer Section Alarm Indication Signal: MS_AIS	There is a major problem on the far end (between multiplexer section [MUX] and the switch) that prohibits the circuit pack from sending a valid signal. 1. See if the ports at the MUX and/or the ATM switch are connected snugly. 2. Run **test board UUCSS** command 3. If Test #1259 fails with Error Code 18, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 4. If it does the problem is off-board. 5. If the yellow LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.
19	Multiplexer Section Remote Defect Indicator: MS_RDI	The far-end is detecting a major problem with the signal that this board is transmitting. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface 2. Run **test board UUCSS** command. 3. If Test #1259 fails with Error Code 19, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 4. If it does the problem is off-board. 5. If the yellow LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.
20	Loss of pointer: LOP	ATM framer chip is unable to access the payload part of the signal. 1. Reset the board (**reset board UUCSS**). 2. If the error persists replace the board.

Continued on next page

Table 9-84. Error type 1281 Aux Data and repair procedures — *Continued*

Aux Data	Alarm Description	Repair procedure
21	Path Signal Error (PSL) (STM1/SONET)	The incoming signal payload is not set up for transmission of ATM data. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface.
22	High-level Path Alarm Indication Signal: HP_AIS	The payload is invalid. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface. 2. Run **test board UUCSS**. 3. If Test #1259 fails with Error Code 22, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 4. If it does the problem is off-board. 5. If the yellow LED continues to flash, replace the circuit pack.
23	High-level path Remote defect Indicator: HP_RDI	The far-end is detecting a major problem with the signal that this board is transmitting. The transmitted payload is invalid. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface. 2. Run **test board UUCSS** command; if the Test #1259 fails with Error Code 23, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 3. If it does the problem is off-board. 4. If the yellow LED continues to flash, replace the circuit pack.
24	Loss of cell delineation (LCD)	On board ATM framer chip is not able to frame cells based on the cell header. 1. Reset the board (**reset board UUCSS**). 2. If the error persists, replace the board.

Continued on next page

Table 9-84. Error type 1281 Aux Data and repair procedures — *Continued*

Aux Data	Alarm Description	Repair procedure
27	SIGCON_DOWN ATM switch high level signal.	The board cannot communicate with the ATM switch. 1. Busyout the board (busyout board UUCSS). 2. Test the board (**test board long UUCSS**). 3. If Test #1260 fails, replace the board. 4. If Test #1260 passes, make sure the ATM address on both the DEFINITY and the ATM switch sides are the same for this board. 5. If the address is the same, change the port on the ATM switch side. This may require administration on the ATM switch. 6. If the error is resolved, the problem is on the ATM switch port.

l. Error Type 1537: LAN bus time out. The circuit pack is transmitting a packet larger than 1,024 bytes. Replace the circuit pack.

m. Error Type 1538: A hyperactive ATM-EI circuit pack is generating an abnormal amount of control messages to the processor. When this error is generated, the system automatically resets the ATM-EI.

Duplicated PNC?	Then:
Y	service to the EPN is disrupted
N	the system switches to the standby PNC

1. Enter the **reset board UUCSS** command for this ATM-EI circuit pack.
2. If the same error persists, replace the ATM-EI circuit pack.

n. Error Type 1793: LANHO transmit FIFO overflow error (the transmit FIFO RAM buffers on the circuit pack overflowed). This most likely indicates a hardware problem on the circuit pack, because the speed of the LAN/Packet Bus is much higher than the speed of the link connected to the port.

1. Test this ATM-EI circuit pack (**test board UUCSS**).
2. If Test #598 fails again, replace the ATM-EI circuit pack.

o. Error Type 2049, 2050: the ATM-EI is out of lock with the backplane system clock.

1. Test this ATM-EI circuit pack (**test board UUCSS**).
2. If Test #304 fails, follow the repair procedures suggested for this test.

p. Error Type 2305: too many parity errors on data received from the LAN/Packet Bus (could be due to packet bus problems).

1. Test the ATM-EI circuit pack (**test board UUCSS**).
2. If Test #598 fails, follow the repair procedures suggested for this test.
3. If the test passes, look for and resolve any PKT-BUS (Packet Bus) alarms/errors.
4. If there are no PKT-BUS errors and the problem persists, escalate the problem.

Error Type 2309: packet interface chip (LANHO) malfunctioning.

1. Test the ATM-EI circuit pack (**test board UUCSS**).
2. If Test #598 fails, follow the repair procedures suggested for this test.

q. Error Type 2561: ATM-EI 2-way Transmission Failure (circuit pack is having problems creating connections to other port networks in the system).

1. Test the ATM-EI circuit pack (**test board UUCSS**).
2. Follow the repair procedures suggested for Test #241.

r. Error Type 2817, 2818: DSP test failure detected along the circuit path of the ATM-EI circuit pack.

Error Type	Description	Aux Data indicates
2817	DSP test failure	The Aux Data field contains the following information about the failed DSPs: ■ X is the number of talker DSPs ■ Y is the number of listener DSPs ■ Z is the number of echo-cancelling DSPs
2818	One or more DSPs failed	DSP number that has failed

1. Test the ATM-EI circuit pack (**test board UUCSS**).
2. Follow the repair procedures suggested for Test #1258.

s. Error Type 3329: on-board LANHO chip is insane, possibly due to a problem in Packet Bus arbitration, the transmission line frame, or the circuit pack itself. The circuit pack cannot talk to the packet bus.

If the packet bus is alarmed:

1. Resolve PKT-BUS errors, if any. The probability of this error being related to Packet bus problem increases with the number of other circuit packs using the Packet bus that are also displaying this error.

If the Packet Bus is *not* alarmed:

1. Reset the circuit pack (**reset board UUCSS**).
2. If the problem persists, replace the ATM-EI circuit pack.

If the system has a duplicated PNC, and the in-line error received is from an active ATM-EI, the system switches to the standby PNC.

CAUTION:
If the system does not have duplicated PNC, services to the EPN could be disrupted.

t. Error Type 3585, 3586 (Major board alarm): failure of critical components involved in the operation of the circuit pack, and the switch may no longer recognize the circuit pack. If the system has a duplicated PNC and the in-line error received is from an active ATM-EI, the system switches to standby PNC.

CAUTION:
If the system does not have duplicated PNC, services to the EPN could be disrupted.

Error Type 3585:

Aux Data (Error Type 3585 only):

Aux Data	Description
1	ATM framer failure
2	NCE failed (only from ATM-EIs in EPN)
4	TDM_PLD_FAILED
5	DSP_ALL FAILED
6	Receive Network Processor (RNP) failure
7	Transmit Network Processor (TNP) failure
8	MEMORY read/write failure

1. If the board is in a PPN, or if the system has duplicated PNC:
   a. Test the ATM-EI (**test board UUCSS l**).
   b. If Error 3585 is detected again, or if the board is not recognized anymore, replace the ATM-EI circuit pack.

2. If the system does *not* have duplicated PNC, and the circuit pack is in an EPN:
    a. Replace the ATM-EI circuit pack.

Error Type 3586: Framer Looparound Test #1260 failed.

Aux Data (Error Code 3586 only):

Aux Data	Description
2	Packet path failed
3	Circuit path failed
4	TDM loop cannot be created
5	Packet loop cannot be created

1. If Error Type 3586 is detected again, replace the circuit pack.

u. Error Type 3841: the board received a message from the switch that it does not recognize, and the board responded with an inconsistent down link error message. This error does not affect service, and no action is required.

v. Error type 3842: the circuit pack received data from the Packet Bus faster than it could distribute the data to its endpoint. This circuit pack should be able to recover by itself, and no action is necessary.

w. Error Type 3999: circuit pack sent a large number of control channel messages to the switch within a short period of time.

If	Then
Error Type 1538 is also present	Circuit pack is taken out of service
If Error Type 1538 is not present	Circuit pack is *not* taken out of service, but has generated 50% of the messages necessary to be considered hyperactive. ■ This may be normal during heavy traffic. ■ If the error is logged during light traffic, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in Table 9-85 when inspecting the errors in the system. By clearing error codes associated with the Expansion InterfaceTest, for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-85. System Technician-Demanded Tests: ATM-EI

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
Expansion Interface 2way-Transmission Test (#241)	X	X		ND
ATM Board Framer Looparound Test (#1260)		X		D
Expansion Interface Lock Query Test (#304)	X	X		ND
ATM Board Error Query Test (#1259)	X	X		ND
ATM Expansion Interface Reset (#1256)			X	D
ATM board DSP test(#1293) for TN2305 and TN2306 circuit packs.	X	X		ND
ATM Cross Talk test(#1298) for TN2305 and TN2306 circuit packs		X		ND

1. D = Destructive, ND = Non-destructive

NOTE:
To get a better indication of a problem's location, test both ATM-EI circuit packs on the associated fiber link, whether the circuit packs are both ATM-EI circuit packs or not.

Expansion Interface 2-way Transmission Test (#241)

This test is non-destructive and applies to all ATM-EIs, both active and standby. It is run as part of craft short and long testing, periodic, scheduled, initialization, and error analysis testing. The test sets up a connection between a Tone/Clock in one cabinet and a Tone Detector in a separate cabinet and transmits a digital test count between the port networks. The ATM-EIs used to set up this connection are chosen by maintenance, not call processing. After the connection is checked for dial-tone, the connection is torn down and re-established in the opposite direction.

In this test the second ATM-EI may be in any port network outside the port network of the ATM-EI under test. Therefore if the test should fail in any direction, the test is repeated with a different port network, if available, which aids the fault isolation procedure.

The test results indicate if the test failed in one or both directions. The test aborts if the ATM-EIs do not exist on both ends (for example, the EIs are not administered correctly). If the test passes, the TDM and ATM framer interfaces of both ATM-EIs are functioning properly. If the test fails, a series of tests are run on the board. Figure 9-3 shows a schematic of this test.

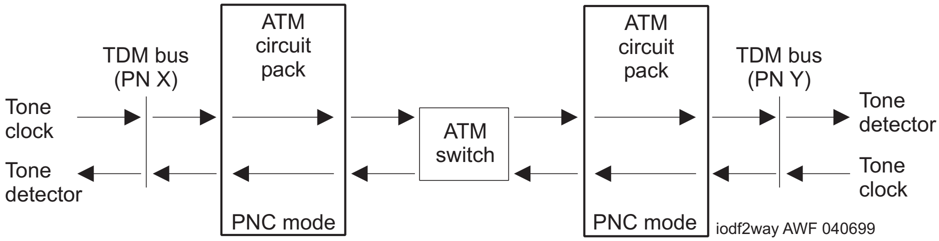

**Figure 9-3. Expansion Interface 2-Way Transmit Test #241
PN X and PN Y represent any of 43 possible port networks.**

Table 9-86. Expansion Interface 2-way Transmission Test (#241)

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out of service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-86. Expansion Interface 2-way Transmission Test (#241) — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out of service. 1. Resolve any TTR-LEV errors. Even if there are not TTR-LEV errors, there may not be a tone detector available on the network that contains the circuit pack being tested. Verify that there is at least one tone detector on this network. If not, this test always aborts for this ATM-EI circuit pack, but does not harm the system. **NOTE:** DEFINITY Systems require that Tone Clock circuit packs (TN2182) must be of vintage “B” or newer. If older Tone Detector circuit packs are installed in the system, this test always aborts with this abort code. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
1033	ABORT	The test cannot run because either the ATM-EI board is not administered, or there were no other PNs administered that had its ATM-EI board in-service. 1. Ensure that the board is administered as ATM PNC Expansion Interface circuit pack. If the board is administered as ATM-EI circuit pack, then there has been some change in the ability of the ATM-EI circuit pack in the other PNs to communicate with the ATM-EI on the other end of its connection. 2. Using **status port *x*** (the port-network number in which the board is administered), see if both ACL and EAL are up to this board. If they are not, see the service procedure for SYS-LINK. 3. Check the Error Log for Error Type 1281 with Aux Data 27 (board cannot talk to the ATM switch). See Table 9-84 for repair procedures. If present, check both the ATM switch and the DEFINITY administrations for consistent ATM addresses. Reset the board and see if the problem resolves. 4. Repeat Test #241. If it continues to abort with this abort code, replace the board.

Continued on next page

Table 9-86. Expansion Interface 2-way Transmission Test (#241) — *Continued*

Error Code	Test Result	Description/ Recommendation
1394	ABORT	1. See Table 9-84 (Error Type 1281) with Aux Data 27 (board cannot talk to the ATM switch), and if present, check both the ATM switch and the DEFINITY administrations for consistent ATM addresses. 2. Reset the board and see if the problem resolves. 3. Repeat the test.
1395	ABORT	This test cannot run on an ATM-EI circuit pack if it is part of the B-side PNC and Duplicated PNC is not enabled. 1. If this test needs to run on this ATM-EI circuit pack, enable PNC with the **change system-parameters duplication** command. 2. Prevent the system from doing a PNC interchange by executing the **set PNC lock** command. 3. Repeat this test.
1413	ABORT	This test requires the use of a Tone/Clock circuit pack in each of the port networks (PN) used in this test. This abort code indicates that a Tone/Clock circuit pack is not present in one of the PNs. 1. Make sure that there is a Tone/Clock circuit pack located in the PN in which the ATM PNC Expansion Interface circuit pack under test is located. 2. In ATM PNC configurations, make sure that there is at least one other PN besides the PN where the ATM-EI circuit pack under test resides that contains a Tone/Clock circuit pack.
1414	ABORT	The active Tone/Clock circuit pack in one of the port networks being used for the test has a MAJOR or MINOR alarm logged against it. 1. Enter **display alarms** and resolve any TONE-BD and TONE-PT alarms.
1956	ABORT	ACL to the board is not up. See ACL status with the **list sys-link** command and follow the repair procedures for SYS-LINK.
2000 2100 2500	ABORT ABORT ABORT	Response to the test request was not received within the allowable time period. System resources required to run this test are not available. Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The test tone was not detected correctly in either direction. 1. Test the active Tone/Clocks on the Port Networks for which the ATM-EI circuit pack under test provides a link. This determines if the dial tone is supplied.

Continued on next page

Table 9-86. Expansion Interface 2-way Transmission Test (#241) — *Continued*

Error Code	Test Result	Description/ Recommendation
10MM	FAIL	The failure codes only apply to a system equipped with an ATM Switch. The letters "MM" refer to the distant or far-end port network (PN), and "NN" to the near-end ATM-EI under test. The test tone was detected correctly in forward direction (data sent from the PN in which the circuit pack under test resides and detected correctly in port network MM), but not the opposite direction. 1. Test the active Tone/Clocks on the "MM" PN and the PN in which the ATM-EI under test resides (test tone-clock UUCSS). This determines if a dial tone is supplied. 2. Ensure that the ATM address of the ATM-EI circuit pack under test matches the ATM address on the ATM switch for the port to which this circuit pack is connected. Refer to the "ATM Tips" section in Chapter 5 for the procedure to check the ATM port address on the ATM switch. 3. Run this Test #241 on the active ATM-EI in port network MM. If this test fails with Error Code 10NN or 30NN, go back to Step 2. If the address was the same, replace the active ATM-EI circuit pack on port network MM. If this test fails with Error Code 20NN or 40NN, replace ATM-EI circuit pack that had the initial problem.
20MM	FAIL	The failure codes only apply to a system equipped with an ATM Switch. The letters "MM" refer to the distant or far-end port network (PN), and "NN" to the near-end ATM-EI under test. The test tone was detected correctly in reverse direction (data sent from the MM port network was detected correctly in the port network in which the circuit pack under test resides, but not the opposite direction). 1. Test the active Tone/Clock on the "MM" PN and the PN in which the ATM-EI under test resides (test tone-clock UUCSS). This determines if dial tone is supplied. 2. Ensure that the ATM address of the active ATM-EI circuit pack under test matches the ATM address on the ATM switch for the port to which this circuit pack is connected. Refer to the "ATM Tips" section in Chapter 5 for the procedure to check the ATM port address on the ATM switch. 3. Run this Test #241 on the active ATM-EI in port network MM. If this test fails with Error Code 20NN or 40NN, go back to Step 2. If the address was the same, replace the active ATM-EI circuit pack on port network MM. If this test fails with Error Code 10NN or 30NN, replace ATM-EI circuit pack with the initial problem.

Continued on next page

Table 9-86. Expansion Interface 2-way Transmission Test (#241) — *Continued*

Error Code	Test Result	Description/ Recommendation
30MM	FAIL	The failure codes only apply to a system equipped with an ATM Switch. The letters "MM" refer to the distant or far-end port network (PN), and "NN" to the near-end ATM-EI under test. The test failed for the first connection from the ATM-EI board under test to another EPN, and the test tone was detected correctly in the forward direction (data sent from the port network in which the circuit pack under test resides was detected correctly in port network MM, but not the opposite direction). 1. Test the active Tone/Clock on the "MM" PN and the PN in which the ATM-EI under test resides (test tone-clock UUCSS). This determines if dial tone is supplied. 2. Ensure that the ATM address of the ATM-EI circuit pack under test matches the ATM address on the ATM switch for the port to which this circuit pack is connected. Refer to the "ATM Tips" section in Chapter 5 for the procedure to check the ATM port address on the ATM switch. 3. Run this Test #241 on the active ATM-EI in port network MM. If this test fails with Error Code 10NN or 30NN, go back to Step 2. If the address was the same, replace the active ATM-EI circuit pack on port network MM. If this test fails with Error Code 20NN or 40NN, replace ATM-EI circuit pack with the initial problem.

Continued on next page

Table 9-86. Expansion Interface 2-way Transmission Test (#241) — *Continued*

Error Code	Test Result	Description/ Recommendation
40MM	FAIL	Failure code only applies to a system equipped with an ATM Switch. The letters "MM" refer to the distant or far-end port network (PN), and "NN" to the near-end ATM-EI under test. The test failed for the first connection from the ATM-EI board under test to another EPN, and the test tone was detected correctly in the reverse direction (data sent from the MM port network was detected correctly in the port network in which the circuit pack under test resides), but not the opposite direction. 1. Test for the Active Tone-Clocks on the MM PN and the PN in which the ATM-EI under test resides. This determines if dial tone is supplied. 2. Ensure that the ATM address of the active ATM-EI circuit pack in port network MM matches the ATM address on the ATM switch for the port to which this circuit pack is connected. Refer to the "ATM Tips" section in Chapter 5 for the procedure to check the ATM port address on the ATM switch. 3. Run this Test #241 on the active ATM-EI in port network MM. If this test fails with Error Code 20NN or 40NN, go back to Step 2. If the address was the same, replace the active ATM-EI circuit pack on port network MM. If this test fails with Error Code 10NN or 30NN, replace ATM-EI circuit pack with the initial problem.
	PASS	Tone successfully transmitted in both directions. Both ATM-EI boards and their lightwave transceivers are functioning properly.
0	NO BOARD	No board was detected by the test. 1. Resolve either wrong board (Error 125) or no board (Error 131) issues. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.

Expansion Interface Lock Query Test (#304)

This test is non-destructive and is used to query the ATM and EI circuit packs (both active and standby) for its status concerning lock to the backplane system clock. It is run as part of periodic, scheduled, initialization, and error analysis testing. When an in-line, “out-of-lock” report comes in, this test is run to check the circuit pack’s status. The ATM-EI responds with “in lock” or “out of lock.” If the response is “in lock,” the test passes; if the response is “out of lock,” the test fails.

Table 9-87. TEST #304 Expansion Interface Lock Query Test (#304)

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The ATM-EI circuit pack responded incorrectly or if it is the EPN active ATM-EI circuit pack, it could not talk to EPN circuit packs. 1. If the active ATM-EI circuit pack in the EPN is failing and duplicated PNC is enabled, attempt to switch to the standby PNC using the **reset PNC interchange** command. 2. Repeat the short test sequence. 3. If test continues to fail, reset the ATM-EI circuit pack with the **reset board UUCSS** command. 4. If the ATM-EI circuit pack in the EPN is failing, enter **display errors** and **display alarms** and follow the associated repair procedures for TDM-CLK, TONE-BD, or SYNC alarms/errors and repeat the Short Test Sequence. 5. If test continues to fail, replace the circuit pack or transceiver.
	PASS	Communication from software to the ATM-EI circuit pack is functioning correctly.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the NCE chip on board may be bad. Replace the board and retest.

Expansion Interface Control Channel Test (#316)

This test is non-destructive. If an ATM-EI circuit pack is an *active* ATM-EI in the EPN (yellow LED on long/off short), the Expansion Interface Control Channel test checks to see if the ATM-EI circuit pack can communicate with other circuit packs in the EPN using the EPN TDM bus.

If the circuit pack is a *standby* ATM-EI (yellow LED off) or if the ATM PNC Expansion Interface is in the PPN (yellow LED on), this test queries the ATM PNC Expansion Interface circuit pack for its circuit pack type and vintage information.

Table 9-88. Expansion Interface Control Channel Test #316

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
	FAIL	The ATM-EI circuit pack responded incorrectly or if it is the EPN active ATM-EI circuit pack, it could not talk to EPN circuit packs. 1. If the active ATM-EI circuit pack in the EPN is failing and duplicated PNC is enabled, attempt to switch to the standby PNC using the **reset PNC interchange** command. 2. Repeat the short test sequence. 3. If test continues to fail, reset the ATM-EI circuit pack with the **reset board UUCSS** command. 4. If the ATM-EI circuit pack in the EPN is failing, enter **display errors** and **display alarms** and resolve any TDM-CLK, TONE-BD, or SYNC alarms/errors and repeat the Short Test Sequence. 5. If test continues to fail, replace the circuit pack or transceiver.
	PASS	The ATM-EI circuit pack did respond correctly to test. Communication from software to the ATM-EI circuit pack is functioning. 1. Refer to other ATM-EI circuit pack tests if the link is not functioning correctly.

Continued on next page

Table 9-88. Expansion Interface Control Channel Test #316 — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	No board was detected by the test. 1. Resolve any wrong board (Error 125) or no board (Error 131) issues. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the NCE chip on board may be bad. Replace the board and retest.

Packet Interface Test (#598)

This test is non-destructive and attempts to send a data packet from the TN1655 Packet Interface circuit pack through any ATM PNC Expansion Interface circuit packs. The path the data packet takes depends on the location of the ATM-PNC Expansion Interface circuit pack being tested and whether the system has duplicate Port Network Connectivity.

The Packet Interface Looparound test checks the Packet Bus interface circuitry on this board. The on-board LANHO chip sends a data stream to the bus, retrieves it back, and checks for its consistency. If the data is consistent, the test passes; otherwise, it fails. The test aborts if the Packet Bus in the specified port network has a minor alarm active, is out of service, or if the Packet Bus in the PPN is out of service. This test runs as a part of initialization, periodic, scheduled, error analysis, and demand test sequences. Figure 9-4 shows a schematic of the test.

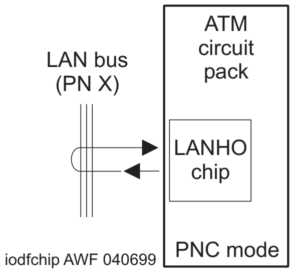

Figure 9-4. Packet Interface Test (#598)

Table 9-89. Packet Interface Test (#598)

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 3 retries. 2. If the test fails repeatedly, attempt to reset the circuit pack. 3. If the test continues to fail, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
ANY	FAIL	The transmitted data packet was not received correctly by the Packet Interface circuit pack. The failure may be in the ATM-EI under test, the DS1 CONV circuit packs, or the intervening Center Stage components. 1. Retry the command at 1-minute intervals a maximum of five times 2. If the test continues to fail, replace the circuit pack.
	PASS	The Packet Interface Test passed.

ATM Board Error Query Test (#1259)

This test is non-destructive. The ATM circuit pack firmware maintains counters for some of the on-board and off-board errors. The maintenance software queries the board for its health information to do error analysis. These alarms have assigned priority: if a higher priority alarm occurs, the remaining alarms are not reported to the software (through the inline errors), avoiding unnecessary up-link, in-line error message traffic. This is run as a part of a craft demand test sequence periodic testing, initialization, and error analysis.

Table 9-90. ATM Board Error Query Test (#1259)

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 3 times.
XXYY	FAIL	On-board hardware or off-board signalling errors on the board. XX indicates the on-board hardware error, and YY indicates the off-board errors on the as shown in Table 9-91. 1. Resolve any errors in error logs.
	PASS	No service effecting errors or alarms were detected on the circuit pack.
0	NO BOARD	No board was detected by the test. 1. Check the Error Log for wrong board (Error Type 125) or no board (Error Type 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error Type 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the NCE chip on board may be bad. Replace the board and retest.

Table 9-91. XXYY Error Codes for Test #1259 (ATM Board Error Query Test)

XX Aux Data	Description
1	ATM framer chip failed
2	NCE chip failed
3	LANHO critical error
4	TDM Prog. logic device failed
5	All on-board DSPs failed
6	Receive network processor failed
7	Transmit network processor failed
8	Memory read failed

Continued on next page

Table 9-91. XXYY Error Codes for Test #1259 (ATM Board Error Query Test) — *Continued*

XX Aux Data	Description
9	Dual UART chip failed
10	LANHO receive parity error
11	LANHO FIFO overflow error
12	LAN Bus timeout
13	LANHO Xmit FIFO overflow
14	One or more on-board DSPs failed
YY Aux Data	**Description**
15	Backplane clock failed
16	Loss of signal
17	Loss of frame
18	Multiplexer Section Alarm indication signal error
19	Multiplexer Section remote defect indicator error
20	Loss of pointer
21	Path signal level mismatch
22	High level path alarm indication signal
23	High level path remote defect indicator
24	Loss of cell delineation
25	Uncorrectable headers sent by the ATM switch
26	Too many cells with invalid Virtual Path Indicator (VPI)/Virtual Circuit Indicator (VCI) combination
27	The signalling link between the board and the ATM switch is down.
28	Board to the ATM switch connection is down
34	AAL5 (ATM signalling protocol) excessive retransmission requests
35	LAPD excessive retransmission requests

ATM Board Framer Looparound Test (#1260)

This test is destructive.

NOTE:
This test can be run on the standby PNC only if the board is busied out.

This test places the ATM circuit pack in ATM framer looparound mode. Once the board receives this message, it creates a dummy virtual circuit that originates and ends on the same board, without leaving the board. This test verifies both the TDM path and the Packet Path. If the TDM test path passes, then the packet path is tested. Definitions of each test path are:

— ***The circuit (TDM) path***: one of the tone generators sends a bit pattern through a TDM bus time slot to the ATM framer. The pattern is converted into ATM cells and looped back to the ATM-EI board, which converts the cell back into the bit pattern and puts it on a pre-determined time slot. A tone detector tests for the bit pattern and reports the test result. This test verifies that a large portion of the ATM-EIs circuit paths are functioning correctly. Figure 9-5 shows a diagram of the test.

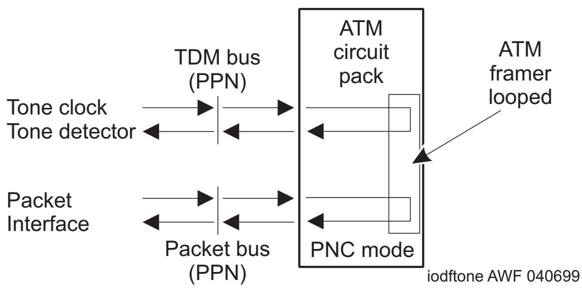

Figure 9-5. ATM Board Framer Looparound Test (#1260)

— ***Packet path***: the Packet Interface circuit pack sends packet data to the ATM framer interface, where it is mapped into ATM cells and then looped around internally. The cells are converted back to packet data after it has been looped. This portion of the test verifies correct operation of the ATM-EI's Packet bus interface and a large portion of the ATM-EI's packet paths. Figure 9-6 shows the packet switched signal path for the ATM circuit pack.

This test verifies the operation of a large portion of the ATM-EI circuit and packet paths, but does not verify the optical portion of the lightwave transceiver. If this test passes, the ATM-EI circuit pack is functioning correctly, but faults may exist in the lightwave transceiver. If the test fails, the fault may lie on the board. After the test results are reported, the ATM framer is taken out of loopback.

NOTE:
This test may be run on active or standby ATM-EIs, but it is *not* allowed if an ATM-EI is the Expansion Archangel.

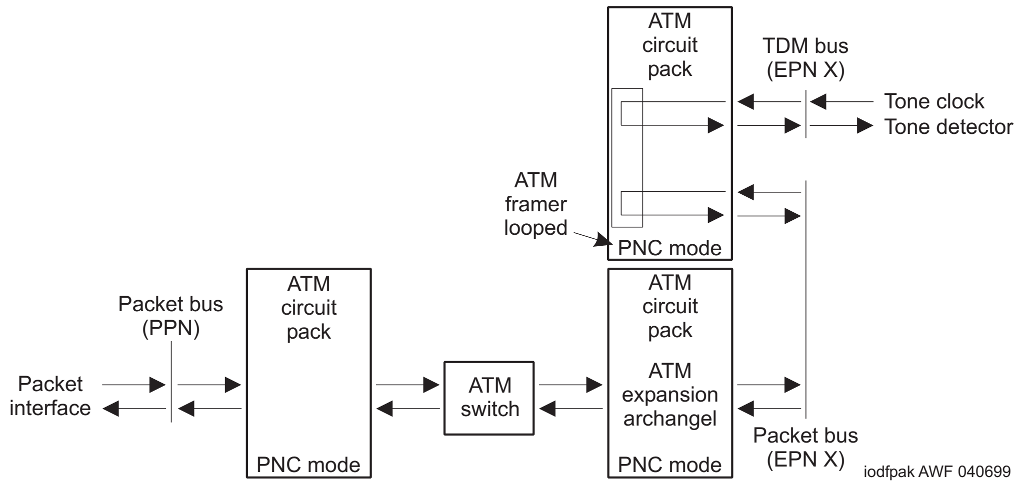

Figure 9-6. ATM Board Framer Looparound Test (#1260) (non-EAA, Packet Path)

Table 9-92. ATM Board Framer Looparound Test (#1260)

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-92. ATM Board Framer Looparound Test (#1260) — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out of service. 1. Resolve any TTR-LEV errors. Even if there are no TTR-LEV errors, there may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. If there is not at least one Tone Detector, this test always aborts for this ATM-EI board. This will not harm the system. **NOTE:** DEFINITY Systems require that Tone Clock circuit packs (TN2182) must be of vintage “B” or newer. If older Tone Detector circuit packs are installed in the system, this test always aborts with this abort code. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
1015	ABORT	The ATM-EI circuit pack has not been busied out. 1. Busyout the ATM-Expansion Interface circuit pack, then repeat the **test board UUCSS long** command.
1031	ABORT	If the ATM Expansion Interface circuit pack is in an EPN and is on the active PNC, this test cannot be executed. 1. If PNC Duplication is enabled, attempt to make the standby PNC active with the **reset pnc interchange** command. 2. If the PNC Interchange is successful, rerun the test.
1033	ABORT	The ATM-EI circuit pack is not present. 1. Issue the **list atm-pnc** command to verify that switch recognizes the circuit pack. 2. Retry the command.
1139	ABORT	The packet bus in the EPN where this ATM-EI board is located has a major alarm against it. This test needs to use the alarmed port network’s Packet Bus. 1. Resolve any PKT-BUS problems. 2. Retry the command.
1141	ABORT	The Packet Interface circuit pack is out of service. 1. Resolve any PKT-INTF problems.

Continued on next page

Table 9-92. ATM Board Framer Looparound Test (#1260) — *Continued*

Error Code	Test Result	Description/ Recommendation
1144	ABORT	The Packet Bus in the PPN has a major alarm against it. This test needs to use the alarmed PPN packet bus. 1. Resolve any PKT-BUS problems. 2. Retry the command.
1394	ABORT	The ATM-EI board is out of service and the test cannot be run. This condition is due to a change in the ATM-EI board's ability to communicate with the ATM switch. 1. Run Test #241. If it does not pass, refer to repair procedures for "Expansion Interface 2-way Transmission Test (#241)".
1395	ABORT	This test cannot be run on an ATM-EI circuit pack if it is part of the B-side PNC and duplicated PNC is not enabled. 1. If this test needs to run on this ATM-EI circuit pack, enable PNC duplication with the **change system-parameters duplication** command. 2. Prevent the system from doing a PNC interchange by executing the **set PNC lock** command. 3. Repeat this test.
1407	ABORT	This test cannot be run on an ATM-EI board that is on the active PNC because it cannot be busied out. This error code indicates that PNC duplication is enabled. 1. Attempt to perform a PNC interchange with the **reset pnc interchange** command. 2. If the PNC interchange is successful, busy out the original ATM-Expansion Interface circuit pack with the **busyout board UUCSS** (address of the original ATM-EI board) command. 3. Retry the command.
2000	ABORT	Response to the test was not received in the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2060	ABORT	The link on the packet bus being used to perform the test has failed. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to abort, resolve any PKT-INTF errors.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-92. ATM Board Framer Looparound Test (#1260) — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The test did not detect the test tone through the looparound connection. **NOTE:** The packet portion of this test was not run since the circuit portion failed. 1. Test the active Tone/Clock (**test tone-clock UUCSS**) on the PN that contains the defective ATM-EI circuit pack to verify that dial tone is being supplied. 2. If the Tone/Clock is healthy, test the ATM-EI circuit pack (**test board UUCSS long**). 3. If this test continues to fail, replace the ATM-EI circuit pack or transceiver. 4. Test the new ATM-EI circuit pack (**test board UUCSS long**).
2	FAIL	The test tone was transmitted and detected correctly, but the correct data packet was not detected by the Packet Interface circuit pack. 1. Test the Packet Interface circuit pack to verify that it is functioning properly. If any tests fail, investigate those tests and repair the Packet Interface circuit pack. 2. If the Packet Interface circuit pack is OK, resolve any DS1 CONV-BD alarms or errors (if so equipped). 3. Test the ATM-EI circuit pack (**test board UUCSS long**). 4. If this test continues to fail, replace the ATM-EI board. 5. Test the new ATM-EI circuit pack (**test board UUCSS long**).
3	FAIL	The test tone was transmitted correctly, but the returned tone was distorted. 1. If the Tone/Clock is healthy, test the ATM-EI circuit pack (**test board UUCSS long**). 2. If this test continues to fail, replace the ATM-EI circuit pack. 3. Test the new ATM-EI circuit pack (**test board UUCSS long**).
4	FAIL	Unable to create loop for TDM path for this test. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If this test continues to fail, replace the ATM-EI circuit pack. 3. Test the new ATM-EI circuit pack (**test board UUCSS long**).

Continued on next page

Table 9-92. ATM Board Framer Looparound Test (#1260) — *Continued*

Error Code	Test Result	Description/ Recommendation
5	FAIL	Unable to create loop for packet path for this test. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If this test continues to fail, replace the ATM-EI circuit pack. 3. Test the new ATM-EI circuit pack (**test board UUCSS long**).
6	FAIL	A previously-established looparound was not released. 1. Issue the **reset board UUCSS** command. 2. Retry the command at 1-minute intervals a maximum of 3 times. 3. If this test continues to fail, replace the ATM-EI circuit pack. 4. Test the new ATM-EI circuit pack (**test board UUCSS long**).
	PASS	The ATM-EI board is functioning properly, however this test does not verify that the optical portion of the lightwave transceiver is functioning.
0	NO BOARD	No board was detected by the test. 1. Resolve either wrong board (Error 125) or no board (Error 131) issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the NCE chip on board may be bad. Replace the board and retest.

ATM Board Time Of Day Update (#1261)

This test is non-destructive. The ATM circuit pack requires a reference time to do SDH/SONET performance monitoring. This test updates the system time to the board and synchronizes the board with the DEFINITY system clock during initialization, scheduled maintenance, and craft long test.

Table 9-93. ATM Board Time Of Day Update (#1261)

Error Code	Test Result	Description/ Recommendation
2031	FAIL	The attempt to send the message to the ATM-EI circuit pack was not successful.
2500	FAIL	Did not send the time of day information to the board. 1. Retry the command at 1-minute intervals a maximum of 3 times.
	PASS	The ATM-EI circuit pack is successfully updated with system time. 1. If the **status port-network** command still indicates that this link is down, it is possible that one or both of the ATM-EI circuit packs have been busied out. 2. If the link still does not come up, reset one or both ATM-EI circuit packs on the link.
0	NO BOARD	No board detected. 1. Resolve either wrong board (Error 125) or no board (Error 131) issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the NCE chip on the circuit pack may be bad. Replace the pack and retest.

ATM Board Reset (#1256)

This test is destructive. If the ATM-EI board is in the PPN or is a standby in the EPN, the reset is done through the SAKI reset interface. If the ATM-EI is an Expansion Arch Angel (active ATM-EI board in the EPN) a special message is sent to the board over the EAL if the EAL is present.

Table 9-94. ATM Board Reset (#1256)

Error Code	Test Result	Description/ Recommendation
1386	ABORT	No Active EAL to the board. This error applies only if the board under test is in EPN. Check the error logs for SYS-LINK errors against the port network in which the ATM-EI is residing and take appropriate diagnostic action for the SYS-LINK.

Continued on next page

Table 9-94. ATM Board Reset (#1256) — *Continued*

Error Code	Test Result	Description/ Recommendation
1015	ABORT	This test cannot be run because the ATM-TRK circuit pack has not been busied out. 1. Busyout the ATM circuit pack, then repeat the **test board UUCSS long** command.
1407	ABORT	1. Perform a PNC Interchange 2. Try to reset the board again.
None	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort escalate the problem.
2000	ABORT	Did not receive the SANITY response in the given time. 1. Wait for 5 minutes and see if board is visible to the system by using list config all command. 2. If the board is visible, run the test again. If same abort code results, escalate the problem. 3. If the board is not visible to the system via list config all command, re-seat the board. 4. If the board is still not recognized by the system, replace the board.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500	ABORT	Internal system error 1. Try to reset the board again.
1	FAIL	The circuit pack failed to reset
2	FAIL	The circuit pack failed to restart. 1. Execute command again. 2. If the problem persists, replace the circuit pack.
	PASS	The ATM-EI circuit pack is successfully reset. 1. If the **status port-network** command still indicates that this link is down, it is possible that one or both of the ATM-EI circuit packs are busied out. 2. If the links do not come up after reset, review the error logs and take appropriate diagnostic action.

ATM Cross Talk Test (#1298)

This test is non-destructive. The ATM board Cross Talk test verifies that the selected TDM bus time slot never crosses over to time slots reserved for other connections. The test also checks for cross connections, where the board talks to time slots other than those specified. Since this test uses many system resources (TDM time slots, tone generator, tone detector, and others), it runs as a part of demand test only.

This test fails if either the TDM programmable logic and/or the interface to the DSP is not operating properly. Failure of these components may result in one-way or noisy connections. Refer to Figure 9-7 for a schematic of this test.

NOTE:
Note: This test takes approximately 12 minutes and applies only to TN2305 and TN2306 circuit packs.

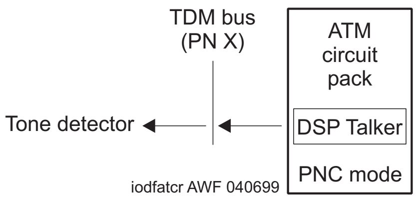

Figure 9-7. ATM Cross Talk Test #1298 schematic

Table 9-95. ATM Crosstalk Test (#1298)

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-Bus errors. Refer to TDM-BUS to diagnose these errors. 1. If system has no TDM-Bus errors and is not handling heavy traffic, repeat test at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-95. ATM Crosstalk Test (#1298) — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors in the Error Log. 2. Resolve any TONE-PT errors in the Error Log. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1962	ABORT	All the TALKER DSPs are busy (an unlikely event). 1. Retry the command at 1-minute intervals a maximum of 3 times.
2302	ABORT	Inconsistent uplink message from the ATM-EI board. This is a very unlikely event. 1. Retry the command at 1-minute intervals a maximum of 3 times.
2752	ABORT	The circuit pack in this location is not a TN230X.
1-8, None	FAIL	The board is writing to unauthorized TDM time slots. The error code indicates the number of faulted TALKER DSPs. 1. Retry the command a maximum of 3 times. 2. If the failure persists, replace the circuit pack.
1-8	PASS	The board is not talking to unauthorized time slots on the TDM Bus. The error code indicates the number of TALKER DSPs that were tested.

ATM Board DSP Test (#1293)

This test is non-destructive and is designed to test the board's interface to the TDM bus and the functions of all 24 on-board DSPs (Digital Signal Processors). There are three functional types of DSPs:

- talkers - put data on the TDM bus
- listeners - take data off the TDM bus
- echo cancelers - as implied

Listener and echo cancelers are tightly coupled because firmware allocates *sets* of DSPs. Since there are a total of 24 DSPs on the board, there may be up to 8 triplets allocated.

If the test fails for all DSPs, a MAJOR alarm is raised against the board. If the test fails for one or more DSPs, a MINOR alarm is raised. If a DSP is "busy," the test for that particular DSP is considered passed. The test aborts if the system resources (for example, the TDM time slots, tone generator, and others) are not available.

This test applies to TN2305 and TN2306 ATM-EIs, both active and standby, and is run as part of craft short and long testing, periodic, scheduled, initialization, and error analysis testing. Refer to Figure 9-8 for a diagram of this looparound test.

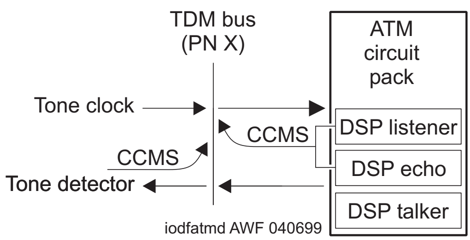

Figure 9-8. ATM Board DSP Test (#1293)

Table 9-96. ATM Board DSP Test (#1293)

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out of service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 3 times.

Continued on next page

Table 9-96. ATM Board DSP Test (#1293) — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out of service. 1. Resolve any TTR-LEV errors. Even if there are no TTR-LEV errors, there may not be a tone detector available on the network that contains the circuit pack being tested. Verify that there is at least one tone detector on the network. If not, this test always aborts for this ATM-EI circuit pack and does not harm the system. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 3 times.
1962	ABORT	All DSPs are busy (an unlikely event). 1. Retry the command at 1-minute intervals a maximum of 3 times.
2000	ABORT	Response to the test was not received within the allowable time period for some of the DSPs. 1. If the board is in standby, reset the board and run the test again. 2. Look into the Error Log for Error Type 1218 (bad DSP). If Error Type 1218 is not logged against this board, run the DSP test again and see if the error persists.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2302	ABORT	Inconsistent uplink message from the ATM-EI board (an unlikely event). 1. Retry the command at 1-minute intervals a maximum of 3 times.
2500	ABORT	Internal system error
2752	ABORT	The circuit pack in this location is not a TN230X.

Continued on next page

Table 9-96. ATM Board DSP Test (#1293) — *Continued*

Error Code	Test Result	Description/ Recommendation
XYZ	FAIL	A device on the circuit pack is failing. There is at least one bad DSP on the board. Values are as follows: ■ The X value indicates the number of talker DSPs ■ Y indicates the number of listener DSPs ■ Z indicates the number of Echo Canceler DSPs that have failed the test. 1. Run the tests for the active Tone-Clock on the PN that contains the indicted ATM-EI circuit pack to verify that dial-tone is supplied. 2. If the tone-clock is healthy, repeat the short test on the ATM-EI board. 3. If this test continues to fail, replace the ATM-EI circuit pack.
XYZ	PASS	The test passed for some or all DSPs depending on XYZ values. XYZ indicates the number of talker, listener and echo-canceler DSPs for which the test passed, respectively. In the DSPs that passed the test, the test tone was correctly detected by the DSP Listener and by tone-detector for the DSP Talkers on both busses, and the Echo Canceler DSPs are working properly.
0	NO BOARD	No board was detected by the test. 1. Check the Error Log for wrong board (Error Type 125) or no board (Error Type 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error Type 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the circuit pack may be bad. Replace the circuit pack and retest.

ATM-INTF (TN2305/6)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ATM-INTF	WARNING	test board UUCSSpp	ATM interface board

The TN2305/6 is recognized by the system as an ATM Interface board (ATM-INTF) if it has not been assigned a personality through the **add atm-pnc** command or **add atm trunk** command. ATM-INTF does not have a maintenance strategy associated with it, although the Control Channel test can be run on demand by using the **test board** command, and the board can be reset by using the **reset board** command. The board is visible through the **list config** and **change circuit-pack** commands.

The circuit packs listed in Table 9-97 are ATM-EI boards if they are administered to serve the ATM Port Network Connectivity (ATM-PNC).

Table 9-97. ATM-EI circuit packs for ATM-PNC

Circuit pack	Fiber	Echo cancellation	Relea se
TN2305	Multi mode	Y	7.1
TN2306	Single mode	Y	7.1

NOTE:
Always replace an ATM-EI circuit pack with the same type.

LED states

The ATM-INTF circuit pack has the standard red, green and yellow LEDs. The red and green LEDs have the traditional use: red indicates an alarm condition, green means maintenance testing in progress. The yellow LED is not used. The possible LED states are listed below:

LED	Condition	LED
Red	Board is not healthy	Solid on never off
Red Green	Board is in the processes of booting	Red: solid on Green: 200 ms on 200 ms off
Green	Maintenance is running tests on the board	Solid on (off when maintenance completed)
Yellow	Fiber LOS	100 ms on, 100ms off
Yellow	Signal to the ATM switch is down	500 ms on, 500 ms off

Error Log Entries and Test to Clear Values

Table 9-98. ATM-INTF Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
23(a)	0	None	WAR	OFF	
125(b)		None	MIN	ON	
217(c)	0	None	WAR	OFF	

Notes:

a. Error Type 23: ATM Expansion Interface circuit pack is administered through a **change circuit-pack** command, but has not been inserted into the system. Insert the circuit pack.

b. Error Type 125: A wrong circuit pack is located in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack or insert the logically administered circuit pack.

c. Error Type 217: The ATM circuit pack is physically present but has not been given a personality. Remove the circuit pack or administer it using the **add atm pnc** command or **add atm trunk** command.

System Technician-Demanded Tests: Descriptions and Error Codes

Failure of this test is not logged in the Error Log.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop Around Test (#52)	X	X	N

1. D = Destructive, ND = Non-destructive

Control Channel Loop-Around Test (#52)

This test is non-destructive. This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 9-99. TEST #52 Control Channel Loop-Around Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	The circuit pack failed to return the circuit pack code or vintage. 1. Retry the command a few times for a maximum of 5 times. 2. If the problem continues to fail, reset the circuit pack. 3. Retry the command a few times for a maximum of 5 times.
	PASS	Communication with this circuit pack is successful.
Any	NO BOARD	This is normal if the test is being done when: ■ the board is not physically in the system. ■ the system is booting up. Otherwise, there is some inconsistency in the data kept in the system. 1. Verify that the board is physically in the system. 2. Verify that the system is not in the process of booting up. 3. Retry the command at 1-minute intervals for a maximum of 5 times.

ATM-NTWK (ATM Network Error)

MO Name (in Alarm Log)	Physical Name in Error Logs[1]	Alarm Level	Full Name of MO
ATM-NTWK	ATUUP	WARNING	ATM Network Error

1. *AT* indicates it is an ATM switch related address, *UU* is the connection number. The connection number can be converted into a board location by the command **display atm pnc UU**, which shows the translations for the board that reported the ATM network error. *P* indicates if the ATM-EI board (reporting the ATM network error) is the A side or the B side of the PNC. If the system is simplex, only A is valid.

In the ATM PNC configuration, the proprietary Center Stage Switch (CSS) is replaced by the ATM network. Since the CSS switch nodes are replaced by the ATM network in the ATM PNC configuration, the SNI boards are no longer needed. In place of SNI board, the ATM EI boards are connected to an ATM switch port over a fiber optic cable. The port on the ATM switch is under the control of ATM switch maintenance software. Refer to Figure 5-6 in the ''ATM Tips'' section in Chapter 5 for a schematic of these connections.

An error against this MO indicates a problem in the ATM network (including the ATM switch) that is affecting the service quality. These error events are reported by the ATM network to the ATM EI board or are detected by the ATM EI board. Since these errors are *not* related to the ATM EI board, these errors are not reported against the ATM-EI Maintenance Object. However, some of these errors invoke alarms that require action by DEFINITY maintenance, while other log-only errors require no action.

Error Codes and Aux Data values

The Cause Code/Error Type information is shown inTable 9-100. These are the possible errors that can be logged against the ATM-NTWK MO.

If the ATM-NTWK Maintenance Object receives more than 6 errors, the most recent errors are discarded.

Table 9-100. Error Codes and Aux Data values ATM-NTWK

Cause Code/ Error Type	Aux Data	Cause Codes Description
NORMAL EVENTS		
0	(a)	Network unreachable
1	(a)	Unallocated (unassigned) number. This cause indicates that the called party cannot be reached because, although the number is in a valid format, it is not currently assigned (allocated).
2	(a)	No route to specified transit network. This cause indicates that the equipment sending this cause has received a request to route the call through a particular network which it does not recognize, either because the transit network does not exist or because that particular transit network does not serve the equipment which is sending this cause. This cause is supported on a network-dependent basis.
3	(a)	No route to destination. This cause indicates that the called party cannot be reached because the network through which the call has been routed does not serve the destination desired. This cause is supported on a network-dependent basis.
10	(a)	VPCI/VCI unacceptable. This cause indicates that the virtual channel most recently identified is not acceptable to the sending entity for use in this call.
16	(a)	Normal call clearing. This cause indicates that the call is being cleared because one of the users involved in the call has requested that the call be cleared. Under normal situations, the source of this cause is not the network.
17	(a)	User busy. This cause indicates that the called party is unable to accept another call because the user busy condition has been encountered. This cause value may be generated by the called user or by the network.
18	(a)	No user responding. This cause is used when a called party does not respond to a call establishment message with a connect indication within the prescribed period of time allocated.
21	(a)	Call rejected. This cause indicates that the equipment sending this cause does not wish to accept this call, although it could have accepted the call because the equipment sending this cause is neither busy nor incompatible. **NOTE:** If the call was rejected by the far-end ATM-EI board, there may also be additional information about this rejection in an ATM-EI error log entry. Look for and ATM-EI error with an Error Type between 1104 and 1119 inclusive, with approximately the same time stamp as this error.

Continued on next page

Table 9-100. Error Codes and Aux Data values ATM-NTWK — *Continued*

Cause Code/ Error Type	Aux Data	Cause Codes Description
22	(a)	Number changed. This cause is returned to a calling party when the called party number indicated by the calling user is no longer assigned. The new called party number may optionally be included in the diagnostic field. If a network does not support this capability, cause number 1 “*unassigned (unallocated) number*” is used.
23	(a)	User rejects all calls with calling line identification restriction (CLIR). This cause is returned by the called party when the call is offered without calling party number information and the called party requires this information.
27	(a)	Destination out of order. This cause indicates that the destination indicated by the user cannot be reached because the interface to the destination is not functioning correctly. The term “not functioning correctly” indicates that a signalling message was unable to be delivered to the remote user; for example, a physical layer or SAAL failure at the remote user or user equipment off-line.
28	(a)	Invalid number format (address incomplete). This cause indicates that the called user cannot be reached because the called party number is not in a valid format or is not complete.
30	(a)	Response to STATUS ENQUIRY. This cause is included in the STATUS message when the reason for generating the STATUS message was the prior receipt of a STATUS ENQUIRY message.
31	(a)	Normal, unspecified. This cause is used to report a normal event only when no other cause in the normal class applies.
32	(a)	DTL transit not-my-node ID
RESOURCE UNAVAILABLE		
35	(a)	Requested VPCI/VCI not available. This cause indicates that the requested VPCI/VCI is not available. This can be caused by mismatched VCI ranges on different ATM switches.
36	(a)	VPCI/VCI assignment failure
37	(a)	User Cell Rate not available
38	(a)	Network out of order. This cause indicates that the network is not functioning correctly and that the condition is likely to last a relatively long period of time; for example, immediately re-attempting the call is not likely to be successful.
41	(a)	Temporary failure. This cause indicates that the network is not functioning correctly and that the condition is not likely to last a long period of time; for example, the user may wish to try another call attempt immediately.

Continued on next page

Table 9-100. Error Codes and Aux Data values ATM-NTWK — *Continued*

Cause Code/ Error Type	Aux Data	Cause Codes Description
43	(a)	Access information discarded. This cause indicates that the network could not deliver access information to the remote user as requested; that is, ATM adaptation layer parameters, Broadband low layer information, Broadband high layer information, or sub-address as indicated in the diagnostic.
45	(a)	No VPCI/VCI available. This cause indicates that there is no appropriate VPCI/VCI presently available to handle the call.
47	(a)	Resource unavailable, unspecified. This cause is used to report a resource unavailable event only when no other cause in the resource unavailable class applies.
SERVICE OR OPTION UNAVAILABLE		
49	(a)	Quality of Service unavailable. This cause is used to report that the requested Quality of Service cannot be provided.
51	(a)	User cell rate not available. This cause is used to report that the requested ATM Traffic Descriptor is unobtainable.
57	(a)	Bearer capability not authorized. This cause indicates that the user has requested a bearer capability which is implemented by the equipment which generated this cause but the user is not authorized to use.
58	(a)	Bearer capability not presently available. This cause indicates that the user requested a bearer capability implemented by the equipment that generated the cause but is not available at this time.
63	(a)	Service or option not available, unspecified. This cause is used to report a service or option not available event only when no other cause in the service or option not available class applies.
65	(a)	Bearer capability not implemented. This cause indicates that the equipment sending this cause does not support the bearer capability requested.
73	(a)	Unsupported combination of traffic parameters. This cause indicates that the combination of traffic parameters contained in the ATM traffic descriptor information element is not supported.
78	(a)	AAL parameters cannot be supported.
INVALID MESSAGES		
81	(a)	Invalid call reference value. This cause indicates that the equipment sending this cause has received a message with a call reference which is not currently in use on the user-network interface.
82	(a)	Identified channel does not exist. This cause indicates that the equipment sending this cause has received a request to use a channel not activated on the interface for a call.

Table 9-100. Error Codes and Aux Data values ATM-NTWK — *Continued*

Cause Code/ Error Type	Aux Data	Cause Codes Description
88	(a)	Incompatible destination. This cause indicates that the equipment sending this cause has received a request to establish a call which has Broadband low layer information, Broadband high layer information, or other compatibility attributes which cannot be accommodated.
89	(a)	Invalid endpoint reference value. This cause indicates that the equipment sending this cause has received a message with an endpoint reference that is currently not in use on the user-network interface.
91	(a)	Invalid transit network selection. This cause indicates that a transit network identification was received in an incorrect format as defined in Annex D.
92	(a)	Too many pending add party requests. This cause indicates a temporary condition when the calling party sends an add party message, but the network is unable to accept another add party message because its queues are full.
93	(a)	AAL parameters cannot be supported. This cause indicates that the equipment sending this cause has received a request to establish a call with ATM adaptation layer parameters that cannot be accommodated.
PROTOCOL ERROR		
96	(a)	Mandatory information element is missing. This cause indicates that the equipment sending this cause has received a message that is missing an information element.
97	(a)	Message type non-existent or not implemented. This cause indicates that the equipment sending this cause has received a message with a message type it does not recognize either because this is a message not defined or defined but not implemented by the equipment sending this cause.
99	(a)	Information element non-existent or not implemented. This cause indicates that the equipment sending this cause has received a message that includes information element(s) not recognized because the information element identifier(s) are not defined or are defined but not implemented by the equipment sending the cause. This cause indicates that the information element was discarded. However, the information element is not required to be present in the message in order for the equipment sending this cause to process the message.

Table 9-100. Error Codes and Aux Data values ATM-NTWK — *Continued*

Cause Code/ Error Type	Aux Data	Cause Codes Description
100	(a)	Invalid information element contents. This cause indicates that the equipment sending this cause has received and implemented an information element. However, one or more of the fields in the information element are coded in such a way that has not been implemented by the equipment sending this cause.
101	(a)	Message not compatible with call state. This cause indicates receipt of a message that is incompatible with the call state.
102	(a)	Recovery on timer expiration. This cause indicates that a procedure has been initiated by the expiration of a timer in association with error handling procedures.
104	(a)	Incorrect message length
111	(a)	Protocol error, unspecified. This cause is used to report a protocol error event only when no other cause in the protocol error class applies.
257 to 300 (b)	(b)	ATM Impaired Paths Examine the error log ('display errors'), atm setup-events log ('list measurements atm svc-setup'), and atm pnc-latency ('list measurements atm latency') screens to help diagnose the problem -- it is possible the switch is operating normally. In this case, you should consider raising the Activation threshold and/or increasing the Timeout value on the ATM-RELEATED System Parameters form. ('change system atm'). You can use the list measurements atm svc-setup command to provide information about errors associated with connection numbers. After entering the above command, make note of the time stamps displayed in the list measurements atm setup-events screen. Execute the above command periodically and note the time stamps. If the time stamps have changed for a particular 'From Conn' 'To Conn' pair, this indicates there are still setup failures/delays for that connection. After verifying that all associated ATM end-points are operating correctly, and if errors are still occurring, contact your local service provider.
301 (c)	ANY	System wide ATM Impaired Paths. See the suggestions listed above to trouble shoot these errors.

Note:

a. Aux Data values (XX = Port Network, YYY = location code).

Table 9-101 is a list of UNI 3.1 location codes:

Table 9-101. Location codes from Aux Data values

Setup (Location Code)	Add Party (Location Code)	Location Code Meaning
0	500	User
1	501	Private network serving the local user
2	502	Public network serving the local user
3	503	Transit network
4	504	Public network serving the remote user
5	505	Private network serving the remote user
7	507	International network
10	510	Network beyond interworking point

b. Error Type 257 to 300: These error type numbers are used to determine the destination PNC connection number of an ATM Network connection that is experiencing an impaired path. The connection number is obtained by subtracting 256 from number that is displayed in the Error Type field. See the following example:

ERROR TYPE field= 263

Subtract -256

PNC destination connection # = 7

The AUX DATA field contains the originating and destination PN number (XXYY). Where XX = the originating PN #, and YY = the destination PN # for example:

1. Example AUX DATA = 302

   3 = orig
   2 = dest

2. Example AUX DATA = 1510

   15 = orig
   10 = dest

c. Error Type 301: This error indicates that there is a system wide impaired path network problem.

NOTE:
Under certain circumstances network errors can be against the ATM EI board.

ATM PNC-DUP (ATM PNC Duplication)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
PNC-DUP	NA	status pnc	PNC duplication

The PNC-DUP maintenance object tracks the health of the active and standby PNCs, controls planned and spontaneous interchanges, and manages related functions such as double call refresh and unrefresh, antithrashing, and so on. The main responsibility of PNC-DUP is to recover the system to full service in the event of a fault. In the event of multiple faults, PNC-DUP does its best to maximize service continuity.

NOTE:
PNC-DUP behaves differently when the system is running the ATM PNC feature. While not a separate maintenance object, this discussion explains the unique behavior of PNC-DUP under the ATM PNC feature.

In systems with the Critical Reliability option, the following components, which together comprise the Port Network Connectivity (PNC), are duplicated:

- ATM-Expansion Interface (ATM-EI) circuit packs in the port networks (PNs)
- Fiber-optic cables connecting the above circuit packs to the ATM Switch Interface Modules
- ATM Switch

Although not part of the PNC, Tone-Clock circuit packs are also duplicated in each PN. All systems have one Processor Port Network (PPN). ATM PNC systems can have up to 43 EPNs.

PNC duplication architecture utilizes an active/standby duplication scheme in which one complete set of PNC components supports call processing, while the duplicate PNC is held in reserve. All calls on the active PNC are simultaneously set up, or shadowed, on the standby PNC in order for it to be capable of instantly assuming active status when necessary, allowing for interchanges without service disruption (in the case of single faults).

PNC duplication does not introduce any additional types of hardware or hardware faults, and there are no tests associated with the PNC-DUP MO. Instead, its error log entries contain useful information about the occurrence and causes of interchanges in order to facilitate diagnosis of problems, which can then be addressed by using the documentation for the individual maintenance object involved.

PNC-DUP Related Commands

The following commands and their output screens are fully described in Chapter 8.

status pnc	Displays information about the operational status of both PNCs including state of health, alarms, busyouts and locks, and so on.
reset pnc interchange	Used to initiate a demand PNC interchange. If the standby is healthy (state of health indexes all zero), there is no effect on service. Otherwise, calls may be dropped.
set pnc	Used to lock or unlock the active PNC, preventing interchanges. It does not interfere with double call setup.
busyout pnc	Removes the standby PNC from service. See also the following section on busyout of PNC components.

Busyouts and PNC-DUP

Busyout pnc puts the standby PNC in the busyout state. In this condition:

- Double call set up is turned off.
- The standby PNC is unrefreshed; existing duplicate call connections are removed.
- PNC interchanges are prevented.

Upon release, interchanges are re-enabled and a global refresh of double call setup on the standby is performed.

When PNC duplication is in effect:

- An active PNC component cannot be busied-out.
- A standby PNC component can only be busied-out when the standby PNC is first busied-out.
- The standby PNC cannot be released unless all standby PNC components are released.

Enabling and removing PNC Duplication

To enable PNC duplication, perform the following sequence of steps:

1. Enable administration of PNC-DUP on the **change system-parameters customer-options** form.
2. Fully administer duplicate fiber link connectivity. Verify by **list atm-pnc**.

3. Activate PNC-DUP through the **change system-parameters duplication** form. This is not allowed if any component of either PNC (A or B) is busied out.
4. The system must insert all connectivity-related components for both standby and active PNC, a process that takes up to 5 minutes, depending upon circuit pack insertion. The process is complete when the first terminal login prompt appears.
5. The PNC-DUP initialization anti-thrashing timer must expire (this occurs 5 minutes after completion of board insertion, PNC interchange, or system reset of level 2 or higher).

To disable PNC duplication perform the following sequence of steps:

1. Verify that the A-PNC is active. A forced interchange may be required. See **reset pnc** in Chapter 8.
2. Busyout the standby PNC (B-PNC).
3. Turn off the system parameter for PNC-DUP through **change system-parameters duplication**.
4. Remove the B-PNC connectivity by removing the Board Locations on the **change fiber** form for ATM-PNC.
5. Remove the B-PNC circuit packs (ATM-EI boards). Use **change circuit pack UUC**.
6. Disable administration of PNC duplication on the **change system-parameters customer-options** form by changing the `PNC Duplication` field to **n**.

NOTE:
Alterations to PNC that involve only the *addition* of connectivity can be done with PNC-DUP operational.
Alterations requiring the *removal* of connectivity must be done with PNC-DUP removed.
PNC-DUP must be removed and translations should be saved before making any hardware changes.

Steady State LEDs

The LEDs of PNC components in a stable duplicated system should appear as follows:

- The *active* ATM-EIs in the EPNs are functioning as Archangels. Their yellow LED flash pattern is 2 seconds on/200 ms off.
- The EPN standby EIs yellow LEDs are off.
- The PPN active EI yellow LED is on steady.
- The PPN standby EI yellow LED is off.

PNC state of health

PNC-DUP software monitors the health of the two PNCs as determined by their state of health (SOH) vectors, and initiates an interchange when the health of the active falls below that of the standby (unless prevented from doing so by a PNC lock, busyout, or antithrashing mechanism). Potentially service-disrupting faults that occur in PNC components are reported to PNC-DUP and incorporated in the state of health for the affected PNC. The SOHs of both PNCs are displayed on the **status pnc** screen, as shown in Figure 9-9.

```
status pnc                                                    page 1 of 1

Figure 9-9. Status PNC screen with standby PNC fully In-Service

PNC state of health indexes

The Inter-PN Index form the state of health vector is used to track and compare the states of health of both PNCs. The fields making up the indexes are two-digit numbers separated by periods (.), with each field representing a different class of faults. The fault class fields are arranged in order of decreasing importance from left to right. In other words, each field in the index supersedes the following fields in determining which PNC is healthiest. A fault class drives an interchange only when all of the higher priority fault classes are equal. A zero entry indicates no faults present for that class. Increasing numbers indicate increasingly higher numbers of faults present in that class.

The Inter-PN Index contains 3 fields (XX.XX.XX). The Inter-PN Index reports faults in connectivity between port networks.

- The meaning of each fault class field is given in Table 9-102.
- A zero entry indicates that there are no faults reported.
- Higher numbers indicate increasing number of faults.
- All zeros indicates perfect state of health.
- Unless the PNCs are locked, the active PNC's state of health should always be equal to or better than the standby's, otherwise, the system performs a spontaneous interchange.

After a PNC-related alarm is cleared, the system performs a partial refresh of the standby PNC. The corresponding fault class field is not updated to reflect the improved state of health until the refresh is done. The state of health indexes do not agree with the current alarm status during this period.

Table 9-102. PNC State of Health Fault Classes

Fault Class	Priority	Description	MOs
FC_EAL	1	Number of PNs with EALs down	EXP-PN
FC_PACL	2	Number of PNs with LINL, RINL, or EI-SNI neighbor link faults	EXP-PN
FC_HW	3	Number of PNs affected by hardware faults in a link having an EI as an endpoint. (Endpoints can be determined with **list atm pnc**.)	ATM-EI

Resolving poor state of health

When the SOHs for both PNCs are not all zeros (perfect health), use the following steps to identify and repair the problem.

1. Look for PNC component alarms (major or minor) for the PNC side whose SOH is not all zero. The standby PNC should be repaired first.
2. Busy-out the standby PNC.
3. Follow the appropriate diagnostic and repair procedures for the alarmed PNC components just as with a simplex PNC. Both the alarm and error logs should be examined to isolate the fault.
4. Verify that the related PNC SOH is restored to all zeros.
5. Release the standby PNC.

Refresh and unrefresh of the standby PNC

In a fully-functional PNC with healthy standby and active sides, the standby PNC has a complete set of call connections corresponding to those in the active PNC. If, however, the state of health of the standby PNC degrades, a selective unrefresh of those connections that utilize the faulted component(s) is performed. If the health of the standby PNC improves, a selective refresh of connections on the affected route is performed so that call setup is consistent between the active PNC and the healthy parts of the standby PNC.

The `Standby Refreshed?` field on the **status pnc** screen does *not* refer to the selective type of refresh. It refers only to a global refresh that is performed when:

- The system is initialized and PNC duplication is enabled.
- There has been a spontaneous PNC interchange.
- The standby PNC has been released from busy-out.
- A system reset of level 2 or higher has taken place.

The refreshed field may display yes when in fact the standby is partially unrefreshed. An interchange into an incompletely refreshed standby results in dropped calls. This can happen when a more severe fault occurs on the active PNC or when **reset pnc interchange** is used with the override option.

PNC interchanges

PNC spontaneous interchanges occur when PNC duplication software determines that the State of Health (SOH) of the standby PNC is better than that of the active PNC.

- PNC-DUP executes a spontaneous interchange in response to a message from a PNC component maintenance object indicating that either a fault has occurred on the active PNC or a fault has been resolved on the standby PNC.
- The PNC SOH is compared to the standby PNC, and an interchange occurs if the state of health of the standby PNC is now better than that of the active PNC.
- A corresponding Major or Minor alarm is logged by the reporting MO, stimulating an alarm report.

When the resolution of a fault on the standby renders it more healthy than a simultaneously-faulted active PNC, the error message indicates the type and location of the *improved* component.

Once the interchange completes, the failed component is on the standby PNC. A demand interchange can be requested in the presence or absence of standby PNC faults. The following sequence of actions can be observed during a fault-free interchange:

1. The ATM-Expansion Interfaces currently acting as archangels in the EPNs are deactivated as indicated by the yellow LEDs going from flashing to on solid.
2. The PPN ATM-EIs are interchanged, indicated by the new standby ATM-EI yellow LED off and the new active ATM-EI yellow LED on steady.
3. One by one the EPN ATM-EIs are interchanged as indicated by new standby ATM-EI yellow LED turning off and the new active ATM-EI yellow LED flashing (2 seconds on/200 milliseconds off). At this point the interchange is functionally complete.

Certain conditions may interfere with the normal execution of the interchange:

1. In a faulted spontaneous interchange, it is possible the EPN/EPNs directly affected by the fault will be the last to interchange.
2. A user directly affected by the single fault instigating a PNC interchange can experience a momentary voice path outage during the switch.
3. If faults exist on both the standby and active PNC, it is possible to have some EPNs go out of service while others are returned to service.

In any multifault situation, rely on **status pnc** to determine which is the active PNC.

PNC duplication informs Timing Synchronization maintenance when a PNC interchange has been completed and indicates which PNC is active. This causes Synchronization to audit and ensure that the primary source for synchronization of Tone-Clocks in each PN is supplied by a path associated with the active PNC.

Antithrashing and PNC interchanges

Following a spontaneous PNC interchange, subsequent PNC interchanges are prevented for 5 minutes. This condition is indicated by y in the `Interchange Disabled?` field of the **status pnc** screen. After 5 minutes, the antithrashing, timer expires, interchange decisions are re-enabled, and the field displays n. *Should a catastrophic failure occur on the active PNC during the period when the* `Interchange Disabled?` *field is set to "yes," there will be no spontaneous PNC interchange.*

Demand PNC interchanges also invoke anti-thrashing, but only for a period of 30 seconds. During antithrashing mode, demand interchanges are also prevented unless the override option is specified.

CAUTION:
Use of this option may cause a service disruption.

Repairs on the standby PNC components

CAUTION:

If there is a TDM-CLK alarm, system timing may be routed through part of the standby PNC, and circuit switched data may be affected by the following repair procedures. This can happen, for example, when a slave tone/clock circuit pack experiences a loss of signal and switches to receive timing from the standby ATM-EI. In this case TDM-CLK 2305 error is logged, and the clock problem should be addressed first, if possible.

To repair PNC components in a duplicated PNC proceed as follows:

1. Most repairs involve fixing a single fault on the standby PNC. Use **set pnc lock** or **busy-out pnc** to prevent an interchange into the PNC being repaired.
2. If a faulty component exists on the active PNC, this also means that the standby PNC is more severely faulted. Normally, the *standby* PNC is repaired first, since it is the most severely impaired.

   To repair the active PNC (standby is already repaired), issue the **set pnc unlock** command, which generates a spontaneous interchange. In a PNC demand interchange with **reset pnc interchange** use the **override-and-lock** qualifier for the active PNC. The *override-and-lock* option ensures that no subsequent interchange can occur during the repair of the standby PNC. A demand interchange may not be necessary if the following conditions drive a spontaneous interchange:

   - The anti-thrashing period from the last interchange has expired.
   - The global refresh from releasing the standby PNC has completed.
   - The standby PNC State of Health is better than the active PNC.

   At this point, the faulty component is on the standby PNC, and the PNCs are locked in their current active/standby state.
3. Busyout the PNC with the **busyout pnc** command.
4. Use fault isolation and component testing procedures for the individual PNC components, just as for a simplex PNC. Replacement of components does disrupt operation of the active PNC.
5. Once the failed component is replaced, use the **status pnc** command to check the health standby PNC component.
6. When confident that the problem has been resolved, as indicated by a state of health with all zeros, unlock (**set pnc unlock**) and release (**release pnc**) the PNC. Note that no further PNC interchange is required since you can test the standby PNC as thoroughly as the active.

Interactions: SPE resets and PNC interchanges

- After a **reset system 4** (reboot), the A PNC is always the active.
- A system reset of level 1 (warm), 2 (cold2) or 3 (cold1) does not change which PNC is active. If a PNC interchange was in progress when the reset took place, the PNC interchange continued until completion.
- If a **reset system 1** (warm) takes place during a PNC interchange, the reset is escalated to level 2 (cold2).

Fault isolation using Duplicated PNC

In some cases, PNC duplication can aid in the fault isolation procedure. PNC interchanges can be used to help isolate the faulty hardware. Two examples demonstrating this technique follow:

1. There is a fault that can occur in either the PPN ATM-EI or the PKT-INT which cannot be readily attributed to one board or the other. If the packet bus transceivers on either the PKT-INT or ATM-EI fail, the two boards cannot communicate, but it will not be clear which board is at fault. In this case, a planned interchange of the PNC can be used to indicate which of the two boards.
   — If the interchange cures the problem, the ATM-EI was at fault.
   — If the interchange does not cure the problem, the PKT-INT is suspect, provided there are no PKT-BUS faults.
2. A similar relationship exists for the EPN Archangel (EAA - the active ATM-EI) and certain TDM bus problems. If the EAA is unable to communicate with a port board over the TDM bus, either the EAA has a fault, the port board has a fault, or there is a problem with the TDM bus itself. If TDM bus maintenance tests find no problems with the bus, then it is either the port board or the EAA. It may be simpler to replace the port board than to request a PNC interchange. However, if it is not clear which port board may be at fault or maintenance is being performed remotely, verify that the EAA is not at fault by executing a PNC interchange. If the interchange solves the problem, then the EAA is faulty. If the problem persists after the interchange, but TDM bus maintenance finds no problem, then the port board is faulty.

Error Log entries

Whenever a PNC interchange takes place, an error is logged against PNC-DUP with a code that conveys information about the cause of the interchange and which PNC became active. There are no alarms associated with PNC-DUP errors, but there should be an alarm against the PNC component that caused the interchange. There are no PNC-DUP test sequences, but **status pnc** provides information regarding the status of the PNCs. The information in Table 9-103 and Table 9-104 can help to identify which areas of the Alarm Log to investigate to find the source of the problem.

Table 9-103. Error Code descriptions and Aux Data correlations

Error Code	Description	Aux Data[1]
00000	Error in generating error code	None
1cxpp	Spontaneous Interchange in response to a constraint for A-PNC	Active PNC
2cxpp	Spontaneous Interchange in response to a constraint for B-PNC	Active PNC
51000	Spontaneous Interchange at expiration of SOH validation timer	Active PNC
52000	Spontaneous Interchange upon PNC UNLOCK	Active PNC
53000	Spontaneous Interchange at completion of Global Refresh	Active PNC
60801	PNC Demand Interchange	Active PNC
60800	PNC Demand Interchange with override	Active PNC

1. The Aux Data indicates which PNC became active after the PNC interchange: “0” denotes PNC-A; “1” denotes PNC-B.

Table 9-104. Error Log Encode Field Decoding

Field	Variable Name	Values	Description
c	Alarm Type	0 1	Alarm retired MAJOR or MINOR alarm on any PNC component
x	Fault class; see description for contributing MOs	0	EAL (Expansion Archangel Link - EXP-PN) carries CCMS messages
		1	PACL (ATM-EI) carries ATM signaling commands from Call Processing to the remote ATM-EI circuit packs.
		2	PNC hardware (providing connectivity of PPN or EPN to EPN or ATM-EI)
pp	Port Network number	0-43	0-2 for constraint class (this is an internal number; add 1 for external port number)

Error Log Entries and Test to Clear Values

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
18	None	busy PNC-DUP	WARNING	ON	release pnc-dup

NOTE:
The **list config port-network** command gives the cabinet number associated with a port network.

ATM-SGRP (ATM Signaling Group)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ATM-SGRP	MINOR	test sig-group *grp#*	ATM-CES Signaling Group
ATM-SGRP	WARNING	test sig-group *grp#*	ATM-CES Signaling Group

1. *grp#* is the signaling group number (1-166); the test sequence can be either short or long.

This Maintenance Object (ATM-SGRP) applies when ATM signaling groups have been administered on an ATM circuit pack as ATM Trunks.

Table 9-105 outlines the differences between ATM interface circuit packs:

Table 9-105. R7 ATM-SGR circuit packs

Circuit pack	Channel types	Interface	Fiber	Echo cancellation
TN2305	B and D channels	24 or 32 channel	Multimode	Y
TN2306	B and D channels	24 or 32 channel	Single mode	Y

The TN2305 and TN2306 ATM Interface circuit boards are referred to as TN230X for the remainder of this MO.

An ATM Signaling Group is a collection of B-channels for which a given ISDN-PRI Signaling Channel Port (ATM D-channel) carries signaling information. ATM B-channels (ATM-BCH) carry voice or data and are assigned to ISDN trunks. For more information see ''ATM-TRK (Circuit Emulation Service Circuit Pack)''.

The operation of the entire ATM signaling group depends on several other entities:

- the ATM-DCH signaling channel port
- the TN230X Interface circuit pack on which the D-channels reside
- the system link that is carried over the packet bus to the processor

When there are problems with ATM-SGRP (ATM signaling group), also investigate:

- "ATM-DCH (ATM D-Channel Port)"
- "ATM-BCH (ATM B-Channel Trunk)"
- "SYS-LINK (System Links)"
- "PKT-BUS (Packet Bus)"

Error Log Entries and Test to Clear Values

Table 9-106. ATM-SGRP Signaling Group Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any		test sig-group *grp#*
1 (a)	Any	None			
18 (b)		MO busied out			
257 (c)	Any	None			test sig-group *grp#*
769 (d)	Any	Primary Signaling Link Hardware Check (#636)			test sig-group *grp#*
1281 (e)	Any	Secondary Signaling Link Hardware Check (#639)			test sig-group *grp#*
1793 (f)	Any	Layer 2 Status (Test #647)	WNG	OFF	test sig-group *grp#*
2305 (g)	Any	Remote Layer 3 Query (Test #637)	MINOR	OFF	test sig-group *grp#*
3585 (h)	Port number	None			
3840 - 3928 (i)	Port number	None			

Notes:

a. Error Type 1: switch sent a message to the far-end switch or terminal adapter, and the far-end did not respond in the allotted time. Possible causes include link failure and congestion or outage at the far-end. The Aux Data field contains Layer 3 protocol information used by internal counters.

   If no other symptoms are present, no action is required. If Layer 3 communication is down:

   a. Check for alarms and errors against link components

   b. Check out other errors against ATM-SGRP, ATM-TRK, and other hardware components on the link.

   There is no test to clear these errors. The error counter is decremented by 1 every 15 minutes.

b. Error Type 18: the ATM circuit pack has been busied out (either **busyout atm sig-grp** or **busyout board UUCSS**).

   1. Release the ATM signaling group (**release atm sig-grp**) or the circuit pack (**release board UUCSS**).

c. Error Type 257: the primary signaling channel connection has been lost for more than 90 seconds.

   - The associated B-channels are placed in the ISDN Maintenance/Far-End state.
   - The B-channels are not usable for outgoing calls, although incoming calls can be accepted.
   - The switch automatically attempts to recover the signaling link.

   1. Pay particular attention to the results of Test #636 (Primary Signaling Link Hardware Check) in the test sequence.

   - When the link does recover, the B-channels are negotiated back to the In-Service state and their alarms are retired.

   2. When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the **status sig-group** command).

d. Error Type 769: signaling link hardware error.
Service-affecting failures of the hardware used to transport the D-Channel are reported to the ATM CES Signaling Group MO. Maintenance logs this error, places the D-Channel into the OOS state, and raises a board-level alarm. The D-Channel is returned to service and the alarm is retired once the hardware failure condition clears.

e. Error Type 1281: Degraded PVC Alarms indicate that a particular Permanent Virtual Circuit, or signaling group, has encountered sufficient errors to exceed firmware thresholds. Operations can continue but at a lower level of reliability or performance. Firmware filters these alarms so that only one is reported active at a given time. The following in-line error is considered a Degraded PVC Alarm:

   - Excessive AAL - The AAL layer is experiencing an excessive number of errors in trying to reconstruct Service Data Unit (SDUs). Possible causes:
     — Something may be wrong with the ATM switch.
     — The communication paths on the other side of the ATM switch may be noisy.
     — The sending node might not be healthy.
     — Could be a problem with congestion on the ATM switch.

f. Error Type 1793: failure of the Layer 2 Query Test for the primary signaling channel.

- Excessive AAL - The AAL layer is experiencing an excessive number of errors in trying to reconstruct Service Data Unit (SDUs). Possible causes:
  - — Something may be wrong with the ATM switch.
  - — The communication paths on the other side of the ATM switch may be noisy.
  - — The sending node might not be healthy. It could also be a problem with congestion on the ATM switch.

g. Error Type 2305: the Remote Layer 3 Query Test (#637) failed. A specific message was sent to the far-end switch, and it did not respond within the allotted time.

1. Investigate elements of the ATM D-channel(s) (ATM-DCH) for both this switch and the Far-end switch.

If Test #637 fails twice in a row, the B-channels are alarmed and made unavailable for outgoing calls (although incoming calls are still accepted). When Test #637 succeeds and the Far-end switch starts responding properly, the ATM Trunk (B-channels) are placed back into normal operation and their alarms retired.

h. Error Type 3585: A SERV or SERV ACK ISDN D-channel message has been received by a non-US-type interface (country option other than 1 on the DS1 administration form). However, these messages are used only for duplex NFAS signaling, which is supported by country protocol 1.

Thus, there may be a mismatch in administration between the local and far-end switches.

1. Consult with the customer's network provider to determine whether the D-channel is set up correctly on the far-end switch.

i. Error Type 3840-3928: These error types are used to report certain error messages received by the ATM-SGRP Signaling Group for one of its associated B-channels. The Aux Data field is the port number of the B-channel from which the message was received.

The error code generated equals 3840+*x*, where *x* is a Cause Value defined by the ISDN PRI Specification. Note that there is no Test to Clear Value for these error types; selected ISDN cause values are placed in the log when they are received, but no direct action or alarming is performed solely in response to receiving them. They provide added data that may prove useful when tracking down obscure networking and routing problems. Table 9-107 provides more information about this range of Error Codes:

Table 9-107. Descriptions and repair recommendations (Error Types 3840-3928)

Error Code	Description	Recommendation
3842	A request has been made to use a transit network or common carrier that cannot be accessed.	From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 1. Check all routing patterns containing this trunk group for validity of interexchange carriers requested (IXC field).
3846	The far-end switch has indicated that the B-channel (trunk) is not acceptable for use in the call for which it was requested.	This could indicate ■ an administration problem (for example, the local switch and the far-end switch have different B-channels administered) ■ a normal race condition (for example, the local switch has requested use of a B-channel which the far-end switch had just reserved for use on another call). 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Issue the **status trunk** command for the indicated trunk. 3. Refer to Table 9-68 in ''ATM-BCH (ATM B-Channel Trunk)'' for recovery suggestions.
3858	Similar to Error Type 1. The switch sent an ISDN message to the far-end switch or terminal adapter which did not respond in the allotted time.	1. Check for alarms and errors against link components 2. Check out other errors against ''ATM-SGRP (ATM Signaling Group)'', ''ATM-TRK (Circuit Emulation Service Circuit Pack)'', and other hardware components on the link.
3878	The far-end switch has indicated that the network is not functioning correctly and that the condition may last a relatively long period of time (for example, immediately re-attempting the call may not be successful).	1. From the circuit pack and port number (in the Aux Data field, determine the trunk group against which the error was reported. 2. Consult with the network provider to determine the nature and expected duration of the out of service condition. 3. Consider modifying all routing patterns containing this trunk group, to route calls around the network which is out of service.

Continued on next page

Table 9-107. Descriptions and repair recommendations (Error Types 3840-3928) — *Continued*

Error Code	Description	Recommendation
3890	A request to use a network service (for example, SDN) has been denied. Administration somewhere on the network has indicated that the requested service has not been subscribed to or purchased for this trunk.	This could indicate ■ a local administration problem ■ a mismatch between the local administration and that of the network provider. 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Display the trunk group form. If the trunk group is Call-by-Call (the `Service Type` field is `cbc`), check all routing pattern forms containing this trunk group to see if the Service/Feature fields contain the correct network services purchased for this trunk. If the trunk group is not Call-by-Call, check that the `Service Type` field contains the single network service purchased for this trunk. 3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.
3892	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	1. If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3894	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	1. Eliminate any transitory state mismatch problems (**test port UUCSSpp** for the trunk port shown in the Aux Data field). Test #256 (Service State Audit) is the important test in the sequence. 2. If Test #256 passes yet the customer continues to complain of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3905	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	1. If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.

Continued on next page

Table 9-107. Descriptions and repair recommendations (Error Types 3840-3928) — *Continued*

Error Code	Description	Recommendation
3906	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	1. If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate to the problem and provide the next tier with this Error Log information.
3909	A request to use a network service has been made, but the network has rejected the request because the requested service is not implemented.	1. Follow the recommendations listed above for Error Type 3890.
3928	A call was denied because of a basic incompatibility between the type of call and either the facilities selected by the routing pattern or the called user itself.	This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone after accessing ISDN trunks or PRI endpoints. 1. Determine the trunk group from the circuit pack and port number (in the aux data field) 2. check the BCC fields of the pertinent routing patterns. 3. Also, investigate whether or not the calling and called endpoints are compatible (for example, some ISDN switches may not allow a voice station to call a data extension).

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the Primary Signaling Link Hardware Check, for example, you may also clear errors generated from other tests in the testing sequence.

Table 9-108. System Technician-Demanded Tests: ATM-SGRP

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Primary Signaling Link Hardware Check (#636)	X	X	ND
Layer 2 Status Test (#647)	X	X	ND
Remote Layer 3 Query Test (#1291)	X	X	ND

1. D = Destructive, ND = Non-destructive

Primary Signaling Link Hardware Check (#636)

The ATM-SGRP Signaling Group D-Channel port depends on the health of the TN230X interface circuit pack on which it resides. This test fails if there are problems with either the ATM-DCH (D-channel port) maintenance object or the TN230X circuit pack. Investigate the ATM TN230X circuit pack (ATM-TRK) anytime there are problems with the ATM D-channel port (ATM-DCH).

Table 9-109. Primary Signaling Link Hardware Check (#636)

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error Retry the command at 1-minute intervals a maximum of 5 times.
8	FAIL	There is a problem with the ATM TN230X Circuit Pack or the ATM Signaling Channel (D-Channel), preventing any ISDN trunk calls until the problem is resolved. 1. Consult the procedures for the TN230X Circuit Pack (ATM-TRK) and the ATM D-channel (ATM-DCH).
	PASS	The basic physical connectivity of the D-channel is intact and functional. 1. Try this test repeatedly to ensure the link is up and to uncover any transitory problems.

Layer 2 Status Test (#647)

The Layer 2 Status Test checks the layer 2 status of the ATM-SRG Signaling Channel (D-channel). This test fails when:

- there is a hardware failure
- there is a facility problem
- the D-channels are not administered correctly

The Signaling Link Hardware Check (Test #637) and the Remote Layer 3 Query Test (#1291) detects most problems caused by hardware failures or incorrect administration.

Table 9-110. TEST #647 Layer 2 Status Query Test

Error Code	Test Result	Description/ Recommendation
1132	ABORT	Internal system error. The port location for the D-channel is not known. This condition should not be possible since an administered ATM circuit pack must be specified when a Signaling Group is administered: 1. Retry the command at one minute intervals a maximum of five times.
1134	ABORT	Internal system error. The associated ATM circuit pack is not administered. This condition should not be possible, since an administered ATM circuit pack must be specified when administering a Signaling Group. 1. Retry the command at one minute intervals a maximum of three times.
2500	ABORT	Internal system error 1. Retry the command at one minute intervals a maximum of five times.
1	FAIL	Layer 2 of the signaling channel is down 1. Examine the results of the Signaling Test (#636) and follow recommendations provided there. 2. If Test #636 (Primary Signaling Link Hardware Check) passes, the Layer 2 Query test may still fail if the Signaling Channel at the far end has not been administered correctly or if the Signaling Channel has been busied out. 3. Verify that the Signaling Channel (D-channel) at the far end has been administered correctly. 4. Verify that the ATM-DCH port used for the D-channel has not been busied out at the far end.

Continued on next page

Table 9-110. TEST #647 Layer 2 Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The D-Channel is down. 1. Examine the results of the Primary Signaling Link Hardware Check (#636) and follow recommendations provided there. 2. If Test #636 (Primary Signaling Link Hardware Check) passes, the Layer 2 Query test may still fail if the Signaling Channel at the far end has not been administered correctly or if the Signaling Channel has been busied out. 3. Verify that the Signaling Channel (D-channel) at the far end has been administered correctly. 4. Verify that the ATM-DCH port used for the Primary and Secondary D-channels has not been busied out at the far end.
	PASS	The Primary Signaling Channel is up.

Remote Layer 3 Query (#1291)

This test queries the far-end switch or terminal adapter to determine if the signaling connection is functioning properly at Layer 3. It selects a B-channel in the in-service or maintenance service state and sends an ISDN Layer 3 SERVice message, which requires a response from the far end (similar to performing Test #256 on an ISDN trunk). The test is not performed if there are no B-channels in an appropriate ISDN service state (for example, when none are administered or they are all out of service).

NOTE:
The service state can be displayed by using the **status trunk <trunk group/trunk member>** or **status pri-endpoint** command.

As is the case with Test #256 for an ISDN trunk, a PASS only indicates that a message was composed and sent to the far-end switch or terminal adapter. The ISDN PRI Specification allows up to 2 minutes for a response. Check the Error Log for ATM-SGRP errors of type 2305 for evidence of a Remote Layer 3 Query failure.

Test #636 checks the health of the D-channels and ATM Interface Circuit Packs. This test goes one step further by checking the communication path from the processor, through the TDM/Packet Bus and ATM Interface circuit pack, and on to the far-end switch or terminal adapter. A special ISDN message is sent to the far-end switch or terminal adapter, which must respond within a specified amount of time. This test is designed to ensure that the communication path between the switch and the far-end is up and operational, and that the two endpoints can properly exchange ISDN control messages.

Table 9-111. TEST #1291 Remote Layer 3 Query

Error Code	Test Result	Description/ Recommendation
1006	ABORT	There are no associated B-channels in an ISDN “in-service” or “maintenance” service state. This is a NORMAL ABORT. 1. Administer or release an ISDN trunk or PRI endpoint before retrying the test. For an ATM trunk, use the **status trunk *grp#/mbr#*** command to verify the ISDN trunk state. 2. Retry this test when at least one B-channel is in the “in-service” or “maintenance” states.
1113	ABORT	The signaling channel is down. Therefore, no messages can be sent to the far-end switch or terminal adapter. 1. Examine the results of Tests #636 and follow recommendations provided there.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2500 or none	ABORT	Internal system error or administration problem 1. Determine if any B-channels are administered. 2. If there are none, then this is a normal ABORT, since this test cannot run unless at least one B-channel is administered. 3. If at least one B-channels is administered, there is an internal system error. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. See description of ABORT with Error Code 2500.
	PASS	A message was sent to the far-end switch or terminal adapter. The ISDN PRI specification allows up to 2 minutes for a reply. 1. Check the Error Log for ATM-SGRP errors of type 2305 for evidence of a Remote Layer 3 Query failure. 2. If no new errors were logged since this test was run, then this switch and the far-end switch can exchange call control messages. 3. If there is still a problem with a particular ATM trunk, busyout the trunk and run the long test sequence, paying particular attention to the results of Test #258 (ISDN Test Call).

ATM-SYNC (ATM Synchronization)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ATM-SYNC	MINOR	display errors	ATM Synchronization
ATM-SYNC	WARNING	test synchronization	ATM Synchronization

This section discusses intra-switch synchronization maintenance and the hardware and software components that provide a common reference frequency for reliable digital communication among the G3r system, the ATM switch, and other PBXs, Central Offices (COs) or Customer-Premises Equipment (CPE). Circuit packs involved in synchronization include:

- TN768, TN780, or TN2182 Tone/Clock
- TN722, TN767, and TN464 DS1 Interfaces (all suffixes)
- TN2305/6 ATM Expansion Interface (multimode fiber)

Synchronization is achieved between the Processor Port Network (PPN) and the Expansion Port Networks (EPNs) through the ATM port network connectivity (ATM PNC) between the networks. Depending on the network synchronization plan and the status of synchronization sources, the system timing reference may be:

- The clock circuit pack on the ATM switch
- A DS1 or UDS1 interface circuit pack-tapped T1 input signal connected to the ATM switch clock circuit
- An OC-3 interface circuit pack on the ATM switch

Stratum 4 synchronization extracts timing information directly from

- A DS1 or UDS1 reference
- An OC3 reference
- The ATM switch clock

For further information about synchronization including network synchronization, see *AT&T Network and Data Connectivity*.

Stratum 4 Synchronization

Systems may have primary and secondary synchronization references (DS1/UDS1 interface circuit packs or ATM-Switch) when using Stratum 4 synchronization.

If the primary synchronization reference in Figure 9-10 is providing a valid timing signal, then the flow of system synchronization would travel from the DS1 interface circuit pack in the EPN to the ATM switch. The primary DS1 interface circuit pack provides a timing signal for the ATM switch clock circuitry. This synchronization source is then distributed to all of its OC3 Interface Modules. Each ATM Expansion Interface circuit pack uses the received data stream from the ATM switch to generate a timing signal. The Tone-Clock circuit packs in the EPNs use this signal to generate timing for all the circuit packs in their respective EPNs. All PNs, in the above mentioned scenario are designated the *slave* port networks. The ATM switch is the *master* that contains the system synchronization source. If the primary synchronization reference does not provide a valid timing signal, ATM synchronization maintenance infers a switch to the secondary reference.

If the primary synchronization reference is not providing a valid timing signal, the system automatically switches to the secondary synchronization reference. If the primary synchronization reference is invalid, and if the secondary reference does not provide a valid timing signal or is not administered as a synchronization reference, the switch infers that the local oscillator of the ATM switch provides the system timing source. If the system is using the local oscillator of the ATM switch as the system timing source because the primary and secondary references are providing invalid timing signals, when either the primary or secondary reference becomes valid again, the system switches back to the primary or secondary source. When both the primary and secondary source become valid, the system switches to the primary source, since the primary source is always preferred over the secondary source when both sources are equally healthy.

Figure 9-10 depicts a simplex ATM PNC with T1/OC3 synchronization reference into the ATM switch.

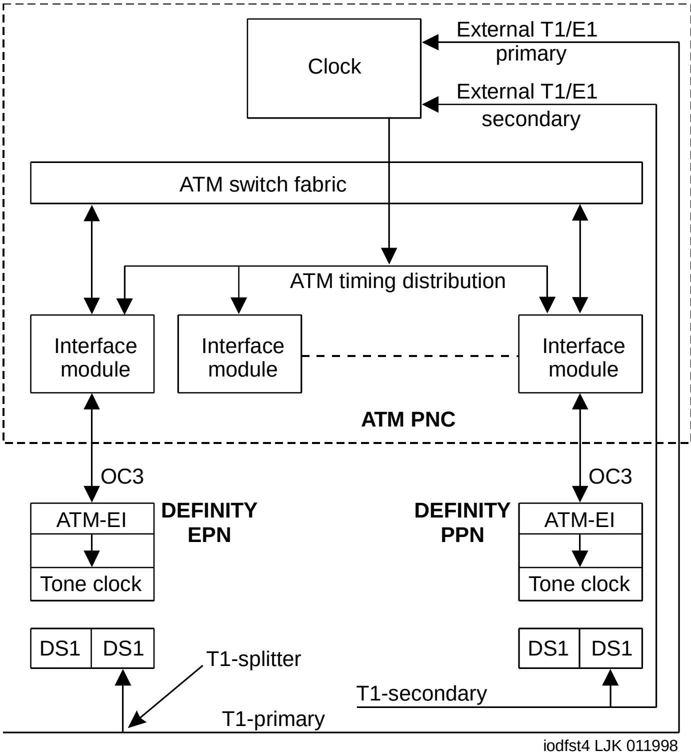

Figure 9-10. Stratum 4 synchronization with simplex ATM PNC

NOTE:
The TN722 DS1 Interface circuit pack does not provide a synchronization reference as reliably as the TN767 or TN464C circuit packs. Therefore, administer the TN767 or TN464C circuit packs as the primary or secondary sources.

Stratum 3 Synchronization

Stratum 3 synchronization is not supported in DEFINITY with ATM PNC.

Synchronization troubleshooting

A significant part of the Synchronization Recovery Strategy for a DEFINITY with ATM PNC resides in the ATM switch's clock hardware, firmware, and software. DEFINITY monitors synchronization performance and alarms faulty components within DEFINITY. Refer to "SYNC (Synchronization)".

ATM-SYNC commands

Use the following commands to help troubleshoot ATM-SYNC problems:

change synchronization	Allows primary and secondary references to be administered for the Stratum 4 option, or `ATM-Switch`, indicating that the synchronization references are input directly to the ATM switch
status synchronization	Shows the current inferred synchronization reference
status synchronization	Shows the administered primary and secondary synchronization references
list timing-source	Displays all DS1 and UDS1 locations that are allowed to be administered as primary or secondary references with the **change synchronization** command
disable/enable synchronization-switch	Prevents or allows switching to another synchronization source
test synchronization	Tests the administered synchronization source

Error Log Entries and Test to Clear Values

Table 9-112. Synchronization Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test synchronization
1 (a) (g)		None	WARNING/ MINOR	OFF	None
257 (b) (g)		None	WARNING/ MINOR	OFF	None
513 (c) (g)		None	WARNING/ MAJOR	OFF	None
1537 (d)[2]		None	WARNING	OFF	None
1793 (e)[2]	0-50	None	NONE	OFF	None
2049 (f)[2]	0	None	WARNING	OFF	None

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. It may take up to 1 hour for these alarms to clear via the "leaky bucket" strategy.

Notes:

a. Error Type 1: problem with the primary DS1 reference. It is cleared when the primary reference is restored. The following steps should give an indication of the source of the problem:

   1. Check if the primary DS1 interface circuit pack is inserted in the carrier with the **list configuration board UUCSS** command.
   2. Verify that the administered primary reference matches the DS1 reference from the network synchronization plan.
   3. Test the primary DS1 interface circuit pack with the **test board UUCSS long** command. Check the Error Log for DS1-BD or UDS1-BD errors and refer to the DS1-BD or UDS1-BD (DS1 Interface Circuit Pack or UDS1 Interface Circuit Pack) Maintenance documentation to resolve any errors associated with the primary DS1 (DS1 or UDS1) interface circuit pack. If the only errors against DS1-BD or UDS1-BD are slip errors, then follow the procedures described in the troubleshooting section above. If no errors are listed in the Error Log for the primary DS1 interface circuit pack, continue with the following steps.
   4. Test the active Tone-Clock circuit pack in the master port network with the **test tone-clock UUC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 (TDM Bus Clock Circuit Status Inquiry Test) passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to the TDM-CLK (TDM Bus Clock) Maintenance documentation to resolve the problem.

b. Error Type 257: problem with the secondary DS1 reference. It is cleared when the secondary reference is restored. Refer to note (a) to resolve this error substituting **secondary** for **primary** in the preceding resolution steps.

c. Error Type 513: the ATM switch clock is inferred to be providing the timing source for the system. The primary and secondary (if administered) are not providing a valid timing signal. Investigate errors 1 and 257 to resolve this error.

d. Error Type 1537: over half of the DS1s that are administered with slip detection enabled through the `Slip Detection?` field set to **y** are experiencing slips.

e. Error Type 1793: inferred excessive switching of system synchronization references has occurred. When this error occurs, it is inferred that the ATM switch clock has become the synchronization reference for the system.

   1. Check for timing loops and resolve any loops that exist.
   2. Test the active Tone-Clock circuit pack in the master port network with the **test tone-clock UUC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 (TDM Bus Clock Circuit Status Inquiry test) passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to TDM-CLK to resolve the problem. If not, continue with the following steps.
   3. *For Duplicated Tone-Clock circuit packs in the master port network:* Switch Tone-Clock circuit packs on the master port network with the **set tone-clock UUC** command.

      For Simplex Tone-Clock circuit packs in the master port network: replace the primary and secondary (if administered) DS1 Interface circuit packs.
   4. Investigate any other SYNC errors.

f. Error Type 2049: the ATM Expansion Interface circuit packs have errors that affect synchronization. Test the ATM Expansion Interface circuit pack with the **test board UUCSS** command.

   This error is cleared by a “leaky bucket” strategy and takes up to one hour to clear (leak away) the error counter once it is cleared.

g. Error Types 1, 257, and 513: noise on the DS1 line can cause transient alarms on synchronization. Therefore, when a synchronization problem occurs on Error Types 1, 257, or 513, a WARNING alarm is first raised for 15 to 20 minutes before the alarm is upgraded to a MINOR or MAJOR alarm.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented below when inspecting errors in the system.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Test Synchronization Test (#417)	X	X	ND

1. D = Destructive, ND = Non-destructive

Test Synchronization Test (#417)

This test updates all the Synchronization Maintenance component circuit packs with the correct information regarding their role in providing synchronization for the system. All the Tone-Clock, ATM Expansion Interface, DS1 Interface, and UDS1 Interface circuit packs in the system are updated through this test. This test either passes or aborts.

Table 9-113. TEST #417 Test Synchronization Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 3 times.
1115	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error
	PASS	The synchronization maintenance component circuit pack parameters have been successfully updated. The system should be synchronized after successful execution of this test. 1. If synchronization problems still exist, refer to the Error Log to obtain information regarding the source of the problem.

ATM-TRK (Circuit Emulation Service Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
ATM-TRK	MAJOR	test board UUCSS	ATM TRUNK (ATM Circuit Emulation Service)
ATM-TRK	MINOR	test board UUCSS	ATM TRUNK (ATM Circuit Emulation Service)
ATM-TRK	WARNING	test board UUCSS	ATM TRUNK (ATM Circuit Emulation Service)

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

This maintenance object explains how you test and repair TN230x ATM Interface circuit packs (TN2305 and TN2306) that have been administered as virtual ISDN-PRI trunks for ATM Circuit Emulation Service (CES). The maintenance instructions for TN230x circuit packs that have been administered as Expansion Interfaces for WAN connectivity are in the ''ATM-INTF (TN2305/6)'' maintenance object.

Description

The TN2305 and TN2306 (Table 9-114) are dual-purpose ATM circuit packs that can be administered as either personality:

- ''ATM Circuit Emulation Service'' or virtual ISDN-PRI signaling trunks.
- Expansion Interfaces (ATM-EI) for Port Network Connectivity (ATM-PNC) between the PPN and the EPNs.

Either circuit pack "personality" requires SONET OC-3 or SDH STM-1 fiber cable connections between the circuit pack and the ATM switch. As a trunk board, it supports direct connection between ATM CES circuit packs without an intervening ATM switch.

Table 9-114. R7 ATM-TRK circuit packs

Circuit pack	Channel types	Interface	Fiber	Echo cancellation
TN2305	B and D channels	24 or 32 channel	Multi mode	Y
TN2306	B and D channels	24 or 32 channel	Single mode	Y

NOTE:
TN230x circuit packs are not interchangeable.

ATM Circuit Emulation Service

Under ATM Circuit Emulation Service (CES), you simulate ISDN-PRI circuits by assigning ports to *signaling groups*. Each signaling group represents a PRI circuit, and the ports in the group represent the D-channel and B-channels of that circuit. TN230x circuit packs support up to 248 ports per circuit pack.

Virtual D-channels. Non-facility associated signaling is not supported under ATM-CES, so you must reserve one port in each signaling group for use as a D-channel (channel 24 when emulating a T-1 ISDN facility, channel 16 when emulating an E-1 facility). The D-channel can be any physical port from 9 to 32.

Virtual circuits. The TN230x can support a varied number of virtual circuits, depending on the switch and the administration of the circuit pack. Table 9-115 lists the possibilities for various G3V4 models.

Table 9-115. Circuit and channel capacities, for each DEFINITY model

Model	Ports	Emulated circuits (signaling groups)	Channels/circuit	Virtual D-channels	Virtual B-channels
R6csi	248	1 to 8	24 (T1), 31 (E1)	1-8	6-240
R6si	248	1 to 8	24 (T1), 31 (E1)	1-8	6-240
R6r	248	1 to 8	24 (T1), 31 (E1)	1-8	6-240

Virtual trunk groups. You cannot bundle physical DS1 ISDN-PRI circuits and virtual ATM-CES circuits into the same trunk groups. Virtual circuits can only be assigned to all-virtual, all-ATM trunk groups. Table 9-116 lists the possible trunk-group capacities.

Table 9-116. ATM CES capacities by DEFINITY model

Model	Ports per trunk group (max)	Trunk groups per switch (max)	Trunks per switch (max)
R6csi	99	99	400
R6si	99	99	400
R6r	255	666	400

Table 9-117 shows the ATM CES capacities for both T1 and E1 circuits.

Table 9-117. Ports available for trunking, for each ISDN facility type

Type	Channels per signaling group (trunk)	Max. signaling groups (trunks) per circuit pack	Max. available ports	Reserved ports	Total ports
T1:	24	8	192	ports 1-8	256
E1:	31	8	248	ports 1-8	256

LEDs

The ATM circuit pack LEDs give you a visual indication of the condition of the TN230x circuit pack (Table 9-118).

Table 9-118. ATM-TRK LED interpretation

LEDs	Condition	LED status
Red	Error (alarm logged)	On
Red and Green	Booting (LEDs being tested)	Blinking (on 200 ms, off 200 ms)
Green	Test/maintenance in progress	On
Yellow	Fiber Loss of Signal (LOS), LOF, MS_RDI, MS_AIS, LCD, HP_RDI, HP_AIS, LOP, PSC	Blinking fast (100 ms on, 100 ms off)
Yellow	Signal to ATM switch down	Blinking slowly (500 ms on, 500 ms off)
Yellow	One or more CES signaling groups administered	On
Yellow	CES signaling group not administered or not reporting to firmware	Off

ATM-TRK-related commands

Table 9-119 lists some commands that can be useful in troubleshooting ATM errors and alarms.

Table 9-119. ATM CES troubleshooting commands

Command	Description
display circuit-packs *cabinet*	Displays the circuit packs in the cabinet, identifying ATM Trunk as well as ATM-EI boards. "ATM Interface" boards have not been administered as CES or PNC.
display atm ports *UUCSSppp*	Displays the 256 ports on the ATM board with the corresponding signaling and trunk group.
list configuration atm	Lists the ATM boards, identifying equipment location, board code, type, and vintage.
list configuration trunks	Lists boards identifying assigned ports. While the ATM board is listed, the 256 ports are not.

Continued on next page

Table 9-119. ATM CES troubleshooting commands — *Continued*

Command	Description
busyout/release atm signaling-group	Busyout or release of an ATM signaling group within a trunk group.
status atm signaling-group	Show current status of an ATM signaling group.
status trunk-group	Shows status of the trunk group (ATM signaling groups are part of trunk groups).

Error Log Entries and Test to Clear Values

Table 9-120. ATM-TRK Error Log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any		test board UUCSS
1(a)		None	MIN	ON	
18(b)	0	busy out board UUCSS	MIN	ON	release board UUCSS
23(c)	0	None	MIN	ON	
125(d)		None	MIN	ON	
257(e)	Any	Control Channel Loop Test (#52)	MIN	ON	test board UUCSS r 2
513(f)	Any	ATM Cross talk Test (#1298)	MIN	ON	test board UUCSS l r 1
769(g)	35	ATM Error Query Test #1259	WRN	OFF	test board UUCSS
770(g)	25	ATM Error Query Test #1259	WRN	OFF	test board UUCSS
771(h)	26	ATM Error Query Test #1259	WRN	OFF	test board UUCSS
1281(i)		ATM Board Error Query Test (#1259)	WRN/ MIN	OFF	test board UUCSS r 1
1537(j)	12	None	WRN/ MIN	ON	
1538(k)	0	None	WRN/ MIN	ON	reset board UUCSS

3330(q)	3		MIN	OFF	
3585(r)		ATM Board Error Query test (#1259)	WRN/ MIN	ON	test board UUCSS l
3841(s)	Any	None			
3842(t)	11	None			
3999(v)	Any	None			

Notes:

a. Error Type 1: the ATM-TRK circuit pack does not appear to be in its assigned slot.

   1. Make sure that the ATM-TRK circuit pack is installed correctly seated in the slot administered for the ATM trunk.

b. Error Type 18: the ATM circuit pack is busied out.

   1. Run **release board UUCSS**.

c. Error Type 23: an ATM trunk is administered, but the corresponding ATM-TRK circuit pack does not appear to be physically installed.

   1. Make sure the ATM-TRK circuit pack is installed and correctly seated in the slot.

d. Error Type 125: an ATM trunk is administered but a non-ATM-TRK circuit pack is installed in the corresponding slot. You have two options:

   - Replace the incorrect circuit pack with an ATM-TRK circuit pack.
   - Or re-administer the slot for the circuit pack that is physically present, locate the slot where the ATM-TRK circuit pack is actually installed, and re-administer the ATM trunk.

e. Error Type 257: Control Channel Loop Test #52 failed. The circuit pack is not properly connected with the control channel on the TDM bus.

   1. Take the corrective action specified by Test #52.

f. Error Type 513: ATM Crosstalk Test (#1298) failed. The board is writing to or reading from a TDM time slot that is not allocated to the board, or the Digital Signal Processor (DSP) selected for this test has malfunctioned.

   1. Run **test board UUCSS**.
   2. Take the corrective action specified for Test #1298.

g. Error Type 769, 770: the ATM switch is requesting too many LAPD retransmissions (off-board ATM cell corruption errors).

Error Type	Aux Data	Description
769	35	LAPD excessive retransmission requests
770	25	ATM uncorrectable cell headers - threshold

   1. Check the connections between the fiber cable, the ATM-TRK circuit pack, and the ATM switch.
   2. See "PKT-BUS (Packet Bus)" for test and corrective procedures.
   3. Determine what type of fiber is installed between the ATM-TRK circuit pack and the ATM switch.

If	Then
There is multimode fiber	Check the length of the fiber. If the cable is longer than 2 km, it is probably causing the errors.
There is single-mode fiber or the length of the multimode fiber is less than 2 km	The source of the errors may lie in the ATM facility, the ATM-TRK circuit pack, or the far-end circuit pack.

4. Perform ATM loopback tests on the near-end ATM-TRK circuit pack and on the far-end circuit pack or ATM switch.

If	Then
The ATM-TRK circuit pack fails the loopback test.	The problem is in the ATM-TRK circuit pack. Replace the circuit pack.
The far-end circuit pack or ATM switch fails the loopback test.	The problem is in the far-end circuit pack or ATM switch. Consult the circuit-pack or ATM switch documentation for advice.
The equipment at each end of the ATM span passes the loopback test	The problem is somewhere in the ATM span. Lack of bandwidth may be forcing an intermediate ATM switch to drop cells.

5. Check capacity and peak bandwidth consumption for the ATM span.

If	Then
The capacity of the span is inadequate or bandwidth consumption is too high.	Reduce traffic on the G3V4 switch to ensure that it is using no more that its subscribed bandwidth.

h. Error Type 771: the ATM switch is sending cells with unknown Virtual Path-Identifier (VPI) and Virtual Channel-Identifier (VCI) addresses.

1. Make sure that the ATM-TRK circuit-pack address is administered identically on the ATM switch and the DEFINITY ECS.

i. Error Type 1281: Board major signals error (loss of high-level signal). The far-end has detected a major problem in transmissions originating from the ATM-TRK circuit pack. The possible Aux Data values for this software counter are listed in Table 9-121.

Table 9-121. Error type 1281 Aux Data and repair procedures

Aux Data	Alarm Description	Repair procedure
15	SYSCLOCK failed	The board is not locked to the TDM backplane clock signal. This is probably due to a Tone Clock problem. 1. Check for TDM-BUS or TONE-BD errors in the Error Log. 2. If no other problems are present, reset the circuit pack (**reset board UUCSS**)

Continued on next page

Table 9-121. Error type 1281 Aux Data and repair procedures — *Continued*

Aux Data	Alarm Description	Repair procedure
16	Loss of Signal: LOS	The fiber is not connected properly to the ATM-TRK board or ATM switch (or to the multiplexer section [MUX] if present).It is possible that the board transceivers are not functioning properly. 1. Run **test board UUCSS** command. 2. If Test #1259 fails with Error Code 16, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. If it does the problem is off-board. 3. If the yellow LED continues to flash, replace the circuit pack.
17	Loss of Frame: LOF	The fiber signal cannot obtain or maintain STM-1/OC-3 framing. 1. Try to more the fiber on the ATM switch side to a different port. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**).
18	Multiplexer Section Alarm Indication Signal: MS_AIS	There is a major problem on the far end (between multiplexer section [MUX] and the switch) that prohibits the circuit pack from sending a valid signal. 1. See if the ports at the MUX and/or the ATM switch are connected snugly. 2. Run **test board UUCSS** command 3. If Test #1259 fails with Error Code 18, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 4. If it does the problem is off-board. 5. If the yellow LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.

Continued on next page

Table 9-121. Error type 1281 Aux Data and repair procedures — *Continued*

Aux Data	Alarm Description	Repair procedure
19	Multiplexer Section Remote Defect Indicator: MS_RDI	The far-end is detecting a major problem with the signal that this board is transmitting. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface 2. Run **test board UUCSS** command. 3. If Test #1259 fails with Error Code 19, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 4. If it does the problem is off-board. 5. If the yellow LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.
20	Loss of pointer: LOP	ATM framer chip is unable to access the payload part of the signal. 1. Reset the board (**reset board UUCSS**). 2. If the error persists replace the board.
21	Path Signal Error (PSL) (STM1/SONET)	The incoming signal payload is not set up for transmission of ATM data. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface.
22	High-level Path Alarm Indication Signal: HP_AIS	The payload is invalid. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface. 2. Run **test board UUCSS**. 3. If Test #1259 fails with Error Code 22, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 4. If it does the problem is off-board. 5. If the yellow LED continues to flash, replace the circuit pack.

Continued on next page

Table 9-121. Error type 1281 Aux Data and repair procedures — *Continued*

Aux Data	Alarm Description	Repair procedure
23	High-level path Remote defect Indicator: HP_RDI	The far-end is detecting a major problem with the signal that this board is transmitting. The transmitted payload is invalid. 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface. 2. Run **test board UUCSS** command; if the Test #1259 fails with Error Code 23, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the yellow LED flash goes away. 3. If it does the problem is off-board. 4. If the yellow LED continues to flash, replace the circuit pack.
24	Loss of cell delineation (LCD)	On board ATM framer chip is not able to frame cells based on the cell header. 1. Reset the board (**reset board UUCSS**). 2. If the error persists, replace the board.
27	SIGCON_DOWN ATM switch high level signal.	The board cannot communicate with the ATM switch. 1. Busyout the board (busyout board UUCSS). 2. Test the board (**test board long UUCSS**). 3. If Test #1260 fails, replace the board. 4. If Test #1260 passes, make sure the ATM address on both the DEFINITY and the ATM switch sides are the same for this board. 5. If the address is the same, change the port on the ATM switch side. 6. If the error is resolved, the problem is on the ATM switch port.

j. Error Type 1537: LANHO bus timeout. The circuit pack is transmitting too many bytes on the LAN bus for a single frame. This may be due to:

- on-board fault
- faulty data received on one of the circuit pack's external ports

If the error occurs 3 times in 10 minutes, the board is isolated from the Packet Bus and the board is alarmed. To clear the alarm:

1. Restore this circuit pack to the Packet Bus with this command sequence:
   - **a. busyout board UUCSS**
   - **b. reset board UUCSS**
   - **c. test board UUCSS long**
   - **d. release board UUCSS**
2. If the problem persists and there are no PKT-BUS or port alarms, replace the circuit pack.

k. Error Type 1538: The ATM-TRK circuit pack is hyperactive (sending an abnormal number of control messages to the processor). Use the following command sequence for this ATM-TRK circuit pack:

1. **busyout board UUCSS**
2. **reset board UUCSS**
3. **test board UUCSS long**
4. **release board UUCSS**
5. If this error persists, replace the circuit pack.

l. Error Type 1794: LANHO transmit FIFO overflow. The circuit pack's transmit buffers have overflowed.

1. Run **test board UUCSS r 5**.

If	Then
Test #598 fails	Replace the circuit pack.

m. Error Type 2049: ACL Link Failure (link is down). The ATM Control Link (ACL) has failed, communication has been interrupted between the SPE and the ATM-TRK circuit packs on the system, and signaling-group parameters are not communicated across the packet bus.

1. Check the "PKT-BUS (Packet Bus)" and SYS-LINK (System Link) maintenance objects, and follow the repair procedures indicated.
2. Run **test board UUCSS** against the ATM-TRK circuit pack.

If	Then
Test 598 fails.	Follow the repair procedures suggested for that test.

n. Error Type 2306: too many parity errors in data received from the LAN/packet bus.

1. Run **test board UUCSS**.

If	Then
Test 598 fails.	Follow the repair procedures suggested for that test
Test 598 passes.	See the "PKT-BUS (Packet Bus)" maintenance object, and perform the specified repair.
There are no errors against the packet bus maintenance object.	This may be a transient condition. Do nothing now, but escalate if the error occurs repeatedly.

o. Error Type 2561: Packet Interface Loop Around Test (598) Failure. The ATM-TRK circuit pack has failed, the packet bus has a minor alarm active, or the packet bus is out of service.

1. Run **test board UUCSS**.

If	Then
Test 598 fails.	Follow the repair procedures suggested for that test
Test 598 passes.	See the "PKT-BUS (Packet Bus)" maintenance object, and perform the specified repair.
There are no errors against the packet bus maintenance object.	This may be a transient condition. Do nothing now, but escalate if the error occurs repeatedly.

p. Error Type 2817, 2818: DSP failure detected along the circuit path.

1. Run **test board UUCSS**.
2. Follow the repair procedures suggested for Test #1293.

Error Type	Description
2818	One or more DSPs failed. The `Aux Data` field contains the ID number of DSP that failed
2817	DSP test failure. The `Aux Data` field contains the following information about the failed DSPs: ■ X is the number of talker DSPs ■ Y is the number of listener DSPs ■ Z is the number of echo-cancelling DSPs

q. Error Type 3330: LANHO critical error. The circuit pack reports that the on-board LANHO chip is insane (possibly due to a problem in Packet Bus arbitration, in the transmission line frame, or in the circuit pack itself). The circuit pack cannot talk to the Packet Bus.

1. Check for PKT-BUS alarms.

If	Then
There is a packet-bus alarm.	There is probably a packet-bus problem, particularly if other circuit packs on the packet bus report the same error. See the "PKT-BUS (Packet Bus)" maintenance object and the packet-bus fault-isolation and recovery sections of the maintenance manual for repair procedures.
There are no packet-bus alarms.	Run the following command sequence: **busyout board UUCSS** **reset board UUCSS**. **test board UUCSS long** **release board UUCSS**
The problem persists.	Replace the ATM-TRK circuit pack.

r. Error Type 3585: Major board alarm; failure of critical components involved in the operation of the circuit pack. The circuit pack has failed, and the switch may no longer recognize it.

Aux Data	Description
1	ATM framer chip failure
2	NCE failed
4	TDM PLD failed
5	All DSPs on the circuit pack have failed
6	Receive Network Processor (RNP) failed
7	Transmit Network Processor (TNP) failed
8	MEMORY read/write failure
9	DUART failure

1. Run **test board UUCSS long**.

If	Then
Test #1259 fails with Error Code XXYY and XX is an AUX value in the preceding table	Replace the ATM-TRK circuit pack.
The system does not recognize the circuit pack	Replace the ATM-TRK circuit pack.

s. Error Type 3841: the ATM-TRK circuit pack received an unrecognized message from the switch and responded with an inconsistent down-link error message.

   1. Do nothing. This error does not affect service.

t. Error Type 3842: LANHO Receive FIFO Overflow error; the packet bus is delivering data to the ATM-TRK circuit pack faster than the circuit pack can distribute it to the endpoint.

   1. Do nothing. The circuit pack can recover by itself.

u. Error Type 3999: circuit pack sent a large number of control channel messages to the switch within a short period of time.

If	Then
Error Type 1538 is also present	Circuit pack is taken out of service
If Error Type 1538 is not present	Circuit pack is *not* taken out of service, but has generated 50% of the messages necessary to be considered hyperactive. ■ This may be normal during heavy traffic. ■ If the error is logged during light traffic, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and error codes

Always investigate problems in the order presented. When you clear one of the error codes associated with a given test, you clear errors generated by other tests in the testing sequence. If you clear errors out of order, you can lose important information.

Table 9-122. System Technician-Demanded Tests: ATM-TRK

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
ATM Board Time Of Day Update (#1261)		X		ND
Connection Audit Test (#50)		X		ND
Control Channel Loop Test (#52)		X		ND
Packet Interface Loop Around Test (#598)	X	X		ND
ATM DSP Test (#1293)	X	X		ND
ATM Board Framer Looparound Test (#1260)		X		D
ATM Board Error Query Test (#1259)	X	X		ND
ATM Cross Talk Test (#1298)		X		ND
ATM Board Reset (#1256)			X	D

1. D = Destructive, ND = Non-destructive

Connection Audit Test (#50)

Non-destructive (in a sane switch environment).

The Connection Audit test updates TDM time slots. It sends network-update Control Channel Message Set (CCMS) messages that tell the ATM-TRK circuit pack to listen to, talk to, or disconnect particular time slots.

The test passes if software successfully sends the downlink network-update messages. It aborts otherwise.

CAUTION:

Though normally non-destructive, this test might unintentionally tear down an active call if the connection-manager software's tables are corrupt.

Table 9-123. TEST #50 Connection Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command up to 5 times at 1-minute intervals.
1019	ABORT	The test aborted because a test was already running on the port. 1. Retry the command up to 5 times at 1-minute intervals.
	FAIL	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
	PASS	The circuit pack has been updated with its translation.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check the board translations. 2. If the ATM-TRK circuit pack is not administered, run **add atm trunk UUCSS**. 3. If the ATM-TRK circuit pack is administered correctly, check the error log. 4. If ATM-TRK circuit pack is hyperactive, shut down, and reseat the circuit pack to force re-initialization. 5. If the ATM-TRK circuit pack is correctly inserted, run **busyout board**. 6. Run **reset board**. 7. Run **release busy board**. 8. Run **test board long** to re-establish the linkage between the internal ID and the port.

Control Channel Loop Test (#52)

The non-destructive Control Channel Loop Test is part of the maintenance subsystem’s Common Port Board Testing feature. The Common Port Board test sends board vintage queries to a port circuit pack and checks the responses. CCMS downlink notifications tell the circuit pack which TDM Bus (A or B) carries the control channel and which carries the touch tones.

The test passes if the port circuit pack responds. The test aborts if the circuit pack does not respond. The test fails otherwise.

Table 9-124. Control Channel Test #52

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Test request timed out.
2100	ABORT	Could not allocate needed system resources.
2500	ABORT	Internal system error 1. Retry the command up to 3 times at 1-minute intervals.
	FAIL	The ATM circuit pack responded incorrectly. 1. Retry the command up to 3 times at 1-minute intervals. 2. If the test continues to fail, reset the ATM-TRK circuit pack (**reset board UUCSS**). 3. If test continues to fail, replace the circuit pack or transceiver.
	PASS	The ATM-TRK circuit pack is communicating correctly with the software.
0	NO BOARD	Circuit pack not detected. 1. Check the error log for Error 125 (wrong board) or Error 131 (no board), and correct any errors found. 2. Make sure that the ATM-TRK circuit pack is properly translated and inserted. 3. Check for Error 1538 (hyperactivity). If hyperactive, run **reset board UUCSS**. 4. Run the test again. If it fails, replace the ATM-TRK circuit pack, and retest.

Packet Interface Loop Around Test (#598)

This nondestructive test checks the ATM-TRK circuit pack's packet-bus interface. The LANHO chip sends data through the bus and back to itself. Figure 9-212 describes this test, substituting "CES mode" for "PNC mode."

If the data received is consistent with the data sent, the test passes. The test does not run if the packet bus in the specified port network has a minor alarm, or is out of service, or if the packet bus in the PPN is out of service.

Table 9-125. Packet Interface Loop Around Test (#598)

Error Code	Test Result	Description/ Recommendation
1144	ABORT	The packet bus in the PPN has a major alarm against it. 1. Run **display alarms** and **display errors**. 2. Perform the PKT-BUS repair procedures associated with the alarms. 3. Retry the command.
2000	ABORT	Test request timed out. 1. Retry the command up to 3 times at 1-minute intervals. 2. If the test fails repeatedly, run **reset board UUCSS**. 3. If the test continues to fail, replace the ATM-TRK circuit pack.
2012	ABORT	Internal system error.
2100	ABORT	Could not allocate needed system resources. 1. Retry the command up to 5 times at 1-minute intervals.
ANY	FAIL	Data packet not received correctly by the ATM Interface circuit pack. 1. Retry the command up to 5 times at 1-minute intervals. 2. If the test continues to fail, replace the ATM-TRK circuit pack.
	PASS	The Packet Interface Test passed.

ATM Board Reset (#1256)

This test is destructive.

This test checks the sanity of the angel processor using the Sanity and Control Interface (SAKI) test (Common Port Board test #53). It resets the circuit pack if the SAKI test fails and runs the test again.The ATM Board Reset test passes if SAKI can successfully reset and retest the board.

Before running the SAKI test, you must:

- Move synchronization off the ATM-TRK circuit pack
- Busyout the ATM-TRK circuit pack

The test aborts if the ATM-TRK circuit pack is supplying synchronization.

Table 9-126. ATM Board Reset (#1256)

Error Code	Test Result	Description/ Recommendation
1005	ABORT	Wrong circuit pack configuration to run this test. The ATM CES Trunk Interface circuit pack provides timing for the system and cannot be reset without major system disruptions. 1. Set synchronization to another ATM CES trunk circuit pack or to the Tone-Clock circuit pack and test again.
1015	ABORT	Test cannot be run because the ATM-TRK circuit pack has not been busied out. 1. Busyout out the circuit pack (**busyout board UUCSS**). 2. Repeat the test (**test board UUCSS long**).
None	ABORT	Could not allocate the required system resources 1. Retry the command up to 5 times at 1-minute intervals. 2. If the test continues to abort escalate the problem.
2000	ABORT	Sanity test timed out. 1. Wait 5 minutes. Then see if ATM-TRK circuit pack is visible to the system by running **list config all**. 2. If the ATM-TRK circuit pack is visible (**list configuration all**), run the test again, and escalate if the problem recurs. 3. If the ATM-TRK circuit pack is not visible to the system (**list configuration all**), re-seat the ATM-TRK circuit pack, and retest. 4. If the ATM-TRK circuit pack is still not recognized by the system, replace the board.
2100	ABORT	Could not allocate required system resources 1. Retry the command up to 5 times at 1-minute intervals.
2500	ABORT	Internal system error. 1. Try to reset the circuit pack (**reset board UUCSS**).

Continued on next page

Table 9-126. ATM Board Reset (#1256) — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The circuit pack failed to reset
2	FAIL	The circuit pack failed to restart. 1. Retry command. 2. If the problem persists, replace the ATM-TRK circuit pack.
	PASS	The ATM-TRK circuit pack is successfully reset.
0	NO BOARD	No board detected. 1. Check the error log for Error 125 (wrong board) or Error 131 (no board), and perform the appropriate repair, if needed. 2. Ensure that the board is properly translated and inserted. 3. Check for Error 1538 (hyperactivity). If hyperactive, run **reset board UUCSS**. 4. Run the test again. If it fails, replace the ATM-TRK circuit pack, and retest.

ATM Board Error Query Test (#1259)

This non-destructive ATM Error Query Test retrieves the most severe, active, on- and off-board problem from the ATM-TRK circuit pack's firmware and increments error counts in the Error Log.

The test passes if there are no errors and fails otherwise. A passing test clears the software counters; a failure increments the counter associated with the problem that caused the failure and clears the others.

Table 9-127. ATM Board Error Query Test (#1259)

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Test request timed out.
2031	ABORT	SCD failure. Unable to sent down-link message.
2100	ABORT	Could not allocate needed system resources.
2500	ABORT	Internal system error 1. Retry the command up to 3 times at 1-minute intervals.

Continued on next page

Table 9-127. ATM Board Error Query Test (#1259) — *Continued*

Error Code	Test Result	Description/ Recommendation
XXYY	FAIL	On-board error XX (Table 9-128) and/or off-board error YY (Table 9-129). 1. Examine the error logs and repair any errors found.
	PASS	The ATM circuit pack has passed this test. No service effecting errors/alarms have been detected on board.
0	NO BOARD	ATM-TRK circuit pack not found 1. Check the error log, and correct Error 125 (wrong board) or Error 131 (no board), if found. 2. Make sure that the board is properly translated and inserted. 3. Check for hyperactivity (Error 1538). Run **reset board UUCSS** if hyperactive. 4. Run the test again. If it fails, replace the board, and retest.

Aux Data XX

Table 9-128. Aux Data XX for ATM Board Error Query Test (#1259)

If XX=	Then
1	ATM framer chip failed
2	NCE chip failed
3	LANHO critical error
4	TDM Programmable Logic Device Failed
5	All on-board DSPs failed
6	Receive Network Processor failed
7	Transmit Network Processor failed
8	Memory read failed
9	Dual UART chip failed
10	LANHO receive parity error
11	LANHO FIFO over flow error

Continued on next page

Table 9-128. Aux Data XX for ATM Board Error Query Test (#1259) — *Continued*

If XX=	Then
12	LAN bus time out.
13	LANHO Xmit FIFO overflow error
14	One or more on-board DSPs failed

Aux Data YY

Table 9-129. Aux Data YY for ATM Board Error Query Test (#1259)

If YY=	Then
15	Back plane clock failed
16	Loss of signal
17	Loss of frame
18	MS alarm indication signal error
19	MS remote defect indicator error
20	Loss of Pointer
21	Path Signal Level mismatch
22	High-level Path alarm indication signal
23	High-level Path remote defect indicator
24	Loss of Cell Delineation
25	Uncorrectable headers sent by the ATM switch.
26	Too may cells with invalid VPI/VCI combination.
27	The signalling link between the board and the ATM switch is down.
34	AAL5 Excessive retransmission requests -per VC
35	LAPD Excessive retransmission requests - per VC

ATM Board Framer Looparound Test (#1260)

Destructive

This test verifies the board's circuit (Time Division Multiplexing) and packet paths using an on-board, dummy virtual circuit. Before running the test, you must

- busyout the ATM-TRK circuit pack (**busyout board UUCSS**) and
- switch synchronization (**change synchronization**) from the ATM-TRK circuit pack

If the ATM-TRK circuit pack is supplying synchronization, the test aborts.

The test sends a digital counter from one of the tone generators via one of the TDM bus time slots. The ATM framer interface converts this digital counter to ATM cells and loops them back internally. The ATM-TRK circuit pack converts the cells back to a digital counter and sends it to the tone receiver for verification. If the circuit pack passes the circuit check, the software checks the packet path by sending a packet from the packet-interface circuit pack to the ATM-TRK circuit pack via the ATM protocol stack.

Figure 9-216 and Figure 9-217 show a diagrams of this two-part test, substituting "CES mode" for "PNC mode."

Table 9-130. ATM Board Framer Looparound Test (#1260)

Error Code	Test Result	Description/ Recommendation
1002	ABORT	Time slots could not be allocated. Traffic may be heavy or time slots may be out-of-service. 1. Run **display errors**, and perform repairs associated with TDM-BUS errors. 2. Retry the command up to 3 times at 1-minute intervals.
1003	ABORT	Tone receiver could not be allocated. 1. Run **display errors**, and perform the repairs associated with TTR-LEV and TONE-PT errors. The test cannot run unless there is at least one Tone Detector available on the network that holds the ATM-TRK circuit pack. 2. Retry the command up to 3 times at 1-minute intervals.
1015	ABORT	ATM-TRK circuit pack not busied out 1. Busyout the ATM circuit pack. 2. Rerun the command.

Continued on next page

Table 9-130. ATM Board Framer Looparound Test (#1260) — *Continued*

Error Code	Test Result	Description/ Recommendation
1033	ABORT	ATM-TRK circuit pack not found 1. See if the switch can see the circuit pack. Run status Trunk Group. 2. Retry the command.
1139	ABORT	Major alarm on the EPN packet bus 1. Run **display alarms**, and perform the repairs associated with PKT-BUS errors. 2. Run **display errors**, and perform the repairs associated with PKT-BUS errors. 3. Retry the command.
1141	ABORT	Packet-interface circuit pack out of service 1. See "PKT-INT (Packet Interface Circuit Pack)".
1144	ABORT	Major alarm on the PPN packet bus 1. Run **display alarms**, and perform the repairs associated with PKT-BUS. 2. Run **display errors**, and perform the repairs associated with PKT-BUS. 3. Retry the command.
1394	ABORT	ATM-TRK circuit pack out of service 1. Run ATM Board Reset Test #1256.
2000	ABORT	Request timed out. 1. Retry the command up to 3 times at 1-minute intervals.
2060	ABORT	Packet-bus link has failed. 1. Retry the command up to 3 times at 1-minute intervals. 2. If the test continues to abort, run **display errors**, and perform the repairs associated with PKT-INT errors.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error 1. Retry the command up to 3 times at 1-minute intervals.

Continued on next page

Table 9-130. ATM Board Framer Looparound Test (#1260) — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Test tone not detected over the looparound; packet-path test aborted. 1. Test the active tone clock on the port network, and verify that a tone is reaching the ATM-TRK circuit pack. If not, correct the condition. 2. Run **test board UUCSS long**. 3. If the test continues to fail, replace the ATM-TRK circuit pack or transceiver. 4. Rerun **test board UUCSS long**.
2	FAIL	TN1655 Packet Interface circuit pack could not detect the correct data packet. 1. Test the TN1655 Packet Interface circuit pack to verify that it is functioning properly. If not, correct the condition. 2. Run **display errors**, and perform the repairs associated with DS1 CONV-BD errors, if applicable. 3. Run **display alarms**, and perform the repairs associated with DS1 CONV-BD alarms, if applicable. 4. Run **test board UUCSS long**. 5. If this test continues to fail, replace the ATM-TRK circuit pack. 6. Run **test board UUCSS long**.
3	FAIL	Distorted tone returned 1. Test the active tone clock on the port network, and verify that a tone is reaching the ATM-TRK circuit pack. If not, correct the condition. 2. Run **test board UUCSS long**. 3. If the test continues to fail, replace the ATM-TRK circuit pack. 4. Run **test board UUCSS long**.
4	FAIL	Unable to create TDM-path loop. 1. Retry the command up to 3 times at 1-minute intervals. 2. If this test continues to fail, replace the ATM-TRK circuit pack. 3. Run **test board UUCSS long**.
5	FAIL	Unable to create packet-path loop. 1. Retry the command up to 3 times at 1-minute intervals. 2. If this test continues to fail, replace the ATM-TRK circuit pack. 3. Rerun **test board UUCSS long**.

Continued on next page

Table 9-130. ATM Board Framer Looparound Test (#1260) — *Continued*

Error Code	Test Result	Description/ Recommendation
6	FAIL	A previously established looparound was not released. 1. Run **reset board UUCSS**. 2. Retry the command up to 3 times at 1-minute intervals. 3. If this test continues to fail, replace the ATM-TRK circuit pack. 4. Rerun **test board UUCSS long**.
	PASS	The non-optical parts of the ATM-TRK circuit pack are functioning properly.
0	NO BOARD	ATM-TRK circuit pack not found 1. Check the error log for Error 125 (wrong board) or Error 131 (no board), and correct as necessary. 2. Check that the board is properly translated and inserted. 3. Check for Error 1538 (hyperactivity), and run **reset board UUCSS** if necessary. 4. Rerun **test board UUCSS long**. 5. If the test fails, replace the board, and rerun **test board UUCSS long**.

ATM Board Time Of Day Update (#1261)

The non-destructive ATM-TOD-UPD test updates the system time that the ATM-TRK circuit pack uses for SDH/SONET performance monitoring and synchronizes the ATM-TRK circuit pack with the DEFINITY system clock. This test is run during initialization, scheduled maintenance, and craft long test.

Table 9-131. ATM Board Time Of Day Update (#1261)

Error Code	Test Result	Description/ Recommendation
2031	FAIL	The attempt to send the message to the ATM-TRK circuit pack was not successful.
2500	FAIL	Internal system error. Did not send the time of day information to the board. 1. Retry the command up to 3 times at 1-minute intervals. 2. If the test aborts with the same error code, escalate the problem.
	PASS	The ATM-TRK circuit pack is successfully updated with system time. 1. If the **status port-network** command still indicates that this link is down, it is possible that one or both of the ATM-TRK circuit packs have been busied out. 2. If the link still does not come up, reset one or both ATM-TRK circuit packs on the link.
0	NO BOARD	No board detected. 1. Check the error log for wrong board (Error 125) or no board (Error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (Error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the board may be bad. Replace the board and retest.

ATM Board DSP Test (#1293)

Non-destructive

There are three kinds of digital signal processors (DSPs): talkers, listeners, and echo cancelers.Talkers put data on the TDM bus, listeners take data off the TDM bus, and echo cancelers filter out echoes of the main transmission. Firmware allocates DSPs in sets of three (one of each type), up to a maximum of 8 sets. This has three parts, one for each type of DSP. If the test fails for all DSPs, a MAJOR alarm is raised. If the test fails for one or more DSPs, a MINOR alarm is raised. If a DSP is busy, the test passes for that DSP. The test aborts if system resources are not available. Each part of the test returns the number of DSPs that passed or failed. This test run during initialization, error analysis testing, periodic, scheduled, and craft short and long testing.

Table 9-132. ATM Board DSP Test (#1293)

Error Code	Test Result	Description/ Recommendation
1002	ABORT	Could not allocate time slots. Traffic may be heavy or time slots may be out-of-service 1. Run **display errors**, and follow associated repair procedures for TDM-BUS. 2. Retry the command up to 3 times at 1-minute intervals.
1003	ABORT	Could not allocate a tone detector. Too few tone detectors present or tone detectors out-of-service. 1. Run **display errors**, and follow the repair procedures associated with any "TTR-LEV (TTR Level)" errors that appear. 2. Make sure that there is at least one tone detector on the network that holds the ATM-TRK circuit pack. 3. Resolve any "TONE-PT (Tone Generator)" errors listed in the Error Log. 4. Retry the command up to 3 times at 1-minute intervals.
1962	ABORT	All DSPs are busy. This is a very unlikely event. 1. Retry the command up to 3 times at 1-minute intervals.
2000	ABORT	Test timed out. 1. If the ATM-TRK circuit pack is in standby, reset the board and run the test again after the ATM-TRK circuit pack is inserted. 2. Examine the Error Log for Error 1218 (bad DSP). 3. Run the test again.
2100	ABORT	Could not allocate required system resources.
2302	ABORT	Inconsistent uplink message from the ATM-TRK circuit pack.
2500	ABORT	Internal system error 1. Retry the command up to 5 times at 1-minute intervals.
2752	ABORT	Circuit pack not a TN2305A/2306A.

Continued on next page

Table 9-132. ATM Board DSP Test (#1293) — *Continued*

Error Code	Test Result	Description/ Recommendation
XYZ	FAIL	There is at least one bad DSP on the board. The ***X*** value indicates the number of bad talker DSPs, ***Y*** indicates the number of bad listener DSPs and ***Z*** indicates the number of bad echo canceler DSPs. 1. Test the Active Tone-Clock on the port network that contains the ATM-TRK circuit pack for dial-tone. Repair as needed. 2. Repeat the short test on the ATM-TRK circuit pack. 3. If the test continues to fail, check for service-affecting MINOR alarms. If a MINOR alarm is raised for Error Type 2817 or 1818, replace the circuit pack. 4. If a WARNING alarm is raised, this is a non-service-affecting error, and the circuit pack can still process calls.
XY8	PASS	The test passed for some or all DSPs. XY8 indicates the number of talker, listener, and echo-canceler DSPs for which the test passed (the rest of the DSPs were skipped). The ***X*** value indicates the number of good talker DSPs, ***Y*** indicates the number of good listener DSPs and ***Z*** indicates the number of good echo canceler DSPs.
0	NO BOARD	No board detected. 1. Check the Error Log for wrong board Error 125 (wrong board) or Error 131 (no board). Replace or insert the circuit pack if necessary. 2. Check that the board is properly translated and inserted. 3. If Error 1538 (hyperactivity) is listed in the Error Log, and run **reset board UUCSS**. 4. Run the test again, and, if it fails, replace the ATM-TRK circuit pack. 5. Retest.

ATM Cross Talk Test (#1298)

This nondestructive ATM Cross Talk test makes sure that TDM time slots are correctly allocated to connections. It is useful for diagnosing one-way or noisy connections. The test fails if the TDM programmable logic and/or the interface to the DSP is not operating properly. The test can take more than 10 minutes.

Figure 9-224 shows a diagram of this test, substituting “CES mode” for “PNC mode.”

Table 9-133. ATM Crosstalk Test (#1298)

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate required system resources. 1. Retry the command up to 5 times at 1-minute intervals.
1002	ABORT	Could not allocate time slots. Traffic may be heavy or time slots may be out-of-service. 1. Identify and correct TDM-bus errors (if any) using the procedures in the "TDM-BUS (TDM Bus)" maintenance object. 2. Repeat the test up to 5 times at 1-minute intervals.
1003	ABORT	Could not allocate a tone receiver. Too few tone detectors installed or tone detectors out-of-service. 1. Identify and correct any "TTR-LEV (TTR Level)" errors listed in the Error Log. 2. Resolve any "TONE-PT (Tone Generator)" errors listed in the Error Log. 3. Retry the test up to 5 times at 1-minute intervals a maximum.
2000 2100	ABORT ABORT	Test timed out. Could not allocate required system resources 1. Retry the command 5 times at 1-minute intervals.
1962 2302	ABORT ABORT	All TALKER DSPs are busy. Inconsistent uplink message from the ATM-TRK circuit pack. 1. Retry the command up to 3 times at 1-minute intervals.
2752	ABORT	The circuit pack in this location is not a TN2305A/2306A.
1-8, None	FAIL	ATM-TRK circuit pack writing on unauthorized TDM time slots. The error code indicates the number of TALKER DSPs that are at fault. These DSPs cannot be used again until this test of the ATM DSP Test (#1293) tells the circuit pack to use them again. 1. Retry the command up to 3 times at 1-minute intervals. 2. If the failure persists, replace the circuit pack.
1-8	PASS	ATM-TRK circuit pack not talking to un-authorized time slots on the TDM bus. The error code indicates the number of TALKER DSPs tested.

AUDIX-BD (AUDIX Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
AUDIX-BD	MINOR	test board UUCSS sh	AUDIX Circuit Pack
AUDIX-BD	WARNING	test board UUCSS sh	AUDIX Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

The AUDIX-BD maintenance object represents a TN566/TN2169 DEFINITY AUDIX circuit pack combination. For circuit-pack-level problems, see “XXX-BD (Common Port Circuit Pack)”.

DEFINITY AUDIX consists of a combination of 2 circuit packs that occupy 5 slots on a port carrier. The tests described in this manual apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

AUDIX-PT (AUDIX Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
AUDIX-PT	MINOR	test port UUCSSpp l	AUDIX Port
AUDIX-PT	WARNING	test port UUCSSpp sh	AUDIX Port

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The AUDIX-PT maintenance object represents a port on a TN566/TN2169 DEFINITY AUDIX circuit pack operating in digital-port (DP) mode. For circuit-pack-level problems (AUDIX-BD), see "XXX-BD (Common Port Circuit Pack)".

The maintenance strategy for ports on the TN566 operating in control-link mode is described in ADX16A-PT.

AUX-BD (Auxiliary Trunk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
AUX-BD	MIN	test board UUCSS sh	Auxiliary Trunk Circuit Pack
AUX-BD	WRN	test board UUCSS sh	Auxiliary Trunk Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

Refer to “XXX-BD (Common Port Circuit Pack)” maintenance information for circuit pack level errors. See also AUX-TRK (Auxiliary Trunk) Maintenance documentation for related trunk information.

AUX-TRK (Auxiliary Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
AUX-TRK	MAJOR[2]	test port UUCSSpp l	Auxiliary Trunk
AUX-TRK	MINOR	test port UUCSSpp l	Auxiliary Trunk
AUX-TRK	WARNING	test port UUCSSpp sh	Auxiliary Trunk

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).
2. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 % of the trunks in this trunk group are alarmed.

The TN763B/C/D and TN417 Auxiliary Trunk circuit packs are used to provide ports for the following features: Music-On-Hold, loudspeaker paging (voice and coded chimes), dictation, automated wake-up with AUDICHRON. Recorder/Announcer, and recorded announcements. TN763C circuit packs support Mu-law companding. TN417 circuit packs support A-law companding. TN763D can support either companding mode and defaults to mu-law on initialization. Companding modes are administered on the country-options system-parameters screen. See *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*.

Music-On-Hold is administered via the Feature-Related System Parameters Form. Loudspeaker paging can be administered via the **change paging loudspeaker** or **add trunk-group** [Customer-Provided Equipment (CPE)] commands. The **change paging loudspeaker** command is used for system-provided paging; the **add trunk group** command is used for access to otherwise-provided (CPE) paging. The translation for code chiming is administered by the **change paging code-calling-ids** command. Recorded announcement and dictation are administered by the **add trunk-group** (CPE) command. Automatic wake-up is administered by the **change system-parameters hospitality** command and uses all four ports on a TN763B Auxiliary Trunk circuit pack.

Music-On-Hold provides audible feedback to a held, parked, or otherwise split-away party indicating that the call is still connected. The feedback can be customer-provided music, a recorded message, or other audible indication. Since the Music-On-Hold port is always busy, some of its port tests always abort.

The Loudspeaker Paging feature provides voice and/or code calling chime paging. If multiple paging zones are provided at a customer’s premises, the Loudspeaker Paging feature gives a user the option of paging to a particular zone or to all zones. If a zone is being used for one type of page, it may not be used at that time for the other one.

An Auxiliary Trunk circuit pack contains four ports and uses DTMF signaling. A different hardware interface between the switch and the auxiliary equipment is used for the four types of signaling that the auxiliary trunk circuit pack supports.

The interface used for the DEFINITY System loudspeaker paging consists of the following three pairs:

- The Tip-Ring (T-R) pair used for voice transmission.
- The S (S-S1) pair that carries answer supervision and/or make busy information.
- The SZ (SZ-SZ1) pair that provides the external equipment with a seizure indication.

The interface used for recorded announcement, dictation, and other loudspeaker paging consists of the following two pairs:

- The Tip-Ring (T-R) pair used for voice transmission.
- The S (S-S1) pair that carries answer supervision and/or make busy information.

The interface used for Music-On-Hold consists of one pair:

- The Tip-Ring (T-R) pair used for voice transmission.

The interface, used for automatic wake-up using an Audichron recorder/announcer unit, consists of the following two pairs:

- The Tip-Ring (T-R) pair used for voice transmission.
- The S (S-S1) pair that carries the synchronization signal.

Error Log Entries and Test to Clear Values

Table 9-134. Auxiliary Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1(a)	57481	None			
1(b)	57782				
15(c)	Any	Audit Update Test (#36)			
18	0	busyout port UUCSSpp	WARNING	OFF	release port UUCSSpp
130(d)		None	WARNING	ON	test trunk <grp>/<mbr> sh
769(b)	57482	None			
257		Hybrid/Conference	MIN/WRN[2]	ON	test port UUCSSpp l r 3
		Circuit Test (#33)			
513		NPE Crosstalk Test (#6)	MIN/WRN[2]	ON	test port UUCSSpp l r 3
1025		Diagnostic Test—Auxiliary Trunk Test (#114)	WARNING	ON	test port UUCSSpp sh r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major or Minor alarms may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. Error Type 1 with Aux Data 57481 indicates a port fault. Use an empty port if one is available until the circuit pack can be replaced.

b. Error Type 1 or 769 with Aux Data 57482 indicates a fault on signaling lead, which is an off-board error. This error should only occur with loudspeaker paging. If the trunk is being used for another application, check that the administration is correct. Otherwise, check the wiring to the external equipment connected to the Auxiliary Trunk and check the external equipment.

c. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors.

d. Indicates the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reseat or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Looparound and Conference Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Looparound and Conference Test (#33)		X	ND
NPE Crosstalk Test (#6)		X	ND
Diagnostic Test (#114)	X	X	ND
Audit Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-135. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times
1000	ABORT	System resources required to run test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-135. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve TTR-LEV errors. 2. Resolve TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The Network Processing Element (NPE) of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. This problem may be caused by defective tone detectors. 1. Test all tone-clock circuit packs, and resolve any errors on these circuit packs before any action is taken on the auxiliary trunk circuit pack. Then, repeat the test. 2. If the test fails again, replace the auxiliary trunk circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Looparound and Conference Test (#33)

This test checks the reflective loop around and conference capabilities of an auxiliary trunk port circuit. The test uses 404-Hz, 1004-Hz, and 2804-Hz tones. Each tone is separately transmitted through the loop and checked. All of these tests are performed on-board.

Table 9-136. TEST #33 Looparound and Conference Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
7	FAIL	The conference capabilities of the port failed. 1. If no service problems exist on the port, continue to use the port until the circuit pack can be replaced.

Table 9-136. TEST #33 Looparound and Conference Test — *Continued*

Error Code	Test Result	Description/Recommendation
129	FAIL	The reflective 404-Hz tone test failed, no transmission was detected to or from the port. The problem may be off-board.
131	FAIL	The reflective 1004-Hz tone test failed. No transmission was detected to or from the port. The problem may be off-board.
133	FAIL	The reflective 2804-Hz tone test failed. No transmission was detected to or from the port. The problem may be off-board. 1. To make sure the problem is on-board, disconnect the port from the auxiliary equipment and retry test. 2. If the test fails, replace the circuit pack. Otherwise, if the test passed after disconnecting the port from the auxiliary equipment, the problem is off-board. Check the wiring and connections to the auxiliary equipment and retry the test after reconnecting the port to the auxiliary equipment. If the test fails, check the auxiliary equipment. See the preceding procedure for a failure with Error Code 7. **NOTE:** If the Looparound and Conference Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, the 631DB AC power unit or the 676B power unit may be defective. The system may contain either a TN736 or a TN752 power unit circuit pack OR a 631DB power unit, *but not both types of power units.* To investigate power problems, refer to “CARR-POW”.
	PASS	Looparound and Conference Test is successful. This port is functioning properly.

Åudit Update Test (#36)

This test will send updates of the auxiliary trunk port translation for all ports on the Auxiliary Trunk circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes:

- Trunk type
- DTMF time slot
- Termination R/RC
- Gain, high/low
- End-to-end signaling, tone, and pause duration
- Trunk state, idle/active/unavailable
- Companding mode (A-law or mu-law) [G3r V2

Table 9-137. TEST #36 Audit Update Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1006	ABORT	Port is in out-of-service state as a result of being busied out. This audit cannot be run. 1. Retry the command once the port is in service (**Release port UUCSSpp** command has been run).
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	This test passed. Translation information was successfully updated on the circuit pack.

Diagnostic Test—Auxiliary Trunk Test (#114)

The system software sends a message to the on-board microprocessor to operate a relay in the port circuit. If ground is detected, the test passes.

Table 9-138. TEST #114 Diagnostic Test—Auxiliary Trunk Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	This test failed to detect ground. 1. Try the test once more. 2. If the test fails again, replace the circuit pack.
	PASS	This test passed. Ground was detected.

AXA12-BD/ADX8D-BD/AXD12-BD (AUDIX Circuit Packs)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
AXA12-BD	MINOR	test board UUCSS[1] sh	AUDIX Circuit Pack
AXA12-BD	WARNING	test board UUCSS sh	AUDIX Circuit Pack
ADX8D-BD	MINOR	test board UUCSS sh	AUDIX Circuit Pack
ADX8D-BD	WARNING	test board UUCSS sh	AUDIX Circuit Pack
AXD12-BD	MINOR	test board UUCSS sh	AUDIX Circuit Pack
AXD12-BD	WARNING	test board UUCSS sh	AUDIX Circuit Pack

1 *UU is the universal cabinet number (1 for PPN; 2-22 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides)(01 to 21).*

The TN 568 is a DEFINITY AUDIX circuit pack that occupies 2 slots on a port carrier. The tests below apply only to switch-side maintenance, which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy of its own that is described in DEFINITY AUDIX System Maintenance, 585-300-110.

AXA12-BD:

On G3r V7 systems, TN568 DEFINITY AUDIX circuit packs (sometimes called Embedded AUDIX) operating in control-link mode appear to the system as TN746 Analog Line circuit packs with vintage greater than 50. For circuit-pack-level problems, see XXX-BD. The maintenance strategy for ports on the TN568 operating in control-link mode is described in ADXCL-PT.

ADX8D-BD:

On G3r V7 systems, TN568 DEFINITY AUDIX circuit packs operating in 8-port digital mode appear to the system as TN754 Digital Line circuit packs with vintage greater than 50. For circuit-pack-level problems, see XXX-BD. The maintenance strategy for ports on the TN568 operating in 8-port digital mode is described in ADXDP-PT.

ADX12-BD:

The ADX12-BD maintenance object represents a TN568 DEFINITY AUDIX circuit pack operating in 12-port digital (DP) mode. On G3r V7 systems, TN568 DEFINITY AUDIX circuit packs operating in 12-port digital mode appear to the system as TN2181 Digital Line circuit packs with vintage greater than 50. For circuit-pack-level problems, see XXX-BD. Port-level problems are covered by ADX12D-PT.

AXA12-RS/ADX8D-RS/AXD12-RS (AUDIX Reserve Slots)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
AXA12-RS	NONE	NONE	TN568 12-port analog reserve slot
ADX8D-RS	NONE	NONE	TN568 8-port digital reserve slot
AXD12-RS	NONE	NONE	TN568 12-port digital reserve slot

There are no tests associated with these MOs. Both the **test board** and **busy out board** commands abort when either is attempted on a reserved slot. An error message indicates that the slot is associated with the circuit pack that the TN568 is emulating, but the requested operation is not valid. If there are errors logged against these maintenance objects, see XXX-BD.

The TN568 circuit pack connects to the switch through a single slot in the backplane; however, the number of slots physically occupied by the circuit pack is supplied by the board when inserted. The TN568 is 2 slots wide: the functional slot and a reserve slot. The reserve (blank) slot to the left of the functional slot is a place holder on the switch and has no interaction with the switch.

These MOs are place holders for the extra slot needed for the DEFINITY AUDIX board. Each instance of these MOs represents a reserve slot associated with the respective circuit pack mode in which the TN568 (DEFINITY AUDIX) is working. They are used for embedded AUDIX and emulation of respective port types.

BRI-BD/LGATE-BD (ISDN-BRI Line Circuit Pack)

MO Name in Alarm Log	Alarm Level	Initial Command to Run[1]	Full Name of MO
BRI-BD	MAJOR	test board UUCSS l	ISDN-BRI Line Circuit Pack
BRI-BD	MINOR	test board UUCSS l	ISDN-BRI Line Circuit Pack
BRI-BD	WARNING	test board UUCSS sh	ISDN-BRI Line Circuit Pack
LGATE-BD	MAJOR	test board UUCSS l	DEFINITY Lan Gateway
LGATE-BD	MINOR	test board UUCSS l	DEFINITY Lan Gateway
LGATE-BD	WARNING - (See Caution)	test board UUCSS sh	DEFINITY Lan Gateway

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

CAUTION:

The "Packet Bus Fault Isolation and Repair" for isolating and resolving Packet Bus faults is included in Chapter 5, "Alarms, Errors, and Troubleshooting". This flowchart, along with the other information presented in the chapter, can help resolve problems that involve more than a single station or circuit pack. Refer to this section whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance.

This section relates to the TN556 ISDN BRI, TN2198 ISDN BRIU, TN2208 Ethernet, (LGATE)-Ethernet Multi-Function (MFB) boards.

The TN2208 LGATE MFB provides DEFINITY with the interface to Adjunct-Switch Application Interface (ASAI) and Lucent adjuncts (for example, CONVERSANT® Voice System). This circuit pack contains 12 ports for line circuit interface (although only 8 are usable by the switch), each of which operates with 2 B-Channels and 1 D-Channel as specified in the Lucent ISDN-BRI Specification. In this context, the term "ISDN-BRI port" is used to refer to ports on the TN2208 MFB circuit pack which are connected to ASAI or Lucent adjuncts. The TN2208 LGATE MFB is handled by the switch software as if it is an ISDN BRI compatible board and all maintenance actions referring to ASAI and Lucent adjunct Links in this section apply.

The TN556, TN2198, and TN2208 ISDN-BRI Lines are packet port circuit packs that provides access to ISDN-BRI endpoints. The ISDN-BRI Line circuit packs supports 12 ports, each of which provides access to ISDN stations. Voice and circuit-switched data from the ISDN stations are carried on the Time Division Multiplex (TDM) Bus. Signaling is carried over the Packet Bus.

LEDS

The ISDN-BRI Line circuit pack performs extensive initialization tests and lights both the red and green LEDS during the initialization testing. See Chapter 7, ''LED Interpretation'', for more details on circuit pack status LEDs.

Hardware Error Log Entries and Test to Clear Values

Table 9-139. BRI-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test board UUCSS sh r 1
1(a)	Any	None	MINOR	ON	
18(b)	0	busyout board UUCSS	WARNING	OFF	release board UUCSS
23(c)	0	None	WARNING	OFF	
257(d)	65535	Control Channel Loop Test (#52)	MINOR	ON	test board UUCSS r 20
513(e)	4352 to 4357				
769(f)	4358				
1025(g)	4363	NPE Audit Test (#50)			
1293 to 1294 (h)	46088 to 46096	SAKI Sanity Test (#534)	MINOR	ON	See footnote (h)
1537 to 1538 (i)	46082		MINOR	ON	
1793 (j)	46080		MINOR	ON	
1794 (j)	46094		MINOR	ON	

Continued on next page

Table 9-139. BRI-BD Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1795 (j)	46085		MINOR	ON	
2306 (j)		LANBIC Receive Parity Error Counter Test (#595)			
3330 (k)	46083		MINOR	OFF	
3840 (l)	4096 to 4101				
3843 (m)	46097				
3999 (n)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

NOTE:
The alarm is logged approximately 11 minutes after the circuit pack has been removed and/or SAKI Sanity Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, then follow the instructions for ''Red (alarm)'' in Chapter 7, ''LED Interpretation''.

b. This circuit pack has been busied out via the **busyout board UUCSS** command.

c. Port(s) has(have) been administered on this circuit pack but the circuit pack is not physically present.

d. This error indicates transient communication problems between the switch and this circuit pack. Execute the **test board UUCSS** command and refer to the repair procedures for the Control Channel Loop Around Test (#52).

e. An on-board hardware failure has been detected by the circuit pack.

The reported aux data values correspond to the following detected errors:

4352	External RAM error
4353	Internal RAM error
4355	ROM Checksum error
4357	Instruction set error

Reset the circuit pack by executing the **busyout board UUCSS** and **reset board UUCSS** commands. When it is reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one of these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedure in footnote (a) for error type 1.

f. This error is reported by the circuit pack when it detects a program logic error. While no action is required, this error may lead to errors of other types being reported against this circuit pack.

g. This error is reported by the circuit pack when it cannot update NPE memory and read it back. This error type can be ignored, but may lead to errors of other types being reported against this circuit pack.

h. A critical hardware failure has been detected on the circuit pack. Reset the circuit pack via the **busyout board UUCSS** and **reset board UUCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm via the **test board UUCSS long clear** command. If the Circuit Pack Restart Test (#594) fails, replace the circuit pack.

The reported error types correspond to the following detected errors:

1293	On-board auxiliary processor insane
1294	Internal memory access error

i. These error types are reported when the following errors are detected:

1537	Frame overrun at Packet Bus interface. This condition may be caused by an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those maintenance objects.
1538	Circuit packet is hyperactive; that is, it is flooding the switch with messages sent over the control channel. The circuit pack is taken out-of-service when a threshold number of these errors is reported to the switch. Clear the alarm via the following commands: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long clear**, **release board UUCSS**. If the error recurs within 10 minutes, then replace the circuit pack.

j. These errors indicate that the circuit pack is having problems transmitting data to the Packet Bus.

1793	Parity errors are detected when transmitting data to the Packet Bus.
1794	Overflow of Packet Bus transmit buffers has occurred.
1795	Circuit pack cannot find end of frame when transmitting to Packet Bus. Clear the alarm via the following commands: **busyout board UUCSS**, **reset board UUCSS**, **test board UUCSS long clear**, **release board UUCSS**. If the error recurs within 10 minutes, then replace the circuit pack.
2306	This error occurs when the circuit pack detects an error in a received frame from the packet bus. These errors are most likely caused by a packet bus problem, but may be due to a circuit pack fault.An invalid Link Access Procedure Data (LAPD) frame error occurs if the frame contains a bad Cyclical Redundancy Checking (CRC), is greater than the maximum length, or violates the link level protocol.When bus parity errors are reported, the LANBIC Receive Parity Error Counter Test (#595) should be performed to determine if the condition had cleared. Refer to the ''PKT-BUS (Packet Bus)'' Maintenance documentation to determine if the problem is isolated to this circuit pack or if the problem is caused by Packet Bus faults.

k. A critical failure has been detected in the Packet Bus interface of the circuit pack. This failure may be due to either a Packet Bus fault or an on-board fault. If the Packet Bus is alarmed, refer to the ‘‘PKT-BUS (Packet Bus)’’ section and the Packet Bus Fault Isolation and Recovery section of the Maintenance documentation for recommended repair procedures. The probability of this error being related to Packet bus problems increases with the number of ISDN-BRI circuit packs displaying this error.

If the Packet Bus is not alarmed, reset the circuit pack via the **busyout board UUCSS** and **reset board UUCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm via the **test board UUCSS long clear** command. If the Circuit Pack Restart Test (#594) fails, replace the circuit pack. If the problem persists after complying with the above instructions, then follow normal escalation procedures.

l. These errors are not service-affecting. No action is required. These errors are reported by the circuit pack when it receives a bad control channel message from the switch. The auxiliary data identifies the following error events:

4096	Bad major heading
4097	Bad port number
4098	Bad data
4099	Bad sub-qualifier
4100	State inconsistency
4101	Inconsistent downlink message

m. This error is not service-affecting. No action is required.

3843	Bad translation RAM detected, but call continues by using another translation location.

n. This error indicates that the circuit pack sent a large number of control channel messages to the switch in a short period of time.

3999	If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 was not present, then the circuit pack has not been taken out-of-service, but has generated 50% of the messages necessary to be considered hyperactive. This may be normal during heavy traffic periods. If traffic is light it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Control Channel Loop Around Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop-Around Test (#52)	X	X	ND
NPE Audit Test (#50)		X	ND
LANBIC Receive Parity Error Counter Test (#595)		X	ND

1. D = Destructive; ND = Nondestructive

NPE Audit Test (#50)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) Maintenance documentation as NPE Audit Test (#50).

Control Channel Loop Around Test (#52)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) Maintenance documentation as Control Channel Loop Around Test (#52).

SAKI Sanity Test (#53)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) Maintenance documentation as SAKI Sanity Test (#53).

LANBIC Receive Parity Error Counter Test (#595)

This test is destructive.

The test reads and clears the LANBIC Receive Parity Error Counter on the circuit pack. This counter is incremented by the circuit pack when it detects a parity error in data received from the Packet Bus.

These errors may be indicative of a circuit pack problem, Packet Bus problem, or a problem with another circuit pack on the bus. This test is useful for verifying the repair of the problem.

Table 9-140. TEST #595 LANBIC Receive Parity Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the **busyout board UUCSS** and **reset board UUCSS** commands. 2. If the test aborts again, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2012	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
1-10	FAIL	The circuit pack is still detecting errors of this type. The error code indicates the value of the on-board error counter. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, verify the validity of the Packet Bus. Run the Packet Bus maintenance test with the **test pkt P long** command. If any Packet Bus tests fail, refer to the ‘‘PKT-BUS (Packet Bus)’’ Maintenance documentation for recommended repair procedures. 3. If the Packet Bus test passes, check the validity of the circuit pack. Execute a test that involves data transmission onto the Packet Bus. For example, the BRI may use the connectivity tests of the port-level maintenance object (BRI-PORT) by executing the **test port UUCSSpp** command. Refer to the repair procedures for the executed test if it fails. Otherwise, proceed to the next step. 4. Other circuit packs on the Packet Bus may be the cause of the parity error. Use the **display errors** command to check the Error Log for other circuit packs that are alarmed. If any alarms are present for the other circuit packs, retire those alarms also. Then, rerun the LANBIC Receive Parity Error Counter Test (#595) on this circuit pack.
	PASS	No errors detected by circuit pack.

BRI-DAT (ISDN-BRI Data Module)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
BRI-DAT	WARNING[1]	test data-module	ISDN-BRI Stand-alone Data Module

1. The alarm level for ASAI or Lucent adjuncts may be administered using the **set options** command. The alarm level can be set independently for Off-Board and On-Board alarms to WARNING, MINOR, or MAJOR for all ASAI adjuncts in the system.

Refer to the BRI-SET (ISDN-BRI Set) section of this chapter.

BRI-PORT (ISDN-BRI Port), ABRI-PORT (ASAI ISDN-BRI Port)]

MO Name (in Alarm Log)	Alarm Level	InitialCommand to Run[1]	Full Name of MO
BRI-PORT	MINOR	test port PCSSpp l	ISDN-BRI Port
BRI-PORT	WARNING	test port PCSSpp sh	ISDN-BRI Port
ABRI-PORT	MAJOR[2,3]	test port PCSSpp l	ASAI ISDN-BRI Port
ABRI-PORT	WARNING[2,3]	test port PCSSpp l	ASAI ISDN-BRI Port
ATT-PORT	MAJOR [2, 3]	test port PCSSpp l	Lucent Adjunct ISDN-BRI Port
ATT-PORT	WARNING [2, 3]	test port PCSSpp l	Lucent Adjunct ISDN-BRI Port
LGATE-PT	MAJOR [2, 3]	test port PCSSpp l	Ethernet ASAI Port
LGATE-PT	WARNING [2, 3]	test port PCSSpp l	Ethernet ASAI Port
ATTE-PT	MAJOR [2, 3]	test port PCSSpp l	Ethernet Lucent Adjunct Port
ATTE-PT	WARNING [2, 3]	test port PCSSpp l	Ethernet Lucent Adjunct Port

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. The alarm level for ASAI and Lucent adjunct ports may be administered using the **set options** command. The alarm level can be set independently for Off-Board and On-Board alarms to WARNING, MINOR, or MAJOR for all ASAI and Lucent adjunct ports in the system.
3. All alarming for an ASAI and Lucent adjunct and OFF-BOARD alarming for an ASAI or Lucent port is disabled if the ASAI or Lucent adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm is logged against the ASAI or Lucent adjunct. The Hardware Error and Alarm Logs should be checked to see if the adjunct has disabled alarming.

NOTE:
Some of the information in this section is reserved for future use.

CAUTION:
The "Packet Bus Fault Isolation and Repair" for isolating and resolving Packet Bus faults is included in Chapter 5, "Alarms, Errors, and Troubleshooting". This flowchart, along with the other information presented in the chapter, can help resolve problems that involve more than a single station or circuit pack. Refer to this section whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance.

WARNING:

If a significant Packet Bus failure occurs, errors and alarms may not be logged as expected for BRI-PORT/ABRI-POR/ATT-PORT/ LGATE-PT/ ATTE-PT. Conditions under which this occurs are detailed in the *''Maintenance of the Packet Bus''* *section of* *Chapter 5, ''Alarms, Errors, and Troubleshooting''*.

The TN2208 LGATE MFB provides DEFINITY with the interface to Adjunct-Switch Application Interface (ASAI) and Lucent adjuncts (for example, CONVERSANT®. Voice System). The circuit pack contains 12 ports of line circuit interface (although only 8 are usable by the switch), each of which operates with two B-channels (referred to as B1 and B2 throughout this section) and one D-channel as specified in the Lucent ISDN-BRI Specification. In this context, the term ''ISDN-BRI port'' is used to refer collectively to ports on the TN2208 circuit pack which are connected to ASAI or Lucent adjuncts.

The TN556 and TN2198 ISDN-BRI Line circuit packs provide DEFINITY with the interface to ISDN-BRI end points, Adjunct-Switch Application Interface (ASAI) and Lucent adjuncts (for example, CONVERSANT®. Voice System). The circuit packs contain 12 ports of line circuit interface, each of which operates with two B-channels (referred to as B1 and B2 throughout this section) and one D-channel as specified in the Lucent ISDN-BRI Specification. In this context, the term ''ISDN-BRI port'' is used to refer collectively to ports on the TN556 an TN2198 circuit packs which are connected to either BRI endpoints, ASAI or Lucent adjuncts.

For BRI endpoints, each B-channel may support voice or circuit-switched data and may be circuit-switched simultaneously. The B-channels are not used on ports connected to ASAI or Lucent adjuncts. The D-channel is used for conveying signaling between the switch and a BRI endpoint(s), ASAI or Lucent adjunct. Each ISDN-BRI D-channel is connected to the switch processor and the ISDN-BRI port through the Packet Control circuit pack and the Packet Bus.

ISDN-BRI endpoints are available in various configurations. All endpoints require the D-channel to convey signaling information to the switch. Only one B-channel is required for a voice-only set or a stand-alone data module (BRI-DAT). A voice and data-capable set requires both B-channels (one for voice and one for data). Therefore, each TN556 or TN2198 port can support either two voice-only sets, two stand-alone data modules (BRI-DAT), or one voice and data-capable set. Only a single ASAI or Lucent adjunct may be connected to an ISDN-BRI port. Multiple adjuncts per line are not supported.

Figure 9-11 illustrates the physical connection (solid line) between an ISDN-BRI Port and its associated ISDN-BRI set(s). Each physical connection allows for two B-channels and one D-channel. Each ISDN-BRI circuit pack can support up to 12 of these *physical* connections to different voice and voice/data sets or ASAI or Lucent adjuncts. On a TN2198 each ISDN-BRI circuit pack can support up to 12 *physical* connections to a NT1 which in turn connects to 2 terminals.

This section covers the maintenance documentation for ISDN-BRI ports. Some of the results of maintenance testing of ISDN-BRI ports may be affected by the health of the ISDN-BRI Line circuit pack (BRI-BD), BRI endpoint (BRI-SET), or ASAI adjunct (ASAI-ADJ/LGATE-AJ/LGATE-AJ) or Lucent adjunct (ATT-ADJ/ATTE-AJ). These interactions should be kept in mind when investigating the cause of ISDN-BRI port problems. For more information on the circuit pack and endpoints, refer to the BRI-BD (ISDN-BRI Line Circuit Pack) Maintenance documentation, the BRI-SET (ISDN-BRI Endpoint) Maintenance documentation, and ASAI-ADJ (Adjunct-Switch Application Interface) Maintenance documentation, ATT-ADJ (Lucent Adjunct) Maintenance documentation, LGATE-AJ (Ethernet Adjunct-Switch Application Interface) Maintenance documentation, ATTE-AJ (Ethernet Lucent Adjunct) Maintenance documentation.

Table 9-141. ISDN-BRI Port Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level BRI-PORT	Alarm Level ABRI-PORT ATT-PORT LGATE-PT ATTE-PT	On/Off Board	Test to Clear Value
3846(n)	TEI	None				
3847(o)	0	None				

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major and Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. This error occurs when the Level 1 Status Inquiry fails or when the BRI circuit pack detects that Level 1 has been deactivated on the port. The aux data field contains one of the following values:

- blank - this indicates that the Level 1 Status Inquiry failed.
- 32773 - this is a message from the BRI-LINE circuit pack indicating Level 1 has been deactivated.

Refer to the repair procedures for Test #621.

b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.

c. This error occurs when the EPF Status Inquiry fails due to an overcurrent condition or when the BRI-LINE circuit pack detects that the EPF is in an over current condition. The aux data field contains one of the following values:

- blank - this indicates that the EPF Status Inquiry failed due to an overcurrent condition.
- 40988 - this indicates that the BRI-LINE circuit pack has detected an overcurrent condition and has turned the EPF off.

Execute the Short Test Sequence and see the repair procedures for Test #622.

d. This error indicates that the circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signaling information over the D-channel. With Aux Data 46222, this error occurs when the Packet Bus transmit buffers overflow. This condition probably indicates a hardware problem. The BRI-PORT Alarm Level for the error with Aux Data 46222 is ''MIN/WRN,'' and the ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT Alarm Level is ''MAJ/MIN/WNR.'' With Aux Data 0, this error occurs whenever the Packet Bus transmit FIFO buffers overflow. This condition can be caused by an on-board hardware problem as well as by problems on the Packet Bus that disrupt the BRI circuit pack's ability to transmit data onto the Packet Bus. Use troubleshooting procedures for both on-board hardware problems and potential off-board Packet Bus problems. See the ''PKT-BUS (Packet Bus)'' section in this chapter as well as ''Packet Bus Fault Isolation and Repair'' in Chapter 5, ''Alarms, Errors, and Troubleshooting'' for more details on Packet Bus troubleshooting procedures. The BRI-PORT Alarm Level for the error with Aux Data 0 is ''MINOR,'' and the ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT Alarm Level is ''MAJOR.''

e. This error occurs when the NPE Crosstalk Test (#617) fails. Run the Long Test Sequence and pay particular attention to the results of Test #617.

f. This error occurs when broadcast signaling links associated with this port have too much link establishment related traffic. This could occur if an endpoint on this port is sending link establishment traffic on a port level broadcast link or if there are Level 1 problems on the port. Check the error logs for Level 1 errors. If Level 1 problems exist, follow the repair procedures listed for test #621. Software will suspend activity to this port for 75 minutes when the port is alarmed due to this error (note that service suspension does not occur if the port is an ABRI-PORT/LGATE-PT/ATTE-PT/ATT-PORT). If this problem persists, replace the endpoint or endpoints associated with this port. If replacing the endpoints does not fix the problem, follow normal escalation procedures.

g. This error occurs when the port receives an invalid frame over the D-channel. When CRC errors exceed five within 15 minutes, the port is taken out of service for five seconds. If five more CRC errors are received within 15 minutes of the first set of five errors, the port is taken out of service for one minute. If five more CRC errors are received within 15 minutes of the last five, the port is taken out of service for 15 minutes.

   This error is most likely due to a problem with the wiring to the set or adjunct, interference on the wiring due to a noise source, or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.

   - Check the wiring to the endpoints or the adjunct.
   - If the problem persists, replace the endpoints or adjuncts, or escalate the problem.

h. This error occurs when the BRI Port Local TDM Loop Around Test (#619) fails. Run the Long Test Sequence and pay particular attention to the results of Test #619.

   There are no Test to Clear Values for the following error types. The error types are simply provided as additional data that may prove useful while troubleshooting.

i. This error occurs when a Layer 1 Transmission error is detected for the port. Run the Long Test Sequence and pay particular attention to the results of the Layer 1 Transmission Error Counter Test (#624).

j. A BRI port supports up to three Terminal Endpoint Identifiers (TEIs). This error occurs when the switch receives a request for a fourth TEI on a port. Check the number of endpoints administered for this port.

k. This error occurs when an SPID initialization request is made from an endpoint and the switch determines that the SPID value is invalid or is a duplicate of another SPID that is already initialized at Layer 3 on the port. Check the administration of the endpoints.

l. This error occurs when the circuit pack detects an overflow of its receive buffers. Run the Long Test Sequence and pay particular attention to the results of the Receive First In First Out (FIFO) Overflow Error Counter Test (#625).

m. This error occurs when the BRI Port Local LAN Loop Around Test (#618) fails. Run the Long Test Sequence and pay particular attention to the results of Test #618.

n. This error most likely occurs when the Terminal Endpoint Identifier (TEI) administered for the ASAI or Lucent endpoint does not match the TEI administered in the ASAI or Lucent adjunct. Check the switch administration of the TEI against that of the adjunct and make sure that both are using the same TEI.

o. Indicates that sets on the port do not support Layer 3 initialization. Consult the Service Set documentation.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#617)		X	D
BRI Port Local LAN Loop Around Test (#618)		X	D
BRI Port Local TDM Loop Around Test (#619)		X	D
Electronic Power Feed Restoral Test (#620)	X	X	ND
Level 1 Status Inquiry Test (#621)	X	X	ND
Electronic Power Feed Inquiry Test (#622)	X	X	ND
CRC Error Counter Test (#623)		X	ND
Layer 1 Transmission Error Counter Test (#624)		X	ND
Receive FIFO Overflow Error Counter Test (#625)		X	ND
Clear Error Counters (#270)	X	X	ND

1. D = Destructive; ND = Nondestructive

NOTE:
The NPE Crosstalk Test and the BRI Port Local TDM Loop Around Test are not executed for ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT.

NPE Crosstalk Test (#617)

This test is destructive.

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes approximately 20 to 30 seconds to complete. Crosstalk testing is performed on both B-channels (B1 and B2) associated with a BRI port. If this test fails on either channel, any endpoints connected to the port are taken out-of-service.

This test is not executed for ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT because the B-channels associated with the port are not used by ASAI or Lucent adjuncts

Table 9-142. TEST #617 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port PCSSpp** command to determine the station extension or trunk group/member number of the port. Use the **status bri-port PCSSpp** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the ''Status Commands'' section in Chapter 8, ''Maintenance Commands'', for a full description of all possible states.) Wait until the port is idle before retesting. 2. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. 1. Use the **status station** command for the station associated with this port and determine when the port is available for testing. 2. Retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	This test is not valid for this type of translation. Ports administered as "ASAI" or "ADJK" can not run this test, because the B channels associated with the port are not used by ASAI or Lucent Adjunct Links. This is a normal condition.

Continued on next page

Table 9-142. TEST #617 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1 2	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. Error code 1 indicates that the NPE Crosstalk Test failed on Channel B1. Error code 2 indicates that the NPE Crosstalk Test failed on Channel B1. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist, examine the station, connections, and wiring.

BRI Port Local LAN Loop Around Test (#618)

This test is destructive.

This test, which verifies the connectivity of a BRI port across the LAN Bus, executes only if the port is out-of-service. The test aborts if calls associated with the port are in-progress. Failures of this test indicate either on-board faults associated with the BRI-PORT hardware on the circuit pack, or problems with the LAN Bus, which is used to form connectivity between the switch and the BRI-PORT.

The dotted lines in Figure 9-12 show how a Loop Around Test is performed across the Packet Bus for the D-channel.

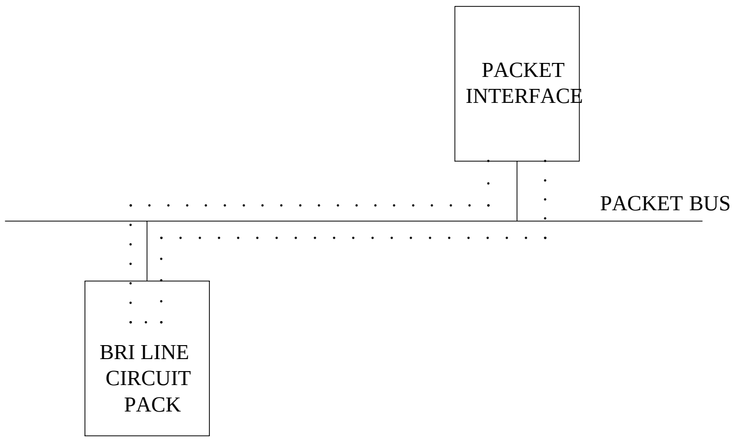

Figure 9-12. Path of the BRI Port Local LAN Loop Around

Table 9-143. Test #618 BRI Port Local LAN Loop Around

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The port is not in the out-of-service state. 1. Display the BRI Port Status form via the **status bri-port PCSSpp** command to determine which stations or adjuncts are on this port. 2. Use the extension shown on this form in the **status station** command to determine if the station or adjunct is in use. 3. If it is in use, wait until it is idle, and then busyout the port (using the **busyout port PCSSpp** command) to place it in the out-of-service state and repeat this test. **WARNING:** *Since the "busyout" command is destructive, execution of this command prior to the port being idle causes all calls associated with BRI endpoints and all transactions associated with ASAI or Lucent adjuncts on the port to be torn down. Note that third party calls established by an ASAI or Lucent adjunct remain connected even though the port is taken out-of-service.*

Continued on next page

Table 9-143. Test #618 BRI Port Local LAN Loop Around — *Continued*

Error Code	Test Result	Description/ Recommendation
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Follow the repair procedures for the PKT-CTRL. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The Loop Around Test has failed. 1. If the test fails repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use. Reset the circuit pack by issuing the **busyout board PCSS** and the **reset board PCSS** commands. 2. If the test fails again, execute **test port-network *<pn#>***. If this fails, follow failure procedures in ‘‘PKT-BUS (Packet Bus)’’ section. 3. If tests executed in Step 2 pass, the problem is local to the BRI board. Replace the circuit pack.
	PASS	The BRI Port Local LAN Loop Around Test has passed.

BRI Port Local TDM Loop Around Test (#619)

This test is destructive.

This test verifies the connectivity of a BRI port across the TDM Bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack.

This Loop Around Test runs a series of individual tests on the two B-channels (B1 and B2) associated with the port. It is a collection of the following:

- A Loop Around Test across the TDM Bus for B1.
- A Conference Circuit Test for B1.
- A Loop Around Test across the TDM Bus for B2.
- A Conference Circuit Test for B2.

The tests are run in the above order. If one fails, the remaining tests in the sequence are not executed. An error code is returned at that point.

This test is not executed for ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT because the B-channels associated with the port are not used by ASAI or Lucent adjuncts.

The dotted lines in Figure 9-13 show how a Loop Around Test is performed for the B-channels. The figure shows a terminal connected to a BRI line board using a TN556. If a TN2198 is used the terminal would be connected to a NT1, and the NT1 to the BRI board.

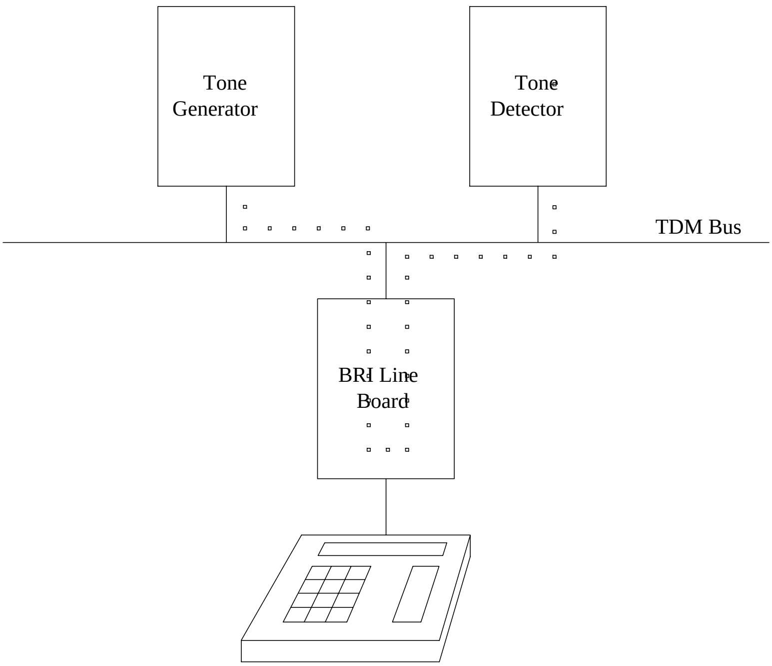

Figure 9-13. Path of the BRI Port Local TDM Loop Around

Table 9-144. Test #619 BRI Port Local TDM Loop Around

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The system resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port PCSSpp** command to determine the station extension or trunk group/member number of the port. Use the **status bri-port PCSSpp** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the “Status Commands” section in Chapter 8, “Maintenance Commands”, for a full description of all possible states.) Wait until the port is idle before retesting. 2. If the port is idle, then retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status station** command for the station associated with this port and determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	This test is not valid for this type of translation. Ports administered as “ASAI” or “ADJK” can not run this test, because the B channels associated with the port are not used by ASAI or Lucent Adjunct Links. This is a normal condition.

Continued on next page

Table 9-144. Test #619 BRI Port Local TDM Loop Around — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the BRI-LINE circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack if the other ports are not in use. Reset the circuit pack by issuing the **busyout board PCSS** and the **reset board PCSS** commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1 2	FAIL	As stated previously, this test runs a TDM Loop Around Test on each B-channel. This indicates that the loop around failed on one of the channels. Error Code 1 indicates that the TDM Loop Around Test failed on B1. Error Code 2 indicates that the TDM Loop Around Test failed on B2.
7 8	FAIL	As stated previously, this test runs a Conference Circuit Test on each B-channel. A failure here indicates that one of these conference tests failed; Error Code 7 means that the test failed on B1; Error Code 8 means that the test failed on B2. 1. If the test fails repeatedly, attempt to reset the circuit pack if the other ports on the circuit pack are not in use. Reset the circuit pack by issuing the **busyout board PCSS** and the **reset board PCSS** commands. 2. If the test fails again, replace the circuit pack.
	PASS	The BRI Port Local TDM Loop Around Test has passed.

Electronic Power Feed Restoral Test (#620)

This test attempts to restore the Electronic Power Feed (EPF) on an ISDN-BRI port twice. In this test, the processor requests that the EPF be turned on for a given port. An attempt is made to turn on the power unit to the station or adjunct. If no current is being drawn by a station, this probably indicates that the station is not connected. No current being drawn by an adjunct is the normal condition. If an overcurrent condition is sensed (that is, too much current is being drawn), this condition may indicate a short in the wiring to the endpoint or adjunct.

Depending on what condition is sensed, a message is returned stating that either the EPF was turned on successfully with no problems or that an overcurrent condition is sensed. This response is reported by the Electronic Power Feed Inquiry (#622), which follows in the testing sequence. EPF Restoral is attempted again by this test five seconds later. This test always passes for the TN2198 because it has no EPF. This test will always abort when run on the TN2208.

Table 9-145. TEST #620 Electronic Power Feed Restoral

Error Code	Test Result	Description/ Recommendation
1005	ABORT	This test is not valid for this port type. The TN2208 does not have an electronic power feed, and the test will abort.
2012	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The EPF Test passed. The message to turn on the power feed to the station or the adjunct was successfully sent to the port. 1. Although this test should not return a fail result, after running this test, the Error Log should be checked for any entries with error type 257 to examine the real results of this test. 2. An error type of 257 in the Error Log indicates some problem with the power to the station or the adjunct. Check for a short in the wiring, a damaged jack, a defective voice terminal or adjunct, or an incorrect type of terminal.

Level 1 Status Inquiry Test (#621)

This test determines the state of the transmission facility of a BRI port at the physical layer (that is, Level 1). Level 1 can be in one of three possible states: Activated, Pending Activation, or Deactivated.

The Activated state is the correct state for an ISDN-BRI port. In this state the Level 1 interface can communicate with the BRI endpoint or ASAI or Lucent adjunct administered on this port. This test passes if the state of Level 1 (L1) is Activated. This test also passes if software has taken this port out of service. See the description of the Level 1 ‘‘Deactivated State’’ below for more details.

The Pending Activation state indicates a problem with the endpoints or adjunct, the wiring to the sets or adjunct, or the BRI-LINE circuit pack. When in this state, the Level 1 interface is either not receiving any L1 framing from the endpoint or adjunct (Endpoint Idle), or it is communicating with the endpoint or adjunct but cannot transition to the Activated state (Endpoint Active).

The Deactivated state indicates a problem with the BRI-LINE circuit pack. When in this state, the Level 1 interface is idle and is not trying to communicate with the BRI endpoints or adjunct. When an ISDN-BRI port is placed in the out-of-service state, Level 1 is also put into the Deactivated state.Thiscouldbedue either to the system detecting a fault with the port or to a **busyout port PCSSpp** request This could be due either to the system detecting a fault with the port or to a **busyout port PCSSpp** request

Table 9-146. TEST #621 Level 1 Status Inquiry

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The board, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port and BRI-BD (board busied out). If this error type is present for BRI-PORT only, then release the port via the **release port pp** command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the board via the **release port PCSS** command and run the test again. **NOTE:** When you release a port, you release all ports associated with it. If certain ports still need to be busied out, use the **release port PCSSpp** command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the **busyout board PCSS** and **reset board PCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.

Continued on next page

Table 9-146. TEST #621 Level 1 Status Inquiry — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Received a status of Level 1 Pending Activation-Endpoint Idle which indicates a problem with the BRI endpoint or ASAI or Lucent adjunct, the wiring to the endpoint or adjunct, or the ISDN-BRI port. For the TN2198, received a status of Level 1 Pending Activation. U interface down, which indicates a problem with a connection between the switch and the NT1. **NOTE:** An NT1 is a 2-to-4 wire converter that is used to connect 4-wire Lucent terminals to a 2-wire TN2198 circuit pack. The NT1 also has status lamps to determine the health of the unit. 1. For the TN556, verify that an end point is connected to the port. If an endpoint is connected to the port then proceed to step 2. For the TN2198 verify that the connections are good between the switch and the NT1. Verify that the NT1 has power. 2. As necessary, check and repair the wiring between the circuit pack and the endpoint or adjunct. If a TN2198 is used the set must have been plugged in for at least 15 seconds before it will stabilize. Execute the **test port PCSSpp** command, and review the results of the Level 1 Status Inquiry Test to verify the repair. If this test is still failing, proceed to Step 3. 3. For BRI endpoints, replace the BRI endpoint(s) connected to the port or the NT1 if a TN2198 is used. For ASAI or Lucent adjuncts, follow the recommended repair procedures of the manufacturer for link communication problems. For the NT1, follow the manufacturers repair procedures. Then execute the **test port PCSSpp** command and review the results of the Level 1 Status Inquiry Test to verify repair. If this test is still failing, proceed to Step 4. 4. Escalate the problem to the next tier.

Continued on next page

Table 9-146. TEST #621 Level 1 Status Inquiry — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	For the TN556 or TN2208, received a status of Level 1 Pending Activation-Endpoint Active which indicates a problem with the BRI endpoint or ASAI or Lucent adjunct, the wiring to the endpoint or adjunct, or the ISDN-BRI port. For the TN2198, received a status of Level 1 Pending Activation. U interface up S/T interface down, which indicates a problem with the NT1 or the wiring between the NT1 and the BRI endpoint (S/T interface). 1. As necessary, check and repair the wiring between the circuit pack and the endpoint or adjunct. Execute the **test port PCSSpp** command, and review the results of the Level 1 Status Inquiry test to verify the repair. If this test is still failing, proceed to Step 2. 2. For BRI endpoints, try replacing the BRI endpoint(s) connected to the port. For ASAI or Lucent adjuncts, follow the recommended repair procedures of the manufacturer for link communication problems. For the NT1, follow the recommended repair procedures of the manufacturer. Then execute the **test port PCSSpp** command, and review the results of the Level 1 Status Inquiry test to verify repair. If this test is still failing, proceed to Step 3. 3. Escalate the problem to the next tier.
3	FAIL	Received a status of Level 1 Deactivated; the port is out-of-service. 1. Issue the **status bri-port PCSSpp** command to verify that the service state of the port is out-of-service. If the service state of the port is not out-of-service, escalate the problem to the next tier. Otherwise, proceed to Step 2. 2. If the port has been placed out-of-service via the **busyout port PCSSpp** command, try releasing the port by executing the **release port PCSSpp** command. Then issue the **test port long PCSSpp** command, and review the results of Level 1 Status Inquiry test. If this test is still failing, proceed to Step 3. 3. After executing the **test port long PCSSpp** command, review the results of all the tests. Follow the repair procedures for any tests that fail. Verify repair of the problem by executing the **test port PCSSpp** command and by determining that the Level 1 Status test passes. If the test continues to fail for this reason, proceed to Step 4. 4. Escalate the problem to the next tier.

Continued on next page

Table 9-146. TEST #621 Level 1 Status Inquiry — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL	For the TN2198 only: Received a status of Level 1 Pending Activation, the NT1 has a loss of power indicating a problem with the NT1. 1. For the NT1 follow the manufacturers recommended repair procedures. 2. Execute the **test port PCSSpp** command, and review the results of the Level 1 Status Inquiry test to verify the repair. If the test is still failing proceed to Step 3. 3. Escalate the problem to the next tier.
	PASS	This test indicates that Level 1 is activated, or that software has taken the port out of service.

Electronic Power Feed Inquiry (#622)

This test queries the BRI-LINE circuit pack for the status of the Electronic Power Feed (EPF) supplied to a BRI endpoint or an ASAI or Lucent adjunct. If the EPF is on and no overcurrent condition exists, this test passes. All other states are not normal and indicate a problem with the endpoint or adjunct, the wiring to the endpoint or adjunct, or the BRI-LINE circuit pack. This test is not run on the TN2208 circuit pack or the TN2198 and will always return a pass for the TN2198. The TN2208 has no power feeds.

Table 9-147. TEST #622 Electronic Power Feed Inquiry

Error Code	Test Result	Description/ Recommendation
1005	ABORT	This test is not valid for this port type. Ports on the TN2208 can not run this test because this board does not have an electronic power feed.
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the **busyout board PCSS** and **reset board PCSS** commands. 2. If the test aborts again, replace the circuit pack.

Continued on next page

Table 9-147. TEST #622 Electronic Power Feed Inquiry — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The BRI-LINE circuit pack reports that it has detected an overcurrent condition and has turned off the EPF. 1. As necessary, check and repair the wiring between the circuit pack and the endpoint or adjunct. Check the endpoints and replace one or both sets if the sets are drawing too much current. Execute the **test port PCSSpp** command and review the results of the EPF Inquiry Test to verify the repair. If this test is still failing, proceed to Step 2. 2. Execute the **test port PCSSpp** command, and review the results of the Level 1 Status Inquiry Test. If this test is also failing, then follow the repair procedure for the Level 1 Status Inquiry Test. Otherwise, escalate this problem to the next tier.
	PASS	The Electronic Power Feed Inquiry Test reports that the EPF is on.

Layer 1 Transmission Error Counter Test (#624)

This test reads and clears the BRI port's Layer 1 Transmission error counter maintained on the BRI-LINE circuit pack. This counter is incremented by the circuit pack when it detects a Layer 1 transmission problem. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error is most likely due to a problem with the wiring or the endpoint or adjunct (verify that the wiring meets the configuration rules defined in *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111. It does not indicate a problem with the ISDN-BRI circuit pack. This test is useful for verifying the repair of the problem.

Table 9-148. TEST #624 Layer 1 Transmission Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the **busyout board PCSS** and **reset board PCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate necessary system resources to run test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
value	FAIL	The BRI-LINE circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, review the results of other tests in the Long Test Sequence. Pay particular attention to the results of the Level 1 Status Inquiry test. Follow repair procedures for any of the executed tests if they fail. Otherwise, go to the next step. 3. If the tests for the endpoints or adjunct pass and the Layer 1 Transmission Error Counter Test continues to fail, check the wiring to the endpoints or adjunct. If the wiring appears to be fine, escalate the problem.
	PASS	The Layer 1 Transmission error counter was read correctly and has a value of 0.

Receive FIFO Overflow Error Counter Test (#625)

This test reads and clears the BRI port's Receive FIFO Overflow error counter maintained on the BRI-LINE circuit pack. This counter is incremented by the circuit pack when it detects an overflow of its receive buffers. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is non-zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error can occur if signaling frames are being received from the Packet Bus at a rate sufficient to overflow the receive buffers on the circuit pack for a port OR if a hardware fault is causing the receive buffers not to be emptied properly by the circuit pack. This test is useful for verifying the repair of the problem.

Table 9-149. TEST #625 Receive FIFO Overflow Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the **busyout board PCSS** and **reset board PCSS** commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
value	FAIL	The BRI-LINE circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, run the Long Test Sequence and pay particular attention to the Loop Around Tests (#618 and #619). See the repair procedures for the executed test if it fails. Otherwise, go to the next step. 3. Replace the circuit pack.
	PASS	The Receive FIFO Overflow error counter was read correctly and has a value of 0.

Clear Error Counters Test (#270)

This test is not an actual test in the strict sense of the word. There are various error counters associated with each BRI-PORT/ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT. This test clears those counters and triggers the auditing of Terminal Endpoint Identifier (TEI) values and layer 3 reinitialization. This test is used only to send messages to the BRI-PORT/ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT and, therefore, should neither abort nor fail

Table 9-150. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	The message to clear the error counters of the BRI-Port/ABRI-Port/ATT-PORT/LGATE-PT/ATTE-PT has been sent.

BRI-SET, ASAI-ADJ, BRI-DAT

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. The alarm level for ASAI and Lucent adjuncts may be administered using the **set options** command. The alarm level can be set independently for Off-Board and On-Board alarms to WARNING, MINOR, or MAJOR for all ASAI and Lucent adjuncts in the system.
3. Alarming for an ASAI and Lucent adjuncts is disabled if the adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm are logged against the endpoint. Busying out and releasing the ASAI station or ADJLK station will clear the alarm.

CAUTION:

The ''Packet Bus Fault Isolation and Repair'' for isolating and resolving Packet Bus faults is included in Chapter 5, ''Alarms, Errors, and Troubleshooting''. This flowchart, along with the other information presented in the chapter, can help resolve problems that involve more than a single station or circuit pack. Refer to this section whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance.

WARNING:

If a significant Packet Bus failure occurs, errors and alarms may not be logged as expected for BRI-PORT/ABRI-POR/ATT-PORT/ LGATE-PT/ ATTE-PT. Conditions under which this occurs are detailed in the *"Maintenance of the Packet Bus" section of Chapter 5, "Alarms, Errors, and Troubleshooting".*

The TN2208 ESAI MFB provides DEFINITY with an Ethernet interface to Adjunct-Switch Application Interface (ASAI) and Lucent adjuncts (for example, CONVERSANT® Voice System). This circuit pack contains 8 ports of line circuit interface, each of which operates with two B-channels (referred to as B1 and B2 throughout this section) and one D-channel as specified in the Lucent ISDN-BRI Specification. In this context, the term ''ISDN-BRI port'' is used to refer collectively to ports on the TN2208 MFB circuit pack which is connected to ASAI or Lucent adjuncts. The TN2208 ESAI MFB is handled by switch software as it is an ISDN BRI compatible board and all maintenance actions referring to ASAI and Lucent Adjunct Links in this section apply.

In G3iV1.1-286 and G3iV2-386, two types of ISDN-BRI endpoints may be connected to ISDN-BRI (ISDN Basic Rate Interface Line) TN556 and TN2198 circuit packs: ISDN-BRI station endpoints, ASAI (Adjunct-Switch Application Interface) and Lucent adjuncts (for example CONVERSANT® Voice System). These circuit packs contain 12 ports of line circuit interfaces, each of which operates at 192 kilobits per second (kbps) with two B-channels and one D-channel as specified in the Lucent ISDN-BRI specification (PUB 801-802-100). For BRI endpoints, each B-channel may support voice or circuit-switched data and may be circuit-switched simultaneously. The B-channels are not used by ASAI or Lucent adjuncts. The D-channel is used for conveying signaling between the switch and a BRI endpoint(s) or ASAI or Lucent adjuncts. Each ISDN-BRI D-channel is connected to the switch processor and the ISDN-BRI port through the PKT-CTRL (Packet Control) and the PKT-BUS (Packet Bus).

ISDN-BRI endpoints come in a number of configurations. All endpoints require the D-channel to convey signaling information to the switch. A voice-only set requires only one B-channel. A voice and data-capable set requires both

B-channels (one for voice and one for data). Therefore, each TN556 port can support either two voice-only sets or one voice and data-capable set. Only a single ASAI or Lucent adjunct may be connected to an ISDN-BRI port. Multiple adjuncts per line are not supported.

Figure 9-14 illustrates the physical connection (solid line) between an ISDN-BRI Circuit Pack and a voice or voice/data set. Each physical connection allows for two B-channels, as stated above, plus one D-channel. Each ISDN-BRI circuit pack can support up to 12 of these PHYSICAL connections to different voice and voice/data sets or ASAI and Lucent adjuncts.

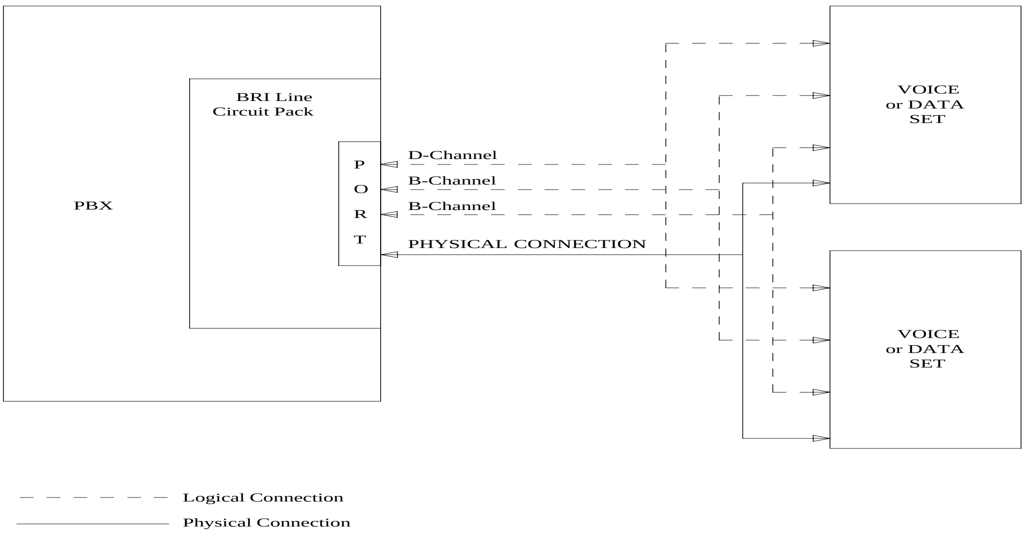

Figure 9-14. ISDN-BRI Set Interactions

This section contains the ISDN-BRI Set, ASAI Adjunct and Lucent Adjunct Maintenance documentation. Some of the results of maintenance testing of the ISDN-BRI Set or the ASAI and Lucent Adjunct may be affected by the health of the ISDN-BRI circuit pack and Port. These interactions should be kept in mind when investigating the cause of ISDN-BRI Set problems.

Hardware Error Log Entries and Test to Clear Values

Table 9-151. BRI-SET/ASAI-ADJ Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level BBRI-SET	Alarm Level ASAI-ADJ ASAI-ADJ ATT-ADJ LGATE-AJ ATTE-AJ	On/Off Board	Test to Clear Value

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. Errors of this type indicate violations of the ISDN-BRI signaling protocol; timers associated with certain Layer 3 messages have expired before a required response was received. In the following table, the aux data field indicates which timer has just expired. (For more information, refer to the Lucent ISDN-BRI Specification.

Aux Data	Timer Type
2	First T303 (SETUP timer)
3	Second T303 (SETUP timer)
4	T305 (DISConnect timer)
5	First T308 (RELease timer)
6	Second T308 (RELease timer)
10	T316 (RESTart timer)
12	T309 (Layer 2 Failure timer)
16	TM100 (Management Information Message timer 1)
17	TM200 (Management Information Message timer 2)
102	TASAI (ASAI Routing Timer)

The switch sent a message to the endpoint which did not respond in the allotted time. This can happen occasionally due to failure of the point-to-point signaling link or because of a problem in the BRI endpoint or ASAI adjunct or Lucent adjunct. Execute the **test station extension sh** command and pay particular attention to the results of the BRI Layer 3 Query Test (#629). If this test fails, follow the repair procedure for Test #629.

b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.

c. This error occurs when the endpoint does not respond to the service state query message sent to the adjunct or the endpoint. This error causes an alarm to be raised. The alarm is retired when the switch receives a response to the service state query to the endpoint or the adjunct.

For BRI endpoints, the Aux Data field for this error contains ‘‘0.’’ When it occurs, execute the **test station extension sh** command and pay particular attention to the results of the BRI Layer 3 Query Test (#629). If this test fails, follow the repair procedure for Test #629.

When this error occurs for an ASAI or Lucent adjunct, the Aux Data field indicates the state of the ASAI link or Lucent link and whether an invalid response or no response was received to the query from the switch, as shown in the following table:

Aux Data	ASAI Link State	Error
102	13-restarting	No response to RESTART message
104	13-restarting	Invalid response to RESTART message
152	13-restarted	No response to Layer 3 query
154	13-restarted	Invalid response to Layer 3 query
202	13-established	No response to Layer 3 query
204	13-established	Invalid response to Layer 3 query

(See "Status BRI-Port" in Chapter 8, ‘‘Maintenance Commands’’, for an explanation of the ASAI link states.)

For ASAI or Lucent adjuncts, the switch automatically queries the adjunct every two minutes (and therefore the Layer 3 Query Test is not executed for ASAI or Lucent adjuncts via a command issued from the G3MT terminal). While alarmed for this error, the switch momentarily (for five seconds) takes the associated port out-of-service every 15 minutes. This action is taken in an attempt to stimulate recovery actions to be taken by the adjunct.

When this error occurs for an ASAI or Lucent adjunct, the service technician should:

1. Execute the **test station extension** command and pay particular attention to any tests which fail and perform the associated repair procedures for those tests.
2. Check the health of the adjunct by following the recommended repair procedures of the manufacturer of the adjunct if the preceding step does not resolve the problem.
3. The alarm condition persists and, if the above steps do not resolve the problem, follow normal escalation procedures.

d. This error and associated WARNING alarm are logged against an ASAI or Lucent endpoint when the adjunct has asked the switch to suspend Maintenance on the ASAI or Lucent endpoint. Busying out and releasing the ASAI station or ADJLK station will clear this alarm.

e. This error occurs when the endpoint sends more messages than the switch can handle. The switch suspends the reception of messages from the endpoint for a short period of time. There is no repair procedure for this error. If the condition persists, replace the endpoint.

f. This error occurs when the signaling link associated with a BRI endpoint has too much link establishment related traffic. This could occur if the signaling link is bouncing between assigned and established states. Software will suspend activity to this endpoint for 75 minutes when the endpoint is alarmed due to this problem (note that service suspension does not occur if the endpoint is an ASAI or Lucent adjunct). If this problem persists, replace the endpoint. If replacing the endpoint does not fix the problem, follow normal escalation procedures.

g. This error occurs when the ASAI-ADJ or ATT-ADJ or LGATE-AJ or ATTE-AJ message is not transmitted because the PKT-CTRL (Packet Control Circuit Pack) transmit buffers are exhausted. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI or Lucent adjunct. Attempt to resolve the problem by following the repair procedures for the PKT-CTRL. If these attempts fail, the problem should be escalated because re-engineering of the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.

h. This error occurs when the ASAI message is not transmitted because the transmit buffer for the ASAI link is full, causing the link to be flow controlled. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI or Lucent adjunct. Attempt to resolve the problem by following the repair procedures issued by the manufacturer of the adjunct. If these attempts fail, the problem should be escalated because re-engineering of the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.

i. This error indicates a problem with Layer 2 over the D-channel between the switch and the endpoint. When this error occurs, an alarm is raised against the station or adjunct. Execute the **test station extension short** command and pay particular attention to the results of the BRI XID Test (#628). If this test fails, follow the repair procedure for Test #628.

j. This error indicates a problem with the B-channel connection between the switch and the endpoint. When this error occurs, a warning alarm is raised against the endpoint. Execute the **test station *<extension>* long** command and pay particular attention to the results of the BRI Remote Loop Back Test (#627). If this test fails, follow the repair procedure for Test #627.

k. This error occurs whenever the point-to-point signaling link to the endpoint goes down (except when it goes down because either the PKT-CTRL or the PKT-BUS has failed or has been busied out by system technician). When this error occurs, an alarm is raised against the endpoint or adjunct. Execute the **test station *<extension>* short** command and pay particular attention to the results of the Signaling Link Status Test (#626). If this test fails, follow the repair procedure for Test #626. The alarm is retired when the signaling link is reestablished to the endpoint or adjunct.

l. Certain ASAI protocol-specific cause codes are logged by switch software. The cause code can be determined from the following formula:

If the error type is greater than 3712, then the ASAI cause code is equal to the error type minus 3712. This code was sent to the adjunct by the switch.

If the error type is less than 3712, then the ASAI cause code is equal to the error type minus 3584. This code was sent to the switch by the adjunct.

A description of the various ASAI cause values is contained in the Table 9-152. This table also contains recommended system technician actions associated with the cause value. Further information can also be found in the Lucent ASAI Specification (288-500-03). In addition, the Aux Data field of the Error Log entry contains additional diagnostic information additional diagnostic.

Table 9-152. ASAI CAUSE VALUES

Error Code	Test Result	Description/ Recommendation
0	Unrecognized ASAIProtocol Operation	Requested ASAI protocol operation is not implemented by the switch or adjunct. Aux Data field of Error Log entry contains protocol identifier for unrecognized operation. 1. Consult switch and adjunct documentation to determine which set of operations is supported by the switch and the adjunct. Adjunct administration turning off operations not implemented by the switch may resolve the problem. 2. If Step 1 does not resolve the problem, escalate to the next tier.
40	Resources not available	No available internal resources to service switch or adjunct request. System transaction capacity for adjunct or switch is exceeded. 1. Re-engineering of adjunct services my be required. If problem persists, escalate problem to the next tier.

Continued on next page

Table 9-152. ASAI CAUSE VALUES — *Continued*

Error Code	Test Result	Description/ Recommendation
63	SERVICE OR OPTION NOT AVAILABLE	Requested ASAI capability or resource is not available on the switch or adjunct. More than one adjunct may be contending for the same switch resources. Potential administration mismatch between the resource domains administered on the switch and those administered on the adjunct. 1. Verify that no overlapping administration of switch resources (e.g., requesting notifications on a single domain by multiple adjuncts or multiple adjuncts attempting to control a single call) exists across all adjuncts connected to the switch. If overlaps exist, then readminister the adjuncts to guarantee that each adjunct is associated with a unique set of switch resources. 2. If Step 1 does not resolve the problem, escalate to the next tier.
79	SERVICE OR OPTION NOT IMPLEMENTED	Requested service or option (or combination of selected options) is not supported (implemented) in switch or the adjunct. 1. Consult switch and adjunct documentation to determine ASAI service and options supported by both switch and adjunct. Readministration of the switch-administered capabilities (see Customer Optional Feature Form) or those of the adjunct may be necessary to correct the problem. 2. If Step 1 does not provide the set of desired services due to deficient implementation, escalate the problem to the next tier.

Continued on next page

Table 9-152. ASAI CAUSE VALUES — *Continued*

Error Code	Test Result	Description/ Recommendation
87	Internal switch audit	There is an inconsistency in switch data records. 1. There is no action needed since the switch has corrected the data inconsistency. 2. If a number of these errors continue to occur, then escalate to next tier.

m. Certain ISDN-BRI cause codes are logged by switch software. The cause code can be determined from the following formula:

If the error type is greater than 3968, then the ISDN-BRI cause code is equal to the error type minus 3968. This code was sent to the endpoint by the switch.

If the error type is less than 3968, then the ISDN-BRI cause code is equal to the error type minus 3840. This code was sent to the switch by the endpoint.

A description of the various ISDN-BRI cause values is contained in Table 9-153. This table also contains recommended system technician actions associated with the cause value. Further information can also be found in the Lucent ISDN-BRI Specification (801-802-100). In addition, the Aux Data field of the Error Log entry contains additional diagnostic information.

n. Error 3847 indicates that sets on the port do not support level 3 initialization. Consult the Set Service documentation

o. For the Error 2567 indicates that the version of ASAI is not supported, check version of the software running on the ASAI or Lucent adjunct.

Table 9-153. ISDN-BRI CAUSE VALUES

Error Code	Test Result	Description/ Recommendation
1		Requested channel is in use by another station on the BRI-PORT. (Not applicable for ASAI or Lucent adjuncts.) For BRI endpoints: 1. Try to originate a call to or from this port. 2. If the error persists, busy out and release the port. 3. If the problem still persists, replace stations on the port. 4. If the problem still persists, escalate to the next tier.
34	No circuit or channel available	A resource on the switch is unavailable for a call. For BRI endpoints: This cause value is not logged. For ASAI or Lucent Adjuncts: This condition means that there are no available trunks for an outgoing call request. 1. Verify that the adjunct is administered to support the trunk capabilities of the switch. 2. Investigate trunk group status by issuing **status trunk** commands from the SAT or by requesting a trunk group query or queries from the adjunct. 3. Perform trunk diagnostic procedures outlined in this manual. 4. If step 3 does not resolve the problem, escalate to the next tier.
42	Switch Equipment Congestion	Switch takes control to limit received traffic. For BRI endpoints: This cause value is not logged. For ASAI or Lucent Adjuncts: 1. See CallVisor protocol reference manual. 2. If step 1 does not resolve the problem, escalate to the next tier.

Continued on next page

Table 9-153. ISDN-BRI CAUSE VALUES — *Continued*

Error Code	Test Result	Description/ Recommendation
50	Requested Facility Not Subscribed	Requested facility is implemented, but not administered. Potential administration problem with endpoint or adjunct. For BRI endpoints: 1. Verify the switch administration of endpoint using either the **display station** or **display data-module** commands. 2. If Step 1 does not resolve the problem, refer to the endpoint's service manual and verify administration on the endpoint. 3. If Step 2 does not resolve the problem, escalate to the next tier. For ASAI adjuncts: 1. Display the Customer Optional Features Form (administration screen) on the switch to determine which ASAI capabilities are turned on in the switch. 2. Verify that the adjunct is administered to support the identical capabilities as the switch. If there is a mismatch in the administered capabilities, then readminister the switch and/or the adjunct to establish a consistent set of desired capabilities on both the switch and the adjunct. 3. If Step 2 does not resolve the problem, escalate to the next tier. For Lucent adjuncts: 1. Display the Customer Optional Features Form (administration screen) on the switch to determine if the Lucent adjunct is set enabled on in the switch. 2. If error type 2567 or 2568, verify the Lucent adjunct version, and readminister if needed. 3. If step 2 does not fix the problem, escalate to the next tier of support

Continued on next page

Table 9-153. ISDN-BRI CAUSE VALUES — *Continued*

Error Code	Test Result	Description/ Recommendation
58	Bearer Capability Not Presently Available	Requested bearer capability is implemented, but not administered. No B-channel administered. See recommendation 50 above.
65	Bearer Service Not Implemented	Requested service not implemented in switch or endpoint.
69	Requested Facility Not Implemented	Requested service not supported in switch or endpoint. 1. Consult switch and endpoint documentation to determine service support. 2. If Step 1 does not resolve the problem, escalate to the next tier.
81	Invalid CRV	An invalid CRV was sent by the adjunct. 1. This may indicate a CRV inconsistency between the switch and the adjunct. See the CallVisor protocol reference manual. 2. If step 1 does not resolve the problem, escalate to the next tier.

p. For Error 2568 indicates that the adjunct id is invalid, check the vender id or software running on the Lucent adjunct.

System Technician-Demanded Tests: Descriptions and Error Codes

When inspecting errors in the system and deciding which ones to address, always investigate errors associated with the circuit pack and port first. Clearing these error codes first may also clear errors generated against the endpoint. When all circuit pack and port errors have been cleared, and errors still exist against the endpoint, always investigate errors in the order they are presented in the table below. By clearing error codes associated with the *Signaling Link Status Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Signaling Link Status Test (#626)	X	X	ND
BRI XID Test (#628)	X	X	ND
BRI Layer 3 Query (#629)	X(a)	X(a)	ND
BRI Remote Loop Back (#627)		X(a)	ND
BRI Set Audits (#630)	X(a)	X(a)	ND
BRI Vendor ID Test (#631)		X(a)	ND
BRI Model/Vintage ID Test (#632)		X(a)	ND

1. D = Destructive; ND = Nondestructive

Note:

a. Will execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Signaling Link Status Test (#626)

This test determines the current status of the signaling link. This test passes if the link is “bound” to an endpoint and fails if the link is “not bound.”

The definition of the term “bound” for a link depends upon the type of endpoint and may depend on the successful completion of procedures at both Layers 2 and 3 of the protocol. The definition of “bound” for each type of endpoint is as follows:

- **BRI endpoints administered for MIM (management information messages) initialization (multipoint):**

  NOTE:
  An MIM is a level 3 message that conveys management and maintenance information between a communications system and a BRI terminal.

  For endpoints of this type, the signaling link is “bound” when the link is connected at Layer 2 and the link has been associated with an endpoint, [that is, the endpoint has completed SPID initialization (L3 established)].

- **ASAI adjuncts and BRI endpoints not administered for MIM initialization (point-to-point):**

  For endpoints of this type, the signaling link is “bound” when the link is connected at Layer 2 (L2 established).

For all endpoint types, a signaling link becomes "unbound" when it is disconnected at Layer 2. For BRI endpoints supporting MIM initialization, a signaling link may also become "unbound" if a subsequent attempt to perform SPID initialization on a "bound" link fails, (that is, wrong SPID is entered into the endpoint by the user)

Table 9-154. TEST #626 Signaling Link Status Test

Error Code	Test Result	Description/ Recommendation
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Continued on next page

Table 9-154. TEST #626 Signaling Link Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. a. If this error type is present for BRI-SET only, then release the station via the **release station** b. If this error type is present for BRI-PORT and BRI-SET, then release the port via the **release port PCSSpp** command and run the test again. c. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the **release port PCSSpp** command and run the test again. If the error is present for BRI-SET only, then release the circuit pack via the **release port PPCSS** command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the **release board PPCSS** command and run the test again. **NOTE:** When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the **release port PCSSpp** command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-154. TEST #626 Signaling Link Status Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1113	FAIL	The signaling link is not "bound" to the adjunct or endpoint. For BRI endpoints supporting MIM initialization, this error indicates that the endpoint has not been bound to a signaling link (that is, SPID initialization has not been completed). Since the signaling link associated with the endpoint is not identified until SPID initialization completes, this error does not imply that the signaling link is connected or disconnected at Layer 2 nor does it provide the status of TEI assignment for the endpoint. For ASAI adjuncts and BRI endpoints not supporting MIM initialization, this error indicates that the link is disconnected at Layer 2. Since the signaling link associated with the endpoint has been identified via administration, the link is only "unbound" from the endpoint when it is disconnected. 1. Execute the **status bri-port PCSSpp** command and refer to the associated procedures for this command contained in the BRI-PORT (ISDN-BRI Port) Maintenance documentation.
	PASS	The signaling link is connected at Layer 2 and "bound" to the BRI endpoint or ASAI adjunct.

BRI Remote Loop Back Test (#627)

This test checks the integrity of a circuit switched B-channel connection between the switch and the endpoint.

In this test, the endpoint is put in the "maintenance busy" state to prevent the switch from issuing calls to the endpoint during the test. An application message containing a loop back activate request for the appropriate B-channel is sent to the endpoint. The endpoint responds with a loop back activated response. Maintenance then sends data to the endpoint over the B-channel under test. Since the B-channel is looped back at the endpoint, maintenance should receive the data that it sent. If no data is detected, the test fails. An application message containing a loop back deactivate request is then sent to the endpoint to terminate the remote loop back test. The endpoint responds with an MIM message containing a loop back deactivate response. Maintenance then releases the endpoint so that it is available to terminate calls.

This test is not executed for ASAI adjuncts because adjuncts do not support MIMs upon which this test is based.

Table 9-155. TEST #627 BRI Remote Loop Back

Error Code	Test Result	Description/ Recommendation
1000	ABORT	Could not seize the endpoint or B-channels for test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	The endpoint's MIMs Supported field is administered to "no." 1. Use the **change station extension** command to change parameter only if the endpoint documentation reflects support for ISDN-BRI Management and Maintenance Procedures.
1113	ABORT	The signaling link between the switch and the endpoint is down. 1. Use the **test port PCSSpp long** command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of the Signaling Link Status Test (#626) which is run as part of this command. If this test aborts or fails, follow the repair procedure for Test #626. 3. If the XID Test #628 continues to abort, escalate the problem.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Table 9-155. TEST #627 BRI Remote Loop Back — *Continued*

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. a. If this error type is present for BRI-SET only, then release the station via the **release station** b. If this error type is present for BRI-PORT and BRI-SET, then release the port via **release port PCSSpp** command and run the test again. c. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the **release port PCSSpp** command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the **release board PPCSS** command and run the test again. If the error is present for BRI-SET only, then release the circuit pack via the **release port PPCSS** command and run the test again. **NOTE:** When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the **release port PCSSpp** command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times.
2012	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2068	ABORT	The endpoint has rejected the switch sent application message. This indicates that the endpoint does not support the ISDN-BRI Management and Maintenance Procedure for Loop Back Testing. 1. Use the **change station extension** command and change the *MIMs Supported* field to **n**.
2069	ABORT	The endpoint has returned an error response to the application message sent by the switch.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

BRI XID Test (#628)

This test checks the D-channel connection between the SPE and the endpoint or adjunct.

In this test, a D-channel XID frame is sent to the endpoint or adjunct over the point-to-point signaling link. The test passes if the endpoint or adjunct responds with a Layer 2 XID-RESPONSE frame

This test must be administered to not run in the station administration form for ports on a TN2208.

Table 9-156. TEST #628 BRI XID

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The BRI-SET, ASAI-ADJ, ATT-ADJ, LGATE-AJ, ATTE-AJ is busy. The test cannot be executed at this time: 1. Pause momentarily (30 seconds) and re-execute at this time. 2. If this problem persists, escalate this problem. **NOTE:** A BRI-PORT can also be busy. When using this for BRI-PORT/ABRI-PORT tests, the words “BRI-SET, ASAI-ADJ, ATT-ADJ,” can be changed to “BRI-PORT, ABRI-PORT, ATT-ADJ.”
1005	ABORT	The endpoint is not administered to support XID Testing. 1. If the endpoint documentation reflects support XID testing, use the **change station extension** command to change the *XID Testing?* field on the form to **y**.
1113	ABORT	The signaling link between the switch and the endpoint is down. 1. Use the **test port PCSSpp long** command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of the Signaling Link Status Test (#626) which is run as part of this command. If this test aborts or fails, follow the repair procedure for Test #626. 3. If the XID Test #628 continues to abort, escalate the problem.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

</table>

Continued on next page

Table 9-156. TEST #628 BRI XID — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	FAIL	The XID-RESPONSE message was not received from the endpoint. 1. Consult the endpoint documentation to determine if the Layer 2 XID and XID-RESPONSE messages are supported. If the documentation reflects no support for these messages, change XID Testing? field to "no" using the **change station extension** command. 2. If the endpoint supports these Layer 2 messages and the test continues to fail, assume the endpoint is defective and replace it. 3. If the test continues to fail, escalate the problem.
	PASS	The switch can successfully pass messages over the D-channel to the BRI endpoint.

BRI Layer 3 Query Test (#629)

This test is used to check the application layer communications between the switch and the endpoint or adjunct.

For BRI endpoints, an application message containing the appropriate endpoint service state is sent by the switch to the endpoint. The endpoint responds with an acknowledgment to the application message.

For ASAI and Lucent adjuncts, this test is not executed from the administration terminal. Rather, a query message is automatically sent by the switch every two minutes. Failure of the switch to receive a response to a query from the adjunct is logged in the Hardware Error Log.

Table 9-157. TEST #629 BRI Layer 3 Query

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The endpoint's MIMs Supported? field is administered to "no." 1. Use the **change station extension** command to change the parameter only if the endpoint documentation reflects support for ISDN-BRI Management and Maintenance Procedures.

Continued on next page

Table 9-157. TEST #629 BRI Layer 3 Query — *Continued*

Error Code	Test Result	Description/ Recommendation
1113	ABORT	The signaling link between the switch and the endpoint or adjunct is down. 1. Use the **test port PCSSpp long** command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of Test #626, which is executed with the command. If this test aborts or fails, follow the repair procedure for the Signaling Link Status Test. 3. Escalate problem if BRI Layer 3 Query Test continues to abort.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Consult the repair procedure for PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Table 9-157. TEST #629 BRI Layer 3 Query — *Continued*

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. a. If this error type is present for BRI-SET only, then release the station via the **release station** b. If this error type is present for BRI-PORT and BRI-SET, then release the port via the **release port PCSSpp** command and run the test again. c. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the **release port PCSSpp** command and run the test again. If the error is present for BRI-SET only, then release the circuit pack via the **release port PPCSS** command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the **release board PPCSS** command and run the test again. NOTE: When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the **release port PCSSpp** command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2068	ABORT	The endpoint has rejected the switch sent application message. This indicates that the endpoint does not support the ISDN-BRI Management and Maintenance Procedure for Endpoint Service Messages. 1. Use the **change station extension** command and change the MIMs Supported? field to “no.”
2069	ABORT	The endpoint has returned an error response to the switch sent application message. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 9-157. TEST #629 BRI Layer 3 Query — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	FAIL	No response is received from the endpoint or the adjunct. For BRI endpoints: 1. Consult the endpoint documentation to determine if ISDN-BRI Management and Maintenance Procedures are supported. If not supported, use the **change station extension** command to change the “MIMs Supported?” field to “no.” Use the **busyout station extension** and **release station extension** commands to busyout and release the endpoint to resolve any endpoint alarms resulting from failure of this test. 2. If the endpoint supports these procedures and the test continues to fail, assume the endpoint is defective and replace it.
	PASS	The endpoint has successfully responded to the switch’s application message.

BRI Set Audits Test (#630)

This is a series of two tests which are classified as audits. The switch sends messages to the BRI endpoint to perform the following tests:

- Ringer Audit - This audit insures that both the switch and the endpoint agree as to the current state of the endpoint's ringer.
- Lamps Audit - This audit insures that both the switch and the endpoint agree as to the current state of the endpoint's lamps.
- Call Activity Audit - This audit insures that the state of calls is consistent between the switch and the endpoint.

This test is not executed for ASAI or Lucent adjunct because adjuncts do not employ ringers or lamps, or establish calls on the B-channels associated with the BRI interface.

Table 9-158. TEST #630 BRI Set Audits

Error Code	Test Result	Description/ Recommendation
1113	ABORT	The signaling link between the switch and the endpoint is down. 1. Use the **test port PCSSpp long** command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of the Signaling Link Status Test (#626) which is run as part of this command. If this test aborts or fails, follow the repair procedure for Test #626. 3. If the BRI Set Audits test continues to abort, escalate the problem.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Continued on next page

Table 9-158. TEST #630 BRI Set Audits — *Continued*

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. a. If this error type is present for BRI-SET only, then release the station via the **release station** b. If this error type is present for BRI-PORT and BRI-SET, then release the port via the **release port PCSSpp** command and run the test again. c. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the **release port PCSSpp** command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the **release board PPCSS** command and run the test again. **NOTE:** When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the **release port PCSSpp** command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The switch has successfully executed the BRI station audits.

SPID Facility Test

This test is used to verify the wiring and operation of the signaling link between the switch and a endpoint or adjunct on a BRI interface. **This test is not executed from the administration terminal, but rather is executed by using a BRI test set equipped with a display.** The test set may replace the BRI set, ASAI or Lucent adjunct under test by plugging it into the same jack or by bridging it onto the wiring at some point between the switch and the endpoint (or adjunct), thereby creating a pseudo-BRI multipoint configuration.

When plugged into the port in this manner, the test set establishes a signaling link connection with the switch and attempts to complete SPID initialization by using the Service SPID administered for the system (see the System Maintenance Administration Form). If the test set displays the correct administered port address for the endpoint or adjunct under test, the test passes (see Service SPID Display, which follows). If after one-minute nothing is displayed on the test set, the test fails.

SPID Facility Test

Test Result	Description / Recommendation
FAIL	No response is received from the endpoint. 1. Check the physical wiring between the switch and the endpoint or adjunct. 2. If test continues to fail, escalate to the next tier.
FAIL	Display does not match administered port address for the endpoint or adjunct. 1. Change station administration for endpoint or adjunct to match displayed port address. 2. If test continues to fail, escalate the problem.
PASS	Display matches administered port address for the endpoint or adjunct. For BRI endpoints: 1. Verify that the SPID values administered in the switch and the endpoint are consistent. 2. If the SPID values are correct, replace the endpoint. 3. If test continues to fail, escalate the problem. For ASAI adjuncts: 1. Verify that the TEI values administered in the switch and the adjunct are consistent. 2. If the TEI values are correct, consult the recommended repair procedures of the manufacturer for the adjunct. 3. If test continues to fail, escalate the problem.

The abbreviations used in (Service SPID Display) have the following meanings:

UU	Universal Cabinet number (1 for PPN, 2 - 44 for EPN)
C	Carrier (A,B,C, ...)
SS	Slot (01, 02, ...)
pp	port (01-12)
ext	extension one and two (one through 99999)
SPID	service order profile identifier

CABINET (Cabinet Sensors)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CABINET	MAJOR	test environment UU	Cabinet Sensors
CABINET	MINOR	test environment UU	Cabinet Sensors

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs).

NOTE:
The CABINET maintenance object is valid only for multi-carrier cabinets. For information about environmental maintenance on single-carrier cabinets, refer to DC-POWER.

The cabinet sensors monitor cabinet temperature and fan rotation. Variable-speed fans are used extensively in DEFINITY Systems.

The SYSAM circuit pack in the PPN cabinet and the EPN Maintenance circuit pack in a multi-carrier EPN cabinet monitor a temperature sensor (S1) at the top of the cabinet and generate a major alarm if the exit air temperature exceeds 65 degrees Celsius (149 degrees Fahrenheit). Another temperature sensor in the top of the cabinet (S2) also monitors exit air temperature. If it exceeds 70 degrees Celsius (158 degrees Fahrenheit), the power distribution unit turns off all cabinet power and invokes emergency transfer. Other sensors monitor fan performance.

The repair procedures that follow rely on your ability to distinguish between high and low fan speeds by the sound of the fans. Experience will allow you to distinguish between the high and low pitches generated by high and low speeds. A thermometer is also required for some of the procedures that follow.

In making replacements, observe the following rules:

- New fan assemblies accept *only* variable-speed fans.
- Old fan assemblies accept either variable-speed or nonvariable-speed fans.
- Replace a fan assembly (carrier) *only* with a fan assembly of the same type (new for new, old for old).

Variable-Speed Fans

A variable-speed fan is identified by the following features:

- A fan and air filter assembly with product code ED-67077-30, Group 4 or greater, labeled on the front of the carrier
- A five-pin white connector mounted next to each fan on the fan assembly cover plate for speed control and alarm circuitry
- A two-pin black -48 V power connector to each fan
- A power filter (ED-1E554-30, G1 or G2) located in a metal box mounted behind the fans on the right-hand cable trough as you face the rear of the cabinet
- The AHD1 circuit pack and the two S4 sensors used with older fan assemblies are *not* present.

Alarm leads from each fan are tied together into a single lead that registers a minor alarm against CABINET whenever a fan's speed drops below a preset limit or fails altogether.

NOTE:
The front fans may run at a different speed than the rear fans since they are controlled by different sensors.

Replacing Variable-Speed Fans

This procedure applies to replacement of a variable-speed fan (KS-23912, L3) in a new type fan assembly (ED-67707-30, G4 or greater). Do *not* use a nonvariable-speed fan in this assembly.

1. If replacing a fan in the front of the cabinet, remove the white plastic fan assembly cover by pulling it outward. There is no cover on the rear fans; they are accessible simply by opening the rear cabinet doors.
2. *Connect the grounding wrist strap to yourself and the cabinet.* The fan alarm circuit can be damaged by ESD.
3. Disconnect the white 5-pin connector on the fan assembly.
4. Loosen and remove the retaining screw nearest the power connector on the defective fan.
5. Disconnect the 2-pin black power plug on the fan.
6. Loosen and remove the other retaining screw on the fan.
7. Remove the fan from the fan assembly.
8. Position the new fan and insert the screw that is opposite the power connector.
9. Connect the 2-pin black power plug on the fan.

10. Connect the white 5-pin connector on the fan assembly. Insert and tighten the retaining screws.
11. Replace the front fan cover, if removed.

Replacing the Fan Power Filter

The fan power filter (ED-1E554-30) is a metal box located behind the fans on the right-hand cable trough as you face the rear of the cabinet. It is not present with nonvariable-speed fan assemblies.

CAUTION:
The fan power filter can be replaced without powering down the cabinet. To avoid damage, you must use the following steps in the order shown. Note that the J2F/P2F connectors on the power filter must not be connected whenever connecting or disconnecting the J2/P2 connectors on the fan assembly.

1. Access the power filter through the rear cabinet doors.
2. *Connect the grounding wrist strap to yourself and the cabinet.* The fan alarm circuit can be damaged by ESD.

   CAUTION:
   Failure to disconnect the J2F connector on the filter before the J2 connector on the fan assembly can damage the fan alarm circuits.

3. Disconnect cabinet local cable connector J2F from the P2F connector on top of the power filter.
4. Disconnect cable connector J2 from the P2 connector on the fan assembly.
5. Loosen the power filter mounting screws using a 5/16” nut driver and remove the filter.

   CAUTION:
   Failure to connect the J2 connector on the fan assembly can damage the fan alarm circuits.

6. Connect the J2 cable connector of the replacement power filter to the P2 connector on the fan assembly.
7. Mount the new power filter on the screws and tighten.
8. Connect cabinet local cable connector J2F to the P2F connector on the top of the power filter.
9. The fans should start rotating after a 4 second delay.

Replacing the Top Temperature Sensor

The top temperature sensors are located at the top rear of the cabinet in some cabinets. On these cabinets, the removable media shelf is located on the rear door, at the bottom.

1. From the rear of the cabinet, remove the screws holding the top temperature sensor.
2. Replace the sensor with a new one using the screws removed above.
3. Route the cable along the path of the existing sensor cable.
4. Unplug the cable on the defective sensor and replace with the plug on the new sensor.
5. Remove the old sensor from the cabinet.

Error Log Entries and Test to Clear Values

Table 9-160. Cabinet Sensors Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	test environment *UU*
1	0 or 1	Cabinet Temperature Query (#122)	MINOR	ON	test environment *UU* s r 3

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with one test, you may also clear errors generated from later tests in the sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND*
Battery & Battery Charger Query Test (#5)[1]	X	X	ND
AC Power Query Test (#78)[2]	X	X	ND
OLS Query Test (carrier E) (#127)[3]	X	X	ND
OLS Query Test (carrier D) (#127)[3]	X	X	ND
OLS Query Test (carrier A) (#127)[3]	X	X	ND
OLS Query Test (carrier B) (#127)[3]	X	X	ND
OLS Query Test (carrier C) (#127)[3]	X	X	ND

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND*
Emergency Transfer Query Test (#124)[4]	X	X	ND
Cabinet Temperature Query Test (#122)	X	X	ND
External Alarm Lead Query Test (#120)[5]	X	X	ND
Analog Ring Generator Initial Test (#117)[6]	X	X	ND
Analog Ring Generator Query Test (#118)[6]	X	X	ND

1. See the POWER section in this chapter.
2. See the AC-POWER section in this chapter.
3. See the CARR-POW section in this chapter.
4. See the EMG-XFER section in this chapter.
5. See the EXT-DEV section in this chapter.
6. See the RING-GEN section in this chapter.

Cabinet Temperature Query Test (#122)

This test queries the SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN for the status of the temperature and fan sensors in the cabinet.

Table 9-161. TEST #122 Cabinet Temperature Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort with error code 2000, check for power problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multi-carrier cabinet or DC-POWER alarms in a single-carrier cabinet. Repeat the test. 3. If the test continues to abort with error code 2000, check for and resolve all SYSAM errors in a PPN or MAINT errors in an EPN. Repeat the test.
2029 2319 2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-161. TEST #122 Cabinet Temperature Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	**VARIABLE-SPEED FAN ASSEMBLIES:** One or more fans have stopped. *If none of the fans are running:* 1. Resolve all alarms against "CARR-POW (Carrier Power Supply)". 2. Verify that 48 VDC is available to the fan power filter at the J2F local cable connector. The voltage range is -42.5 V to -52.5 V. There should be 48 VDC between the following pin pairs: 2/3, 8/9, 10/11. If -48 VDC is not present, replace the CFY1B current limiter card. 3. If there is 48 VDC at the power filter input, verify that there is 48 VDC at the power filter output using the following procedure exactly to avoid damage to the fan alarm circuit. Note that the J2F/P2F connectors on the power filter must be disconnected whenever connecting or disconnecting the J2/P2 connectors on the fan assembly. *First* disconnect connector J2F from P2F on the top of the filter. *Then* disconnect J2 from P2 on the fan assembly. Reconnect J2F to P2F on the filter. There should be 48 VDC between the following pin pairs on the J2 connector: 2/3, 8/9, 10/11. If not, replace the fan power filter using the procedure described previously. *Be sure to disconnect the J2F/P2F connector again before reconnecting the J2/P2.* If 48 VDC is present, the fans should have power. Make sure all power connectors are sound and making good contact. *Be sure to disconnect the J2F/P2F connector again before reconnecting the J2/P2.*
1 *(Cont'd.)*	FAIL *(Cont'd.)*	*If some of the fans are running and some are not:* 1. Replace the defective fans. If all fans can then be started, wait 5 minutes and rerun the test. If the test fails again, proceed to the next step below. 2. Remove all 6 white 5-pin connectors on the front and back of the fan assembly. This will cause all fans to run at high speed and the alarm to be cleared. If the alarm does not clear, the SYSAM (in a PPN) or EPN Maintenance circuit pack is incorrectly reporting the problem. Check for and resolve all errors against SYSAM or MAINT, and then rerun the test. 3. One at a time, replace the 5-pin connectors and check to see if the alarm recurs. Replace each fan whose reconnection causes a recurrence of the alarm.

Continued on next page

Table 9-161. TEST #122 Cabinet Temperature Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 *(Cont'd.)*	FAIL *(Cont'd.)*	**NONVARIABLE-SPEEDFAN ASSEMBLIES** (older or upgraded cabinets): The AHD1 circuit pack has reported an air flow problem. The temperature difference between the air intake and the air exhaust is at least 15^{0}C (59^{0}F)) and the absolute temperature at the top of the cabinet is at least 50^{0}C (122^{0}F). The fans should be running at high speed. If none of the fans are running then: 1. Look for an resolve all alarms against CARR-POW. 2. Verify that 48 VDC is available to the fan wiring harness connector between pin pairs 2/3, 8/9, and 10/11. The tolerable range for this measurement is -42.5 V to -52.5 V. If 48 VDC is present and the fans are not running, replace the AHD1 circuit pack. 3. If the fans still do not run, escalate the problem. 4. If 48 VDC is not present, replace the CFY1B current limiter card. If the fans still do not run, escalate the problem. If some fans are running and some not, replace the defective fans. 5. If all fans can then be started, wait 5 minutes and rerun the test. If the test fails again, proceed to the next step. 6. If all fans are running but not at high speed, measure the cabinet temperature at the air intake and the air exhaust at the top of the cabinet. a. If the 15^{0}C/50^{0}C criteria is met, there is a problem with the AHD1 circuit pack or the fans. Replace the AHD1 circuit pack and/or fans. If the fans run at high speed, wait 5 minutes for the cabinet to cool, then retest. If the test fails, escalate the problem. b. If the 15^{0}C/50^{0}C criteria is not met, the SYSAM (in a PPN) or EPN Maintenance circuit pack is incorrectly reporting this condition. Resolve all SYSAM or MAINT errors and retest. If the test fails, escalate the problem.

Continued on next page

Table 9-161. TEST #122 Cabinet Temperature Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 *(Cont'd.)*	FAIL *(Cont'd.)*	**NONVARIABLE-SPEEDFAN ASSEMBLIES** (continued): If the fans are running at high speed, check the following items, any of which can restrict or redirect airflow within the cabinet. 1. Check both filters. If a filter is dirty or clogged, clean with soapy water or a vacuum. 2. Ensure that there is nothing other than circuit packs in the carrier slots that could be restricting the airflow. 3. Ensure that there are no missing circuit pack faceplates or blanks. 4. The cabinet door must be closed for proper cooling. 5. Wait 5 minutes for the cabinet to cool and rerun the test. 6. If the test fails, check temperatures for the 15^0C/50^0C criteria. If the 15^0C/50^0C criteria is present, then the fans should be running at high speed. 7. Wait 5 minutes and rerun the test. 8. If the test still fails, then the ambient room temperature is probably too high. Cool the room. 9. If the 15^0C/50^0C criteria does not exist, one of the following components if defective: ■ AHD1 circuit pack ■ fans ■ S3 sensors ■ S4 sensors Replace these items one at a time in the order listed, running the test after each replacement. If many environmental tests are failing, it can be a problem that is undetected by maintenance on the SYSAM or EPN Maintenance circuit packs, depending on the cabinet type. Replace the circuit pack. Escalate if the problem persists.

Continued on next page

Table 9-161. TEST #122 Cabinet Temperature Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The SYAM or the EPN Maintenance circuit pack has reported a temperature problem due to the S1 sensor detecting a temperature of at least 65^0C (149^0F). The entire cabinet is in danger of power-down if the temperature reaches 70^0C (158^0F). 1. If any of the fans are not running, there should be a FAIL with Error Code 1 present. Follow the procedures for that Error Code, noting the differences for variable and nonvariable-speed fan assemblies. 2. If the fans are running, check the temperature at the top of the cabinet. a. If the temperature is at least 65^0C (149^0F), the ambient room temperature is too high and the fans cannot cool the system. Unless the room temperature is reduced, the system will shut down soon. 3. If the temperature at the top of the cabinet is less than 65^0C (149^0F), either the S1 sensor or the SYSAM or EPN Maintenance circuit packs are incorrectly reporting the problem. a. Resolve any errors against SYSAM or MAINT, then rerun the test. b. If there are errors, replace the S1 sensor and retest. If the test fails, escalate.
3	FAIL	Fan failures and temperature alarms have been reported. 1. Resolve the fan failure (Error Code 1). This should also resolve the temperature alarm. (With nonvariable-speed fan assemblies, fan failures correspond to air flow problems.)
	PASS	Temperature measurements and fan performance are satisfactory.

CARR-POW (Carrier Power Supply)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CARR-POW	MAJOR	Cycle carrier *UUC*	Carrier Port Power Supply

1. *UU* is the universal cabinet number (1 for PPN, 2-44 for EPNs), *C* is the carrier designation (A, B, C, D, or E). Cycle the carrier indicated by the PORT field in the alarm log.

DEFINITY systems support two different cabinet types: multi-carrier and single-carrier. Single-carrier cabinets are used only for EPNs. Both cabinet types may be powered by either AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply.

CAUTION:

Before powering down a cabinet or carrier that contains DEFINITY AUDIX circuit packs (TN566), first power down the AUDIX unit to avoid damaging the AUDIX software. Instructions for powering down this unit are in the "DEFINITY AUDIX System Power Procedures" in Chapter 5, "Alarms, Errors, and Troubleshooting", on the circuit pack, and in DEFINITY AUDIX documentation.

The CARR-POW maintenance object represents the pair of power supplies that supply +5V, -48V and -5 VDC power to each carrier in a multi-carrier cabinet. In AC-powered cabinets, these are called Off Line Switches (OLS); in DC-powered cabinets, they are DC/DC converters.

Cycling Power Supplies

When a port carrier power supply problem is reported by hardware, the system can cycle the power supplies in that carrier. When a carrier is cycled, the power supplies are turned off for 2 seconds and then turned back on. The system cannot cycle the power supplies on any of the following types carriers even if they are duplicated:

— PPN control carrier

— Expansion control carrier

— Switch node carrier

— Single-carrier cabinet

WARNING:

When port carrier power is cycled, all service dependent upon circuit packs in that carrier are disrupted.

Carrier Port Power Supplies—Multi-Carrier Cabinets

Code	System Power	Output (VDC)	Location
631DA	AC	+5	Left side
631DB	AC	-48/-5	Right side
644A	DC	+5	Left side
645B	DC	-48/-5	Right Side
TN755B		165	Slots 17 and 18
631WA/AR	AC	+5	Left side
631WB/BR	AC	-48	Right side
TN736	AC	-5	Used with 631
TN752	AC	165/-5	WA/WB or AR/AB
649A	AC	-48 at 10 Amps +5 VDC and -5 VDC at 6 Amps	Right side on control and port carriers. Left and right side on switch node carriers.

AC-Powered Cabinets

AC Power Distribution Unit and Battery Charger (J58890CE-2)

Figure 9-15 shows an AC Power Distribution Unit (List 9 or List 10). This unit sits at the bottom of some Multi-Carrier Cabinets.

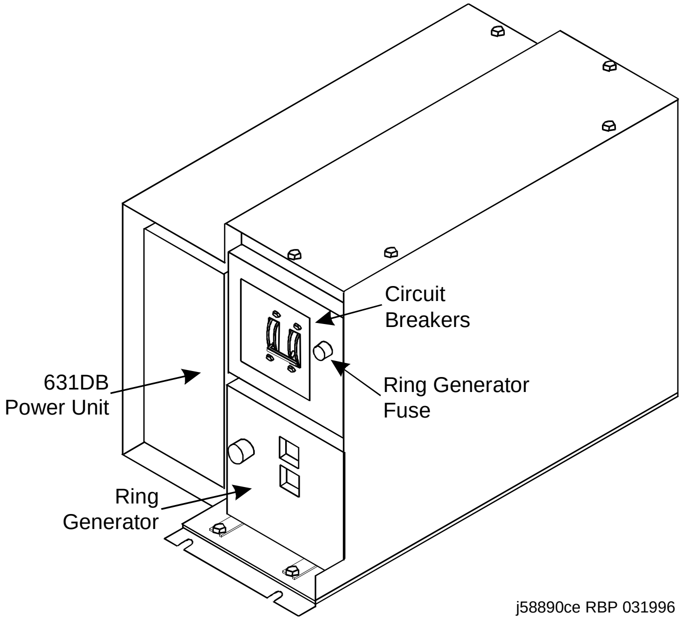

Figure 9-15. AC Power Distribution Unit (J58890CE-2) — Front

The AC Power Distribution Unit contains the following components:

- Circuit breaker
- Electromagnetic Interference (EMI) filter
- Ring generator
- AC input fuse
- 20 Amp fuses
- Signal connector
- -48 VDC fan power

The optional battery charger (List 11) sits at the bottom of some Multi-Carrier Cabinets. See Figure 9-16.

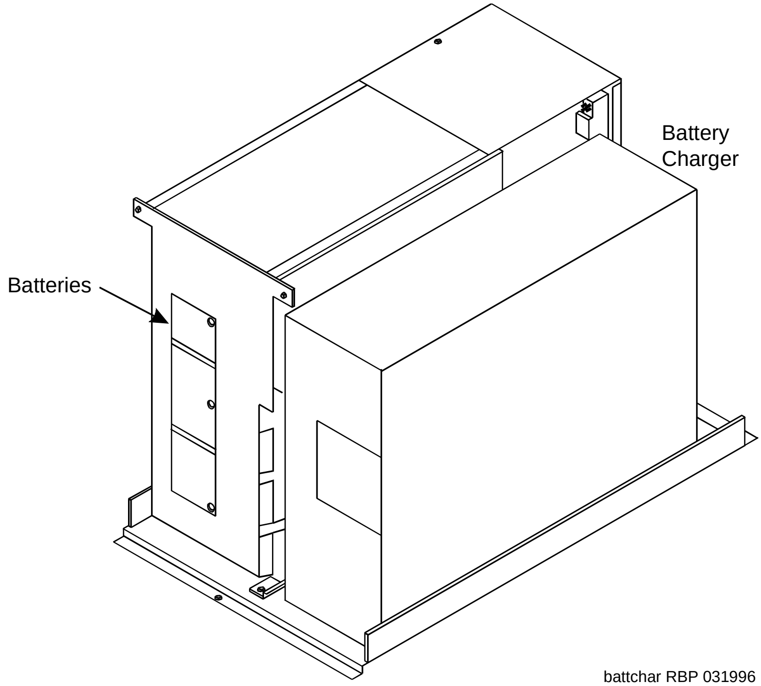

Figure 9-16. Battery Charger (Optional Part of J58890CE-2) — Front

The charger is used only without an Uninterruptible Power Supply (UPS). The charger contains:

- Three 48 VDC batteries for backup power to the cabinet
- A DC power relay to automatically switch the batteries into the power circuit if a main power failure is detected

Figure 9-17 shows AC power distribution in some Multi-Carrier Cabinets. The DC power distribution cables are on both sides of the cabinet. These cables supply power to each of the carriers. The optional battery charger is at the right side of the power distribution unit.

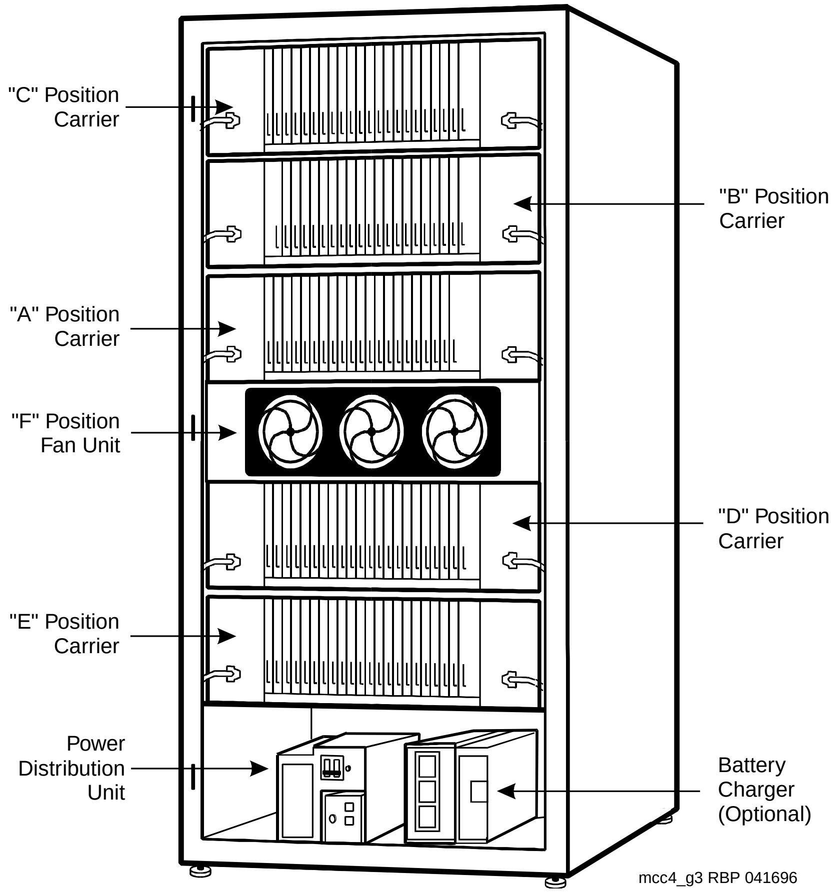

Figure 9-17. AC Power Distribution in Multi-Carrier Cabinets

Power Backup

If AC power fails, three 48 VDC batteries power the system for 10 seconds in a PPN cabinet, for 15 seconds in an EPN cabinet, and for 10 minutes in the control carrier in a standard reliability system. The batteries also supply system power for five minutes in the control carrier in high and critical reliability systems, and for 10 minutes in the expansion control carrier in the “A” position of an EPN cabinet (Release 5r only).

Uninterruptible Power Supply

An external UPS provides a longer backup time than holdover batteries and can replace the batteries and battery charger. The unit connects from the AC power source to a cabinet's AC power cord. If AC power fails, the unit supplies its own AC power to the cabinet.

J58890CH-1

In AC powered cabinets, the power distribution unit (J58890CH-1), distributes 170 to 264 VAC from a wall outlet to a set of BU3200A Battery Interface Units (BIU). See Figure 9-18 and Figure 9-19.

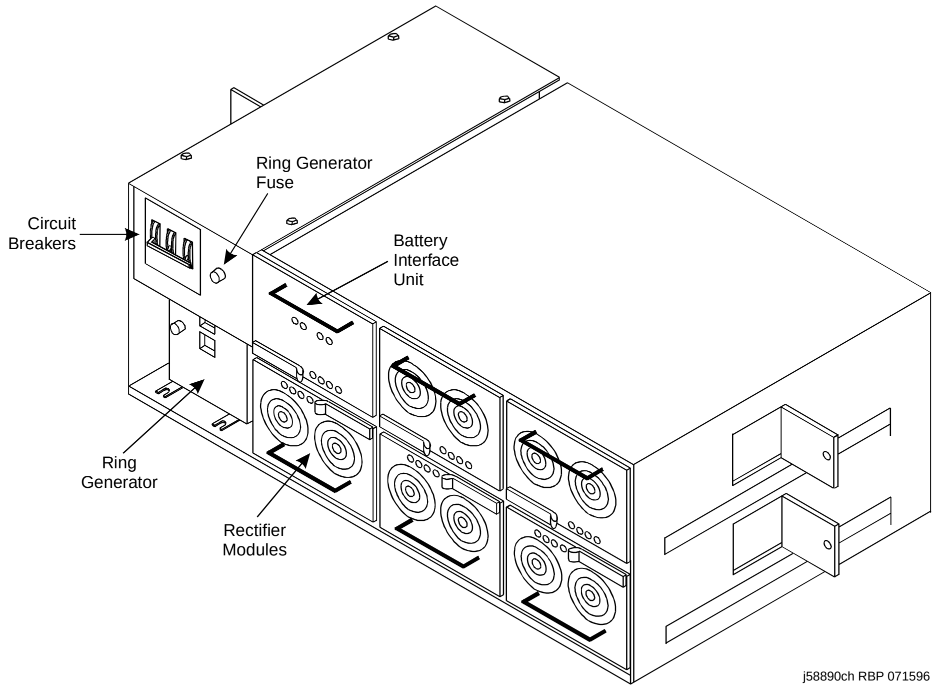

Figure 9-18. AC Power Distribution Unit (J58890CH-1) — Front

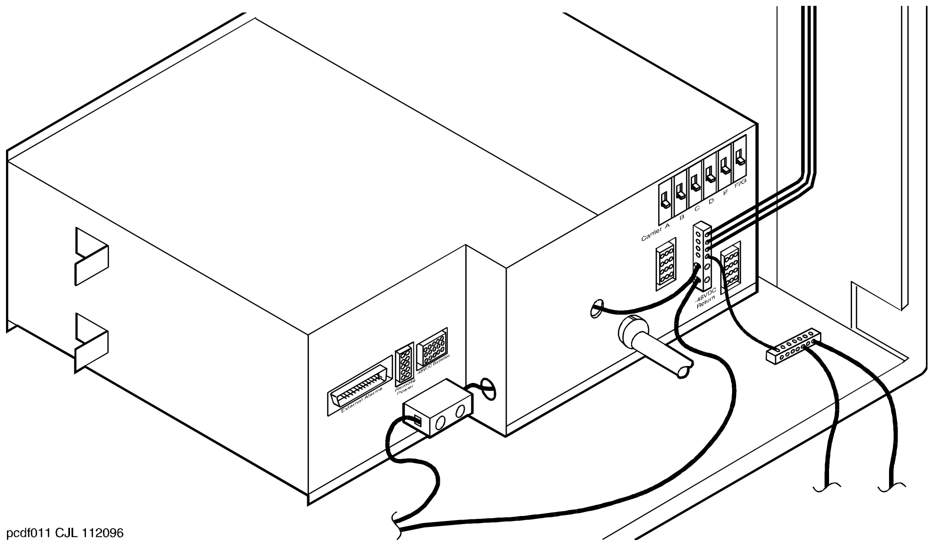

Figure 9-19. Power Distribution Unit (J58890CH-1)

Power Backup

The small battery is at the center rear of the Multi-Carrier Cabinet. This eight Amp Hour (AH) battery is fused for short circuit protection and is charged by the J58890CH-1. The batteries also contain a thermal sensor that changes the charging voltage depending on battery temperature.

The small batteries provide short-term battery holdover. If AC power fails, 48 VDC batteries power the system for 10 seconds in a PPN cabinet, for 15 seconds in an EPN cabinet, and for 10 minutes in the control carrier in a standard reliability system. The batteries also provide system power for five minutes in the control carrier in high and critical reliability systems, and for 10 minutes in the expansion control carrier in the “A” position of an EPN cabinet (Release 5r only).

Figure 9-20 shows the small battery assembly.

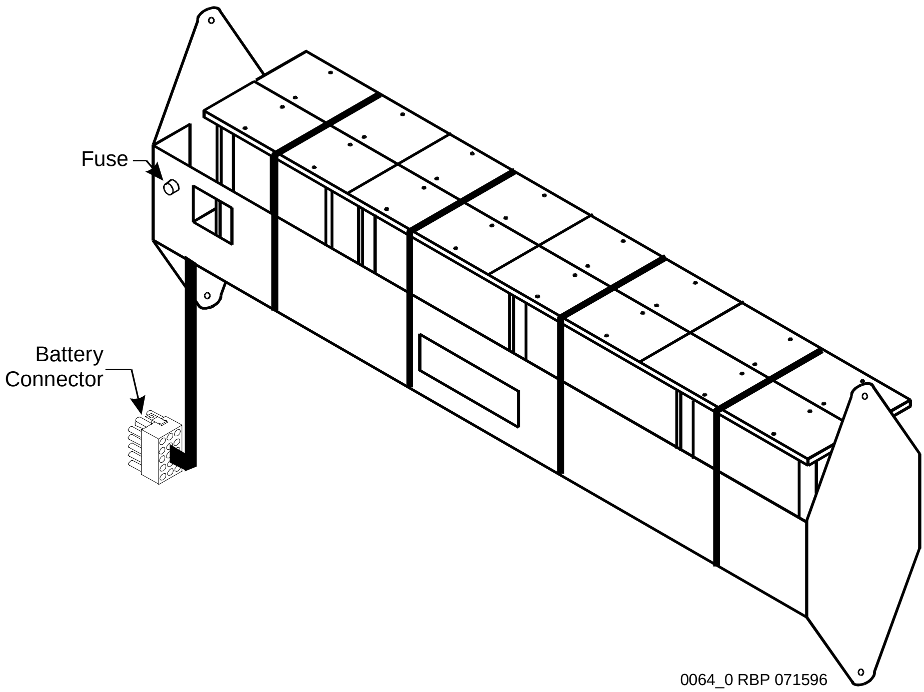

Figure 9-20. Small Battery Assembly

DC-Powered Cabinets

DC Power Distribution Unit (J58890CF-2)

Figure 9-21 shows a power distribution unit in some DC-powered Multi-Carrier Cabinets. The unit sits at the bottom of the cabinet and contains the ring generator, 20 Amp circuit breakers, terminal blocks, and system fan power.

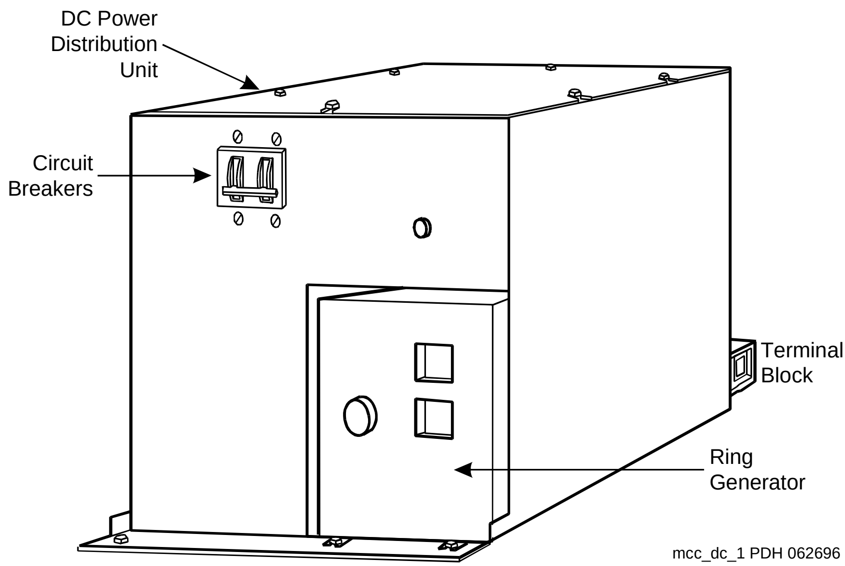

Figure 9-21. DC Power Distribution Unit (J58890CF-2) — Front

Some carriers may contain two power supplies, the 644A and the 645B, which together supply the required voltages to the carrier. Other carriers may contain one 649A power supply located on the right side of the carrier. In these systems, an additional 649A is located on the right of the optional switch node carriers.

Loss of the 645B Carrier Port Power Supply in the active PPN control carrier causes the management terminal login to drop. In a system with duplicated SPEs CARR-POW alarms do not cause an interchange, but loss of power to PROC, MEM-BD, SW-CTL, SYSAM, and PKT-INT maintenance objects (powered from the left side of the active control carrier) reduces the SPE state of health, possibly causing an interchange. Loss of power on the right side of the active control carrier causes the H-ADAPTR, DISK, and R-MEDIA maintenance objects to fail, these failures do not cause an SPE interchange.

Figure 9-22 shows a typical AC powered Multi-Carrier Cabinet.

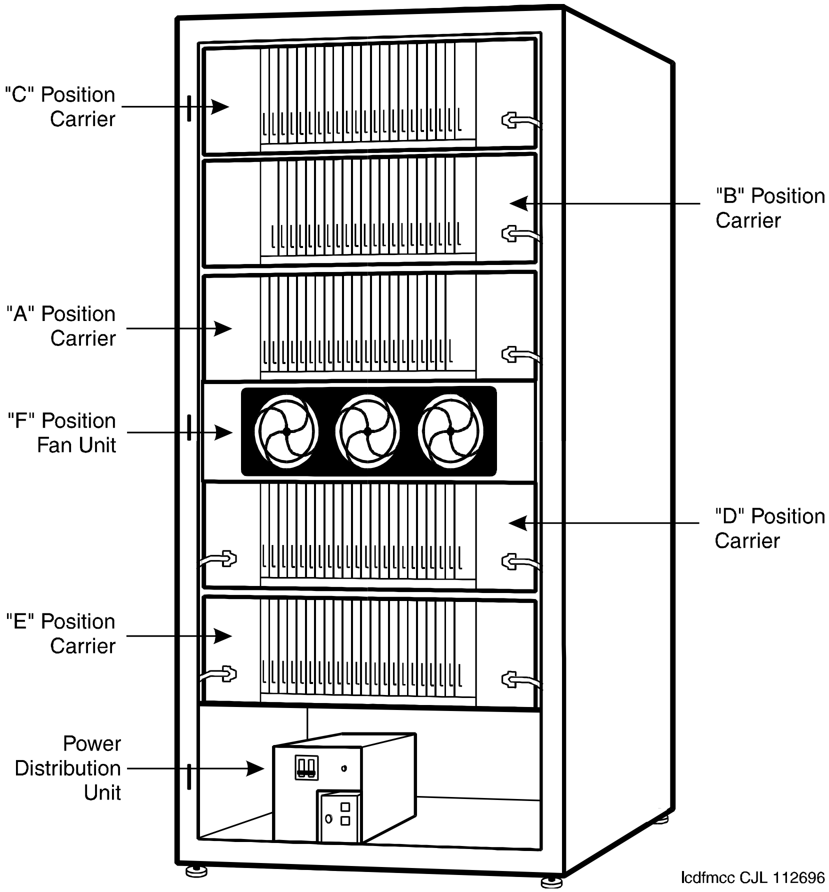

Figure 9-22. Typical Multi-Carrier Cabinet with 649A Power Units

The table below shows which carriers are protected by each circuit breaker on the J58890CF-1. The ring generator is protected by a fuse located next to the main circuit breaker on the front of the unit.

Circuit Breaker	Associated Carriers
CB1	Carrier A, both sides
CB2	Carrier B, both sides
CB3	Carrier C, both sides
CB4	Carrier D, both sides
CB5	Carrier E, both sides
CB6	Level F (Fans) and Level G (Ring Generator)

The table below shows which carriers are protected by each circuit breaker on the J58890CH-1. The ring generator is protected by a fuse located next to the main circuit breaker on the front of the unit.

Circuit Breaker	Associated Carriers
CB1	Carrier A, both sides
CB2	Carrier B, both sides
CB3	Carrier C, both sides
CB4	Carrier D, both sides
CB5	Carrier E, both sides
CB6	Level F (Fans) and Level G (Ring Generator)

Neon Lamp Power

The system can also support neon message waiting lamps on analog telephones. Any carrier containing a TN769 Neon Analog Line circuit packs must also be supplied with 150 Volts from a TN755B power supply circuit pack. See the table above for other supported neon power circuit packs.

Error Log Entries and Test to Clear Values

Table 9-162. Carrier Port Power Supply Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1[1]	0 or 1	OLS Query Test (#127)	MAJOR	ON	test environment *UU* r 2 recycle carrier *UUC*

1. Run the OLS Query Test (#127) first using the **test environment** UU**r 2** command. Then, if a carrier must be recycled to clear the CARR-POW alarm, use the **recycle carrier** UUC command to run the OLS Recycle Test (#126). The OLS Recycle Test (#126) is not included in either the long or short test sequences.

WARNING:
The OLS Recycle Test (#126) is destructive. For more information, refer to the description of this test.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
OLS Query Test (carrier E) (#127)	X	X	ND
OLS Query Test (carrier D) (#127)	X	X	ND
OLS Query Test (carrier A) (#127)	X	X	ND
OLS Query Test (carrier B) (#127)	X	X	ND
OLS Query Test (carrier C) (#127)	X	X	ND
OLS Recycle Carrier Test (#126)			D
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Temperature Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1. D = Destructive; ND = Nondestructive

Notes:

a. Refer to "POWER" section for a description of this test.

b. Refer to "AC-POWER" section for a description of this test.

c. Refer to "EMG-XFER" section for a description of this test.

d. Refer to "CABINET" section for a description of this test.

e. Refer to "EXT-DEV" section for a description of this test.

f. Refer to "RING-GEN" section for a description of this test.

OLS Recycle Test (#126)

This test is destructive.

This test removes power from the specified carrier and causes all circuit packs in the recycled carrier to be removed and inserted. These actions cause all calls originating or terminating on circuit packs in this carrier to be dropped. The pair of OLSs in the specified carrier is recycled. Both OLSs in the carrier are turned off for 2 seconds and then back on again. After the OLSs have been turned back on, the test queries the SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN for the status of the pair of OLSs in the specified carrier. If both OLSs are on and functioning, then the test passes. If both OLSs are not on and functioning, the test fails, and BOTH OLSs are turned off.

Table 9-163. TEST #126 OLS Recycle Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1366	ABORT	Indicates that the active Tone/Clock for the EPN is in requested carrier. 1. If duplicated Tone/Clock boards exist, issue the **set tone-clock** command to switch Tone/Clocks, otherwise the power cannot be cycled. 2. If the switch succeeds, rerun the test.
1367	ABORT	Indicates that the active Expansion Interface link for the EPN is in requested carrier. 1. If duplicated EIs exist, issue the **reset pnc interchange** command to switch EIs, otherwise the power cannot be cycled. 2. If the switch succeeds, rerun the test.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2029 2319 2320 2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	There is a problem with one or both OLSs on the cycled carrier. 1. Since the OLS Recycle Test failed, both OLSs in the cycled carrier should have been powered off by the system software. Both OLSs should be showing a red status LED, instead of a yellow one. Since the OLS Query Test is a subset of the OLS Recycle Test, the OLS Query Test (#127) should also fail. Run the OLS Query Test by using the **test environment UU** command where UU is the appropriate cabinet number. 2. If test #127 fails, follow the repair procedures described for Test #127.
	PASS	Both OLSs in the recycled carrier were found to be healthy by the SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN after the OLSs were powered down and back up. If the status LEDs on both OLSs are not showing yellow, then the SYSAM or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the OLSs. Resolve any alarms on these MOs.

Off-Line Switcher (OLS) Query Test (#127)

This test queries the SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN for the status of the pair of OLSs in the specified carrier. If both OLSs are on and functioning, then the test passes. If both are not on and functioning, it fails.

Table 9-164. TEST #127 OLS Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Resolve all AC-POWER and CARR-POW alarms in a multi-carrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, resolve all SYSAM errors in the PPN or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test.
2029 2500	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	**AC POWERED SYSTEMS** There is a problem with one or both OLSs on the tested carrier. 1. For each OLS that has all status LEDs OFF, check the AC input to the OLS at the OLS outlet. If there is no AC, then check the appropriate fuses for the affected OLS. Replace open fuses. If the fuses open again or AC does not show up at the OLS outlet, then there is probably a power wiring problem in the cabinet. 2. At this point, AC should be present at the OLS outlet. Use the **recycle carrier UUC** command (where *UUC* is the appropriate cabinet and carrier) in an attempt to bring back the OLSs for this carrier. If the test passes, the trouble is cleared. If the test does not pass, one OLS or both, in the tested carrier is defective. If only one OLS is defective, then the status LEDs on the healthy OLS will light green for a moment. When the recycle test determines that both OLSs are defective, the software will turn off power to both the good and defective OLSs. This will cause the status LED(s) on the good OLS to light red. 3. Unplug both OLSs, and wait approximately 1-minute to allow the OLSs to cool down. Plug in the OLSs. If either OLS is operating properly (the status LEDs show green), then replace the defective OLS(s). See OLS Replacement Procedures in this section.

Continued on next page

Table 9-164. TEST #127 OLS Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	4. If the replaced OLS(s) still do not operate properly, then a circuit pack or a defective telephone connected to a circuit pack in the affected carrier could be causing an electrical load which is preventing the OLS from operating properly. Unseat all the circuit packs in the carrier, and reissue the **recycle carrier** command. a. If the recycle passes, then the OLSs are healthy, and the problem is with one of the circuit packs. Reinsert the circuit packs one at a time. If the status LED shows red after reinserting a circuit pack, then replace the defective circuit pack. If the status LED still shows red, then remove the amphenol connector on the back of the slot containing this circuit pack and reissue the **recycle carrier** command. If the status LED shows green, then the problem is with one of the telephones or the wiring to one of the telephones on this slot. b. If either OLS still shows a red status LED, then check for bent pins and cable placement in the affected carrier. There are failures that can occur on the SYSAM and EPN Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.
	FAIL	**DC POWERED SYSTEMS** There is a problem with one or both port carrier power supplies on the tested carrier. 1. For each port carrier power supply that has all status LEDs OFF, check the DC input to the port carrier power supply at the port carrier power supply outlet. If there is no DC, then check the appropriate circuit breakers for the affected port carrier power supply. If the circuit breaker has tripped, reset the circuit breaker. If the circuit breaker trips again or DC is not present at the port carrier power supply outlet, then there is probably a power wiring problem in the cabinet. 2. At this point, DC should be present at the port carrier power supply outlet. Use the **recycle carrier UUC** command (where *UUC* is the appropriate cabinet and carrier) in an attempt to bring back the port carrier power supplies for this carrier. If the test passes, the trouble is cleared. If the test does not pass, one port carrier power supply, or both, in the tested carrier is defective. If only one port carrier power supply is defective, then the status LEDs on the healthy port carrier power supply will light green for a moment. When the recycle test determines that both port carrier power supplies are defective, the software will turn off power to both the good and defective port carrier power supplies. This will cause the status LED(s) on the good port carrier power supply to light red.

Continued on next page

Table 9-164. TEST #127 OLS Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	3. Unplug both port carrier power supplies, and wait approximately 1-minute to allow the power supplies to cool down. Plug in the power supplies. If either power supply is operating properly (the status LEDs show green), then replace the defective power supply(s). See "Port Carrier Power Supply Replacement Procedures" above. 4. If the replaced port carrier power supply(s) still do not operate properly, then a circuit pack or a defective telephone connected to a circuit pack in the affected carrier could be causing an electrical load which is preventing the power supply from operating properly. Unseat all the circuit packs in the carrier, and reissue the **recycle carrier** command. a. If the recycle passes, then the port carrier power supplies are healthy, and the problem is with one of the circuit packs. Reinsert the circuit packs one at a time. If the status LED shows red after reinserting a circuit pack, then replace the defective circuit pack. If the status LED still shows red, then remove the amphenol connector on the back of the slot containing this circuit pack and reissue the **recycle carrier** command. If the status LED shows green, then the problem is with one of the telephones or the wiring to one of the telephones on this slot. b. If either port carrier power supply still shows a red status LED, then check for bent pins and cable placement in the affected carrier. There are failures that can occur on the SYSAM and EPN Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.
	PASS	AC POWERED SYSTEMS Both OLSs in the tested carrier were found to be healthy by the SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN. If the status LEDs on both OLSs are not showing green, then the SYSAM or the EPN MAINT circuit pack may have incorrectly reported the state of the OLSs. Resolve any alarms on these MOs. DC POWERED SYSTEMS Both port carrier power supplies in the tested carrier were found to be healthy by the SYSAM in a PPN or the EPN Maintenance circuit pack in an EPN. If the status LEDs on both port carrier power supplies are not showing green, then the SYSAM or EPN MAINT circuit pack may have incorrectly reported the state of the port carrier power supplies. Resolve any alarms on these MOs.

CDR-LNK (Call Detail Recording Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
CDR-LINK	MINOR	test cdr [primary/secondary] l	CDR Link
CDR-LINK	WARNING	test cdr [primary/secondary]	CDR Link

Refer to the PRI-CDR/SEC-CDR (Primary and Secondary CDR Links) section for Call Detail Recording Link problems.

CLAN-BD (Control LAN Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CLAN-BD	MINOR	**test board UUCSS long**	Control LAN Circuit Pack
CLAN-BD	WARNING	**test board UUCSS short**	Control LAN Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Control LAN Circuit Pack

The TN799 Control LAN (CLAN) packet port circuit pack provides TCP/IP connection to adjuncts applications such as CMS, Intuity, and DCS Networking. The CLAN circuit pack has 1 10baseT Ethernet connection and up to 16 DS0 physical interfaces for PPP connections. In addition to the TCP/IP functionality, CLAN extends the ISDN capabilities for csi models by providing Packet bus access.

A remote socket control link (RSCL) links the CLAN and the SPE to pass call control and other management information. Since one link serves all the ports on the circuit pack, maintenance of the RSCL is part of the CLAN circuit pack maintenance.

The CLAN TN799 circuit pack combines the functions of the PGATE and PI circuit packs into one circuit pack. The PGATE or PI can be used with the CLAN to create an X.25-to-TCP/IP bridge for adjunct and DCS connectivity.

Control LAN Congestion Controls

The switch activates congestion controls on CLAN when it detects buffers exceeding the threshold. The switch releases the congestion controls when the CLAN reports that its buffer level has returned to normal levels.

If congestion:	Then the switch:
Persists for a 14-minute interval,	Raises MINOR alarm.
Exhausts buffers,	Raises MINOR alarm.
Ceases for 12 minutes,	Retires MINOR alarm.

Error Log Entries and Test to Clear Values

Table 9-165. CLAN-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1(a)	0		MINOR	ON	
18 (b)	0		WARNING	OFF	release board UUCSS
217 (c)	0	None	WARNING	ON	
257	65535	Control Channel Loop Test (#52)	MINOR	ON	test board UUCSS l r 20
257 (d)					
513 (e)	4352-4357		MINOR	ON

Table 9-165. CLAN-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3842 (t)					
3844 (u)	Any				
3845 (v)	Any				
3846 (w)	Any				
3848 (x)	Any				
3849 (y)	Any				
3850-3861 (z)	Any				
3862 (aa)	Any				

Notes:

a. **Error Type 1**: Circuit pack stopped functioning or is not physically present.

1. Verify that the circuit pack is present.
2. If circuit pack is present, reset the circuit pack (**reset board UUCSS**).
3. If the error persists, replace the circuit pack.

b. **Error Type 18**: The CLAN circuit pack busied out.

c. **Error Type 217**: applies to 10 circuit packs:

1. Remove the circuit pack(s) against which the error is logged.

d. **Error Type 257**: Transient communication problem between switch and circuit pack; does not affect service and can be ignored.

1. Ignore this error, unless the Control Channel Loop Test (#52) fails.
2. If Test #52 fails, replace the circuit pack.

Repetitive failures of the Control Channel Loop Test indicate circuit pack hardware failure.

e. **Error Type 513**: Circuit pack detected and reported hardware failure.

   1. Reset the circuit pack (**reset board UUCSS**).

   Aux Data:

4352	External RAM error
4353	Internal RAM error
4355	ROM Checksum error
4356	Angel Message Corruption error
4357	Instruction set error

f. **Error Type 769**: Logic error. By itself this error may be ignored, but it may result in other error types being reported.

g. **Error Type 1293-1295**: Critical hardware or firmware error.

If the switch detects:	Then the switch:
1 error,	Resets circuit pack.
3 errors in 15 minutes,	Raises MINOR alarm.

   Error Type descriptions are as follows:

1293	Insane onboard processor
1294	Onboard translation RAM error
1295	(Aux 3) RSCL link down
	(Aux 0) RSCL keep alive failure

   1. Attempt to clear the alarm (**reset board UUCSS**).
   2. If alarm persists, replace circuit pack.

h. **Error Type 1537**: Switch removed hyperactive circuit pack that reported threshold number of errors.

   1. Attempt to clear the alarm (**reset board UUCSS**).
   2. If the error recurs within 15 minutes, replace the circuit pack.

i. **Error Type 1794**: Packet bus transmit buffers have overflowed..

   1. Attempt to clear the alarm (**reset board UUCSS**).
   2. If the error recurs within 15 minutes, replace the circuit pack.

j. **Error Type 1798**: Unable to write translation RAM.

   1. Attempt to clear alarm (**reset board UUCSS**).
   2. If alarm recurs within 15 minutes, replace the circuit pack.

k. **Error Type 2049**: Packet Interface Test (#598) failed.

1. Attempt to clear the alarm (**test board UUCSS l r 3**).
2. If alarm does not clear, reset the circuit pack (**reset board UUCSS**).
3. If circuit pack resets, execute Packet Interface Test (#598) several times.
4. If Packet Interface Test (#598) continues to fail, replace the circuit pack.

l. **Error Type 2305-2306**: Error in received frame from packet bus.

Error Type:	Description
2305	Received invalid LAPD frame.
2306	Detected parity error on received frame.

Most likely cause—packet bus problem.
Other cause—circuit pack fault.

Invalid LAPD frame errors occur when the frame

- contains a bad Cyclic Redundancy Check (CRC),
- is greater than the maximum length,
- violates the link level protocol.

1. Retry the command (**test board UUCSS**) and see if the condition clears.
2. If condition persists, execute PPE/LANBIC Receive Parity Error Counter Test (# 597) and determine if the condition clears.
3. If condition persists, execute Packet Interface Test (# 598) to verify circuit pack integrity.
4. If Packet Interface Test (# 598) fails, consult repair procedure for the packet bus.

m. **Error Type 2561-2668:** System software received an indication that the socket was closed due to an error. Errors are reported as log only. Errors logged here are for the sockets that had *no* processor channels associated with them, for example, sockets to read SNMP data. The counter base is offset by the application type of the application associated with this socket that is down. The Aux Data field of the log entry contains this application’s number, for example, a SNMP application would have its application number in the Aux Data field.

NOTE:
2561 - 2668 is a range of reserved numbers for future aplications. 2570 currently represents an SNMP socket failure.

n. **Error Type 2817-2819**: Congestion Query Test (#600) failed.

The Error Types correspond to the descriptions:

2817	All buffers exhausted.
2819	Utilized buffers exceed threshold.

If:	Then:
Active buffers exceed threshold,	CLAN enters congested state.

1. Refer to Congestion Query Test (# 600) for Abort and Fail 3601s.

o. **Error Type 3073**: Remote Socket Control Link (RSCL) or Link Status Test (#601) failed. This failure may be due to:

- This circuit pack
- The packet bus
- The packet interface circuit pack.

If:	Then:
RSCL disconnects at link level	Link fails
Link cannot be reconnected quickly	Switch raises MINOR alarm

p. **Error Type 3330**: Critical failure in Packet Bus interface.

Below, Error Types correspond to descriptions.

If the switch detects:	Then it:
1 error,	Resets circuit pack.
2 errors in 15 minutes,	Raises MINOR alarm.

1. Attempt to clear the alarm (**reset board UUCSS**).
2. If alarm persists, replace circuit pack.

q. **Error Type 3586 and 3999**: Switch removed hyperactive circuit pack that reported threshold number of errors. One or more of the following symptoms may be present:

- Circuit pack port tests return `NO BOARD`.
- List configuration command shows circuit pack and ports are installed properly

If Error Type 3999:	And traffic volume is:	Then:
Does not accompany Error Type 3586,	Heavy	Circuit pack is in service, but sent at least half hyperactive threshold. With heavy traffic, this is normal.
Does not accompany Error Type 3586,	Light	Circuit pack is in service, but sent at least half hyperactive threshold. With light traffic, this error indicates a problem with the circuit pack, its links, or the equipment attached to the links.
Accompanies Error Type 3586,	Either Light or Heavy	Switch removed hyperactive circuit pack.

1. Busyout (**busyout board UUCSS**) and release (**release board UUCSS**) circuit pack
2. Allow 30 minutes for condition to clear itself.
3. To re-establish circuit pack into service manually, busyout (**busyout board UUCSS**), reset (**reset board UUCSS**), and release (**release board UUCSS**) the circuit pack.
4. If error recurs within 15 minutes, replace the circuit pack.
5. If the same error occurs on a different circuit pack, follow normal escalation procedures.

r. **Error Type 3840**: Circuit pack received bad control channel message from switch.

Aux Data:

4096	Bad major heading
4097	Bad port number
4098	Bad data
4099	Bad sub-qualifier
4100	State inconsistency
4101	Bad logical link
4102	Bad application identifier

s. **Error Type 3841-3843**: errors do not affect service.

Below, Error Types correspond to descriptions.

3841	Internal firmware error.
3843	Bad translation RAM. Call uses another translation location.

These errors do not affect service, however, they may cause reports of other errors that do affect service.

If Error Type 3843 begins to affect service, it escalates to Error Type 1294.

t. **Error Type 3842**: Packet interface receive buffers overflowed.

If this error occurs frequently, the overflow may be congesting the circuit pack.

1. Refer to Receive FIFO Overflow Error Counter Test (#596).

u. **Error Type 3844**: LAPD frame contains LAPD Protocol Error.

By themselves, these errors do not affect service.

v. **Error Type 3845**: Angel inter processor error.

By themselves, these errors do not affect service.

w. **Error Type 3846**: High CPU occupancy.

By themselves, these errors do not affect service.

x. **Error Type 3848**: Interprocessor LAPD protocol error.

By themselves, these errors do not affect service.

y. **Error Type 3849**: Interprocessor LAPD frame error.

By themselves, these errors do not affect service.

z. **Error Type 3850 - 3861**: IBL error.

By themselves, these errors do not affect service. These errors can occur only on a G3csi machine that has an Interboard Link (IBL).

aa. **Error Type 3862**: Memory allocation failure.

By themselves, these errors do not affect service.

System Technician-Demanded Tests: Descriptions and Error Codes

Investigate errors in the order they appear in the table below.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Loop-Around Test #52	X	X	ND
Circuit Pack Restart Test #252			D
Invalid LAPD Frame Error Counter Test #597		X	ND
PPE/LANBIC Receive Parity Error Counter Test #595		X	ND
Receive FIFO Overflow Error Counter Test #596		X	ND
Packet Interface Test #598	X	X	ND
Congestion Query Test #600	X	X	ND
Link Status Test #601	X	X	ND

1. D = Destructive; ND = Nondestructive

Control Channel Loop-Around Test (#52)

This non-destructive test fails if the circuit pack does not return to a sane state after being reset. This test queries the circuit pack for its code and vintage, and verifies its records.

Table 9-166. TEST #52 Control Channel Loop-Around Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	Could not allocate the necessary system resources to run test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
	FAIL	The circuit pack failed to return the code or vintage. 1. Retry command at 1-minute intervals, up to 5 times. 2. Reset the board (**reset board UUCSS**). 3. If reset aborts with error code 1115, busyout (**busyout board UUCSS**), reset (**reset board UUCSS**), and release board (**release board UUCSS**). 4. If test continues to fail, replace the circuit pack. 5. Escalate the problem if failures continue.
	PASS	Test successful.

Circuit Pack Restart Test (#252)

NOTE:
This test is destructive.

Execute this test (not part of either short or long demand test sequence) to reset the circuit pack only if there are PPCPU errors. This test fails if the circuit pack does not return to a sane state after being reset. The circuit pack resets through the SAKI Sanity Test (#53).

Table 9-167. Test #252 Circuit Pack Restart Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	Could not allocate the necessary system resources to run test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack (**busyout board UUCSS**). 2. Retry the command at 1-minute intervals, up to 5 times. 3. If the problem persists, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
1, 2	FAIL	The circuit pack failed to reset. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, pull out and reseat the circuit pack. 3. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initialized correctly.

PPE/LANBIC Receive Parity Error Counter Test (#595)

This test is non-destructive. When the CLAN circuit pack detects a parity error with a received frame, it increments the PPE/LANBIC Receive Parity error counter. This test reads and clears the counter, and may verify repair of problem.

Errors may indicate a problem with:

- This circuit pack
- A packet bus
- Another circuit pack on the bus

Table 9-168. TEST #595 PPE/LANBIC Receive Parity Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**). 3. If the problem persists, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run test.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
1-10	FAIL	Circuit pack detects parity errors. The Error Code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the test continues to fail, execute the Packet Interface Test (#598) (**test board UUCSS**). 3. If Packet Interface Test (#598) fails, see Packet Bus repair procedures.
	PASS	Circuit pack detects no errors.

Receive FIFO Overflow Error Counter Test (#596)

This test is non-destructive. When the CLAN circuit pack detects packet bus buffer overflow, it increments the error on the FIFO Overflow error counter. This test reads and clears the counter.

If errors are:	Then they may be due to:
Occasional	Statistical buffer sizing
Persistent	Circuit pack congestion that requires redistribution of traffic load

Table 9-169. TEST #596 Receive FIFO Overflow Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**). 3. If the problem persists, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run test.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
1-10	FAIL	Circuit pack detects overflow errors. The error code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the test continues to fail, execute the Packet Interface Test (#598) (**test board UUCSS**). 3. If Packet Interface Test (#598) fails, refer to Packet Bus repair procedures.
	PASS	Circuit pack detects no errors.

Invalid LAPD Frame Error Counter Test (#597)

This test is non-destructive.

CLAN detects invalid frames when it receives

- a frame with a CRC error
- an unrecognizable frame
- a recognizable frame in an unexpected state

When the CLAN circuit pack detects an invalid LAPD frame, it increments the Invalid LAPD Frame error counter. This test reads and clears the counter, and verifies the repair of the problem.

Errors may indicate a

- circuit pack problem
- packet bus problem
- problem with another circuit pack on the bus

Table 9-170. TEST #597 Invalid LAPD Frame Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**). 3. If the problem persists, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
1-10	FAIL	The circuit pack detects LAPD frame errors. The error code indicates the value of the on-board error counter. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the test continues to fail, execute the Packet Interface Test (#598) (**test board UUCSS long**). 3. If Packet Interface Test (#598) fails, refer to Packet Bus repair procedures.
	PASS	Circuit pack detects no errors.

Packet Interface Test (#598)

This non-destructive test checks the packet bus interface circuitry on the CLAN circuit pack. Test failure indicates faulty circuit pack.

Table 9-171. TEST #598 Packet Interface Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**). 3. If the problem persists, replace the circuit pack.
2012	ABORT	Could not allocate the necessary system resources to run test.
2100	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
	FAIL	Circuit pack has detected a failure of the Packet Interface Test (#598). 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**). 3. If the test continues to fail, replace the circuit pack.
	PASS	The Packet Interface Test (#598) passed.

Congestion Query Test (#600)

This non-destructive test queries the number of used buffers to determine if the CLAN circuit pack is congested.

If:	Then:
Used buffers are, or are nearly, exhausted,	The test fails
The test fails,	The switch redirects outgoing calls to another available CLAN, and denies new incoming calls

Normal call handling resumes when the CLAN circuit pack has recovered from congestion.

Table 9-172. TEST #600 Congestion Query Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Did not receive circuit pack test response within the allowable time period. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**). 3. If the problem persists, replace the circuit pack.
2012	ABORT	Could not allocate the necessary system resources to run test.
2100	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.

Continued on next page

Table 9-172. TEST #600 Congestion Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The buffer level is nearly exhausted.
2	FAIL	The CLAN is congested, and no buffers are available. 1. Retry command at 1-minute intervals, up to 5 times. 2. If command continues to fail, examine the CLAN port measurements to determine which ports are heavily utilized and the processor occupancy of the circuit pack. *Low processor occupancy* when CLAN congested indicates circuit pack failure. 1. If the problem persists, reset the circuit pack (**reset board UUCSS**). 2. If congestion recurs, replace the circuit pack. *High processor occupancy* indicates the CLAN is congested due to traffic load. 1. To relieve congestion in the short term, selectively busyout ports (**busyout port UUcSSpp**) on the Control LAN circuit pack. 2. To achieve a more permanent resolution, it may be necessary to move ports on this circuit pack to other Control LAN circuit packs. 3. Consider replacing affected CLAN ports with new ports.
3	FAIL	The CLAN circuit pack is not operating normally and is congested.
	PASS	Hardware setting and attached cable type match CLAN circuit pack administration. The circuit pack detects no errors.

Link Status Test (#601)

This non-destructive test determines the state of the call control signaling link for Control LANs. If the signaling link is physically connected, the test sends a test frame over the link and checks for a response. The test passes only if both the signaling link is connected and the test frame is successfully transmitted.

A failure may indicate a problem with::

- This circuit pack
- The packet bus
- The packet interface circuit pack

Table 9-173. TEST #601 Link Status Test

Error Code	Test Result	Description/ Recommendation
1125	ABORT	RSCL link or C-LAN board not in service. 1. Release the board. 2. Repeat the test. 3. Escalate if the problem persists.
2012	ABORT	Could not allocate the necessary system resources to run this test.
2100	ABORT	Internal system error. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, escalate the problem.
2	FAIL	The RSCL control link disconnected. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the test continues to fail, execute the Packet Interface Test (#598) (**test board UUCSS**) to determine if the problem is due to the circuit pack. 3. If the Packet Interface Test (#598) fails, refer to Packet Interface Test repair procedures. 4. If the Packet Interface Test (#598) passes, refer to Packet Control Circuit Pack and Packet Bus repair procedures.
3	FAIL	Received no response to RSCL control link test frame. 1. Retry command at 1-minute intervals, up to 5 times. 2. If the problem persists, reset the circuit pack (**reset board UUCSS**). 3. If test continues to fail, replace the circuit pack.
	PASS	RSCL control link connected.

CLSFY-BD (Call Classifier Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CLSFY-BD	MIN	test board UUCSS sh	Call Classifier Circuit Pack
CLSFY-BD	WRN	test board UUCSS sh	Call Classifier Circuit Pack

1. 4UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Refer to “XXX-BD (Common Port Circuit Pack)” for circuit pack level errors. See also “Call Classifier Port (CLSFY-PT)” for related port information.

CLSFY-PT (Call Classifier Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CLSFY-PT[1]	MAJOR	test port UUCSSpp sh	Call Classifier Port
CLSFY-PT	MINOR	test port UUCSSpp sh	Call Classifier Port
CLSFY-PT	WARNING	test port UUCSSpp sh	Call Classifier Port

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The TN744 Call Classifier is a service circuit pack that provides specialized tone detection capabilities to support the Outbound Call Management (OCM) and Inbound Call Management (ICM) features. The TN744 supports both A-law and Mu-law companding.

The TN744 has eight ports (CLSFY-PTs), each capable of supporting call classification, touch-tone reception and MFC-tone generation and detection. The CLSFY-PT maintenance object implements a set of tests designed to ensure proper operation of the Call Classifier.

Error Log Entries and Test to Clear Values

Table 9-174. Call Classifier Port (CLSFY-PT) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1	any	Tone Detector Audit/Update Test (#43)	MAJOR/ MINOR(a)	ON	test port UUCSSpp r 2
18		busyout port	WARNING	OFF	release port UUCSSpp
257(b)	17666	Tone Detection Audit Update Test (#43)	MAJOR/ MINOR(a)	ON	test port UUCSSpp r 3
513(c)	any	Tone Detection Verification Test (#42)	MAJOR/ MINOR(a)	ON	test port UUCSSpp r 3

Notes:

a. There are two possible alarm levels for this error type: MAJOR and MINOR. A major alarm is raised if the total number of call classifier ports currently in-service is less than or equal to 1/2 of the administered threshold number. Otherwise, a minor alarm is raised. In either case, run the short test sequence on the alarmed port and follow the error code procedures for the individual tests.

   The in-service threshold number for alarming call classifier ports is administered using the **change system-parameters maintenance** command. For details, refer to Chapter 8, ''Maintenance Commands''.

   1. Issue these commands in order: **busyout board**, **reset board**, **release board**. The board reset is required to reload on-board RAM associated with the TN744's DSPs. This takes all 8 tone detector ports out of service for a few seconds. Only 4 of the 8 would be out of service due to the alarm. (There are 5 tone detectors on each of the two DSPs.) Other than the unlikely potential of running out of tone detector resources in the switch, there is no other effect when the board is reset.
   2. Test the board (**test board UUCSS long**).
   3. If the test still fails, replace the board.

b. The CLSFY-PT lost its translation. Testing the CLSFY-PT is sufficient to reload its translation. If testing the call classifier port does not clear the error, then the call classifier circuit pack containing the defective call classifier port should be replaced.

c. This error indicates the call classifier port is having problems detecting call classification tones or detecting and generating R2-MFC tones This is usually accompanied by failures of some incoming or outgoing calls. If this error type is persistently logged, then replace the call classifier circuit pack containing the defective CLSFY-PT.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test(#42)	X	X	ND
Tone Detection Audit/Update Test(#43)	X	X	ND

1. D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test checks the operation of the TN744 in touch-tone receiver, call classifier and R2-MFC modes. It verifies the circuit pack's ability to detect DTMF, ring back, busy reorder and modem answer tones and to generate and detect forward and backward MFC tones.

Table 9-175. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test OR there was an internal system error.
1	ABORT	The system could not allocate all the resources needed to test the tones.
1001	ABORT	The system was unable to put the call classifier port in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This situation could occur when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the **test tdm** command. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a Tone-Clock for the test connection. This may be caused by a heavy load on the system or by a faulted Tone-Clock. 1. Check to see if there are any alarms against the Tone-Clock in the port network where the test aborted. If so refer to the recommended procedures for TONE-BD or TONE-PT. 2. If a new Tone-Clock has been inserted, allow about 1-minute for maintenance to run on the newly inserted circuit pack. 3. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Call classifier circuit pack's response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2006	ABORT	Indicates that the active Tone-Clock circuit pack or a Tone Detector circuit pack may not be functioning properly. 1. Test the *active* Tone-Clock circuit pack in the port network with the **test tone-clock** UUC command and refer to the TONE-BD section for failures. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-175. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1-3	FAIL	DTMF digits were not detected correctly. This may or may not impact reception of R2-MFC calls. 1. Run the short test sequence via the **test port UUCSSpp sh r 1** command. 2. If the problem persists, the system is still operating properly but capacity will be reduced. To restore performance to normal, replace the call classifier circuit pack containing the defective CLSFY-PT (Call Classifier Port).
102	FAIL	2225 Hz Modem Answer Tone was not detected correctly. This will impact call-classification operation. 1. Run the short test sequence via the **test port UUCSSpp sh r 1** command. 2. If the problem persists, the system can still operate properly but capacity will be reduced. In order to restore performance to normal, replace the call classifier circuit pack containing the defective port.
130	FAIL	Forward or backward R2-MFC signals were not correctly generated or detected. This will impact R2-MFC calls. 1. Run the short test sequence via the **test port UUCSSpp sh r 1** command. 2. If the problem persists, the system can still operate properly but capacity will be reduced. In order to restore performance to normal, replace the call classifier circuit pack containing the defective port.
	PASS	Tone detection verification is successful. The call classifier port is able to detect and generate all necessary tones.

Tone Detector Audit/Update Test (#43)

This test performs a sanity audit on the CLSFY-PT (Call Classifier Port).

Table 9-176. TEST #43 Tone Detector Audit/Update Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate the resources for this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Hardware audit failed. 1. Issue these commands in order: **busyout board**, **reset board**, **release board**. The board reset is required to reload on-board RAM associated with the TN744's DSPs. This takes all 8 tone detector ports out of service for a few seconds. Only 4 of the 8 would be out of service due to the alarm. (There are 5 tone detectors on each of the two DSPs.) Other than the unlikely potential of running out of tone detector resources in the switch, there is no other effect when the board is reset. 2. Test the board (**test board UUCSS long**). 3. If the test still fails, replace the board.
	PASS	The call classifier port has passed the sanity inquiry.

CO-BD (Central Office Trunk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CO-BD	MIN	test board UUCSS sh	Central Office Trunk Circuit Pack
CO-BD	WRN	test board UUCSS sh	Central Office Trunk Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Refer to “XXX-BD (Common Port Circuit Pack)” for circuit pack level errors. See also “CO-TRK (CO Trunk)” for related trunk information.

CO-DS1 (DS1 CO Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CO-DS1	MAJOR[2]	test trunk *group# member#* l	DS1 CO Trunk
CO-DS1	MINOR	test trunk *group# member#* l	DS1 CO Trunk
CO-DS1	WARNING	test trunk *group# member#*	DS1 CO Trunk

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed. For more information on the **set options** command, see Chapter 8, ''Maintenance Commands''.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY Enterprise Communications Server Release 5.4 Administrationa nd Feature Description*, for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

A DS1 CO (central office) trunk provides a link for digitized voice or data communications between the system and a central office switch. There are two types of DS1 interfaces:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link

NOTE:
32-channel mode is supported only on TN464 circuit packs and on G3r V2 systems.

The DS1-CO maintenance object monitors and maintains a CO trunk port on either a TN767 DS1 Interface circuit pack or a TN464 UDS1 Interface circuit pack. Throughout this discussion, the term DS1 circuit pack applies to both. See ''DS1-BD (DS1 Interface Circuit Pack)'' and ''UDS1-BD (UDS1 Interface Circuit Pack)'' in this chapter for more information about these circuit packs. The DS1 circuit pack supports low level CO trunk signaling interfaces for both ground-start and loop-start trunks. This maintenance strategy covers the in-line errors log, initialization tests, periodic tests, scheduled tests, demand tests, and alarm resolution.

Three trunk service states are specified by DS1 CO trunk maintenance:

out-of-service	The trunk is in a deactivated state and cannot be used for either incoming or outgoing calls.
in-service	The trunk is in an activated state and can be used for both incoming and outgoing calls.
disconnect (ready-for-service)	The trunk is in an activated state but can only be used for an incoming call.

Error Log Entries and Test to Clear Values

Table 9-177. DS1 CO Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test trunk <grp>/<mbr>
1(a)	57408				
1(a)	57487				
15(b)	Any	Port Audit and Update Test (#36)			
18(c)	0	busyout trunk <grp>/<mbr>	WARNING	OFF	release trunk <grp>/<mbr>
130(d)		None	WARNING	ON	test trunk <grp>/<mbr>
257(e)	57392	DS1 CO Dial Tone Seizure Test (#314)	MIN/MAJ[2]	OFF	
513(f)	57393	DS1 CO Dial Tone Seizure Test (#314)	MIN/MAJ[2]	OFF	
769(g)	57484				
1025		DS1 CO Dial Tone Seizure Test (#314)	MIN/ WRN[3]	OFF	test trunk <grp>/<mbr> r 2
1281		Conference Circuit Test (#7)	MIN/ WRN[3]	ON	test trunk <grp>/<mbr> l r 4
1537		NPE Crosstalk Test (#6)	MIN/ WRN[3]	ON	test trunk <grp>/<mbr> l r 3
1793(h)					test board UUCSS l
2562(i))	16665				
2817(j)	52992				
3840(k)		Port Audit and Update Test (#36)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2. This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
3. Major alarms MO may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. Error Type 1—Aux Data 57408—No tip ground is detected on an outgoing call.

   Aux Data 57487—PBX could not get "loop close" signal.

   The DS1 Interface circuit pack detected a hardware fault. These errors will cause the Dial Tone Test (#314) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in the ready-for-service state (shown as "disconnected" by the status command), which allows only incoming calls. Run the Dial Tone Test (#314) and follow the procedures.

b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

c. Error Type 18—System Technician has busied out the trunk to the out-of-service state. No calls can be made on this trunk except the Facility Access Test Call. For details on this feature, refer to "Facility test calls" section in Chapter 6, "Additional Maintenance Procedures".

d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.

e. Error Type 257—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57392 indicates no external release on PBX disconnect.

f. Error Type 513—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57393 indicates belated external release on PBX disconnect.

g. Error Type 769—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type:—57484, fault is detected on tip/ring.

h. Error Type 1793—DS1 Interface circuit pack is out-of-service. Look for DS1-BD errors in the Hardware Error Log if the port is on a TN767 DS1 board. Look for UDS1-BD errors in the Hardware Error Log if the port is on a TN464 UDS1 board. Refer to the DS1-BD or UDS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for details

i. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

j. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the Dial Tone Seizure Test (#314) and follow those procedures.

k. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back into in-service. Retry the test command.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 CO Trunk Seizure Test (#314)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-178. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. The **status health** command can be used to determine if the system is experiencing heavy traffic. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some tone detectors may be out-of-service. The **list measurements tone-receiver** command will display information on the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-178. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a user for a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2053	ABORT	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Continued on next page

Table 9-178. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. **NOTE:** Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands will not work (even though the **reset board** command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

Conference Circuit Test (#7)

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 9-179. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-179. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The test was aborted. System resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. 1. Use the **status station** or **status trunk** command to determine when the port is available for testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1018	ABORT	The test was disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Administration' screen is set to 'n.' To enable the test, change the trunk administration and enter 'y' into the 'Maintenance Test' field. 2. Repeat the test.

Continued on next page

Table 9-179. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2053	ABORT	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later. The error log may have error type 1281 entries. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW. 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the CO. Make sure that the switch, the CO, and any NTCE equipment (the CSU's) have the correct administration. 6. Replace the circuit pack. **NOTE:** If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. To investigate problems with a power unit, refer to "CARR-POW". If a red LED on a TN736 or TN752 power unit circuit pack is on, replace the pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 9-179. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. **NOTE:** Hyperactivity causes some special problems with the sequence suggested above.If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands will not work (even though the **reset board** command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of trunk.

Table 9-180. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Issue **display port UUCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025. The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1006	ABORT	The DS1 CO trunk is out of service. 1. Use **status trunk** to verify that the trunk is out of service. 2. If the trunk is out of service, determine why. 3. If it is OK to put the trunk back in service, issue the **release trunk** command to put the trunk back in service, and then retry the test.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Test failed due to internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run but will return PASS. To verify that the trunk is in-service: 1. Enter **status trunk** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service. 2. Enter **release trunk** to put the trunk back into in-service. 3. Retry the test command.

Continued on next page

Table 9-180. TEST #36 Port Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port. This result could be due to incorrect translations, no board inserted, an incorrect board inserted, an insane board inserted, or the board is hyperactive. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If not, to check that there is a valid board inserted. Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands do not work (even though the **reset board** command does work). The software puts the hyperactive board back in service after the hyperactivity clears.

DS1 CO Dial Tone Seizure Test (#314)

DS1 CO Dial Tone Seizure Test checks the trunk's signaling capability provided by the DS1 Interface circuit pack. The maintenance software initiates the test by sending a "seizure" message to the DS1 Interface circuit pack and expects an "active" reply from the DS1 interface circuit pack. If the "active" message is received, then the test passes. If no message is received and the timer expires, the test is aborted. If the DS1 Interface circuit pack sends a "reorder" message back to maintenance software, then the test fails.

This test cannot be run on a trunk in any of the following conditions:

a. The trunk direction is administered as an incoming only trunk.

b. The trunk has been seized by a normal trunk call.

c. The trunk is administered with maintenance test disabled.

Table 9-181. TEST #314 DS1 CO Dial Tone Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	The test was aborted because system resources required to run this test were not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025. The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The test was aborted because the port was seized by a user for a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Look at the trunk group administration form and see whether the trunk is incoming only, port 24 on a DS1 Interface with common control channel signaling, or an automatic CO type such as FX. Under any of these conditions this is a normal abort.
1018	ABORT	Test is disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Group' form is set to 'n'. To enable the test, issue the **change trunk-group x** command (x equals the number of the trunk group to be tested). Then, change the entry in the 'Maintenance Test' field on the form to 'y'. 2. Repeat the test.
1040	ABORT	The test was aborted because this port may be an access endpoint. 1. Verify that this port is an access endpoint by issuing the **display port** command. 2. If the port has been administered as an access endpoint, then this is a normal abort.

Continued on next page

Table 9-181. TEST #314 DS1 CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for DS1-BD/UDS1-BD errors in the Hardware Error Log. If present, refer to the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Trunk Circuit Pack). 2. Retry the command.
2012	ABORT	The test was aborted due to an internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources for this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	FAIL	Response to the seizure message was not received within the allowable time period. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, a failure of test 314 causes a subsequent failure of test 7 due to a firmware bug. Eventually, the board and all of its ports will be taken out of service and extraneous on-board alarms will be generated. Replace the circuit pack with a TN767C V3 or later. 2. Verify that the ’Trunk Type’ field on the ’Trunk Administration’ screen matches the trunk type administered on far-end switch. 3. Look for DS1-BD or UDS1-BD errors in the hardware error log. If present, refer to the DS1-BD (DS1 trunk circuit pack) maintenance documentation or to the UDS1-BD (UDS1 trunk circuit pack) maintenance documentation. 4. Retry the command at 1-minute intervals for a maximum of 5 times.
2053	FAIL	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for these error types in the hardware error log and then follow the procedures given in the maintenance documentation that is appropriate for the error type that was found.
	FAIL	The trunk cannot be seized for an outgoing call. This could cause in-line failures to be reported against the trunk (no answer would report error type 257 with auxiliary data 57487 in the error log). 1. Verify the Trunk Type field on the trunk administration screen form matches the trunk type administered on far end switch. 2. Look for DS1-BD/UDS1-BD errors in Error Log. If present, refer to DS1-BD/UDS1-BD (DS1/UDS1 Trunk Circuit Pack). 3. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-181. TEST #314 DS1 CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The trunk can be seized for an outgoing call.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands will not work (even though the **reset board** command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

CO-TRK (Analog CO Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CO-TRK	MAJOR[2]	test port UUCSSpp l	Analog CO Trunk
CO-TRK	MINOR	test port UUCSSpp l	Analog CO Trunk
CO-TRK	WARNING	test port UUCSSpp l	Analog CO Trunk

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75% of the trunks in this trunk group are alarmed.

If ATMS testing is enabled, check the error log for ATMS errors 3840 and 3841. If the error log indicates that measurements exceeded acceptable thresholds, and no other trouble is found with **test trunk**, run the ATMS test call with **test analog-testcall port UUCSSpp full**.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

Analog CO trunks are 2-wire analog lines to the CO which support both incoming and outgoing calls. CO trunk circuit packs have eight ports, each of which provides an interface between the 2-wire CO line and the 4-wire TDM bus. The system supports the following CO trunk circuit packs:

TN438	TN2138
TN447	TN2147
TN465	TN2148
TN747	

The following sequences show the interactions between the switch and the CO during call setup for both loop-start and ground-start trunks.

Loop Start Operation

Idle State: Tip = ground, Ring = CO Battery **Outgoing Call:**

1. PBX Off-Hook (Seize Message): Closes the Tip-Ring Loop

   CO Response: DC loop current + Dial tone

2. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current

   CO Response: CO goes to idle state (see Note)

Incoming Call:

1. CO Applies Ringing Voltage

   PBX Response: Detect ringing current

2. PBX Off-Hook (Answer Message): Close loop

   CO Response: Trip ringing, provide loop current

3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current

   CO Response: CO goes to idle state (see Note)

NOTE:
CO does not normally provide an On-Hook (Disconnect) signal. Exceptions to this rule include Netherlands loop start and UK loop-calling guarded-clearing.

Ground Start Operation

Idle state: Tip = open, Ring = CO Battery **Outgoing Call:**

1. PBX Off-Hook (Seize Message): Places ground on Ring

   CO Response: Places ground on Tip

   PBX Response: Close the loop

   CO Response: Provide loop current

   PBX response: Dial out digits

2. PBX On-Hook first (Drop Message): Open the Tip-Ring Loop, no loop current

   CO Response: Open circuit on Tip

3. CO On-Hook first (Disconnect): Open circuit on Tip, no loop current

   PBX Response: Open Tip-Ring loop

Incoming Call:

1. CO Off-Hook (Seizure): CO applies ground on Tip and applies ringing voltage

   PBX Response: Make trunk busy for outgoing calls
2. CO Ringing: CO applies ringing voltage

   PBX Response: Detect ringing, ring destination
3. PBX Off-Hook (Answer Message): Close loop

   CO Response: Trip ringing, provide loop current
4. PBX On-Hook first (Drop Message): Open the Tip-Ring Loop, no loop current

   CO Response: Open circuit on Tip
5. CO On-Hook first (Disconnect): Open circuit on Tip, no loop current

Error Log Entries and Test to Clear Values

Table 9-182. CO Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port *UUCSSpp* sh r 1
1 (a)	57347	None			
15 (b)	any	Port Audit Update Test (#36)			
18	0	busyout trunk	WARNING	OFF	release trunk *grp#/mbr#*
130(c)		None	WARNING	ON	test port *UUCSSpp* sh r 2

Continued on next page

Table 9-182. CO Trunk Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1793		Looparound and Conference Test (#33	MAJ/MIN/ WRN[2]	ON	test port *UUCSSpp* l r 3
2049		NPE Cross Talk Test (#6)	MAJ/MIN/ WRN[2]	ON	test port *UUCSSpp* l r 3
2561 (d)	57345	None			
2817 (a)	57360	None			
2817 (a)	57393	None			
2817 (d)	57484	Dial Tone Test(#0)	MAJ/MIN/ WRN	OFF	test port *UUCSSpp* l r 1
3073 (d)	57376	None			
3329 (d)	57408	None			
3329 (d)	57484	Dial Tone Test(#0)	MAJ/MIN/ WRN	OFF	test port *UUCSSpp* l r 1
3585 (d)	57424	None			
3840 (f)	8000	Transmission Tests (ATMS)(#844-848)		OFF	test analog-testcall
3841 (f)		Transmission Tests (ATMS)(#844-848)	MINOR	OFF	test analog-testcall

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. These are in-line errors that have no specific test associated with them. Refer to the following table for an explanation and appropriate action.

b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors.

c. This error type indicates that the circuit pack has been removed or has been insane for at least 11-minutes. To clear the error, reinsert or replace the circuit pack.

d. Aux data 57345 — Single polarity ringing current

Aux data 57376 — No loop current on incoming call

Aux data 57408 — No tip ground detected on outgoing call

Aux data 57424 — No loop current on outgoing call

Aux data 57484 — No dial tone on outgoing call

These errors will cause the Dial Tone Test (#0) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1537 will also show up). In this case, the trunk may be put in "Ready-for-Service" state (shown as "disconnected" by status command), which allows only incoming calls. Run the Dial Tone Test (#0) and follow its outlined procedures.

If error count associated with this error type is very high (i.e., 255) and if Alarm Status on the Hardware Error Report is "n" (not alarmed), then the existence of this error type indicates that, despite the fact that many in-line error messages have been received, all Call Seizure Tests have passed. Problems at the CO may cause this condition rather than problems with the PBX.

e. These errors will be logged for all versions of the CO-TRK/CO-BD. However, no MINOR alarms will be generated for Central Office Trunks [TN747B] with vintages V8 or greater. Any failures received by this test will still be logged as Error type 1025/1281.

   Check for the use of MFT/Range extenders. If there are extenders present, and there are no other complaints or maintenance errors against this trunk, then there is a good chance that Test #3 failed due to excessive loop current and may be ignored.

f. Error 3840 indicates that test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements in the unacceptable range. Error 3841 indicates measurements were in the marginal range. Use **list testcall detail** to examine the specific transmission parameters which are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, then the AMTS thresholds administered on page 4 of the trunk group form should be changed.

Table 9-183. CO Trunk Errors with No Tests

Error Type	Aux Data	Error Description and Repair Action
1	57347	Port error. Ringing without ground. This error is detected on an incoming call on a ground-start CO trunk. The CO trunk circuit pack has not detected a Tip ground before ringing current is detected. This may indicate that the ground detector is not working. However, the call will be accepted. Busyout the affected port, and run a long test. Observe the test results. If any tests fail, refer to the description of the tests and the associated error codes. Release the port. If users continue to report troubles, check for other errors and make test calls to determine whether the problem should be referred to the CO.

Continued on next page

Table 9-183. CO Trunk Errors with No Tests — *Continued*

Error Type	Aux Data	Error Description and Repair Action
257	50176	Battery reversal detected. This is usually caused by the CO (often seen with step-by-step and cross-bar offices in connection with outgoing calls). This is detected if the direction of the loop current changes from normal to reverse for at least 40 msec. Could occur if the trunk was just installed and for some reason the Tip and Ring wires were reversed at the PBX. If battery reversals occur during dialing, wrong numbers may result. Refer problem to CO. Ask them to remove the battery reversal option.
513	57364	Ground detector stuck active. After several occurrences, an on-board minor alarm is generated. Run the short test sequence. If test aborts with Error Code 1000, disconnect Tip and Ring and repeat short test. If test still aborts, replace circuit pack. If test passes, refer problem to CO. If any other error code is received, pursue that problem.
769	57392	CO not releasing after call is dropped from PBX end (TN747B), or the loop is not open after a disconnect (TN765). After several occurrences, an off-board (TN747B) or on-board (TN465) warning alarm is generated. Refer problem to CO.
2561	57345	Single polarity ringing current. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) Another cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the dial tone test will also fail. The last cause could be that certain types of noise are present on the CO line during the silent period of ringing. First check for other errors. If the count for this error is very high (255), and all tests pass, then either the reverse current detector is defective or the CO line is noisy. If the CO line is suspect, make Tip and Ring observations. If the line is determined to be noisy, refer the problem to the CO. If the reverse current detector is defective, ignore this error.
2817	57360	Ground but no ringing. This error occurs on an incoming call on a ground-start trunk. If ringing is not detected within 5 seconds of the Tip being grounded, the call is still accepted. If the CO is of the No. 5ESS. switch type, ringing delays of more than 5 seconds during heavy traffic are fairly common. Check for other errors.
2817	57393	On the TN465, the loop is opening too slowly after a disconnect. This error indicates an on-board problem, although the trunk may be functional. Check for other errors.
3073	57376	No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the dial tone test and all outgoing calls should also fail. Check for other errors.

Continued on next page

Table 9-183. CO Trunk Errors with No Tests — *Continued*

Error Type	Aux Data	Error Description and Repair Action
3329	57408	Trunk error. No Tip ground detected on outgoing call. This error occurs when an attempt is made to seize a ground-start CO trunk for an outgoing call and Tip ground is not detected or the caller hangs up before Tip ground is detected. 1. Busyout the affected port, and run a long test. Observe the test results. If any tests fail, refer to the description of the tests and the associated error codes. Release the port. 2. If users continue to report troubles, check for other errors and make test calls to determine whether the problem should be referred to the CO. Busyout the affected port, and run a long test. If Dial Tone Test #0 passes, ignore this error. Release the port.
3585	57424	No loop current on outgoing call. This error occurs on attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected. Busyout the affected port, and run a long test. If CO Demand Diagnostic Test #3 passes and this error keeps occurring, refer problems to CO. Release the port.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Dial Tone Test (#0)		X	ND
CO Demand Diagnostic Test (#3) (a)	X	X	ND
Looparound and Conference Test (#33)		X	ND
Audit Update Test (#36)	X	X	ND
Transmission Test - ATMS (#844-848)	(b)	(b)	ND

1. D = Destructive; ND = Nondestructive

Notes:

a. A demand test of Diagnostic Test (#3) will always return a PASS indication for CO-TRK/CO-BD [TN747B] version 8 or greater. However, any errors produced as a result of this test will be logged and produce no alarms.

   If errors logged by test #3 are the only complaints against this trunk, then the system technician should check if MFT/Range Extenders are being used. If extenders are present, then there is a good chance that there is excessive loop current, which will cause Test #3 to log errors.

   However, all else being normal, these errors should not affect the customer.

b. The ATMS tests are not part of either test sequence. They are run either on demand with **test analog-testcall** or by the ATMS schedule.

Dial Tone Test (#0)

This test attempts to seize a port and checks for the return of a dial tone.

Table 9-184. TEST #0 Dial Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the command **display port UUCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	System resources required to run this test were not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-184. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a user for a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	Trunk has been administered as incoming-only; dial tone can only be obtained on outgoing trunks. This is a normal condition.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the **change trunk-group x** command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Trunk was seized, but dial tone could not be detected. 1. Test all administered outgoing ports on the board. Failure of 1 indicates a problem toward the CO. 2. If all fail, see note below. 3. Check for errors on the TONE-BD or TONE-PT. Clear any errors found, and repeat the test. 4. If the error has still not cleared, refer the problem to the CO. 5. If no service problems exist on the port, continue to use the port until the circuit pack can be replaced (as a last resort). Perform a trunk test call to see if the trunk is operable. **NOTE:** If the dial tone test fails for all ports on a circuit pack, a -5 volt power problem is indicated. To investigate problems with a power unit, refer to “CARR-POW”.

Continued on next page

Table 9-184. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2002	FAIL	Seizure portion of test failed due to hardware problem. Fault is usually caused by a disconnected trunk. 1. If the CO Demand Diagnostic Test (#3) also failed, display the Hardware Error Log. If the CO Demand Diagnostic Test failed because it could not detect ground (indicated by Error Type 1281 in the Hardware Error Log) AND Error Type 3329 or 3585 appears in the Hardware Error Log (with the same last occurred time as Error Type 1281 and 1537), replace the circuit pack. 2. Check trunk wiring to ensure good connection; repeat test if wiring correction made. 3. Locate another identical CO trunk and swap its wiring with one under test. Repeat test on both trunks and determine if problem follows trunk or remains at original port. If problem follows trunk, refer problem to CO. If problem remains at port, replace circuit pack and repeat test.
1009	PASS	Detected tone was not pure dial tone. No action required.
	PASS	Trunk was seized, and dial tone was detected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port. 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

CO Demand Diagnostic Test (#3)

For ground start trunks, port circuit pack relays are operated and checks are made to see if the port can detect and apply ground on the Tip lead. This test also verifies that there is no external ground on the Ring lead. In the absence of other failures, the circuit pack should be replaced only if this test fails with the CO line disconnected.

For the TN2147, this test also checks the on-board programmable transmission circuits that allow the circuit pack to support transmission characteristics of several different countries.

Table 9-185. TEST #3 CO Demand Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port was seized by a user for a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	Test inapplicable to present configuration. This is a normal condition.
1018	ABORT	Test has been disabled via administration. 1. For this test to run, the `Maintenance Tests?` field on the trunk group form must be set to n. The form is accessed with the change trunk-group grp# command.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-185. TEST #3 CO Demand Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Failure to detect ground or faulty ground detected on Ring lead. Display the hardware errors for this trunk, to determine if the fault was on- or-off board. Look for Error Type 1025 or 1281 (if both appear in the Hardware Error Log, pick the most recent error). Error Type 1025 indicates a faulty ground detected on Ring lead (an off-board fault) and Error Type 1281 indicates failure to detect (internally generated) ground (an on-board fault). Faulty ground detected on Ring lead (Error Type 1025): **NOTE:** On TN747B vintage 8 and greater circuit packs, an incoming seizure during this test may cause it to fail with an off-board fault. 1. Repeat test. If test passes, ignore the original failure. If test aborts, follow the recommended procedures. 2. Repeat test with CO line removed. 3. If test fails, replace the circuit pack. 4. If test passes, refer problem to CO. Failure to detect ground (Error Type 1281): 1. Run the long test sequence. If the CO Demand Diagnostic Test fails, the Dial Tone Test (#0) fails with Error Code 2002, AND Error Type 3329 or 3585 appears in the Hardware Error Log (with the same last occurred time as Error Type 1281 and 1537), replace the circuit pack. 2. Repeat test with CO line removed. 3. If test fails, replace the circuit pack. 4. If test passes, the CO may be drawing too much current. Refer problem to CO.
	PASS	This test verifies that the port is able to apply ground for outgoing calls and detect ground for incoming calls; however, it does not provide information on whether a CO line is actually connected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and noisy connections may be observed. This test is usually only part of a port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 9-186. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	The port was seized by a user for a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. Check the CO wiring, check for excessive loop current, and check the trunk translations. (If the trunk is translated incorrectly, this test will abort.) 3. If the port status is idle, busyout and release the trunk, and retry the command at 1-minute intervals for a maximum of 5 times. 4. If the test still aborts, replace the circuit pack.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times..
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-186. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Looparound and Conference Circuit Test (#33)

This test checks the reflective loop around and conference capabilities of a CO port circuit. The test uses 404-Hz, 1004-Hz, and 2804-Hz tones. Each tone is transmitted separately through the loop and checked.

Table 9-187. TEST #33 Looparound and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test.
7	ABORT	Conference Circuit Test aborted.
129	ABORT	The 404-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
131		The 1004-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
133		The 2804-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 769 (see the error log table for a description of this error and required actions). The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized force. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-187. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times..
1018	ABORT	The test was disabled via administration. Verify that the ’Maintenance Test’ field on the ’Trunk Group’ form is set to ’n’. To enable the test, issue the ’change trunk-group x’ command (x equals the number of the trunk group to be tested). Then, change the entry in the ’Maintenance Test’ field on the form to ’y’. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
7 129 131 133	FAIL	The conference capabilities of the port failed (Error Code 7). The reflective 404-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 129). The reflective 1004-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 131). The reflective 2804-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 133). FAULT ISOLATION: Proceed as follows unless power or tone problems are suspected (see notes on the next page). 1. To make sure the problem is on-board, disconnect the port from the CO and retry the test. Coordinate this with the CO, or do it after busy hours; otherwise, the CO may put the connection out of service. 2. If the retry fails, replace the circuit pack. 3. If the retry passes and no troubles have been reported, disable the test. If the retry passes and troubles have been reported, refer the problem to the CO.

Continued on next page

Table 9-187. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7, 129, 131, or 133	FAIL	**NOTE:** If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. To investigate problems with a power unit, refer to "CARR-POW". If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see FAULT ISOLATION above.
	PASS	CO Trunk Looparound and Conference Test is successful. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Port Audit Update Test (#36)

This test will send updates of the CO port translation for all ports on the circuit pack which have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: ground or loop start trunk, tone or rotary dialing trunk, rotary dialing inter-digit timing, network balance R/RC, and disconnect timing.

Table 9-188. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-188. TEST #36 Port Audit Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The port has been placed out of service, perhaps by craft busyout. 1. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
2100	ABORT	System resources required to run this test were not available. 1. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring. If the trunk is busied out, the test will not run, but will return PASS. To verify that the trunk is in-service: 1. Enter **status trunk** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release trunk** command to put trunk back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Transmission Test (#844-848)

This test is non-destructive.

NOTE:
Tests #844-848 are not supported on a International switch.

These tests are run by the Automatic Transmission Measurement System (ATMS). They are not part of the long or short trunk test sequences. Instead, they are run on demand with the **test analog-testcall** command or as part of ATMS scheduled testing. For more information, see "Automatic Transmission Measurement System (ATMS)" in Chapter 6, "Additional Maintenance Procedures".

The test call is run from an analog port on a TN771 Maintenance/Test circuit pack. It attempts to seize a port and make a call to a terminating test line (TTL) on the trunk's far end. Transmission performance measurements are made and compared to administered thresholds. Errors are generated when results fall outside of "marginal" or "unacceptable" thresholds. Detail and summary measurement reports are obtainable via the **list testcalls** command.

Table 9-189. TEST #844-848 Transmission Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the trunk group/member number of the port. Use the "status trunk" command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals for a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM bus errors. 1. If system has no TDM bus errors and is not handling heavy traffic, retry the command at 1-minute intervals for a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use status trunk to determine when the port is available for testing. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1005	ABORT	Trunk has been administered as incoming-only; transmission tests can only be run on outgoing trunks.

Continued on next page

Table 9-189. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1115	ABORT	The near end test line on the TN771 circuit pack could not be allocated. 1. Verify that the TN771 circuit pack is in service and that port 1 is administered and in service with the **status port** command. 2. Retry the command at 1-minute intervals for a maximum of 5 times.
1900	ABORT	The test completion message was not received from the TN771 circuit pack. 1. Test the TN771 circuit packs.
1901	ABORT	This error occurs when the TN771 circuit pack uplinks a message that is not the proper response for this test. The anticipated uplink messages are seize, ring or answer. 1. Verify that the Trunk is administered properly.
1905	ABORT	Intercept tone detected from far end. 1. Get the test line data from theand verify it with the far end. Dial the test number manually to see if the TTL is reached. If it is not, then either the number is wrong, or the far end is administered incorrectly.
1906	ABORT	Reorder tone detected from far end. 1. See actions for error code 1905.
1907	ABORT	Other unexpected tone detected from far end. 1. See actions for error code 1905.
1913	ABORT	Audible Ring detected from far end. 1. See actions for error code 1905.
1914	ABORT	Unidentified interrupted tone detected from far end. 1. See actions for error code 1905
1915	ABORT	Busy tone detected from far end. 1. Since the test line at the far end was busy. Try the test again. 2. If the test continues to abort, the problem is with the far end system.
1918	ABORT	Test progress tone not removed from far end (type 105 test line only). 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1919	ABORT	Unexpected far end release 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1920	ABORT	No response from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).

Continued on next page

Table 9-189. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1921	ABORT	No data returned from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1922	ABORT	Steady, unidentifiable tone from far end 1. See actions for error code 1905.
1923	ABORT	Broadband energy detected from far end (such as voice or announcement). 1. See actions for error code 1905.
1924	ABORT	No test tone from far end 1. See actions for error code 1905.
1938	ABORT	Near-end self test failed. 1. Test the TN771 circuit packs.
1939	ABORT	Loss self check at 0dBm at 1004 Hz failed. 1. Test the TN771 circuit packs.
1940	ABORT	Far end noise self check failed. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1941	ABORT	High frequency singing return loss self check failed. 1. Test the TN771 circuit packs.
1942	ABORT	Echo return loss self check failed. 1. Test the TN771 circuit packs.
1943	ABORT	Singing return loss self check failed. 1. Test the TN771 circuit packs.
1944	ABORT	Loss self check at -16 dBm at 1004 Hz failed. 1. Test the TN771 circuit packs
1945	ABORT	Loss self check at -16 dBm at 404 Hz failed. 1. Test the TN771 circuit packs.
1946	ABORT	Loss self check at -16 dBm at 2804 Hz failed. 1. Test the TN771 circuit packs.
1947	ABORT	Noise with tone self check failed. 1. Test the TN771 circuit packs.
2000	ABORT	The test timed out while waiting for a response from the TN771 circuit pack. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 9-189. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	An internal software error occurred. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2053	ABORT	The test call could not be established, but no information on why is available. 1. Retry the command at 1-minute intervals for a maximum of 5 times.
2056	ABORT	An error occurred while trying to obtain results from the TN771 circuit pack. 1. Test the TN771 circuit packs.
	FAIL	Measured transmission performance was in the unacceptable range as administered on the trunk group form. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form. Besides the facility, test failures can be caused by faulty test lines or switch paths. If the measurements point to a facility problem, report the results to the trunk vendor.
8000	FAIL	Measured transmission performance was in the marginal range as administered on the trunk group form. This generally means that the trunk is usable but has an undesirable amount of noise or loss. If the user does not report unacceptable effects, it may not be necessary to take any action. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form.

CONFIG (System Configuration)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
CONFIG	none	none	System Configuration

The System Configuration maintenance object (MO) oversees logical insertion and removal of circuit packs in the system. When Switch Control detects that a circuit pack is present in a port slot, it informs System Configuration and System Configuration queries the circuit pack to determine the type and vintage of the circuit pack. Similarly, when Switch Control detects that a circuit pack has been removed from a port slot, it informs System Configuration.

There are no alarms or tests for System Configuration, but three types of errors are logged to the Hardware Error Log.

Error Log Entries and Test to Clear Values

Table 9-190. System Configuration Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	none	none	N/A	none
1-119 (a)	0-21	none			
257(b)		none	MAJOR		
1001-1119 (c)	0-21	none			

1. This error should not occur. It indicates that an attempt was made by software to raise an alarm against CONFIG without first logging a CONFIG error.

Notes:

a. This error indicates that a port circuit pack in the system did not respond to a circuit pack type inquiry. Follow the procedures outlined in (b) to determine if there is an error.

b. This error indicates that less than 25% of Trunk Group is available.

c. This error indicates that a port circuit pack in the system did not respond to a vintage inquiry.

   As a result of either of these errors, a port circuit pack may be physically inserted in a port slot, but the system may not recognize its existence. The Aux Data field specifies the circuit pack's port-network number as indicated in the following table.

Converting Aux Data to Port-Network Number

Aux Data	Port-Network Number
0	1
1	2
2	3
3	4
4	5
5	6
6	7
7	8
8	9
9	10
10	11
11	12
12	13
13	14
14	15
15	16
16	17
17	18
18	19
19	20
20	21
21	22

The Error Type field specifies the carrier and slot location of the circuit pack that caused the error as indicated in Table 9-191. If the Error Type field is greater than 1000, subtract 1000 from the Error Type field before consulting the table.

If more than one CONFIG error is logged with an Aux Data of 1 at the same time, investigate any EXP-INTF (Expansion Interface) errors before proceeding. Once the port circuit pack location has been determined from Table 9-191, use the **list configuration all** command to determine if the circuit pack is inserted. If not, insert the pack. If the circuit pack has already been inserted but the error persists, replace the circuit pack.

118	C00 (d)
119	(a)

Notes:

a. These error types do not represent physical port circuit pack slots and are not logged against CONFIG.

b. If this error type occurs in the PPN, it refers to the A-Carrier Tone Generator circuit pack. If it occurs in any EPN, it refers to the circuit pack in slot A01.

c. If this error type occurs in the PPN, it refers to the B-Carrier Tone Generator circuit pack. If it occurs in any EPN, it refers to the circuit pack in slot A10.

d. Slots B00, C00, D00, and E00 refer to the *Service Slots* in the B, C, D, And E carriers.

e. In EPN A-Carriers, slot A00 is the Tone Generator slot.

CUST-ALM (Customer-Provided Alarming Device)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
CUST-ALM	none	test customer-alarm UUC	Customer-Provided Alarming Device

1. where UUC is an appropriate cabinet number and carrier (duplicated SPE system only, that is, can be 1a or 1b).

The system provides customers a way to connect their own alarm indication device to a switch. The CUST-ALM maintenance object represents this customer-provided alarming device (CPAD).

The customer administers the level of alarm for which the CPAD will be activated via the **change system-parameter maintenance** form (CPE Alarm Activation Level field). The customer sets this field to: **none, warning, minor,** or **major** depending on the level of alarm at which the CPAD should be activated. When an alarm occurs of at least the level to which the CPAD is administered, the CPAD in the PPN and the EPN will be activated. The CPAD will also be activated within a cabinet whenever Emergency Transfer is invoked within that cabinet.

The CPAD is connected to the SYSAM in the PPN (in a duplicated SPE system, the CPAD is connected to both SYSAMs), and to the EPN Maintenance circuit pack in the EPN. The CUST-ALM maintenance object is not maintained by the system, and will not generate any alarms. If a problem is suspected with the CPAD, it may be tested using the **test customer-alarm** command, which will activate the device by closing the relay on either the SYSAM or the EPN Maintenance circuit pack (whichever is specified) for 1-minute. In a duplicated SPE system the CPAD on the PPN is connected to the SYSAM on both carrier A and carrier B, and the **test customer-alarm** command will close the relay on the active SYSAM. The repeat parameter may be used to close the relay for a longer length of time where the number of the repeat is the number of minutes for which the device will be activated (5 minutes is the suggested repeat value).

System Technician-Demanded Tests: Descriptions and Error Codes

The **test customer-alarm UUC** command is provided to allow a technician to check that the customer-provided alarming device is correctly installed and functional. It is recommended that this test be run at least once after both the switch and the customer alarm have been installed.

Customer-Provided Alarming Device Test (#115)

The Customer-Provided Alarming Device (CPAD) Test closes the relay that activates the CPAD for 1-minute only within the port network specified. If it takes longer than 1-minute to check that the CPAD has been activated, the Repeat field on the **test customer-alarm UUC** command can be used to close the relay for up to 99 minutes. Note that when the repeat option is used, the results for Test #115 come back immediately and, for each test that passed, the CPAD is kept on for that many minutes. The CPAD does not go off after 1-minute and then come back on. Instead, the CPAD is kept on continuously for the entire time. If the CPAD is being activated and deactivated in a flickering fashion, there is a problem with either the CPAD, or the SYSAM, or the EPN Maintenance circuit pack.

Table 9-192. TEST #115 Customer-Provided Alarming Device Test

Error Code	Test Result	Description/ Recommendation
Any	ABORT	Internal system error 1. Retry the command at 1-minute intervals for a maximum of 5 times.
	PASS	The switch software successfully sent the request to the SYSAM or EPN Maintenance circuit pack to turn on the CPAD. The CPAD must be physically inspected to verify that it is working. If the CPAD is working but the customer has complained that the CPAD did not indicate a system alarm when it occurred, then check the administered alarm level for turning on the CPAD. This is on the **display system-parameter maintenance** form. Compare this level with the customer's specifications. If the level does not match the customer's specifications, change it using the **change system-parameter maintenance** form. If Test #115 passes, and the CPAD is not being activated, check the connection of the CPAD to the SYSAM or EPN Maintenance circuit pack. If the CPAD can be activated but cannot be deactivated, first check to make sure Emergency Transfer is not activated in the affected port network via the **status port-network** command. Emergency Transfer can be forced to manual OFF via the Emergency Transfer switch on the SYSAM or EPN Maintenance circuit pack. If Emergency Transfer is OFF and the CPAD still cannot be deactivated, check the administered levels for the CPAD via the **display system-parameter maintenance** form and compare against the alarm levels currently present in the system (**display alarms** command).

DAT-LINE (Data Line Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DAT-LINE	MINOR	test port UUCSSpp l	Data Line Port
DAT-LINE	WARNING	test port UUCSSpp l	Data Line Port

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

The TN726 Data Line circuit pack has 8 ports, each of which supports an RS-232 interface to asynchronous Customer Premises Equipment (CPE). Each of these ports and the equipment connected to it constitute a data line. For DT-LN-BD (Data Line Circuit Pack) errors, refer to "XXX-BD (Common Port Circuit Pack)". Check circuit pack-level errors first since the usability of the ports depend on the health of the circuit pack.

Data line ports are administered at the terminal with the **add data-module** command. The data module type is *data-line*. The **list data-module** command will list all administered data modules in the system. See “PDATA-PT” for details on how data lines are used as system ports.

The TN750 Announcement circuit pack also has one data line-type port on it. This data line port is used for saving and restoring announcements. For a description of this feature and repair instructions for the TN750, refer to “ANN-BD”.

NOTE:
If the tests for the data line port in question pass, and user-reported complaints persist, there is probably an external problem. Test the asynchronous data unit (ADU), following the procedures outlined in *User Manual Z3A Asynchronous Data Unit*, 555-401-701. If the ADU appears to be working properly, check the external wiring, and then check the customer equipment.

Error Log Entries and Test to Clear Values

Table 9-193. Data Line Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port UUCSSpp sh r 1
1		Digital Looparound Test (#171)	MINOR	ON	test port UUCSSpp s r 2
15(a)	Any	Audit Update Test (#36)			
18	0	Busyout port UUCSSpp	WARNING	OFF	rel port UUCSSpp
130 (b)		None	WARNING	ON	test port UUCSSpp sh
257		Conference Circuit Test (#7)	MINOR	ON	test port UUCSSpp l r 2
513		NPE Crosstalk Test (#6)	MINOR	ON	test port UUCSSpp l r 2
769(c)	40983	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate errors.

b. Indicates the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reseat or replace the circuit pack.

c. Error type 769 indicates that the data line circuit pack found an error in the transmit/receive circuitry of an administered data line when the circuit pack was inserted. Perform the following:

   1. Enter **busyout board UUCSS f**or the circuit pack on which the port resides.
   2. Enter **reset board UUCSS**. Check the Error Log to determine if Error Type 769 is logged again for DAT-LINE. Make sure that the `Active Alarms Only` field is set to n.

      If error type 769 reappears, replace the data line circuit pack. If Error Type 769 does not reappear, proceed to Step 3.
   3. Enter **release board UUCSS**.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Digital Looparound Test,* for example, you may also clear errors generated from other tests in the testing sequence. For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Digital Looparound Test (#171)	X	X	ND
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Audit Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of a port's long test sequence and takes about 20 to 30 seconds to complete.

Table 9-194. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run test are not available. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-194. TEST #6 NPE Crosstalk Test — ***Continued***

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. 1. Resolve TDM-BUS errors, if any. 2. If the system is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Resolve TTR-LEV and TONE-PT errors, if any. 2. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was in use on a valid call. 1. Determine whether the port is available for testing (**status data-module**). 2. When available, retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	An existing Error Type 769 on this port prevented the test from running. 1. Follow the procedures for Error Type 769.
2000 2100	ABORT ABORT	Response to the test command was not received within the allowable time period. Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The NPE of the tested port was transmitting in error, which can cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. Investigate user-reported troubles on this port using other port tests and examining the ADU, external wiring, and customer equipment.

Conference Circuit Test (#7)

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 9-195. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	An existing error type 769 on this port prevented the test from running. 1. Follow the procedure following the Error Log Table for error type 769.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The conference circuit test failed (possible off-board problem). 1. Busyout and release the port (data line), and then retest. 2. Replace the circuit pack if the test continues to fail.
	PASS	The port can correctly conference multiple connections. Investigate user-reported troubles on this port using other port tests and examining the ADU, external wiring, and customer equipment.

Audit Update Test (#36)

This audit verifies that the hardware state of the data line is consistent with the system translations. The audit queries the port for the switchhook state, the software state is updated according to the returned value. Also, the audit data line options down to the port.

Table 9-196. TEST #36 Audit Update Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. Escalate the problem if the test continues to abort.
1006	ABORT	An existing error type 769 on this port prevented the test from running. 1. Follow the procedure following the Error Log Table for error type 769.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal system error 1. Try the command again at 1-minute intervals up to 5 times.
7	FAIL	Internal system error 1. Try the command again at 1-minute intervals up to 5 times.
	PASS	The hardware port state is consistent with the software state. Investigate user-reported troubles on this port using other port tests and examining the ADU, external wiring, and customer equipment.

Digital Looparound Test (#171)

The Digital Looparound Test checks the data line port's ability to transmit and receive data on the TDM Bus. Data is sent through an available Maintenance/Test digital port over the TDM Bus, internally looped through the data line port back onto the TDM Bus, and received again by the same Maintenance/Test digital port.

Note that only one of the two digital ports on a Maintenance/Test circuit pack is used for this test, and that port must be the **first** such port; such as port 02. If port 02 is in use, out-of-service, or not present, the test aborts. This test may fail if the Maintenance/Test digital port used by the test is not functioning properly. If there are any M/T-DIG errors in the Error Log, refer to the "M/T-BD" to clear them first. This test will pass regardless of any customer equipment that might be connected to the port, as long as the port is not in use by the equipment.

Table 9-197. TEST #171 Digital Looparound Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error
1000	ABORT	System resources required to run test are not available. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	An existing error type 769 on this port prevented the test from running. 1. Follow the procedure following the Error Log Table for error type 769.
1042	ABORT	Port under test is a TTI port and has only default translations with no assigned extension. The executed test requires an assigned extension associated with the port being tested. Therefore, this test cannot successfully execute. 1. If there is a need to execute the test on this particular port then the tester must insure that the port is fully translated such that the port has an assigned extension.
1180	ABORT	There is no Maintenance/Test circuit pack digital port available to carry out the test. 1. Check to see if the Maintenance/Test digital ports are present. (Enter **list config** command; ports 02 and 03 should show). 2. If the digital ports (02 and 03) on the Maintenance/ Test circuit pack are not present, refer to “M/T-BD”. 3. If the digital ports are present, retry the command at 1-minute intervals a maximum of 5 times.
1181	ABORT	No time-slots available to connect digital ports for the test.
1182	ABORT	Internal system error. Failed to connect the digital ports with time-slots. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1340	ABORT	No Maintenance/Test digital port is currently available to perform this test. 1. Use **list config** to determine whether any Maintenance/Test digital ports (ports 02 and 03 on the Maintenance/Test circuit pack) are present in the system. At least one Maintenance/Test circuit pack must be present in the PPN of a Release 5r system. There should be at least two such ports present. If the ports are present, proceed to step 2. Otherwise, determine why no ports appear in the **list config** display. Refer to “M/T-DIG” and “M/T-BD”. 2. Look for M/T-DIG errors in the Error Log. If present, refer to “M/T-DIG”. 3. If the ports are present and no errors are logged against them, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, replace the Maintenance/Test circuit pack.

Continued on next page

Table 9-197. TEST #171 Digital Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a "t" for the port). 2. If either **list config** or **display port** indicate that the port is **not** a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct for the test, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. Escalate the problem if the test continues to abort.
2004	ABORT	Off hook was not received from the data line device. 1. Busyout the digital port being tested on the data line circuit pack. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test still aborts, replace the circuit pack.
2005	ABORT	The handshake between the Maintenance/Test circuit pack digital port and the data line port failed. 1. Resolve M/T-DIG errors, if any. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test still aborts, replace the data line circuit pack.
2312	ABORT	Test did not complete, did not receive loop back data. 1. Resolve M/T-DIG errors, if any. 2. Retry the test, if still aborts, replace the Data Line circuit pack.
2313	ABORT	Failed to receive a response from the Maintenance/Test digital port. 1. Resolve M/T-DIG errors, if any. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, replace the Maintenance/Test circuit pack.
2314	ABORT	Data line port did not respond to downlinked message. 1. Busyout the digital port being tested on the data line circuit pack. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test still aborts, replace the circuit pack.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-197. TEST #171 Digital Looparound Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The test failed because the data received did not match the data sent. This would indicate that there is a fault somewhere in the transmit/receive path to the TDM Bus, which will probably result in data corruption over this port. This test may fail if the Maintenance/Test digital port used by the test is not functioning properly. 1. Resolve M/T-DIG errors, if any. 2. Repeat Test #171. 3. If the test fails again, replace the data line circuit pack.
	PASS	The port can correctly transmit/receive data. Investigate user-reported troubles on this port using other port tests and examining the ADU, external wiring, and customer equipment.

DC-POWER (Single Carrier Cabinet Environment)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DC-POWER	MAJOR	test environment UU	Single Carrier Cabinet Environment

1. UU is the universal cabinet number indicated in the PORT field of the alarm log.

DEFINITY Generic 3r systems support two different cabinet types: multicarrier and single carrier. Single carrier cabinets are used only for EPNs. Both cabinet types may be powered by either AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply. Refer to the following table to determine which maintenance object documentation to use for environmental maintenance.

Cabinet Type	Power Source	Environmental Maintenance Objects
Single carrier (EPN)	AC or DC	DC-POWER (all environmental maintenance)
Multicarrier	AC	AC-POWER for AC-powered systems (external power source) POWER for AC-powered systems (battery backup) CARR-POW (carrier port power supply) CABINET (temperature and fan sensors)
Multicarrier	DC	CARR-POW (carrier port power supply) CABINET (temperature and fan sensors)

The DC-POWER maintenance object represents all environmental maintenance for single-carrier cabinets, whether the external power supply is AC or DC. This includes the external power supply and all Carrier Port Power Supplies in a port network composed of a single-carrier cabinet stack. The Carrier Port Power Supplies provide +5/-5/-48V DC to the circuit packs on the carrier. The following power supplies are used:

WP-91153	Accepts AC power input
676B	Accepts DC power input

Each power unit has one yellow LED. A lit LED signifies normal operation. An unlit LED signifies a loss of external power to the cabinet, or a fault in the power unit. When hardware detects a problem with any of these components, it reports the information to the system software through a single lead. System software does not differentiate between different environmental failures. Since several environmental elements of single-carrier cabinets are logged against the DC-POWER maintenance object, it is possible to have a DC-POWER alarm while there is still power to the system.

If a Carrier Port Power Supply is physically removed from a carrier in a single-carrier cabinet, there will not be a DC-POWER alarm. DC-POWER maintenance cannot distinguish between removal of the power supply and the physical absence of the cabinet.

There is a nominal power holdover of .25 second in an EPN single carrier cabinet.

Hardware Error Log Entries and Test to Clear Values

Single Carrier Cabinet Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value[1]
0[2]	0	Any	Any	Any	test environment UU
513	0 or 1	Single Carrier Cabinet Power Query (#79)	MAJOR	ON	test environment UU r 2

1. UU is the universal cabinet number indicated in the PORT field of the Alarm Log.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Single Carrier Cabinet Power Query Test*, for example, you may also clear errors generated from other tests in the testing sequence. Test description(s) and recommended maintenance procedures follow for all errors that can occur during system technician-demanded testing.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Single Carrier Cabinet Power Query Test (#79)	X	X	ND
Emergency Transfer Query Test (#124) (a)	X	X	ND
External Alarm Lead Query Test (#120) (b)	X	X	ND
Analog Ring Generator Initialization Test (#117) (c)	X	X	ND
Analog Ring Generator Query Test (#118) (c)	X	X	ND

1. D = Destructive; ND = Nondestructive

Notes:

a. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.

b. Refer to EXT-DEV (External Alarm Lead) Maintenance documentation for a description of this test.

c. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

Single Carrier Cabinet Power Query Test (#79)

This test queries the EPN Maintenance circuit pack (in an EPN) about the status of the power in a single carrier cabinet system. This test can only detect power problems in carriers in the Port Network for which the Carrier Port Power Supply is physically present.

Table 9-198. TEST #79 Single Carrier Cabinet Power Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to ABORT with a 2000 error code, check for and resolve all MAINT (EPN Maintenance circuit pack) errors. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, then escalate the problem.
2029 2319 2320 2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	There is currently a problem with the environment of the power system. 1. The power supply to any one of the carriers may have been lost. a. Verify, and if necessary restore, AC power at the wall outlet for each carrier. b. Rerun the test. If the test still fails, proceed to Step 2. 2. One of the WP-91153 or 676-B power units for one of the carriers could be defective. a. If a WP-91153 or 676-B power unit does not have its yellow status LED on, then replace the power unit (procedure in Chapter 5, ‘‘Alarms, Errors, and Troubleshooting’’). b. Rerun the test. If the test still fails, proceed with Step 3. 3. The MAINT (EPN Maintenance Circuit Pack) could be incorrectly reporting this error. Resolve all alarms on these MOs, and rerun the test. There are failures that can occur on the EPN Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many, if not all, environment tests to fail. If more than two environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If the test still fails, follow normal escalation procedures.
	PASS	The MAINT (EPN Maintenance Circuit Pack) has reported no problem with the power.

DETR-BD (Tone Detector Circuit)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DETR-BD	MINOR	test board UUCSS	Tone Detector Circuit Pack
DETR-BD	WARNING	test board UUCSS	Tone Detector Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

For proper tone detection, the companding mode administered for the system must match that of the DETR-BD circuit pack. The companding mode is administered on the system-parameters country-options form. Refer to *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*.

For all DETR-BD (Tone Detector Circuit Pack) errors, refer to "XXX-BD (Common Port Circuit Pack)".

DID-BD (Direct Inward Dial Trunk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DID-BD	MIN	test board UUCSS sh	Direct Inward Dial Trunk Circuit Pack
DID-BD	WRN	test board UUCSS sh	Direct Inward Dial Trunk Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

Refer to "XXX-BD (Common Port Circuit Pack)" for circuit pack level errors. See also “DID-TRK” (DID Trunk) for related trunk information.

DID-DS1 (Direct Inward Dial Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DID-DS1	MAJOR[1]	test trunk *grp*/*mbr* l	Direct Inward Dial Trunk
DID-DS1	MINOR	test trunk *grp*/*mbr* l	Direct Inward Dial Trunk
DID-DS1	WARNING	test trunk *grp*/*mbr*	Direct Inward Dial Trunk

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed. For more information on the **set options** command.

The DID-DS1 trunk provides a digital Direct Inward Dial (DID) trunk from a CO switch to the system through a DS1 link. A 24-channel DS1 link can support up to 24 DID-DS1 trunk calls simultaneously. A 32-channel link can support up to 30. A DID-DS1 trunk can be used for digitized voice and data communications with appropriate DS1 signaling mode (for example, common channel signaling). The TN767 and TN464 series circuit packs support wink-start and immediate-start trunks and call processing signaling. See "DS1-BD (DS1 Interface Circuit Pack)" and "UDS1-BD (UDS1 Interface Circuit Pack)" for more information. Throughout this section, the term DS1 applies to both the DS1 or UDS1 circuit packs.

Information included in this section covers the in-line errors log, initialization tests, periodic tests, scheduled tests, system technician demand tests, and alarms escalation and elimination. Two trunk service states are specified in the DID-DS1 trunk maintenance:

`out-of-service`	The trunk is in a deactivated state and cannot be used for incoming calls.
`in-service`	The trunk is in an activated state and can be used for incoming calls.

If the DS1 circuit pack is out-of-service, then all trunks on the DS1 Interface circuit pack are put into the out-of-service state and a Warning alarm is raised.

Error Log Entries and Test to Clear Values

DID-DS1 Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test trunk *grp#/mbr#*
1(a)	Any				
15(b)	Any	Port Audit and Update Test (#36)			
18(c)			WARNING	OFF	release trunk *grp#/mbr#*
130(d)		None	WARNING	ON	test trunk *grp#/mbr#*
257(e)	57474 57473				
513(f)	57392		MIN/MAJ[2]		
769(g)	57393		MIN/MAJ[2]		
1281		Conference Circuit Test (#7)	MIN/ WRN[3]	ON	test trunk *grp#/mbr#* l r 4
1537		NPE Crosstalk Test (#6)	MIN/ WRN[3]	ON	test trunk *grp#/mbr#* l r 3
1793(h)					test board *UUCSS* l
2305(i)	50944	None	MIN/MAJ[2]	OFF	
3840(j)		Port Audit and Update Test (#36)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
3. Major alarms may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. Error Type 1—DS1 Interface circuit pack detects a hardware error on the DS1 DID trunk. The Aux Data field indicates the following:

57476	On-hook before wink
57477	On-hook before ready to receive digits
57485	Wink too short for valid signal

Maintenance does not start any testing or generate any alarms in response to these errors.

b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate errors (if any).

c. Error Type 18—The trunk has been taken out of service by a demand busyout. No calls can be made on this trunk.

d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. Error Type 257—DS1 Interface circuit pack detects a hardware error on the DS1 DID trunk. The Aux Data field indicate the source of the error:

57474	Rotary dial rate above 12 pulses per second
57473	Rotary dial rate below 8 pulses per second

f. Error Type 513—DS1 Interface circuit pack detects a hardware error on the DS1 DID trunk. Aux Data 57392 indicates no external release on PBX disconnect.

g. Error Type 769—DS1 Interface circuit pack detects a hardware error on the DS1 DID trunk. Aux Data 57393 indicates belated external release on PBX disconnect.

h. Error Type 1793—DS1 Interface circuit pack is out-of-service. Look for DS1-BD/UDS1-BD errors in Hardware Error Log. Refer to the appropriate “DS1-BD/UDS1-BD” information for details.

i. Error Type 2305—This error indicates that a signaling change was detected by the PBX trunk circuit pack which is inconsistent with the present state of the trunk.

j. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back to in-service. Retry the test command.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Port Audit and Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-199. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required for this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the trunk group/ member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025. The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-199. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of- service due to TDM BUS error. Use **status health** to determine if the system is experiencing heavy traffic. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. Use **list measurements tone-receiver** to display information on the tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a user for a valid call. 1. Use **display port UUCSSpp** to determine the trunk group/member number of the port. Use **status trunk** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack (DS1-BD or UDS1-BD): 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, or 1537—Hyperactivity 1. Resolve any of the above error types.

Continued on next page

Table 9-199. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	This can be due to off-board problems, including EXP-PN and EXP-INTF faults, TDM-BUS faults, and tone detectors/tone generators. Clear all off-board problems before replacing the board. A TDM-BUS problem is usually a faulty board or bent pins on the backplane. 1. Resolve any EXP-PN, EXP-INTF, TDM-BUS, TONE-BD, and TONE-PT errors in the error log. 2. Retest when errors are cleared. Replace the board if the test fails.
	PASS	The port is correctly using its allocated time slots. Investigate user-reported troubles on this port using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port. This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use **list config** and resolve any problems that are found. 2. Issue the **busyout board** command. Issue the **reset board** command. Issue the **release busy board** command. 3. Issue the **test board long** command. This should re-establish the link between the internal ID and the port. If not, check to see that there is a valid board inserted.

Conference Circuit Test (#7)

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together.

Table 9-200. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources for this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required for this test were not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the trunk group/member number of the port. Use **status trunk** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025. The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Use **list measurements tone-receiver** to display information about the tone receivers. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port was seized by a user for a valid call. 1. Use **display port UUCSSpp** to determine the trunk group/member number of the port. Issue the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-200. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test was disabled via translation. Determine why the test has been disabled before you enable it. 1. Verify that the `Maintenance Test` field on the Trunk Administration screen is set to n. To enable the test, change the trunk administration and enter **y** for this field. 2. Repeat the test.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack (DS1-BD or UDS1-BD): 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, 1537—Hyperactivity 1. Resolve any of the above error types.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This can cause noisy and unreliable connections. 1. Enter **list configuration board UUCSS**. The circuit pack must be a TN767C V3 or later. The error log may have error type 1281. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, a -5 volt power problem is indicated. Check “CARR-POW”. 4. If several ports fail, resolve any “TONE-BD” or “TONE-PT” errors and rerun the test. 5. If the retry passes and troubles are reported, coordinate isolation with the CO. Make sure that the switch, the CO, and any NTCE equipment (the CSUs) have the correct administration. 6. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. Investigate user-reported troubles on this port using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 9-200. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port. This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the link between the internal ID and the port. If not, check to see that there is a valid board inserted.

Port Audit and Update Test (#36)

This test sends port level translation data from the switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. The port audit operation verifies the consistency of the current state of the trunk as kept in the DS1 Interface circuit pack and in the switch software.

Table 9-201. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	The port may be busy with a valid call. 1. Issue **display port UUCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for error type 1025. The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-201. TEST #36 Port Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The test was aborted because the trunk is out of service. 1. Use **status trunk** to verify that the trunk is out of service. 2. If the trunk is out of service, determine why. 3. To put the trunk back in service, issue the **release trunk** command. Retry the test.
2000	ABORT	Response to the test was not received in the allowable time period.
2100	ABORT	Could not allocate resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Test failed due to internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run but will return PASS. To verify that the trunk is in-service: 1. Enter **status trunk** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service. 2. Enter **release trunk** to put the trunk back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

DID-TRK (Direct Inward Dial Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DID-TRK	MAJOR[2]	test port *UUCSSpp* l	DID Trunk
DID-TRK	MINOR	test port *UUCSSpp* l	DID Trunk
DID-TRK	WARNING	None	DID Trunk

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY. Enterprise Communications Server Release 5.4 Administration and Feature Description*, for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

Direct Inward Dial trunks connect the switch to the CO, and allow outside parties to call directly to an extension in the system. DID trunk circuit packs support eight incoming-only ports. Each port provides an interface between the 2-wire analog CO line and the 4-wire TDM bus on the switch.

DID Trunk Operation

The DID port receives three to five digits from the CO that are used to directly connect an outside caller to the called station without assistance from an attendant. For each call, the CO switch signals the system by opening and closing individual DID loops (one of the eight ports), causing the starting or stopping of loop current.

DID Trunk Testing

The system uses four tests of on-board circuitry to diagnose the health of the trunk. These are described in the following sections. Additionally, in-line testing which can generate errors, is performed while a call is in progress. See the Error Log table for a description of these errors. These errors may be reproduced by placing a call on the trunk and checking the Hardware Error Log.

Problems detected during signaling may be caused by off-board faults in the CO switch or connections for which a Warning alarm is raised.

Before a maintenance test can be run on a port, the port must be idle. If an incoming call seizes a port that is being tested, the test will abort and the incoming call will proceed.

For transmission and signaling standard specification, refer to *Digital PBX Standards*, RS4648.

Ports Out-of-Service without Errors or Alarms

A common trouble on DID trunks that produces no errors or alarms occurs when the CO busies out (disconnects) the port. This situation occurs when the CO thinks there are problems with the DID port. In this case, no incoming calls will be possible through this port. This may result in complaints from outside callers trying unsuccessfully to call in. This problem can be diagnosed by listing measurements on lightly used trunks. If a particular port is detected as not in use, a call to the CO will be necessary to get the connection back in service.

Error Log Entries and Test to Clear Values

Table 9-202. DID Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port *UUCSSpp* sh r 1
1(a)	Any	None	WRN	OFF	
1(b)	57476	None	WRN	OFF	
1(c)	57477	None	WRN	OFF	
1(d)	57483	None	WRN	OFF	
15(e)	Any	Port Audit Update (#36)			
18	0	busyout trunk *grp/mbr*	WRN	OFF	release trunk *grp/mbr*
130(f)		None	WRN	ON	test trunk *grp/mbr*

Continued on next page

Table 9-202. DID Trunk Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
257(g)	57472	None	WRN	OFF	
257(h)	57473	None	WRN	OFF	
257(i)	57474	None	WRN	OFF	
257(j)	57475	None	WRN	OFF	
513(k)	57392	None	MIN/ WRN[2]	OFF	
510(l)	57393	None			
769	Any	Port Diagnostic (#35)	MIN/ WRN[2]	ON	test port *UUCSSpp* r 3
1025		Looparound and Conference (#33)	MIN/ WRN[2]	ON	test port *UUCSSpp* l r 3
1281		NPE Crosstalk (#6)	MIN/ WRN[2]	ON	test port *UUCSSpp* l r 3
1537	Any	Port Diagnostic (#35)	MAJ/ MIN/ WRN[2]	OFF	test port *UUCSSpp* r 3
1793(m)	57489	None	None		

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

See also the preceding section on trunk problems without errors or alarms.

a. This condition occurs when the tone detector times out waiting for digits. Change wink/immediate-start parameter to wink/immediate-start and rotary/tone-dial parameters.

   1. Verify trunk administered wink/immediate-start parameter.
   2. Test trunk using BUTT set.
   3. Refer problem to CO.

b. Rotary dial before wink — This condition occurs when the CO starts dialing before the PBX sends wink on a wink-start trunk.

   1. Verify trunk administered wink/immediate-start parameter.
   2. Refer problem to CO.

c. Rotary dial too early — This condition occurs when the CO starts dialing too soon after seizure on an immediate-start trunk.

1. Verify trunk administered wink/immediate-start parameter.
2. Refer problem to CO.

d. Rotary dial pulse during wink — This condition occurs when the CO sends rotary dial digits too soon after seizure on a wink-start trunk.

1. Verify trunk administered wink/immediate-start parameter.
2. Refer problem to CO.

e. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

f. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

g. Rotary dial pulse on-hook longer than 105 msec — Break between rotary pulses is too long.

1. Test trunk by performing an incoming test call.
2. Refer problem to CO.

h. Rotary dial rate below 8 pulses/sec — More than 135 msec between two successive breaks.

1. Verify trunk administered interdigit-timing parameters.
2. Refer problem to CO.

i. Rotary dial rate above 12 pulses/sec — Less than 75 msec between two successive breaks.

1. Verify trunk administered interdigit-timing parameters.
2. Refer problem to CO.

j. Digit detection — CO is starting new rotary dial digit within 150 msec of previous digit.

1. Verify trunk administered interdigit timing parameters.
2. Refer problem to CO.

k. Loop current active — CO not releasing trunk after PBX disconnect. Occurs when the PBX end drops first and the CO does not release the trunk within 4 minutes.

   1. Verify the interface to the network with a hand telephone set. If calls are placed correctly, then refer problem to the CO.

   2. If unable to place calls or this equipment is not available, check the status on port using the **status trunk** command. If active but not connected, disconnect bridging clips at the network interface. Check status on the trunk. If trunk went idle, then replace clips. If trunk is still active but unable to place calls, refer problem to the CO.

l. Late CO trunk release — This event only occurs after the occurrence of Error Type 513. The CO released the trunk 4 minutes after the PBX dropped the call. This event decrements the severity (error count) of Error Type 513, or may mean the problem related to Error Type 513 has been fixed.

   Verify that Error Type 513 does not occur again. Refer to Error 513.

m. Incomplete Dial timer expired. This error only applies to the TN459 and indicates a problem with incoming dialing stream. Refer the problem to the CO.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *NPE Crosstalk Test* for example, you may also clear errors generated from subsequent tests in the testing sequence..

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Port Diagnostic Test (#35)	X	X	ND
Looparound and Conference Circuit Test (#33)		X	ND
Port Audit Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot on the TDM bus and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 9-203. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources for this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Enter **display port UUCSSpp** to determine the station extension, attendant number, or trunk group/member number of the port. Enter **status station**, **status attendant**, or **status trunk** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is active but the port is not in use (no calls), check the Error Log for Error Type 513. The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of- service due to TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, retry the command at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any TTR-LEV errors. 2. Resolve any TONE-PT errors. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-203. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. 1. Enter **display port UUCSSpp** to determine the station extension, attendant number, or trunk group/member number of the port. Enyer **status station**, **status attendant**, or **status trunk** to determine the service state of the port. If the the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources for this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	This test can fail due to off-board problems, including EXP-PN and EXP-INTF faults, TDM-BUS faults, and tone detectors/tone generators. Clear all off-board problems before replacing the board. A TDM-BUS problem is usually a faulty board or bent pins on the backplane. 1. Resolve any EXP-PN, EXP-INTF, TDM-BUS, TONE-BD, and TONE-PT errors in the error log. 2. Retest the board. Replace the board if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Looparound and Conference Circuit Test (#33)

This test checks the reflective and non-reflective loop around and conference capabilities of a DID port circuit. The test that uses 404-Hz, 1004-Hz, and 2804-Hz tones is an on-board test only. Each tone is separately transmitted to and from the port (loop around within the port) and verified.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration Test field. (This also disables the port diagnostic test.)

Table 9-204. TEST #33 Looparound and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
3	ABORT	System resources required to run this test are not available. The seized tone detector did not respond. This abort code is usually associated with tone-clock (TONE-BD, TONE-PT, and TDM-CLK) resources. 1. Clear any tone errors in the error log. 2. Retry the command a 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Enter **display port UUCSSpp** to determine the station extension, attendant number, or trunk group/member number of the port. Use **status station**, **status attendant**, or **status trunk** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. If the port status is active but the port is not in use (no calls), check the Error Log for Error Type 513. The port may be locked up. 3. If the port status is idle, retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-204. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. 1. Enter **display port UUCSSpp** to determine the station extension, attendant number, or trunk group/member number of the port. Use **status station**, **status attendant**, or **status trunk** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook), if the handset is plugged in and the port is not busied out. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via administration. Verify that the `Maintenance Tests?` field on the Trunk Group Form is set to n. To enable the test, issue the **change trunk-group x** command (x is the trunk group number). Then change the entry in the `Maintenance Tests?` field to **y**.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	System resources required to run this test are not available. This may be due to the port being seized. 1. This abort code is usually associated with tone-clock (TONE-BD, TONE-PT, and TDM-CLK) resources. Clear any tone errors in the error log. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-204. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The nonreflective 1004 Hz tone test of the port failed. An echo was detected from the port. Poor quality transmission was detected to or from the port. The problem may be off-board.
7		The conference capabilities of the port failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
129		The reflective 404-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
131		The reflective 1004-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
133		The reflective 2804-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board. **CAUTION:** *The port may still be operational, or the fault may be off-board (connections or CO). Off-board problems include incoming seizures or off-hook port seizures during the test and, perhaps, noise induced by adjacent electric power lines. The test may be disabled from trunk administration 'Test' field. This turns off all testing for that trunk group except for tests 6 and 36.*

Continued on next page

Table 9-204. TEST #33 Looparound and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3 7 129 131 133 *(cont'd.)*	FAIL *(cont'd.)*	Proceed as follows unless power or tone problems are suspected (see note below). 1. To see if the problem is on-board, disconnect the port from the far-end and retry the test. Coordinate this with the CO, or do it after busy hours. 2. If the retry fails, replace the circuit pack. 3. If the retry passes and no troubles have been reported, disable the test in the trunk group administration. If the retry passes and troubles are reported, coordinate isolation with the CO. **NOTE:** If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. A power unit may be defective (CARR-POW). If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT maintenance objects. 4. Rerun the test.
	PASS	DID Trunk Looparound and Conference Test is successful. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port and refer problem to the CO.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should establish the link between the internal ID and the port.

Port Diagnostic Test (#35)

This test checks a port's battery feed circuitry for on-/off-hook detection, battery shutdown, and battery reversal (wink) capabilities.

Table 9-205. TEST #35 Port Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required to run this test were not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. 1. Enter **display port UUCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is active but the port is not in use (no calls), check the error log for Error Type 513. The port may be locked up. 3. If the port status is idle, busyout and release the trunk, and retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, check for wiring errors toward the CO which may cause the trunk to lock up. 5. If the wiring is good and the test continues to abort, replace the TN753.
1004	ABORT	The port was seized by a valid call during the test. 1. Enter **display port UUCSSpp** to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via administration. Verify that the `Maintenance Tests?` field on the Trunk Group Form is set to n. To enable the test, issue the **change trunk-group x** command (x is the trunk group number). Then change the entry in the `Maintenance Tests?` field to **y**.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 9-205. TEST #35 Port Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
61446	FAIL	Battery feed test failed. A loop current fault was detected. This is most probably an incoming CO-line problem. This failure code is only reported by the TN2139 Italian DID circuit pack. 1. Check the incoming CO-line for loop current. If none is detected refer the problem to the CO. 2. If the CO-line checks out OK, the failure must be on the DID port. Replace the circuit pack.
61456	FAIL	Battery feed test failed. An on-board problem was detected. This port is out-of-service. 1. Replace circuit pack.
61472	FAIL	Battery feed test failed. A problem with the incoming CO-line was detected. 1. Check the incoming CO-line for proper operation. If warranted, refer the problem to the CO. 2. If the CO-line is not at fault, the failure must be on the DID port. Replace the circuit pack.
	PASS	Current flow was detected for this port. 1. User-reported troubles on this port should be investigated using other port tests and by examining connections. 2. Refer problem to the CO.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Port Audit Update Test (#36)

This test sends updates of the DID port translation for all ports on the circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes:

- Wink or immediate start trunk
- Dial tone or rotary dialing trunk

- Rotary dialing inter-digit timing
- Network balance R/RC
- Disconnect timing

Table 9-206. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1006	ABORT	The port is out of service, perhaps busied out. 1. Use **display port UUCSSpp** to determine the trunk group/member number of the port. Use **status trunk** to determine the service state of the port. If the port is out of service, wait until the port is in service and idle before testing. 2. If the port status is in service and idle, then retry the command at 1-minute intervals a maximum of 5 times.
2100	ABORT	Could not allocate the necessary system resources to run the test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. 1. If signaling troubles are reported (Error Types 1, 257, or 513), verify translation for this port. 2. Refer problem to the CO.
0	NO BOARD	The test could not relate the internal ID to the port. 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

DIG-BD (Digital Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DIG-BD	MIN	test board UUCSS sh	Digital Line Circuit Pack
DIG-BD	WRN	test board UUCSS sh	Digital Line Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

Refer to "XXX-BD (Common Port Circuit Pack)" for circuit pack level errors. See also “DIG-LINE” for related line information.

DIG-IP-STN (Digital IP Station)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DIG-IP-STN	WARNING	test station *extension*	Digital IP Station

This maintenance object covers implementation of the maintenance for Lucent-provided IP Softphone or the Centre-Vu Remote IP Agent. The Lucent-provided endpoint consists of a service provider, an application layer called the Telephony Manager, and a registration application. The service provider terminates DCP signaling carried over TCP. The Telephony Manager provides the GUI emulating the DCP set. The registration application handles H323.RAS and is used to register and authenticate the endpoint with DEFINITY. This group of modules is called Vphone. Note that the Vphone does not include any type of audio path of bearer channel. The Vphone provides a DCP control plane for an alternate bearer channel. Tha alternate bearer channel is provided by either a native H.323 station or a POTS line or trunk. The Vphone is used only in a dual-connect arrangement.

The Vphone supports some level of existing DCP maintenance in the form of audits and updates.

This station type is not attached to a port board. Insertion of the station is not driven by board insertion, rather it is driven by successful registration of the endpoint. It is maintained via a set of explicit TCP/IP ping requests and errors reported by the User Manger software, which terminates the H.323 signaling portion of each endpoint. The MO follows standard mtce methodology and supports test, busyout, release and status commands.

Error Log Entries and Test to Clear Values

Table 9-207. DIG-IP-STN Digital IP Station Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any		test station *extension*
1 (a)		Registration Status Inquiry (#1372)	WARNING	OFF	
257 (b)		Signaling Path PING Test (#1373)	WARNING	OFF	
(c)		Digital Terminal Lamp Update (#16)	WARNING	OFF	

Continued on next page

Table 9-207. DIG-IP-STN Digital IP Station Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
(d)		Digital Terminal Audit Update (#17)	WARNING	OFF	
2817 (e)		Station Hyperactivity			

Notes:

a. **Error Type 1**: this error reports the registration status of the endpoint. If call processing SW claims the endpoint is registered and receives keep-alive handshakes from the endpoint, the test passes. If keep-alive handshaking has failed, the test fails. If the user has intentionally un-registered from DEFINITY, the station is now basically an AWOH station and is no longer being maintained; no tests will run for this station.

b. **Error Type 257**: this error tracks failures of the signaling path PING test. The test attempts to send a PING packet to the endpointIP address, as reported during registration. The PING packet originates with the C-LAN board through which the endpoint is registered. If the PING response packet is received, the test passes. If the PING response packet times out, the test fails.

c. This is a refresh of the lamp states for all lamps on the Virtual DCP station. The update always passes, if it runs successfully. It may abort, but it will never fail. This update is the same update used for existing DCP stations. It is test number 16.

d. This is a refresh of the ringer state on the Virtual DCP station and a query of the virtual station's switch-hook state. The audit always passes, if it runs successfully. It may abort, but it will never fail. This runs a subset of the complete audit update that runs for standard DCP sets.

e. **Error Type 2817**: this error tracks failures of the port hyperactivity counter. If a port generates more than 50 uplink CCMS messages within 10 seconds, the port is taken out-of-service for 30 seconds. Even though the Virtual phone actually signals over a TCP/IP link, DCP CCMS messages received over the TCP link are counted as regular CCMS uplinks and can cause the station to marked as hyperactive.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the Signaling Path PING Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Registration Status Inquiry (#1372)	X	X	ND
Signaling Path PING Test (#1373)	X	X	ND
Digital Terminal Lamp Update Test (#16)	X	X	ND
Digital Terminal Audits Test (#17)		X	ND

1. D = Destructive; ND = Nondestructive

Registration Status Inquiry (#1372)

The Registration status inquiry reports the H.323 registration status of the endpoint. An endpoint must be registered and authenticated in order to receive service from the system.

Registration is initiated when the endpoint user attempts to login using the Lucent registration software application running on the endpoint PC. The user must provide a valid extension and security code. The registration messages are sent to the IP address of a C-LAN ethernet port.

A registered extension has a port type SNNNNN, where N is a digit from 0-9. A non-registered extension has an X port.

Table 9-208. TEST #1372 Registration Status Inquiry

Error Code	Test Result	Description/Recommendation
1,2,3	FAIL	The endpoint is not successfully registered. 1. Verify that the user is entering: ■ the correct extension and security code ■ the C-LAN IP address 2. Verify that the extension has been enabled for IP softphone operation. 3. If many endpoints cannot register, investigate any errors of the C-LAN ethernet port. 4. Examine the ethernet cabling from the endpoint PC to the ethernet hub.
	PASS	The endpoint is successfully registered and continues to respond to registration handshaking.

Signaling Path PING Test (#1373)

This test is nondestructive.

The test determines the local C-LAN through which the signaling originates and the endpoint's IP address. It then requests the local C-LAN to execute a PING on the endpoint's address. If the PING is successful, the test passes, if the PING is not successful, the test fails.

NOTE:
Multiple failures of this test can take the Digital IP Station out of service.

This test checks the circuitry involved in the data path of a peer-to-peer IP layer connection.

This nondestructive test runs due to in-line errors, during periodic and schedule maintenance, and on demand.

Table 9-209. TEST #1373 Signaling Path PING Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not locate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals, up to 5 times. 2. Escalate if the problem persists.
2500	ABORT	Internal system error. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Escalate if the problem persists.
1003	FAIL	Ping to the destination failed. 1. Retry the command at 1-minute intervals, up to 3 times. 2. Investigate any C-LAN ethernet port errors.

Continued on next page

Table 9-209. TEST #1373 Signaling Path PING Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1007	FAIL	The system could not PING the registered endpoint via the C-LAN. 1. Verify that at least one destination reachable through this port. PING this destination (**ping ip-address *xxx.xxx.xxx.xxx***). 2. If the PING to any destination is successful through this port, the link is up. 3. If PING to all destinations fail, test the C-LAN port (**test port UUCSSpp short**) and follow repair procedures for Session Status Test (#1286) failures. 4. If only this station cannot be pinged: ■ Make sure the PC is up ■ Make sure the PC has a network connection (ethernet or dialup) ■ Check the ethernet cabling
	PASS	The system can successfully send IP packets to the registered endpoint from the C-LAN.

Digital Terminal Lamp Update (#16)

This test updates internal lamp states that may or may not be displayed on the actual PC graphical user interface. The lamp updates will run only if the station is in-service. The status of the station is checked and the lamp updates are blocked from taking place if the station is not in the in-service state. This test does not affect the status of the Message Waiting lamp.

Table 9-210. TEST #16 DIG-LINE Station Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
3	ABORT	Station may be in ready-for-service or out-of-service state. 1. Use **status station** command to verify state of station. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. 1. Use **display port UUCSSpp** to determine the station extension of the port. Use **status station** to determine the service state of the port. If the port is in use, wait until the port is idle before testing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The message to light all of the station lamps was sent successfully to the port.

Digital Terminal Audits Test (#17)

This is a series of tests that are classified as audits. The SPE sends messages to the softphone application to perform the following tests. These audits run only if the station is in-service.

- Switchhook Inquiry Test — This is an update of the SPE records according to the softphone switch hook state.
- Ringer Update Test — This updates the softphone ringer state according to the processor records.

Table 9-211. TEST #17 Station (Digital) Audits Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switchhook audit timed out.
2	ABORT	ID request fails, health bit returned from voice terminal is bad. 1. Make sure voice terminal is connected and repeat test. 2. If test fails, replace voice terminal and repeat test.
4	ABORT	Internal system error 1. Resolve any outstanding circuit pack maintenance problems. 2. Retry the command at 1-minute intervals a maximum of 5 times.
5	ABORT	Ringer update aborted due to station being in ready-for-service or out-of-service state.
6	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error is present, the release the port via **release station** 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required for this test are not available.
2000	ABORT	Response to the test was not received in the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Station Audits passed. 1. If complaints persist, investigate by using other port tests, and by examining the station, wiring, and connections.

DIG-LINE (Digital Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run[1]	Full Name of MO
DIG-LINE	MINOR	test port *UUCSSpp* l	Digital Line
DIG-LINE	WARNING	test port *UUCSSpp* sh	Digital Line

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).
